PROJECTIVE STRUCTURES, NEIGHBORHOODS OF RATIONAL CURVES
AND PAINLEVÉ EQUATIONS

MAYCOL FALLA LUZA\textsuperscript{1}, FRANK LORAY\textsuperscript{2}

Abstract. We investigate the duality between local (complex analytic) projective structures on surfaces and two dimensional (complex analytic) neighborhoods of rational curves having self-intersection +1. We study the analytic classification, existence of normal forms, pencil/fibration decomposition, infinitesimal symmetries. We deduce some transcendental result about Painlevé equations. Part of the results were announced in \cite{20}; an extended version is available in \cite{21}.

1. Introduction

Duality between lines and points in $\mathbb{P}^2$ has a nice non linear generalization which goes back at least to the works of Élie Cartan, and even appears in Alfred Koppisch’s thesis in 1905. The simplest (or more familiar) setting where this duality takes place is when considering the geodesics of a given Riemannian metric (say, real analytic, or holomorphic) on the neighborhood $U$ of the origin in the plane. The space of geodesics is itself a surface $U^\vee$ that can be constructed as follows. The projectivized tangent bundle $\mathbb{P}(T_U)$ is naturally a contact manifold: given coordinates $(x,y)$ on $U$, the open set of “non vertical” directions is parametrized by triples $(x,y,z) \in U \times \mathbb{C}$ where $z$ represents the class of the vector field $\partial_x + z\partial_y$; the contact structure is therefore given by $dy - zd\bar{x} = 0$. Each geodesic on $U$ lifts uniquely as a Legendrian curve on $\mathbb{P}(T_U)$, forming a foliation $\mathcal{G}$ on $\mathbb{P}(T_U)$. A second Legendrian foliation $\mathcal{F}$ is defined by fibers of the canonical projection $\pi : \mathbb{P}(T_U) \to U$. The two foliations $\mathcal{F}$ and $\mathcal{G}$ are transversal, spanning the contact distribution. Duality arises when we permute of the role of these two foliations. The space of $\mathcal{F}$-leaves is the open set $U$; if $U$ is small enough, then the space of $\mathcal{G}$-leaves is also a surface $U^\vee$. However, $U^\vee$ is “semi-global” in the sense that it contains (projections of) $\mathbb{P}^1$-fibers of $\pi$. If $U$ is a small ball, then it is convex, and we deduce that any two $\mathbb{P}^1$-fibers are connected by a unique geodesic (G-leaf) on $\mathbb{P}(T_U)$, i.e. intersect once on $U^\vee$. Finally, we get a 2-dimensional family
parametrized by $U$) of rational curves on $U^\vee$ with normal bundle $\mathcal{O}_{\mathbb{P}^1}(1)$. Note that $\mathbb{P}^2(T_U) \subset \mathbb{P}(T_{U^\vee})$ as contact 3-manifolds.

In fact, we do not need to have a metric for the construction, but only a collection of curves on $U$ having the property that there is exactly one such curve passing through a given point with a given direction. This is what Cartan calls a projective structure, not to be confused with the homonym notion of manifolds locally modelled on $\mathbb{P}^n$ (see [17, 31]). In coordinates $(x, y) \in U$, such a family of curves is defined as the graph-solutions to a given differential equation of the form

$$y'' = A(x, y) + B(x, y)(y')' + C(x, y)(y')^2 + D(x, y)(y')^3$$

with $A, B, C, D$ holomorphic on $U$. Then the geodesic foliation $\mathcal{G}$ is defined by the trajectories of the vector field

$$\partial_x + z\partial_y + [A + Bz + Cz^2 + Dz^3] \partial_z.$$ 

Since it is second order, we know by Cauchy-Kowalevski Theorem that there is a unique solution curve passing through each point and any non vertical direction. That the second-hand is cubic is exactly what we need to insure the existence and unicity for vertical directions. In a more intrinsic way, we can define a projective structure by an affine connection, i.e. a (linear) connection $\nabla : T_U \to T_U \otimes \Omega^1_U$ on the tangent bundle. Then, $\nabla$-geodesics are parametrized curves $\gamma(t)$ on $U$ such that, after lifting to $T_U$ as $(\gamma(t), \dot{\gamma}(t))$, they are in the kernel of $\nabla$. All projective structures come from an affine connection, but there are many affine connections giving rise to the same projective structure: the collection of curves is the same, but with different parametrizations. An example is the Levi-Civita connection associated to a Riemannian metric and this is the way to see the Riemannian case as a special case of projective structure. We note that a general projective connection does not come from a Riemannian metric, see [6].

A nice fact is that the duality construction can be reversed. Given a rational curve $\mathbb{P}^1 \simeq C_0 \subset S$ in a surface, having normal bundle $\mathcal{O}_{\mathbb{P}^1}(1)$, then Kodaira Deformation Theory tells us that the curve $C_0$ can be locally deformed as a smooth 2-parameter family $C_\epsilon$ of curves, likely as for a line in $\mathbb{P}^2$. We can lift this family as a Legendrian foliation $\mathcal{F}$ defined on some tube $V \subset \mathbb{P}(T_{U^\vee})$ and take the quotient: we get a map $\pi : V \to U$ onto the parameter space of the family. Then fibers of $\pi^\vee : \mathbb{P}(T_{U^\vee}) \to U^\vee$ project to the collection of geodesics for a projective structure on $U$. We thus get a one-to-one correspondence between projective structures at $(C^2, 0)$ up to local holomorphic diffeomorphisms and germs of $(+1)$-neighborhoods $(U^\vee, C_0)$ of $C_0 \simeq \mathbb{P}^1$ up to holomorphic isomorphisms (see Le Brun’s thesis [33] for many details).

Section 2 recalls in more details this duality picture following Arnold’s book [1], Le Brun’s thesis [33] and Hitchin’s paper [27]. In particular, the euclidean (or trivial) structure by lines, defined by the second order differential equation $y'' = 0$, corresponds to the linear neighborhood of the zero section $C_0$ in the total space of $\mathcal{O}_{\mathbb{P}^1}(1)$, or equivalently of a line in $\mathbb{P}^2$. But as we shall see, the moduli space of projective structures up to local isomorphisms has infinite dimension.

We recall in section 2.5 some criteria of triviality/linearizability. The neighborhood of a rational curve $C_0$ in a projective surface $S$ is always linear (see Proposition 2.10). As shown by Arnol’d, if the local deformations of $C_0$ are the geodesics of a projective structure on $U^\vee$, then we are again in the linear case. In fact, in the non linear case, it is shown in Proposition 2.8 that deformations $C_\epsilon$ of $C_0$ passing through a general point $p$ of $(U^\vee, C_0)$ are only defined for $\epsilon$ close to 0: there is no local pencil of smooth analytic curves through $p$ that contains the germs $C_\epsilon$ at $p$. We show in Proposition 2.8 that, in the non linear case, there is at most one point $p$ where we get such pencil.

Going back to real analytic metrics, the three geometries of Klein, considering metrics of constant curvature, give birth to the same (real) projective structure, namely the trivial one. Indeed, geodesics of the unit 2-sphere $S^2 \subset \mathbb{R}^3$ are defined as intersections with planes passing through the origin: they project on lines, from the radial projection to a general affine plane. Similarly, for negative curvature, geodesics
are lines in Klein model. It would be nice to understand which \((+1)\)-neighborhoods \((U^\vee, C_0)\) come from the geodesics of a holomorphic metric.

In section 3 we introduce the notion of foliated projective structure, when the projective structure is defined by a flat affine connection \(\nabla\), i.e. satisfying \(\nabla \cdot \nabla = 0\). Equivalently, the collection of geodesics decomposes as a pencil of geodesic foliations. On the dual picture \((U^\vee, C_0)\), such a decomposition corresponds to an analytic fibration transversal to \(C_0\), i.e. a holomorphic retraction \(U^\vee \rightarrow C_0\). This dictionary appear in Kryński [30]. Our main result, announced in [20], is that non linear \((+1)\)-neighborhoods \((U^\vee, C_0)\) have 0, 1 or 2 transverse fibrations, no more (see Theorem 5.1). We show that each case occur with an infinite dimensional moduli space.

The main ingredient to study the existence and unicity of transverse fibrations is the classification of \((+1)\)-neighborhoods up to analytic isomorphisms, which is due to Mishustin [40] (section 4). It was known since the work of Grauert [25] that there are infinitely many obstructions to linearize such a neighborhood. Hurtubise and Kamran [28] provided a normal form for the formal neighborhood, and one year later, Mishustin showed the convergence of that normal form by a different and geometrical approach in [40]. Precisely, any positive neighborhood can be described as the patching of two open sets of the linear neighborhood by a non linear cocycle, that can be reduced to an almost unique normal form (Theorem 4.2 and Proposition 4.4). The moduli space appears to be isomorphic to the space of convergent power series in two variables. Hurtubise and Kamran [28] also provide explicit formulae linking these invariants (coefficients of the cocycle) with Cartan invariants for the equivalence problem for projective structures (or second order differential equations). It is quite surprising that these two works have never been quoted until our announcement [20], although it answers a problem left opened since the celebrating works of Grauert and Kodaira.

In Proposition 4.4 we get a more precise description of the freedom in the reduction to normal form which is necessary for our purpose, namely the action of a 4-dimensional linear group (see Corollary 4.5).

From Mishustin’s cocycle (and its non unicity), we see in Proposition 4.7 that the first obstruction to the existence to a transverse fibration arise in 5-jet, i.e. in the 5\(^{th}\) infinitesimal neighborhood of the rational curve, which was also surprising for us. Another surprising fact is the existence of many neighborhoods with two fibrations: we get a moduli space (Theorem 5.13) isomorphic to the space of power series in one variable. One remarkable example (see section 5.3) is given by the two-fold ramified covering \((U^\vee, C_0) \rightarrow (\mathbb{P}^1 \times \mathbb{P}^1, \Delta)\) of a neighborhood of the diagonal \(\Delta \subset \mathbb{P}^1 \times \mathbb{P}^1\) that ramifies precisely along \(\Delta\): the two fibrations of \(\mathbb{P}^1 \times \mathbb{P}^1\) lift as fibrations tangent all along \(C_0\). This example is non linear, and in particular non algebraic (the covering can be only defined at the neighborhood of \(\Delta\) for topological reasons). However, the field of meromorphic functions on \((U^\vee, C_0)\) identifies with the field of rational functions on \(\mathbb{P}^1 \times \mathbb{P}^1\) and has transcendance dimension 2. We expect that the general \((+1)\)-neighborhood has no meromorphic function, but we have no proof, and no example.

We are able to compute the differential equation defining the dual projective structure, namely \(y'' = (xy' - y)^3\). This example is also remarkable because it has the largest symmetry group, namely \(\text{SL}_2(\mathbb{C})\), and this is an ingredient of the proof.

