Introduction

The global importance of cancer is unquestionable, considered the second cause of death worldwide. The incidence of different cancers had increased both in developed and developing countries as a result of increasing exposure to risk factors and life expectancy\(^1\). Breast cancer is one of the most common cancers with more than 1,300,000 cases and 450,000 deaths each year worldwide\(^2\). In less-developed countries it is also the most frequently diagnosed life-threatening cancer and leading cause of cancer death in women\(^3\). Locally advanced breast cancer at presentation was also common in developing countries\(^6\).

Since 1990, mortality rate from breast cancer in United States and other industrialized countries has been decreasing at the rate of approximately 2.2% per year. In the United States, this decline has been attributed both to advances in adjuvant therapy and to increasing use of screening mammography\(^7\). However, opposite trend was observed in developing countries.

Breast cancer is a challenge for the oncologist and health policy makers in a country like Bangladesh as it is the leading cause of death among women\(^8\). This study was done to observe epidemiology, risk factors and pattern of presentation in respect to the clinicopathological status of locally advanced Breast Cancer in Bangladesh.

Abstract

Worldwide, breast cancer is the most frequently diagnosed life-threatening cancer in women. This cross sectional study was done to assess the presenting features of locally advanced breast cancer. The mean age was 42.6 years with standard deviation 9.56, 86% were housewife, 53.5% were illiterate, 16% were postmenopausal and 75.8% had BMI of 20Kg/m\(^2\). Ninety one point five percent had menarche at or above 12 years of age and 26.6% had history of using hormonal contraceptives. Tobacco user and positive family history were found in 21.2% and 5.35% of the cases. 84% were presented with only lump and 16% with both lump and ulceration. Right breast was involved in 51.1%. About 37% cases presented on 3rd month of their symptoms. Around 71.2% patients presented with lump >5cm in diameter, axillary lymph nodes were palpable in 81% and fixed in 31% of patients. Around Sixty three percent of patients were in stage IIIA. Still a large fraction of patients present with advanced stage with varied presentation, sometimes surgeons face difficulties to offer the treatment. Proper awareness, early presentation and early detection give them the opportunity to receive the best treatment.
Methods

This was a cross sectional study, was carried out from July 2014 to June 2016 among patients attending at outpatient department and indoor of NICRH, Mohakhali. Women included were the locally advanced breast cancer patients sent for neoadjuvant chemotherapy from surgical oncology outdoor department. All the particulars of the patients, detailed history, physical examination and laboratory finding were recorded in the data collection sheet. Weight and height were measured during their visit and recorded. For analysis of data SPSS for Windows (IBM SPSS Statistics for Windows, version 23.0) software was used. Ethical clearance was taken from the Ethical Committee of NICRH for this study. Written informed consent was obtained from each and every patient after elaborate explanation regarding the undergoing study. Confidentiality of the research finding was ensured.

Results

Ninety four (94) patients with locally advanced breast cancer were included in the study. Mean age of the patients was 42.6 years, standard deviation was 9.56. (Figure-1)

More than 80% of patients came from rural area. Only 5% were single and among the married women, 94% have children. Most of the cases were house wife (86.2%). More than half of patients had family income of 10000-20000 Taka per month. Majority of the patients 85 (75.8%) had normal weight. More than half (53.5%) were illiterate. (Table-I)

Most of patients (91.5%) had menarche at or above 12 years of age and 26.6 % had history of using hormonal contraceptives. Among the patients, tobacco user and positive family history were found in 21.2% and 5.3% of the cases. Menopause was found in only 15 (16%) of cases.

About 97% of cases had their first child birth below the age of 30 and 95.5% patient feed their babies from both breasts.

Eighty four percent (84%) of the patients were presented with only lump and 16% patient presented with both lump and ulceration. Right breast was involved in 51.1%. About 37% patients were presented on 3rd month of their symptoms and rest of the patients presented later. Fifty one percent patients were diagnosed by tru-cut biopsy. FNAC was second most common method of diagnosis. Incision biopsy was done in11.7% of cases. (Figure-2)

Regarding tumour size prior to neoadjuvant chemotherapy (NACT), 71.2% patients presented with lump >5cm in diameter and axillary lymph nodes were palpable in 81% and fixed in 31% of patients. Regarding staging prior to NACT, stages II B subgroup was found in 18 % of patients and maximum patients were in stage IIIA subgroup comprising 62.7% of patients.(Table-II)
The study showed that 95% were married and among the married women, 94% have children. Data from the NICRH cancer registry\(^\text{a}\) show that over 93% of all breast cancer patients (n = 5255) were married. Most of patients (91.5%) had menarche at or above 12 years of age. Breast cancer risk reduced if a woman is older when she was menstruating and risk reduced 5% for 1 year delay\(^{10}\). 26.6% had history of using hormonal contraceptives. About 54% patients had menarche at eleven or below age and 42% patients used oral contraceptive \(^\text{a}\). In an analysis of data from a multicenter, population-based case-control study, breast cancer risk did not vary by oral contraceptive use\(^{12}\).