The paper is mostly a survey putting together some results that were scattered in the litterature. There are however original results as the complete proof of Theorem 5.1 announced in [20], the precise description of non unicity for Mishustin cocycle given in Proposition 4.4, the meromorphic propagation of foliated structures in Lemma 3.10 and finally the application to Painlevé equations in section 6. Our work is used in the recent publication [18].
2. Projective structure, geodesics and duality

2.1. Second order differential equations and duality. Let \((x, y)\) be coordinates of \(\mathbb{C}^2\).

Given a 2nd order differential equation
\[
y'' = f(x, y, y')
\]
with \(f(x, y, z)\) holomorphic at the neighborhood \(V\) of some point \((0, 0, z_0)\) say, local solutions \(y(x)\) lift as Legendrian curves for the contact structure defined by
\[
\alpha = 0 \quad \text{where} \quad \alpha = dy - zdx.
\]

We get two transversal Legendrian foliations on \(V\). The first one \(\mathcal{F}\) is defined by the fibers of the projection \(V \to U\): \((x, y, z) \mapsto (x, y)\). The second one \(\mathcal{G}\) is defined by solutions \(x \mapsto (x, y(x), y'(x))\) or equivalently by trajectories of the vector field
\[
v = \partial_x + z\partial_y + f(x, y, z)\partial_z.
\]

More generally, given a germ of contact 3-manifold together with two transversal Legendrian foliations, the space of \(\mathcal{F}\)-leaves can be identified with an open set \(U \subset \mathbb{C}^2\) with coordinates \((x, y)\) and \(\mathcal{G}\)-leaves project on \(U\) as graphs of solutions of a 2nd order differential equation \(y'' = f(x, y, y')\), see [1] Chapter 1, Section 6.F.

It is now clear that the role of \(\mathcal{F}\) and \(\mathcal{G}\) can be permuted: on the space \(U^\vee\) of \(\mathcal{G}\)-leaves, \(\mathcal{F}\)-leaves project to solutions of a 2nd order differential equation \(Y'' = g(X, Y, Y')\) (once we have chosen coordinates \((X, Y) \in U^\vee\)). This is the duality introduced by Cartan (see also [1] Chapter 1, Sections 6.F, 6.G). Points on \(U\) correspond to curves on \(U^\vee\) and vice-versa. We will call \(V\) the incidence variety by analogy with the case of lines in \(\mathbb{P}^2\).

For instance, lines \(y = ax + b\) are solutions of the differential equation \(y'' = 0\). Using \((X, Y) = (a, b) \in \mathbb{P}^2\) for coordinates of dual points, we see that foliations \(\mathcal{F}\) and \(\mathcal{G}\) given before are liftings of lines on the projective and dual plane, thus the dual equation is also \(Y'' = 0\).

If there is a diffeomorphism \(\phi: U \to \tilde{U}\) sending solutions of the differential equation to the solutions of another one \(y'' = f(x, y, y')\) on \(\tilde{U}\), then \(\phi\) can be lifted to a diffeomorphism \(\Phi: V \to \tilde{V}\) conjugating the pairs of Legendrian foliations: \(\Phi_\ast \mathcal{F} = \tilde{\mathcal{F}}\) and \(\Phi_\ast \mathcal{G} = \tilde{\mathcal{G}}\). We say that the two differential equations are Cartan-equivalent in this case.

2.2. Projective structure and geodesics. When the differential equation \(y'' = f(x, y, y')\) is cubic in \(y'\)
\[
y'' = A(x, y) + B(x, y)(y') + C(x, y)(y')^2 + D(x, y)(y')^3
\]
where \(A, B, C, D\) are holomorphic functions on \(U\), then the foliation \(\mathcal{G}\) is global on \(V := \mathbb{P}(T_U) \cong U \times \mathbb{P}^1_z, z = \frac{dy}{dx}\), and transversal to the fibration \(\mathcal{F}\) everywhere. Precisely, setting \(\tilde{z} = \frac{1}{z} = \frac{\partial z}{\partial y}\), then the foliation \(\tilde{\mathcal{G}}\) is defined by the two vector field
\[
v = \partial_x + z\partial_y + (A + Bz + Cz^2 + Dz^3)\partial_z
\]
for \(z\) finite, and
\[
\tilde{v} = \tilde{z}\partial_x + \partial_y - (D + C\tilde{z} + B\tilde{z}^2 + A\tilde{z}^3)\partial_{\tilde{z}}
\]
for \(z = \infty\).

Remark 2.1. For equations \(y'' = f(x, y, y')\) having right-hand-side \(f(x, y, y')\) polynomial with respect to \(y'\), but higher than cubic degree, the foliation \(\tilde{\mathcal{G}}\) globalizes on \(U \times \mathbb{C}_z\) but transversality is violated at \(z = \infty\). Indeed, the corresponding vector field
\[
\tilde{v} = \tilde{z}\partial_x + \partial_y - \tilde{z}^3 f \left( x, y, \frac{1}{\tilde{z}} \right) \partial_{\tilde{z}}
\]
becomes meromorphic; after multiplication by a convenient power of \(\tilde{z}\), the vector field becomes holomorphic but tangent to \(\mathcal{F}\) along \(\tilde{z} = 0\), and its trajectories become singular after projection on \(U\).
With the previous remark, it is easy to check that any foliation $G$ on $\mathbb{P}(T_U)$ which is

- Legendrian, i.e. tangent to the natural contact structure $(dy - zdx = 0)$,
- transversal to the projection $\mathbb{P}(T_U) \to U$,

is locally defined by a vector field like above, cubic in $z$, i.e. by a second order differential equation with $y'' = A + B(y') + C(y')^2 + D(y')^3$. We call projective structure such a data. We call geodesic a curve on $U$ obtained by projection of a $G$-leaf on $\mathbb{P}(T_U)$. The following is proved by Le Brun in [33 Section 1.3]

**Proposition 2.2.** If $U$ is a sufficiently small ball, then all geodesics are properly embedded discs and we have the following properties:

- convexity: through any two distinct points $p, q \in U$ passes a unique geodesic;
- infinitesimal convexity: through any point $p \in U$ and in any direction $l \in T_U|_p$ passes a unique geodesic.

We say that $U$ is geodesically convex in this case.

The second item just follows from Cauchy-Kowalevski Theorem for the differential equation defining the projective structure.

### 2.3. Space of geodesics and duality.

It is proved in [33 Section 1.4] the following

**Proposition 2.3.** If $U$ is geodesically convex, then the space of geodesics, i.e. the quotient space

$$U^\vee := \mathbb{P}(T_U)/G$$

is a smooth complex surface. Moreover, the projection map

$$\pi^\vee : \mathbb{P}(T_U) \to U^\vee$$

restricts to fibers of $\pi : \mathbb{P}(T_U) \to U$ as an embedding.

We thus get a two-parameter family (parametrized by $U$) of smooth rational curves covering the surface $U^\vee$: for each point $p \in U$, we get a curve $C_p \subset U^\vee$, namely $\pi^\vee(\pi^{-1}(p))$. The curve $C_p$ parametrizes in $U^\vee$ the set (pencil) of geodesics passing through $p$. Any two curves $C_p$ and $C_q$, with $p \neq q$, intersect transversely through a single point in $U^\vee$ representing the (unique) geodesic passing through $p$ and $q$. The normal bundle of any such curve $C_p$ is in fact $\mathcal{O}_{\mathbb{P}^1}(1)$ (after identification $C_p \simeq \mathbb{P}^1$).

One might think that rational curves define the geodesics of a projective structure on $U^\vee$, but it is almost never true: for instance, the set of rational curves (of the family $C_p$) through a given point of $U^\vee$ cannot be completed as a pencil of curves (as it would be for geodesics of a projective structure), see [11 Chapter 1, Section 6-D]. In fact, we will prove (see Proposition 2.5) that, if such a pencil exists at two different points of $U^\vee$, then we are essentially in the standard linear case of lines in $\mathbb{P}^2$.

From a germ of projective structure at $p \in U$, we can deduce a germ of surface neighborhood of $C_p \simeq \mathbb{P}^1$. Conversely, it is proved in [33 Section 1.7] that we can reverse the construction. Indeed, given a rational curve $C \subset S$ in a surface (everything smooth holomorphic) having normal bundle $\mathcal{O}_{\mathbb{P}^1}(1)$, then $C$ admits by Kodaira Deformation Theory a local 2-parameter family of deformation and the parameter space $U$ is naturally equipped with a projective structure: geodesics on $U$ are those rational curves passing to a common point in $S$.

In the sequel, we call $(+1)$-neighborhood of a rational curve $C$ a germ $(S, C)$ of a smooth complex surface $S$ where $C$ is embedded with normal bundle $\mathcal{N}_C \simeq \mathcal{O}_C(+1)$.

**Theorem 2.4** (Le Brun). We have a one-to-one correspondence between germs of projective structures on $(\mathbb{C}^2, 0)$ up to diffeomorphism and germs of $(+1)$-neighborhood of $\mathbb{P}^2$ up to isomorphism.

More details (and generalizations) can be found in [33] (see also [26]).
2.4. Affine connections, metric. Let $S$ be a smooth complex surface. An affine connection on $S$ is a (linear) holomorphic connection on the tangent bundle $T_S$, i.e. a $\mathbb{C}$-linear morphism $\nabla : T_S \to T_S \otimes \Omega^1_S$ satisfying the Leibnitz rule
\[
\nabla(f \cdot Z) = Z \otimes df + f \cdot \nabla(Z)
\]
for any holomorphic function $f$ and any vector field $Z$. Given a two vector fields $Z,W$, we denote as usual by $\nabla_W Z$ the contraction of $\nabla Z$ with $W$.

By a parametrized geodesic for $\nabla$, we mean a holomorphic curve $t \mapsto \gamma(t)$ on $S$ such that $\nabla_{\dot{\gamma}}(\dot{\gamma}) = 0$ on the curve. The image of $\gamma(t)$ on $S$ is simply called a (unparametrized) geodesic and is characterized by $\nabla_{\dot{\gamma}}(\dot{\gamma}) = f(t)\dot{\gamma}$ for any parametrization. Geodesics define a projective structure $\Pi_{\nabla}$ on $S$.

In coordinates $(x,y) \in U \subset \mathbb{C}^2$, a trivialization of $TU$ is given by the basis $(\partial_x, \partial_y)$ and the affine connection is given by
\[
\nabla(Z) = d(Z) + \Omega \cdot Z, \quad \Omega = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}
\]
where $Z = z_1\partial_x + z_2\partial_y$ and $\alpha, \beta, \gamma, \delta \in \Omega^1(U)$. On the projectivized bundle $\mathbb{P}(TU)$, with trivializing coordinate $z = z_2/z_1$, equation $\nabla = 0$ induces a Riccati distribution
\[
\ker(dz + \gamma - (\alpha - \delta)z - \beta z^2).
\]
Intersection with the contact structure $\ker(dy - zdx)$ gives the geodesic foliation $\mathcal{G}$ of the projective structure. Precisely, if we set
\[
\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} \alpha_1 & \beta_1 \\ \gamma_1 & \delta_1 \end{pmatrix} dx + \begin{pmatrix} \alpha_2 & \beta_2 \\ \gamma_2 & \delta_2 \end{pmatrix} dy
\]
(with $\alpha_i, \beta_i, \gamma_i, \delta_i \in \mathcal{O}(U)$) then the projective structure is given by substituting (4) and $z = dy/\frac{dA}{dx}$ into (3), namely
\[
\begin{pmatrix} \frac{d^2y}{dx^2} \\ \frac{dy}{dx} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} \frac{dy}{dx} \\ \frac{d^2y}{dx^2} \end{pmatrix} + \begin{pmatrix} E & F \\ G & H \end{pmatrix} \begin{pmatrix} \frac{d^2y}{dx^2} \\ \frac{dy}{dx} \end{pmatrix} + \begin{pmatrix} I & J \\ K & L \end{pmatrix} \begin{pmatrix} \frac{dy}{dx} \\ \frac{d^2y}{dx^2} \end{pmatrix}.
\]
We say that two affine connections are (projectively) equivalent if they have the same family of geodesics, i.e. if they define the same projective structure. The following is straightforward

**Lemma 2.5.** Two affine connections \( \nabla \) and \( \nabla' \) on \( U \), with matrices \( \Omega \) and \( \Omega' \) respectively, define the same projective structure if, and only if, there are \( a, b, c, d \in \mathcal{O}(U) \) such that
\[
\Omega' = \Omega + a \begin{pmatrix} dx/2 & 0 \\ dy & -dx/2 \end{pmatrix} + b \begin{pmatrix} -dy/2 & dx \\ 0 & dy/2 \end{pmatrix} + c \begin{pmatrix} dx & 0 \\ 0 & dx \end{pmatrix} + d \begin{pmatrix} dy & 0 \\ 0 & dy \end{pmatrix}.
\]

**Remark 2.6.** Any projective connection \( \Pi : U' \to U \) is an embedding of \( U \) into \( U' \) if it is Cartan-equivalent to the standard linear structure whose geodesics are lines: in \([1]\), it is proved that there are infinitely many obstructions, the first one arising at order 5.

**Question 2.7.** Can we characterize in a geometric way those projective structures arising from a holomorphic metric? And what about the corresponding \((+1)\)-neighborhood ?

2.5. **Some criteria of linearization.** A projective structure \((U, \Pi)\) is said linearizable if it is Cartan-equivalent to the standard linear structure whose geodesics are lines: there is a diffeomorphism
\[
\Phi : U \to V \subset \mathbb{P}^2
\]
such that geodesics on \( U \) are pull-back of lines in \( \mathbb{P}^2 \). When \( U \) is geodesically convex, this is equivalent to say that \((U', C_0)\) is the neighborhood of a line in \( \mathbb{P}^2 \). As we shall see later, there are many projective structures that are non linearizable (even locally).

Here follow some criteria of local linearizability.

**Proposition 2.8.** Let \( \Pi \) be a germ of projective structure at \((\mathbb{C}^2, 0)\) and let \((U', C_0)\) be the corresponding \((+1)\)-neighborhood. If for 2 distinct points \( p_1, p_2 \in C_0 \) the family of rational curves through \( p_i \) is contained in a pencil of curves based in \( p_i \), then \((U', C_0) \simeq (\mathbb{P}^2, \text{line}) \) (and \( \Pi \) is linearizable).

**Proof.** For \( i = 1, 2 \), let \( F_i : U' \to \mathbb{P}^1 \) be the meromorphic map defining the pencil based at \( p_i \); deformations of \( C_0 \) passing through \( p_i \) are (reduced) fibers of \( F_i \). We can assume \( C_0 = \{ F_i = 0 \} \) for \( i = 1, 2 \). Then, maybe shrinking \( U' \), the map
\[
\Phi : U' \to \mathbb{P}^2_{(z_0:z_1:z_2)} : p \mapsto (1 : \frac{1}{F_1} : \frac{1}{F_2})
\]
is an embedding of \( U' \) onto a neighborhood of the line \( z_0 = 0 \). Indeed, \( \Phi \) is well-defined and injective on \( U' \setminus C_0 \); one can check that it extends holomorphically on \( C_0 \) and the extension does not contract this curve.

**Corollary 2.9.** [1 Chapter 1] Let \( \Pi \) be a germ of projective structure at \((\mathbb{C}^2, 0)\) and let \((U', C_0)\) be the corresponding \((+1)\)-neighborhood. If deformations of \( C_0 \) are geodesics of a projective structure \( \Pi' \) in a neighborhood of a point \( p \in C_0 \), then \((U', C_0) \simeq (\mathbb{P}^2, \text{line}) \) (and \( \Pi \) is linearizable).

**Proposition 2.10** ([PS, Proposition 4.7]). Let \( S \) be a smooth compact surface with an embedded curve \( C_0 \simeq \mathbb{P}^1 \) with self-intersection +1. Then \( S \) is rational and \((S, C_0) \simeq (\mathbb{P}^2, \text{line}) \).
Proof. As $S$ contains a smooth rational curve with positive self-intersection, we deduce from \cite[Proposition V.4.3]{2} that $S$ is rational. This implies $H^1(S,\mathcal{O}_S) \cong H^{0,1}(S) \cong H^0(S,\mathcal{O}_S^*) = 0$ thus the Chern-class morphism $H^1(S,\mathcal{O}_S^*) \to H^2(S,\mathbb{Z})$ is injective. We can take deformations $C_1$, $C_2$ of $C_0$ such that $C_0 \cap C_1 \cap C_2 = \emptyset$ and by the previous discussion the three curves determine the same element $\mathcal{O}_S(C)$ of $H^1(S,\mathcal{O}_S^*)$, then we have sections $F_i$ of $\mathcal{O}_S(C)$ vanishing on $C_i$, $i = 0, 1, 2$. We define
\[
\sigma := (F_0 : F_1 : F_2) : S \longrightarrow \mathbb{P}^2
\]
which is in fact a morphism. Moreover, by the condition on the intersection of the curves we deduce that the generic topological degree of $\sigma$ is $1$. In particular $\sigma$ is a sequence of blow-ups with no exceptional divisor intersecting $C_0$. \hfill \Box

Proposition 2.11. There is a unique global projective structure on $\mathbb{P}^2$, namely the linear one.

Proof. If $\mathcal{F}_\Pi$ is the associated regular foliation by curves defined in $M = \mathbb{P}(T\mathbb{P}^2)$ with cotangent bundle $\mathcal{O}_M(ah + bh)$ and $\mathcal{V}$ stands for the foliation defined by the fibers, then $\text{Tang}(\mathcal{F}_\Pi, \mathcal{V}) = (a+2)h + (b-1)\widetilde{h}$ (see \cite[Proposition 2.3]{19}). So, the only second order differential equation totally transverse to $\mathcal{V}$ is the one given by $y'' = 0$. \hfill \Box

Finally, we end-up with an analytic criterium proved by Liouville in \cite{36} (and later by Tresse and Cartan):

Proposition 2.12. Given a projective structure $\Pi$ defined by equation \cite{1} in the introduction, then consider the two functions $L_i(x, y)$ defined by
\[
\begin{cases}
L_1 = 2B_{xy} - C_{xx} - 3A_{yy} - 6AD_x - 3A_y D + 3(AC)_y + BC_x - 2BB_y, \\
L_2 = 2C_{xy} - B_{yy} - 3D_{xx} + 6A_y D + 3AD_y - 3(BD)_x - B_y B + 2CC_x.
\end{cases}
\]
Then, the tensor $\theta := (L_1 dx + L_2 dy) \otimes (dx \wedge dy)$ is intrinsically defined by the projective structure $\Pi$, i.e. its definition does not depend on the choice of coordinates $(x, y)$. Moreover, $\Pi$ is linearizable if, and only if, $\theta = 0$.

We promptly deduce:

Corollary 2.13. Let $\Pi$ be a projective structure on a connected open set $U$. If $\Pi$ is linearizable at the neighborhood of a point $p \in U$, then it is linearizable at the neighborhood of any otherpoint $q \in U$. 

3. Foliated structures vs transverse fibrations

A (non singular) foliation $\mathcal{F}$ on $U$, defined by say $y' = f(x, y)$, can be equivalently defined by its graph $S := \{ z = f(x, y) \} \subset \mathbb{P}(T_U)$, a section of $\pi : \mathbb{P}(T_U) \to U$. The foliation is geodesic if, and only if, the section $S$ is tangent to $\mathcal{G}$; in this case, the section projects onto a curve $D := \pi^\vee(S)$ intersecting transversally the rational curve $C_0$ at a single point on $U^\vee$. We thus get a one-to-one correspondence between geodesic foliations on $U$ and transversal curves on $(U^\vee, C_0)$.

3.1. Pencil of foliations and Riccati foliation. A (regular) pencil of foliations on $U$ is a one-parameter family of foliations $\{ \mathcal{F}_t \}_{t \in \mathbb{P}^1}$ defined by $\mathcal{F}_t = \ker(\omega_t)$ for a pencil of 1-forms $\{ \omega_t = \omega_0 + t\omega_\infty \}_{t \in \mathbb{P}^1}$ with $\omega_0, \omega_\infty \in \Omega^1(U)$ and $\omega_0 \wedge \omega_\infty \neq 0$ on $U$. The pencil of 1-forms defining $\{ \mathcal{F}_t \}_{t \in \mathbb{P}^1}$ is unique up to multiplication by a non vanishing function: $\tilde{\omega}_t = f \omega_t$ for all $t \in \mathbb{P}^1$ and $f \in \mathcal{O}^\vee(U)$. In fact, the parametrization by $t \in \mathbb{P}^1$ is not intrinsic; we will say that $\{ \mathcal{F}_t \}_{t \in \mathbb{P}^1}$ and $\{ \mathcal{F}'_t \}_{t \in \mathbb{P}^1}$ define the same pencil on $U$ if there is a Moebius transformation $\varphi \in \text{Aut}(\mathbb{P}^1)$ such that $\mathcal{F}_t' = F_{\varphi(t)}$ for all $t \in \mathbb{P}^1$.

There exists a unique projective structure $\Pi$ whose geodesics are the leaves of the pencil. Indeed, the graphs $S_t$ of foliations $\mathcal{F}_t$ are disjoint sections (since foliations are pairwise transversal) and form a codimension one foliation $\mathcal{H}$ on $\mathbb{P}(T_U)$ transversal to
the projection $\pi : \mathbb{P}(T_U) \to U$. The foliation $\mathcal{H}$ is a Riccati foliation, i.e. a Frobenius integrable Riccati distribution:

$$\mathcal{H} = \ker(\omega), \quad \omega = dz + \alpha z^2 + \beta z + \gamma, \quad \omega \wedge d\omega = 0.$$  

Intersecting $\mathcal{H}$ with the contact distribution yields a Legendrian foliation $\mathcal{G}$ (also transversal to the $\mathbb{P}^1$-fibers) and thus a projective structure.

In local coordinates $(x, y)$ such that $\mathcal{F}_0$ and $\mathcal{F}_\infty$, are respectively defined by $\ker(dx)$ and $\ker(dy)$, we can assume the pencil generated by $\omega_0 = dx$ and $\omega_\infty = u(x, y)dy$ (we have normalized $\omega_0$) with $u(0, 0) \neq 0$. Then, the graph of the foliation $\mathcal{F}_i$ is given by the section $S_i = \{z = -\frac{1}{\eta_0(x, y)}\} \subset \mathbb{P}(T_U)$. These sections are the leaves of the Riccati foliation $\mathcal{H} = \ker(dz + \frac{\eta}{u} z)$, and we can deduce the equation of the projective structure:

$$y'' + \frac{u_x}{u} y' + \frac{u_y}{u} (y')^2 = 0.$$  

Note that the projective structure is also defined by the affine connection

$$\nabla = d + \Omega, \quad \Omega = \begin{pmatrix} \frac{\partial}{\partial x} & 0 \\ \frac{\partial}{\partial y} & -\frac{\partial}{\partial x} \end{pmatrix}$$  

which is flat (or integrable, curvature-free) $\Omega \wedge d\Omega = 0$, and trace-free $\text{trace}(\Omega) = 0$.