Among the patients, tobacco user and positive family history were found in 21.2% and 5.35% of the cases. Majorities (97%) of the respondents were non smoker and only 3% was smoker\(^{11}\). Epidemiological investigations of the relations between smoking and breast cancer have yielded conflicting results. Several studies have suggested that smoking may decrease the risk of breast cancer. Others have reported no evident association, while a few have suggested that smoking may increase the risk of breast cancer, especially in pre-menopausal women \(^\text{a}\). A study by Anderson T showed that about 20% of breast cancer patients have a family history of the disease in a first degree relative\(^{14}\).

In this study, menopause was found in only 15 (16%) of cases which was 57.2% in a study conducted by Rahman \(^\text{b}\). The higher proportion of premenopausal cases in Bangladesh might be due to the fact that the overall population is much younger than in high-income countries, and possibly missing cases of older women who often feel shy about seeking medical help as well as getting lower priority for treatment compared to younger family members in South Asian countries.

The study finding showed that about 97% of cases had their first child birth below the age of 30. Many studied found that late age at first birth increases risk of breast cancer and risk increased 40% with first child birth at 35 years or later\(^{7}\). About 95.5% patient feed their babies from both breasts. Palmer showed that longer duration of breast feeding has been associated with a greater reduction in breast cancer risk\(^{15}\).

Most of the cases were house wife (86.2%) and more than half were illiterate. Due to illiteracy, they seek medical attention later and presented at advanced stage. More than half of patients had family income of 10000-20000 Taka per month. Majority of the patients 85 (75.8%) had normal weight followed by overweight 16 (14.28%) of cases. Obesity increases risk of breast cancer in postmenopausal women about 50% than lean women but reverse in premenopausal women\(^{16}\).

In the current study, mean age was 42.6 years and standard deviation was 9.5 years. Most of the patients (48/94) were in the 41-60 years age group. No patient was found below 20 or above 80 years of age. Mean age was much lower compared to western data with 10-15 years variation. In Iran, average age of diagnosis was 15 years lower than western countries\(^\text{a}\). According to an NICRH report, the mean age of the breast cancer patients was 41.8 years (age range 15-94 years) and over 56% of the cases were women of reproductive age (15-44 years)\(^{8}\).
Acknowledgement

lymph node involvement was present in 80% of cases size >5cm) and T4 (skin involvement) were 52.6% and axillary fixed in 31% of patients. Rahman reported that T3 (tumour diameter and axillary lymph nodes were palpable in 81% and maximum patients were in stage IIIA subgroup comprising 62.7% of patients. Ozmens reported that 21% of patients had stage IIIB and 79% had stage III breast cancer prior to NACT 18. Due to illiteracy, poverty, lack of awareness, distance and socioeconomic circumstances, patients in this study group presented at advanced stage.

Regarding tumour size prior to neoadjuvant chemotherapy (NACT), 71.2% patients presented with lump >5cm in diameter and axillary lymph nodes were palpable in 81% and fixed in 31% of patients. Rahman reported that T3 (tumour size >5cm) and T4 (skin involvement) were 52.6% and axillary lymph node involvement was present in 80% of cases 5. Regarding staging prior to NACT, stages IIIB subgroup was found in 18 % of patients and maximum patients were in stage IIIA subgroup comprising 62.7% of patients. Ozmens reported that 21% of patients had stage IIIB and 79% had stage III breast cancer prior to NACT 18. Due to illiteracy, poverty, lack of awareness, distance and socioeconomic circumstances, patients in this study group presented at advanced stage.

Conclusion

Still a substantial number of locally advanced breast cancer patients are attending every day to the health care providers. Illiteracy and poverty plays key role for delayed presentation. Creating awareness regarding self-examination and effective screening programme may detect early stage of breast cancer and can ensure satisfactory treatment outcome. The health care provider, social worker, media and NGOs can play substantial role to create awareness and remove fear and uncertainty regarding breast cancer treatment.

Acknowledgement

The authors express their gratitude to the patients of locally advanced breast cancer of National Institute of Cancer Research and Hospital, Dhaka and also to Department of Histopathology, National Institute of Cancer Research and Hospital, Dhaka.