**Remark 3.1.** A Riccati distribution $\mathcal{H} = \ker(\omega)$ on $\mathbb{P}(T_U)$,

$$\omega = dz + \alpha z^2 + \beta z + \gamma, \quad \alpha, \beta, \gamma \in \Omega^1(U),$$

is the projectivization of a unique trace-free affine connection, namely

$$\nabla = d + \Omega, \quad \Omega = \begin{pmatrix} -\frac{\beta}{\gamma} & -\frac{\alpha}{\gamma} \\ \gamma & \beta \end{pmatrix}.$$  

Are equivalent

- $\nabla$ is flat: $\Omega \wedge \Omega + d\Omega = 0$;
- $\omega$ is Frobenius integrable: $\omega \wedge d\omega = 0$.

There are many other affine connections whose projectivization is $\omega$ which are not flat: in general, we only have the implication $[\nabla \text{ flat}] \Rightarrow [\mathcal{H} \text{ integrable}]$.

### 3.2. Transverse fibrations on $U^\vee$

If we have a Riccati foliation $\mathcal{H}$ on $\mathbb{P}(T_U)$ which is $\mathcal{G}$-invariant, then it descends as a foliation $\mathcal{H}$ on $U^\vee$ transversal to $C_0$. Maybe shrinking $U^\vee$, we get a fibration by holomorphic discs transversal to $C_0$ that can be defined by a holomorphic submersion

$$H : U^\vee \to C_0$$

satisfying $H|_{C_0} = id|_{C_0}$ (a holomorphic retraction). Indeed, we can define this map on $\mathbb{P}(T_U)$ first (construct a first integral for $\mathcal{H}$) and, then descend it to $U^\vee$.

Conversely, if we have a holomorphic map $H : U^\vee \to \mathbb{P}^1$ which is a submersion in restriction to $C_0$, then fibers of $\tilde{H} := H \circ \pi^\vee : \mathbb{P}(T_U) \to \mathbb{P}^1$ define the leaves of a Riccati foliation $\mathcal{H}$. Indeed, the restriction of $\tilde{H}$ to $\mathbb{P}^1$-fibers must be global diffeomorphisms, and in coordinates, $\tilde{H}$ take the form

$$\tilde{H}(x, y, z) = \frac{a_1(x, y)z + b_1(x, y)}{a_2(x, y)z + b_2(x, y)}$$

which, after derivation, give a Riccati distribution:

$$\ker(d\tilde{H}) = \ker \left( dz + \frac{a_2 da_1 - a_1 da_2}{a_1 b_2 - a_2 b_1} z^2 + \frac{a_2 db_1 - b_1 da_2 + b_2 da_1 - a_1 db_2}{a_1 b_2 - a_2 b_1} z + \frac{b_2 db_1 - b_1 db_2}{a_1 b_2 - a_2 b_1} \right).$$

By construction, the Riccati foliation $\mathcal{H}$ is $\mathcal{G}$-invariant. One therefore deduce:

**Proposition 3.2** (Krynski [30]). Let $\Omega$ be a projective structure on $(U, 0)$ and $(U^\vee, C_0)$ be the dual. The following data are equivalent:

- a pencil of geodesic foliations $\{\mathcal{F}_t\}_{t \in \mathbb{P}^1}$,
• a $G$-invariant Riccati foliation $\mathcal{H}$ on $\mathbb{P}(T_1)$,
• a fibration by discs transverse to $C_0$ on $U^\vee$.

In this case, we say that the projective structure is \textit{foliated}.

**Example 3.3.** Let $\Pi_0$ be the trivial structure $y'' = 0$ with Riccati distribution $\omega_0 = dz$. We fix coordinates $(a, b) \in \mathbb{P}^2$ for the line $\{ax + by = 1\} \subseteq \mathbb{P}^2$ and observe that $0$ is the line of the infinity $L_\infty$ in this coordinates. It is straightforward to see that the Riccati foliation associated to the pencil of lines through $(a, b)$ is

$$\omega = dz + \left(\left(\frac{a}{1 - ax - by}\right) + z \left(\frac{b}{1 - ax - by}\right)\right)(dy - zdx).$$

Remark that the fibrations induced by $\omega_0$ and $\omega$ have a common fiber, which is the fiber associated to the radial foliation with center at $\{ax + by = 1\} \cap L_\infty$.

3.3. \textit{Webs and curvature.} We recall that a (regular) $k$-web $\mathcal{W} = \mathcal{F}_1 \boxtimes \ldots \boxtimes \mathcal{F}_k$ on $(\mathbb{C}^2, 0)$ is a collection of $k$ germs of (smooth) pair-wise transversal foliations. We say that the projective structure $\Pi$ is compatible with a web $\mathcal{W}$ if every leaf of $\mathcal{W}$ is a geodesic of $\Pi$. For 4-webs we have the following proposition.

**Proposition 3.4 ([46] Proposition 6.1.6).** If $\mathcal{W}$ is a (regular) 4-web on $(\mathbb{C}^2, 0)$ then there is a unique projective structure $\Pi_{\mathcal{W}}$ compatible with $\mathcal{W}$.

Let $\mathcal{W} = \mathcal{F}_1 \boxtimes \mathcal{F}_2 \boxtimes \mathcal{F}_3 \boxtimes \mathcal{F}_4$ be a 4-web on $(\mathbb{C}^2, 0)$

$$\mathcal{F}_i = [X_i = \partial_x + e_i(x, y)\partial_y] = [\eta_i = e_idx - dy], \quad i = 1, 2, 3, 4.$$  

The cross-ratio

$$\{\mathcal{F}_1, \mathcal{F}_2; \mathcal{F}_3, \mathcal{F}_4\} := \frac{(e_1 - e_3)(e_2 - e_4)}{(e_2 - e_3)(e_1 - e_4)}$$

is a holomorphic function on $(\mathbb{C}, 0)$ intrinsically defined by $\mathcal{W}$. Then, we have:

**Proposition 3.5.** If $\mathcal{W} = \mathcal{F}_0 \boxtimes \mathcal{F}_1 \boxtimes \mathcal{F}_\infty$ is a regular 3-web on $(\mathbb{C}^2, 0)$, then there is a unique pencil $\{\mathcal{F}_t\}_{t \in \mathbb{P}^1}$ that contains $\mathcal{F}_0$, $\mathcal{F}_1$ and $\mathcal{F}_\infty$ as elements. Precisely, $\mathcal{F}_t$ is defined as the unique foliation such that

$$\{\mathcal{F}_0, \mathcal{F}_1; \mathcal{F}_t, \mathcal{F}_\infty\} \equiv t.$$  

We denote by $\Pi_{\mathcal{W}}$ the corresponding projective structure on $(\mathbb{C}^2, 0)$.

Conversely, any foliated projective structure comes from a 3-web: it suffices to choose 3 elements of a pencil. In particular, any 4 elements of a pencil $\{\mathcal{F}_t\}_{t \in \mathbb{P}^1}$ have constant cross-ratio.

**Remark 3.6.** The projective structure $\Pi_{\mathcal{W}}$ is linearizable if, and only if, the pencil $\{\mathcal{F}_t\}$ can be defined by a pencil of closed 1-forms (see [11] or [35]). Equivalently, any extracted 3-web is hexagonal (i.e. hexagonal, see [3] section 6] or [46] Chap. 1, Sect. 2]).

**Example 3.7.** We can easily construct non linearizable projective structure by using Remark [3.6]. For instance, the projective structure generated by the pencil of 1-forms $\omega_t := dx + te^{ay}dy$ cannot be defined by a pencil of closed 1-forms. Therefore, it defines a non linearizable pencil $\mathcal{W}$, and a non linearizable projective structure $\Pi_{\mathcal{W}}$.

3.4. **Prolongation of foliated structures.** Let $\Pi$ be a projective structure defined on an open set $\Omega \subset \mathbb{C}^2$ by the differential equation

$$y'' = A(x, y) + B(x, y)(y') + C(x, y)(y')^2 + D(x, y)(y')^3$$

We assume that $\Pi$ is foliated: it can be defined from a Riccati foliation on $\mathbb{P}^2T\Omega$, i.e. a Pfaffian equation

$$dz = \alpha z^2 + \beta z + \gamma$$
where Frobenius integrability condition writes:

\[
\begin{aligned}
\alpha &= \alpha \wedge \beta \\
\beta &= 2\alpha \wedge \gamma \\
\gamma &= \beta \wedge \gamma
\end{aligned}
\]

Substituting \( z = \frac{dy}{dx} \) in (9) and comparing with (8) yields

\[
y'' = \gamma_1 + (\beta_1 + \gamma_2)(y') + (\alpha_1 + \beta_2)(y')^2 + \alpha_2(y')^3
\]

with

\[
\begin{aligned}
\alpha &= \alpha_1 dx + \alpha_2 dy = (C - g)dx + Ddy \\
\beta &= \beta_1 dx + \beta_2 dy = f dx + gdy \\
\gamma &= \gamma_1 dx + \gamma_2 dy = A dx + (B - f)dy
\end{aligned}
\]

By substituting (11) in (10), we promptly deduce:

**Proposition 3.8.** The projective structure \( \Pi \) defined by (8) is foliated if, and only if, there exist functions \( f, g \in \mathcal{O}(\Omega) \) such that

\[
\begin{aligned}
f_x &= f^2 - Bf + Ag + Bx - Ay \\
g_x - f_y &= 2(fg - Bg - Cf + BC - AD) \\
g_y &= -g^2 + Cg + Cy - Dx
\end{aligned}
\]

We want to understand if the existence of a foliated structure at the neighborhood of a point of \( \Omega \) propagates on the whole of \( \Omega \), maybe assuming \( \Omega \) simply connected. We first notice that \( \Omega \) might have meromorphic extension even if the projective structure is holomorphic as shown by the following example:

**Example 3.9.** Consider the linear projective structure \( \Pi_0 \) defined by \( y'' = 0 \). Then the meromorphic Riccati equation

\[
dz = \frac{dy - zdx}{x}
\]

is Frobenius integrable and induces the projective structure \( \Pi_0 \). In fact, it defines a pencil of foliations by lines, namely the family of radial foliations with center along \( x = 0 \). The foliated structure has a pole along \( x = 0 \).

Therefore, we cannot expect to have a holomorphic prolongation in general, but we are going to prove that it admits a meromorphic prolongation to \( \Omega \) assuming that \( \Omega \) is simply connected. Let us first prove it assuming that the projective structure is normalized with \( A = D = 0 \).

**Lemma 3.10.** Assume that \( \Omega \) is a polydisc and the projective structure \( \Pi \) is given by (8) with \( A = D = 0 \) on \( \Omega \). Then any local \( f, g \) holomorphic at a point \( p \in \Omega \) and satisfying (12) extend meromorphically on the whole of \( \Omega \).

Recall that \( A = D = 0 \) is equivalent to say that the foliations \( dx = 0 \) and \( dy = 0 \) are \( \Pi \)-geodesic.

**Proof.** Assume that \( f \) and \( g \) are holomorphic on an open ball \( U \subset \Omega = \mathbb{D}_1 \times \mathbb{D}_2 \) satisfying equations (12). We want to prove that we can extend \( f \) and \( g \) meromorphically on \( \Omega \); indeed, in that case, the Riccati equation (11) will be integrable on \( U \), and therefore on the whole of \( \Omega \) by analytic continuation. Setting \( A = D = 0 \) in (12) gives

\[
\begin{aligned}
f_x &= f^2 - Bf + Bx \\
g_x - f_y &= 2(fg - Bg - Cf + BC) \\
g_y &= -g^2 + Cg + Cy
\end{aligned}
\]

The basic idea of the proof is to use successively the different differential equations (all of Riccati type either in \( f \) or \( g \)) to extend the solutions \( f, g \) firstly along a vertical cylinder, and then horizontally on the whole of \( \Omega \). However, we have to be careful because solutions may have poles, and equations also differ after substitution.
Denote by \( \pi_1(x, y) = x \) and \( \pi_2(x, y) = y \) are the projections on coordinates, and consider the vertical cylinder \( U_1 := \pi_1^{-1}(\pi_1(U)) \). The last equation of (13) is a Riccati equation in \( y \) over \( U_1 \) with respect to variable \( y \). As we already get a solution on \( U \), the Riccati equation provides by integration w.r.t. \( y \) a meromorphic extension along the vertical cylinder \( U_1 \), solving the same equation, that we still denote by \( g \). Substituting the meromorphic solution \( g \) in the second equation yields a meromorphic Bernoulli equation on \( U_1 \) for \( f \) with respect to variable \( y \). Therefore, the holomorphic solution \( f \) on \( U \) admits an analytic continuation along any path in \( U_1 \setminus (g)_{\infty} \), where \((g)_{\infty}\) denotes the polar locus of \( g \) in \( U_1 \). However, \( f \) needs not be meromorphic at \((g)_{\infty}\) a priori, and might have multiform extension to the complement.

We claim that \( f \) has meromorphic extension along horizontal branches of \((g)_{\infty}\). Indeed, if \( \Gamma \) is such a branch, then the extension of \( f \) along a general line \( L : \{y = \text{constant}\} \) intersecting \( \Gamma \) also intersects \( U_1 \setminus (g)_{\infty} \) where \( f \) admits an analytic continuation, and the first equation shows that \( f \) extends meromorphically all along \( L \), and in particular across \( \Gamma \). Therefore, \( f \) admits a meromorphic continuation along any path inside \( \Gamma_1 = U_1 \setminus \Gamma_2 \) where \( \Gamma_2 \) is the union of horizontal branches of \((g)_{\infty} \), i.e. fibers of \( \pi_2 \); moreover, the polar locus \((f)_{\infty} \) has no horizontal branch (apart from \( \Gamma_2 \) where it is not defined).

We now consider the first equation which allows us to provide a meromorphic continuation of \( f \) along all horizontal lines \( L \) intersecting \( \Gamma_1 \). In other words, \( f \) admits a meromorphic continuation along any path inside \( \Gamma_1 = \pi_2^{-1}(\pi_2(U)) \); if we still denote by \( \Gamma_2 \) the extension of horizontal branches of \((g)_{\infty} \) \( \Omega \), then we see that \( \Gamma_1 = \Omega \setminus \Gamma_2 \).

Finally, we use the second equation again to provide the analytic continuation of \( g \) in the horizontal paths. Since we have to substitute \( f \) in that equation, we get, as before, that \( g \) admits meromorphic continuation along \( \Gamma_2 = \Omega \setminus \Gamma_1 \) where \( \Gamma_1 \) is contained into vertical branches of the polar locus \((f)_{\infty} \).

So far, we have proved that the foliated structure can be continued meromorphically along every path avoiding the union \( \Gamma_1 \cup \Gamma_2 \) of vertical and horizontal geodesics. We have that \( f \) and \( g \) have a pole at \( \Gamma_1 \) and \( \Gamma_2 \) respectively, but \( g \) and \( f \) do not a priori extend meromorphically on \( \Gamma_1 \) and \( \Gamma_2 \) respectively, and might have monodromy around. In order to conclude the proof, we have to check that these are fake obstructions and the foliated structure extends meromorphically on the whole of \( \Omega \). One way to prove this is to notice that the vertical and horizontal geodesic foliations have been chosen arbitrarily: we can repeat our arguments in other coordinates, by normalizing two geodesic foliations that are transversal to both \( \Gamma_1 \) and \( \Gamma_2 \), so that these curve become neither horizontal, nor vertical in the new coordinates. Another way to prove it is to make a closer analysis at differential equations near a generic point of \( \Gamma_1 \), say. The first equation can be rewritten as

\[
\frac{f_x - B_x}{f - B} = f
\]

so that we see that the meromorphic solution \( f \) must have simple poles with constant residue \(-1\). Now, let \( x = 0 \) such a pole. The second equation is a Bernoulli equation for \( g \) with simple poles, of the form

\[
g_x = \left( -\frac{2}{x} + \text{holomorphic} \right) \cdot g + \frac{\text{holomorphic}}{x};
\]

but such equation has only meromorphic solutions: indeed, \( x^2g \) satisfies a holomorphic Bernoulli equation and is therefore holomorphic. We can make a similar discussion with horizontal branches \( \Gamma_2 \).

\[\square\]

**Corollary 3.11.** Assume that \( \Omega \subset \mathbb{C}^2 \) is an open set equipped with a projective structure \( \Pi \). If \( \Pi \) is foliated at the neighborhood of some point \( p \in \Omega \), then the foliated structure (or Riccati foliation) can be meromorphically continued along any path in \( \Omega \).
Proof. It suffices to cover the path by local polydiscs on which we can normalize II as in Proposition 3.10 and then use that proposition successively along the path to propagate the Riccati structure. □

A similar prolongation result has been obtained for first integrals of the affine connection in [15] (degree 1) and [6] (degree 2). However, these do not imply similar results for first integrals of the projective structure. And indeed, in the case of affine connections, there are no pole along prolongation.

4. Classification of neighborhoods of rational curves

Let \( \mathbb{P}^1 \hookrightarrow S \) be an embedding of \( \mathbb{P}^1 \) into a smooth complex surface and let \( C \) be its image. The self-intersection of \( C \) is also the degree of the normal bundle of the curve \( C \cdot C = \deg(N_C) \). When \( C \cdot C < 0 \), it follows from famous work of Grauert [25] that the germ of neighborhood \((S, C)\) is linearizable, i.e. biholomorphically equivalent to \((N_C, 0)\) where 0 denotes the zero section in the total space of the normal bundle. Such neighborhood is called rigid since there is no non trivial deformation. When \( C \cdot C = k \geq 0 \), it follows from Kodaira [32] that the deformation space of the curve \( C \) in its neighborhood is smooth of dimension \( k + 1 \). In particular, for \( C \cdot C = 0 \), the neighborhood is a fibration by rational curves, which is thus trivial by Fisher-Grauert [24]: the neighborhood is again linearizable (see also Savel’e\v{v} [48], thus rigid. However, in the positive case \( C \cdot C > 0 \), it is also well-known that we have huge moduli. The analytic classification is due to Mishustin [40] but a formal version was already given by Hurtubise and Kamran in [28] one year before; in this section, we recall the case \( C \cdot C = 1 \).

Let us first decompose \( C = V_0 \cup V_\infty \) where \( x_i : V_i \hookrightarrow C \) are affine charts, \( i = 0, \infty \), with \( x_0x_\infty = 1 \) on \( V_0 \cap V_\infty \). Then any germ of neighborhood \((S, C)\) can be decomposed as the union \( U_0 \cup U_\infty \) of two trivial neighborhoods \( U_i \simeq V_i \times \mathbb{D}_\epsilon \) with coordinates \((x_i, y_i)\) patched together by a holomorphic map

\[
(x_\infty, y_\infty) = \Phi(x_0, y_0) = \left( \frac{1}{x_0} + \sum_{n \geq 1} a_n(x_0)y_0^n, \sum_{n \geq 1} b_n(x_0)y_0^n \right)
\]

where \( a_n, b_n \) are holomorphic on \( V_0 \cap V_\infty \simeq \mathbb{C}^* \). Moreover, \( b_1 \) does not vanish on \( V_0 \cap V_\infty \) and, viewed as a cocycle \( \{b_i\} \in H^1(\mathbb{P}^1, \mathcal{O}^*_C) \), defines the normal bundle \( N_C \). Denote \( U_\Phi \) the germ of neighborhood defined by such a gluing map. The gluing map \( \Phi \) can also be viewed as a non linear cocycle encoding the biholomorphic class of the neighborhood, as illustrated by the following straightforward statement.

Proposition 4.1. Given another map \( \Phi' \), then the following data are equivalent:

- a germ of biholomorphism \( \Psi : U_\Phi \sim U_{\Phi'} \) inducing the identity on \( C \),
- a pair of biholomorphism germs

\[
\Psi^i(x_i, y_i) = \left( x_i + \sum_{n \geq 1} a_n^i(x_i)y_i^n, \sum_{n \geq 1} b_n^i(x_i)y_i^n \right), \quad (i = 0, \infty)
\]

(with \( b_1^0, b_1^\infty \) not vanishing) satisfying \( \Phi' \circ \Psi^0 = \Psi^\infty \circ \Phi \):

We will say that the two “cocycles” \( \Phi \) and \( \Phi' \) are equivalent in this case.

Since \( H^1(\mathbb{P}^1, \mathcal{O}^*_C) = \mathbb{Z} \) there exist \( b^i \in \mathcal{O}^*(V_i) \), \( i = 0, \infty \), such that \( b^\infty b_1 = x_0 b^0 \). Thus, the pair \( \Psi^i(x_i, y_i) = (x_i, b^i y_i), \quad i = 0, \infty \), provides us with an equivalent cocycle
such that \( b_1(x_0) = x_0^k \). Now, this exactly means that \( C \cdot C = -k \). As conclusion, (+1)-neighborhoods can be defined by a cocycle of the form

\[
\Phi(x_0, y_0) = \left( \frac{1}{x_0} + \sum_{n \geq 1} a_n(x_0) y_0^n, \frac{y_0}{x_0} + \sum_{n \geq 2} b_n(x_0) y_0^n \right) =: \left( \frac{1}{x_0} + a, \frac{y_0}{x_0} + b \right).
\]

4.1. Normal form. Using the equivalence defined in Proposition 4.1 above, we can reduce the cocycle \( \Phi \) into an almost unique normal form:

**Theorem 4.2** (Mishustin). Any germ \((S, C)\) of (+1)-neighborhood is biholomorphically equivalent to a germ \( U_\Phi \) for a cocycle \( \Phi \) of the following “normal form”

\[
(14) \quad \Phi = \left( \frac{1}{x} + \sum_{v(\mathbb{Z}^2)} a_{m,n} x^m y^n, \frac{y}{x} + \sum_{v(\mathbb{Z}^2)} b_{m,n} x^m y^n \right),
\]

where \( v(k, l) := \{(m+k, n+l) \in \mathbb{Z}^2 : -n \leq m \leq 0\} \). \((k, l) \in \mathbb{Z}^2\).

Moreover, when the neighborhood \((S, C)\) admits a fibration transverse to \( C \), then one can choose all \( a_{m,n} = 0 \) so that the fibration is given by \( x_0 = x_\infty : S \to C \).

As we shall see in the next section, this normal form is unique up to a 4-dimensional group action.

**Remark 4.3.** This normal form was firstly established by Hurtubise and Kamran in [28], but without convergence. They obtained it by an iterative procedure, where the \( y^n \)-part of the coefficients are simplified at the \( n \)-th step. In fact, when we modify the cocycle as in Proposition 4.1, \( \Phi' = \Psi_\infty \circ \Phi \circ \Psi_0^{-1} \), it can be shown that:

\( \Psi_0 \) (resp. \( \Psi_\infty \)) can be choosen at each step so as to eliminate all coefficients \( a_{m,n}, b_{m,n} \) with \((m, n)\) lying in the corresponding pink (resp. yellow) area in Figure 2.

Mishustin’s proof in [40] is of very different nature though. Denote \( p_0 \) and \( p_\infty \) the points \( x_0 = 0 \) and \( x_\infty = 0 \) in \( C \). After blowing-up \( p_\infty \), the neighborhood of the strict transform of \( C \) becomes a product \( C \times (\mathbb{C}, 0) \) with global coordinates \((x_0, y_0)\); these define coordinates on some neighborhood \( U_0 \) of \( V_0 \) in \( U \). By blowing-up \( p_0 \) instead of \( p_\infty \), we get coordinates \((x_\infty, y_\infty)\) on a neighborhood of \( U_\infty \) of \( V_\infty \). It turns out that this choice of coordinates provide the normal form (in a geometric, and therefore convergent way) up to a last normalization. Full details are given in [21].

**Figure 2. Normal Form**

4.2. Isotropy group for normal forms. During the proof of Theorem 4.2 we have the possibility to normalize coefficients

\[
a_{-1,1} = a_{-2,1} = a_{-2,2} = 0 \quad \text{and} \quad b_{-1,1} = 1
\]

by either using \( \Psi^0 \) or \( \Psi^\infty \) (the green intersecting area of Figure 2). This underline a 4-parameter degree of freedom in the choice of normalizing coordinates systems \((x_0, y_0)\) and \((x_\infty, y_\infty)\).
Proof. See [21], page 20 for a detailed proof.

0 of a given cocycle in normal form \( \Phi \) is determined by the quadratic part of \( \Psi \)

Then an equivalent cocycle \( \Psi^\alpha,\beta,\gamma \) and \( \Psi^\alpha,\beta,\gamma \)

This group law can be easily computed by composing the quadratic parts (16) of \( \Psi = \frac{x^2}{x + \gamma y^2}, y_\infty \) \( \circ \Phi = \frac{x_0 + \beta y_0}{1 + \alpha y_0}, \theta y_0 \).

We promptly deduce from Proposition 4.4 that any change of normalization of a given cocycle in normal form \( \Phi \) is determined by the quadratic part of \( \Psi^0 \):

\[ (x_\infty + \gamma y^2_\infty, y_\infty) \circ \Phi = \frac{x_0 + \beta y_0}{1 + \alpha y_0}, \theta y_0 \]

gives another a new normal form. The 4-parameter of freedom is a combination of those two actions.

**Proposition 4.4.** Consider a cocycle in normal form

\[
\Phi = \left( \frac{1}{x} + \sum_{V(-3,4)} a_{m,n} x^m y^n, \frac{y}{x} + \sum_{V(-2,3)} b_{m,n} x^m y^n \right).
\]

Then an equivalent cocycle \( \Psi^\infty \circ \Phi = \Phi' \circ \Psi^0 \) is also in normal form if, and only if, there are constants \( \alpha, \beta, \gamma \in \mathbb{C} \) and \( \theta \in \mathbb{C}^* \) such that

\[
\Psi^\infty = \left( \frac{x_\infty + \alpha y_\infty + \gamma (1 + \beta y_\infty)^2}{1 + \beta y_\infty}, \frac{\theta y_\infty}{1 + \beta y_\infty} \right)
\]

\[
\Psi^0 = \left( \frac{x_0 + \beta y_0 + \gamma (1 + \alpha y_0)^2}{1 + \alpha y_0}, \frac{\theta y_0}{1 + \alpha y_0} \right)
\]

where \( k^0(y_0) = \sum_{n \geq 3} b_{-n,n} y_0^n \) and \( k^\infty(y_\infty) = \sum_{n \geq 3} b_{-n+1,n} y_\infty^n \).

Proof. See [21], page 20 for a detailed proof.

For instance, starting with the linear neighborhood \( \Phi_0 = (\frac{1}{x}, \frac{y}{x}) \), then we obtain the following equivalent cocycles in normal form (with \( c = \frac{2}{\pi} \in \mathbb{C} \) arbitrary)

\[
\Phi = \left( \frac{1}{x} + \frac{2c^2 x^2}{(1 + c^2 x^2)^2}, \frac{y}{x} \right) \sim \Phi_0.
\]

We promptly deduce from Proposition 4.4 that any change of normalization \( \Phi' = \Psi^\infty \circ \Phi \circ (\Psi^0)^{-1} \)

of a given cocycle in normal form \( \Phi \) is determined by the quadratic part of \( \Psi^0 \):

\[
\Psi^0 = (x + (\beta - \alpha x)y + (\alpha^2 x - (\alpha \beta + \gamma))y^2 + \cdots, \theta y - \theta_1 \alpha y^2 + \cdots).
\]

Conversely, for any \( \vartheta = (\alpha, \beta, \gamma, \theta) \in \mathbb{C}^3 \times \mathbb{C}^* \), the above quadratic part can be extended as a new normalization \( (\Psi^0_{\vartheta,\phi}, \Psi^\infty_{\vartheta,\phi}) \) for each cocycle \( \Phi \) in normal form. We thus get an action of \( \mathbb{C}^3 \times \mathbb{C}^* \) on the set of normal forms \( (\vartheta, \Phi) \mapsto \vartheta \cdot \Phi := \Psi^\infty_{\vartheta,\phi} \circ \Phi \circ (\Psi^0_{\vartheta,\phi})^{-1} \)

with the group law given by

\[
\vartheta_1 \cdot (\vartheta_2 \cdot \Phi) = \Psi^\infty_{\vartheta_1,\phi} \circ \left( \Psi^\infty_{\vartheta_2,\phi} \circ \Phi \circ (\Psi^0_{\vartheta_2,\phi})^{-1} \right) \circ (\Psi^0_{\vartheta_1,\phi})^{-1} = \vartheta_3 \cdot \Phi.
\]

This group law can be easily computed by composing the quadratic parts (16) of \( \Psi^0_{\vartheta_1} \) and \( \Psi^0_{\vartheta_2} \), and we get

\[
\vartheta_3 = (\alpha_2 + \theta_2 \alpha_1, \beta_2 + \theta_2 \beta_1, \gamma_2 + \theta_2^2 \gamma_1, \theta_1 \theta_2).
\]
In other words, the group law on parameters \( \vartheta = (\alpha, \beta, \gamma, \theta) \) is equivalent to the matrix group law

\[
\Gamma := \left\{ \begin{pmatrix} 1 & \alpha & \beta & \gamma \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 \theta^2 \end{pmatrix} \right\}, \quad (\alpha, \beta, \gamma, \theta) \in \mathbb{C}^3 \times \mathbb{C}^* \subset \text{GL}_4(\mathbb{C}).
\]

We deduce:

**Corollary 4.5.** The 4-dimensional matrix group \( \Gamma \) acts on the set of normal forms \([13]\) as defined in Proposition \([4.4]\) and the set of equivalence classes is in one-to-one correspondence with the set of isomorphisms classes of germs of \((+1)\)-neighborhoods \((S, C)\) of the rational curve \(C \simeq \mathbb{P}^1_x\) (with fixed coordinate \(x\)).

Let us describe this action on the first coefficients of the cocycle \( \Phi' = \vartheta \cdot \Phi \):

\[
\begin{align*}
\alpha'_{-3,4} &= \frac{a_{-3,4} - \gamma^2 + 2b_{-2,4} - \beta b_{-2,4} + \alpha b_{-3,4}}{\theta^4} \\
\alpha'_{-3,5} &= \frac{a_{-3,5} + \alpha a_{-3,4} + (2\gamma - \alpha) b_{-2,4} + \alpha^2 b_{-2,4} - \beta b_{-2,4} + \alpha b_{-3,4}}{\theta^4} \\
\alpha'_{-4,5} &= \frac{a_{-4,5} + 2\beta a_{-3,4} + 3\beta^2 \gamma - \beta^3 b_{-2,4} + (2\gamma + \alpha) b_{-3,4} - \beta b_{-2,4} + \alpha b_{-3,5} + \alpha b_{-4,5}}{\theta^4} \\
\cdots \\
\beta'_{-2,3} &= \frac{b_{-2,3} - \gamma}{\theta^4} \\
\beta'_{-2,4} &= \frac{b_{-2,4}}{\theta^4} \\
\beta'_{-2,5} &= \frac{b_{-2,5} + \alpha b_{-2,4}}{\theta^4} \\
\cdots \\
\beta'_{-3,4} &= \frac{b_{-3,4}}{\theta^4} \\
\beta'_{-3,5} &= \frac{b_{-3,5} + \alpha b_{-3,4} - 2\gamma b_{-2,4} + \gamma^2}{\theta^4} \\
\beta'_{-4,5} &= \frac{b_{-4,5} + \beta b_{-3,4}}{\theta^4}
\end{align*}
\]

4.3. Existence of transverse fibration. We go back to the notion of transversal fibration by discs on \((S, C)\) considered in \([3.2]\). If we have such a fibration, it can be defined by a submersion \(H : S \to C\) inducing the identity on \(C\); equivalently, after composition with \(x : C \to \mathbb{P}^1\) we get an extension of the coordinate \(x\) on the neighborhood \(S\). In this case, recall (see Theorem \([4.3]\)) that one can choose a normal form with zero \(a\)-part:

\[
\Phi(x, y) = \left( \frac{1}{x}, \frac{y}{x} + \sum_{V(-2,3)} b_{m,n} x^m y^n \right)
\]

compatible with the fibration in the sense that \(x \circ H = x_0 = \frac{1}{x}\).

**Proposition 4.6.** A \((+1)\)-neighborhood with normal form \(\Phi\) admits a transversal fibration if, and only if, there is a \(\vartheta = (\alpha, \beta, \gamma, 1) \in \Gamma\) such that the \(a\)-part of \(\vartheta \cdot \Phi\) is trivial. Moreover, the set of transversal fibrations is in one-to-one correspondence with the set of those \((\alpha, \beta, \gamma) \in \mathbb{C}^3\) for which the \(a\)-part of \((\alpha, \beta, \gamma, 1) \Phi\) is zero.

**Proof.** Just observe that, once we get a normal form with trivial \(a\)-part, the fibration given by \(x_0 = 1/x\) is only preserved by the action of \((0, 0, 0, \theta)\). We thus have to divide the group action by this normal subgroup to get a bijection with the set of fibrations.

It is clear that we cannot kill the \(a\)-part in general by means of the above 3-dimensional group action and therefore that we have infinitely many obstructions to have a transversal fibration.

**Proposition 4.7.** Any \((+1)\)-neighborhood admits a normal form with \(a\)-part vanishing up to the order 4 in \(y\)-variable, i.e. with \(a_{-3,4} = 0\). In other words, the 4th infinitesimal neighborhood always admit a transversal fibration; the first obstruction to extend it arrives at order 5.

**Example 4.8.** The neighborhood \(U_5\) given by the cocycle in normal form

\[
\Phi = \left( \frac{1}{x} + \frac{y^5}{x^4} + \sum_{V(-3,4)\cap\{n>5\}} a_{m,n} x^m y^n, \frac{y}{x} + \sum_{V(-2,3)\cap\{n>5\}} b_{m,n} x^m y^n \right)
\]
does not admit transversal fibration.

Proof of Proposition 4.7 and Example 4.8. Looking back at the explicit action \[ (17) \] of \( \Gamma \) on the \( a \)-coefficients, we see that whatever is \( a_{-3,4} \), we can assume \( a_{-3,4}' = 0 \) by setting \( a = \beta = 0, \theta = 1 \) and \( \gamma^2 = a_{-3,4} \). On the other hand, the coefficient \( a_{-3,5} \) cannot be killed in general, and in particular in the example. Indeed, since all other coefficients \( a_{m,n}, b_{m,n} \) occuring in \( a_{-3,5}' \) - formula \[ (17) \] - are zero, we see that \( a_{-3,5}' = \theta^5 \neq 0 \) whatever are \( (a, \beta, \gamma) \in \mathbb{C}^3 \).

Example 4.9. The neighborhood \( U_5 \) given by the cocycle in normal form

\[
\Phi = \left( \frac{1}{x} \frac{y}{x} + \sum_{V(-2,3)\cap \{n \geq 5\}} b_{m,n} x^m y^n \right) \quad \text{with} \quad b_{-2,5} b_{-4,5} \neq b_{-3,5},
\]

admits no other transversal fibration than \( dx = 0 \). Indeed, following Proposition 4.6, another fibration would correspond to a triple \( (\alpha, \beta, \gamma) \neq (0,0,0) \) such that the \( a \)-part of \( (\alpha, \beta, \gamma, 1) \Phi \) is zero. However, formula \[ (17) \] gives

\[
a_{-3,4}' = -\gamma^2, \quad a_{-3,5}' = \alpha b_{-3,5} - \beta b_{-2,5} \quad \text{and} \quad a_{-4,5}' = \alpha b_{-4,5} - \beta b_{-3,5},
\]

which shows that we must have \( \alpha = \beta = \gamma = 0 \).

From previous examples, we understand that neighborhoods with exactly one transversal fibration have infinite dimension and codimension in the moduli of all \((+1)\)-neighborhoods.

5. Neighborhoods with several transverse fibrations

In this section, we study \((+1)\)-neighborhoods having several fibrations. The following was recently announced and partly proved in \[ 20 \]; Paulo Sad and the first author gave another proof in \[ 23 \].

Theorem 5.1 \[ 20, 23 \]. If a germ \((S, C)\) of \((+1)\)-neighborhood admits at least 3 distinct fibrations \( \mathcal{H}, \mathcal{H}' \) and \( \mathcal{H}'' \) transversal to \( C \), then \((S, C)\) is equivalent to \((\mathbb{P}^2, L)\), where \( L \) is a line in \( \mathbb{P}^2 \).

In this case, recall (see example 3.3) that there is a 2-parameter family of transverse fibrations (each of them is a pencil of lines through a point) and any two have a common fiber. These results are very similar to \[ 15 \] Theorem 1; however, a foliated structure (or Riccati foliation) needs not lift as a linear first integral for the affine connection, and conversely we need two independent linear first integrals to produce a Riccati foliation, i.e. a first integral for the projective structure having degree 1 in \( z \). Although the results obtained look very similar, the problems seem to be independent so far.

Before proving Theorem 5.1, full details in section 5.5, we need first to classify pairs of fibrations on \((+1)\)-neighborhoods.

5.1. Tangency between two fibrations. Given two (possibly singular) distinct foliations \( \mathcal{H} \) and \( \mathcal{H}' \) on a complex surface \( X \), define the tangency divisor \( \text{Tang}(\mathcal{H}, \mathcal{H}') \) as follows. Locally, we can define the two foliations respectively by \( \omega = 0 \) and \( \omega' = 0 \) for holomorphic 1-forms \( \omega, \omega' \) without zero (or with isolated zero in the singular case); then the divisor \( \text{Tang}(\mathcal{H}, \mathcal{H}') \) is locally defined as the (zero) divisor of \( \omega \wedge \omega' \).

Proposition 5.2. If a germ \((S, C)\) of \((+1)\)-neighborhood admits 2 distinct fibrations \( \mathcal{H} \) and \( \mathcal{H}' \), then

- either \( \text{Tang}(\mathcal{H}, \mathcal{H}') = |C| \) (without multiplicity),
- or \( \text{Tang}(\mathcal{H}, \mathcal{H}') \cdot |C| \) is a single point (without multiplicity).

The former case is rigid and will be described in section 5.3. In the latter case, the tangency divisor is reduced and transversal to \( C \) (equivalently the restriction \( \text{Tang}(\mathcal{H}, \mathcal{H}')|_C \) has degree one); moreover, the support \( \text{Tang}(\mathcal{H}, \mathcal{H}') \) of the divisor is
• either a common fiber of $\mathcal{H}$ and $\mathcal{H}'$, 
• or is generically transversal to $\mathcal{H}$ and $\mathcal{H}'$ (but might be tangent at some point).

**Proof.** See [23 Section 2] or [21]. □

5.2. **Two fibrations having a common leaf.** Let us start with the simplest case.

**Theorem 5.3.** Let $(S,C)$ be a $(+1)$-neighborhood that admits two transversal fibrations $\mathcal{H}$ and $\mathcal{H}'$ with a common leaf $T$. Then $(S,C)$ is linearizable.

**Proof.** By Proposition 5.2, $\mathcal{H}$ and $\mathcal{H}'$ have contact of order 1 along $T$ and are transversal outside. Let $H,H' : S \to \mathbb{P}^3$ be the two submersions defining these foliations and coinciding with $x : C \to \mathbb{P}^1$ in restriction to $C$. For simplicity, assume $T = \{H = \infty\} = \{H' = \infty\}$. We can use $H$ and $H'$ as a system of coordinates to embed $(S,C)$ into $\mathbb{P}^2$ as illustrated in Figure 3. Precisely, consider the map given in homogeneous coordinate $(u:v:w) \in \mathbb{P}^2$ by

$$\Phi := (H:H':1) : S \to \mathbb{P}^2.$$ 

The complement $S \setminus T$ is clearly embedded by $\Phi$ as a neighborhood of the diagonal $\Delta = \{u = v\}$ in the chart $w = 1$. Moreover, the two fibrations are send to fibrations $du = 0$ and $dv = 0$. We just have to check that this map is (well-defined and) still a local diffeomorphism at $T \cap C$. In local convenient coordinates $(x_\infty,y_\infty) \sim (0,0)$ at the source, we have

$$\frac{1}{H} = x_\infty \quad \text{and} \quad \frac{1}{H'} = x_\infty (1 + y_\infty \cdot f(x_\infty,y_\infty)), \quad f(0,0) \neq 0$$

(we used that $1/H$ and $1/H'$ coincide along $y_\infty = 0$, vanish at $x_\infty = 0$ and have simple tangency there). Coordinates at the target are given by

$$(X,Y) = \left( \frac{1}{u}, \frac{u}{v} - 1 \right).$$

Therefore, our map is given by

$$\Phi : (X,Y) = (x_\infty,y_\infty \cdot f(x_\infty,y_\infty))$$

which is clearly a local diffeomorphism. □
5.3. Two fibrations that are tangent along a rational curve. The goal of this section is to describe a very special neighborhood. As we shall see later, it is the only one having a large group of symmetries (i.e. of dimension > 2) but not linearizable.

Let us consider the diagonal Δ ⊂ P¹ × P¹. The self-intersection is Δ · Δ = 2 and its neighborhood is a (+2)-neighborhood. Therefore, we can take (see section 7.2) the 2-fold ramified cover, ramifying over Δ:

\[ \pi : (S, C) \to (\mathbb{P}^1 \times \mathbb{P}^1, \Delta) \]

and we get a (+1)-neighborhood. Moreover, the two fibrations on P¹ × P¹ defined by projections on the two factors lift as fibrations H₁ and H₂ on S transversal to C whose tangent locus is Tang(H₁, H₂) = C.

Remark 5.4. The two fibers passing through a given point p ∈ S close enough to C intersect twice: the Galois involution \( \iota : (S, C) \to (S, C) \) permutes these two points.

Proposition 5.5. The germ \((S, C)\) is not linearizable.

Proof. Assume by contradiction that \((S, C)\) is equivalent to the neighborhood of a line \( L \subset \mathbb{P}^2 \). Then each foliation \( H_i \) extends as a global singular foliation on \( \mathbb{P}^2 \). Since \( H_i \) is totally transversal to \( L \), it must be a foliation of degree 0, i.e. a pencil of lines. But if \( H_i \) and \( H_j \) are pencil of lines, their tangency must be invariant (the line through the to base points), contradiction. \( \square \)

Corollary 5.6. The germ \((S, C)\) is not algebrizable, but the field \( M(S, C) \) of meromorphic functions has transcendence degree 2 over \( \mathbb{C} \).

Proof. It immediately follows from Proposition 2.10 that \((S, C)\) is not algebrizable; the field \( M(S, C) \) contains the field or rational functions on \( \mathbb{P}^1 \times \mathbb{P}^1 \) which has indeed, as an algebraic surface, transcendence degree 2 over \( \mathbb{C} \). \( \square \)

Remark 5.7. The fundamental group \( \pi_1(\mathbb{P}^1 \setminus \Delta) \) is trivial, and this is a reason why we cannot extend the ramified cover to the whole of the algebraic surface. It is proved in [22] that there exist neighborhoods without non constant meromorphic functions.

The cocycle \( \Phi \) defining the germ \((S, C)\) can be constructed as follows. We can give local coordinates \((x_0, y_0), (x_\infty, y_\infty)\) on \( S \) and \((u_0, v_0), (u_\infty, v_\infty)\) on \( V \supset \Delta \) such that

\[
\begin{cases}
  u_0 = x_0 \\
v_0 = x_0 - y_0^2,
\end{cases}
\begin{cases}
  u_\infty = x_\infty \\
v_\infty = x_\infty + y_\infty^2,
\end{cases}
(u_\infty, v_\infty) = \left( \frac{1}{u_0}, \frac{1}{v_0} \right)
\]

where \( \Delta = \{ v_0 = u_0 \} = \{ v_\infty = u_\infty \} \). So the cocycle is explicitly given by

\[
\Phi(x_0, y_0) = \left( \frac{1}{x_0}, \frac{y_0}{x_0} \left( 1 - \frac{y_0^2}{x_0^2} \right)^{-1/2} \right) = \left( \frac{1}{x_0} \frac{y_0}{x_0} + \frac{y_0^3}{2x^2} + \frac{3y_0^5}{8x^3} + \cdots \right),
\]

which is already in normal form. The fibrations are given by

\[ h_1 = x_0 = \frac{1}{x_\infty} \quad \text{and} \quad h_2 = x_0 - y_0^2 = \frac{1}{x_\infty + y_\infty^2}. \]

Proposition 5.8. The fibrations \( H_1 \) and \( H_2 \) are the only two fibrations on \( S \) that are transverse to \( C \).

Proof. Recall [see Proposition 4.6] that transverse fibrations are in one-to-one correspondence with \( \vartheta = (\alpha, \beta, \gamma, \theta) \in \mathbb{C}^4 \times \{ 1 \} \) such that the \( a \)-part of the equivalent cocycle \( \vartheta \cdot \Phi \) is zero. Substituting the explicit cocycle above in formula (17), we get

\[ a'_{-3,4} = \gamma(1 - \gamma), \quad a'_{-3,5} = \frac{3}{8} \alpha \quad \text{and} \quad a'_{4,5} = \frac{3}{8} \beta, \]

so that the only two possibilities are \( (\alpha, \beta, \gamma, \theta) = (0, 0, 0, 1) \) or \( (0, 0, 1, 1) \) which respectively correspond to the two fibrations \( H_1 \) and \( H_2 \). \( \square \)
Theorem 5.9. Let $(S,C_0)$ be a $(+1)$-neighborhood and suppose that there are two fibrations $H_1$ and $H_2$ transverse to $C$ such that $\text{Tang}(H_1, H_2) = C_0$. Then $(S,C_0)$ is the previous example.

Proof. Let $x : C_0 \to \mathbb{P}^1$ be a global coordinate on $C_0$ and consider $h_1, h_2 : S \to \mathbb{P}^1$ first integrals of $H_1$ and $H_2$ such that $h_1|_{C_0} = h_2|_{C_0} = x$. Consider the map
\[ \pi : S \to \mathbb{P}^1 \times \mathbb{P}^1 ; \quad \Phi(p) = (h_1(p), h_2(p)). \]
Clearly, $\pi|_{C_0} : C_0 \to \Delta$ is an isomorphism, and we claim that $\pi$ is a 2-fold covering of a neighborhood $V$ of $\Delta$, ramifying over $\Delta$. In order to prove this claim, it suffices to check it near $p_0 : \{x = 0\}$ since $x$ is well-defined up to a Moebius transform. Fix local coordinates $(x,y)$ on $(S,p_0)$ such that $C_0 = \{y = 0\}$ and $h_1(x, y) = x$. Therefore, $h_2(x, y) = x - y^2 f(x, y)$ with $f(0,0) \neq 0$; here we have used that $h_1$ and $h_2$ coincide on $C_0$ and are tangent there, without multiplicity. We can change coordinate 
\[ (X, Y) = (x, y\sqrt{f(x, y)}) \] so that
\[ h_1(X, Y) = X \quad \text{and} \quad h_2(X, Y) = X - Y^2. \]
From this, it is clear that $\pi$ is a 2-fold cover ramifying over $\Delta \subset \mathbb{P}_u^1 \times \mathbb{P}_v^1$ since in coordinates $(U,V) = (u, u-\nu)$ we have $\Delta = \{V = 0\}$ and $\pi : (X,Y) \mapsto (U,V) = (X, Y^2)$. By construction, $H_1$ and $H_2$ are sent to $\ker(dX)$ and $\ker(dY)$. □

Now we want to write explicitly the differential equation associated to this example. In order to do that, we consider the automorphism group
\[ \text{Aut}(\mathbb{P}_u^1 \times \mathbb{P}_v^1, \Delta) = \text{PSL}_2(\mathbb{C}) \times \mathbb{Z}/2\mathbb{Z} \]
where the $\text{PSL}_2(\mathbb{C})$-action is diagonal
\[ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : (u,v) \mapsto \begin{pmatrix} au + b \\ cv + d \end{pmatrix} \]
and the $\mathbb{Z}/2\mathbb{Z}$-action is generated by the involution $(u,v) \mapsto (v,u)$. After 2-fold cover $(S,C) \to (\mathbb{P}_u^1 \times \mathbb{P}_v^1, \Delta)$, we get an action of
\[ \Gamma \simeq \{ M \in \text{GL}_2(\mathbb{C}) : \det(M) = \pm 1 \} \]
where $\text{det}$ is the Galois involution of the covering, and we have
\[ \text{Aut}(\mathbb{P}_u^1 \times \mathbb{P}_v^1, \Delta) = \Gamma/\{ \pm I \}. \]
Indeed, the $\text{PGL}_2(\mathbb{C})$-action is given by $\text{SL}_2(\mathbb{C})/\{ \pm I \}$ and $\langle \sqrt{-1} \rangle/\{ \pm 1 \} \simeq \mathbb{Z}/2\mathbb{Z}$ is the permutation of coordinates $u \leftrightarrow v$. In coordinates $(u,v) = (x, x - y^2)$ (see (18)), the $\text{SL}_2(\mathbb{C})$-action on $(S,C)$ writes
\[ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : (x,y) \mapsto \begin{pmatrix} ax + b \\ cx + d \end{pmatrix} \begin{pmatrix} y \\ \sqrt{cx + d} \end{pmatrix} \]
where $ad - bc = 1$ and the square-root chosen so as $\sqrt{1} = 1$ (note that its argument is 1 along $y = 0$). The involution writes
\[ \begin{pmatrix} \sqrt{-1} & 0 \\ 0 & \sqrt{-1} \end{pmatrix} : (x,y) \mapsto (x - y^2, \sqrt{-1}y). \]
Going to the dual picture, we get a projective structure $\Pi$ on $(\mathbb{C}^2,0)$ invariant by an action of the same group $\Gamma$, and fixing the origin 0. By Bochner Linearization Theorem, the action of the maximal compact subgroup $\Gamma_0 \subset \Gamma$ is holomorphically linearizable, and since $\Gamma$ is just the complexification of $\Gamma_0$ (and therefore Zariski dense in $\Gamma$) the action of $\Gamma$ itself is linearizable.

Proposition 5.10. The unique non-trivial projective structure $\Pi$ on $(\mathbb{C}^2,0)$ which is invariant by the linear action of $\text{SL}_2(\mathbb{C})$ is given (up to homothety) by
\[ y'' = (xy - y)^3. \]
Proof. See [17] Theorem 3]. □
Theorem 5.11. The two pencils of geodesic foliations for the $\text{SL}_2(\mathbb{C})$-invariant projective structure $y'' = (xy' - y)^3$ are given by

$$\omega_t^\pm = (y^2 dx - (xy + \sqrt{-1})dy) + t((xy + \sqrt{-1})dx - x^2dy) = 0, \quad t \in \mathbb{P}^1$$

where $\pm$ stand for the two determinations of $\sqrt{-1}$. For each $t$, we see that the line $y = tx$ is a common leaf for the two foliations $\mathcal{F}_{\omega_t^+}$ and $\mathcal{F}_{\omega_t^-}$.

Proof. Recall (see Proposition [5.3]) that there are exactly 2 pencils of geodesic foliations for this special projective structure. We can just verify by computation that the pencils in the statement are geodesic, however we think that it might be interesting to explain how we found them.

In order to find the elements of the pencils, we will use again the $\text{SL}_2(\mathbb{C})$ invariance. We first construct the two foliations (i.e. for the two pencils) having the geodesic $y = 0$ as a special leaf, i.e. $\omega_0^\pm$; then it will be easy to deduce the full pencil by making $\text{SL}_2(\mathbb{C})$ acting on $\omega_t^\pm$. In order to characterize $\omega_0^\pm$, let us go back to the dual picture $(S,C)$. The two foliations we are looking for come from the two fibers passing through $p_0 = \{x_0 = y_0 = \infty\}$ in $C$, or equivalently the two fibers $u_0 = \infty$ and $v_0 = \infty$ on $\mathbb{P}^1 \times \mathbb{P}^1$ (here we use coordinates given by formula (18)). These curves are invariant making $\text{SL}_2(\mathbb{C}) = 0$ as a special leaf, i.e. $\omega_0^\pm$. In order to characterize $\omega_0^\pm$, let us go back to the dual picture $(S,C)$. The two foliations we are looking for come from the two fibers passing through $p_0 = \{x_0 = y_0 = \infty\}$ in $C$, or equivalently the two fibers $u_0 = \infty$ and $v_0 = \infty$ on $\mathbb{P}^1 \times \mathbb{P}^1$ (here we use coordinates given by formula (18)). These curves are invariant.

Finally, the foliation $\mathcal{F}_\omega$ is geodesic if, and only if, the corresponding surface $\{z = f\}$ in $\mathbb{P}(TC^2)$ is invariant by the geodesic foliation defined by $v = \partial_x + z\partial_y + (xz - y)^3\partial_z$.

In other words

$$i_x dz - f dx = 0 \quad \iff \quad (xf - y)^3 - f_x - ff_y = 0.$$ 

The combination of the three constraints gives (after eliminating $f_x$ and $f_y$)

$$\left(f - \frac{y^2}{x}\right) \left(f - \frac{y^2}{xy + \sqrt{-1}}\right) \left(f - \frac{y^2}{xy - \sqrt{-1}}\right) = 0.$$ 

The first factor gives the radial foliation and the two other ones yield $\omega_0^\pm$. We conclude by applying the one-parameter subgroup $\varphi^t(x,y) = (x,tx + y)$ to each of these foliations and get the two pencils. \hfill $\square$

Remark 5.12. It is interesting to complete the picture by the well-know two-fold cover

$$\pi' : \begin{cases} 
\mathbb{P}^1 \times \mathbb{P}^1 & \to \mathbb{P}^2 \\
\Delta & \to C 
\end{cases} : \begin{pmatrix} u_0 : u_{\infty} \end{pmatrix}, \begin{pmatrix} v_0 : v_{\infty} \end{pmatrix} \mapsto \begin{pmatrix} u_0 v_0 : u_0 v_{\infty} + u_{\infty} v_0 : u_{\infty} v_{\infty} \end{pmatrix}$$

ramifying over $C := \pi'(\Delta)$, a conic. This map $\pi'$ is the quotient by the involution $\varphi : (u,v) \mapsto (v,u)$ on $\mathbb{P}^1 \times \mathbb{P}^1$ that fixes the diagonal $\Delta$. We therefore have successive ramified covers

$$(S,C_0) \xrightarrow{\pi} (\mathbb{P}^1 \times \mathbb{P}^1, \Delta) \xrightarrow{\pi'} (\mathbb{P}^2, C)$$

described in Figure [4]. Since $(S,C_0)$ is not linearizable, the same holds for the two other ones (linearization can be lifted). So the $(+4)$-neighborhood of a conic $C \subset \mathbb{P}^2$ is not linearizable. In fact, we can say more.
If, moreover, the curve
explicitly given by
acts by conjugacy on each $Diff_{\geq} H C$
translating to the neighborhood of a nearby fiber
in one point $C$
to classify.

As before, we consider diffeomorphisms
where $\Delta = \{v_0 = u_0\} = \{v_\infty = u_\infty\}$, $C = \{y_0 = 0\} = \{y_\infty = 0\}$. So the cocycle is explicitly given by

$$
\Phi(x_0, y_0) = \left(\frac{1}{x_0} + \frac{y_0^3}{4x_0^4} + \frac{y_0^6}{16x_0^8} + \ldots, \frac{y_0^3}{2x_0^4} + \frac{3y_0^6}{16x_0^8} + \ldots\right).
$$

As before, we consider diffeomorphisms

$$
\Phi^i(x, y) = \left(x + \sum_{n \geq 1} a_n^i(x)y^n, \sum_{n \geq 1} b_n^i(x)y^n\right),
$$

with $b_1^i(0) \neq 0$, $i = 0, \infty$, obtaining

$$
\Phi^\infty \circ \Phi \circ \Phi^0 (x, y) = \left(\frac{1}{x} + \left(\frac{a_1^0(x)}{x^2} + \frac{b_1^0(x)}{x^3} + \frac{a_1^\infty(x)}{x^4} + \frac{1}{x} \frac{b_1^0(x)}{x^4}\right)y + \ldots, b_1^\infty \left(\frac{1}{x}\right) b_1^0(x) \frac{y}{x^4} + \ldots\right).
$$

As a consequence we see that there is no transverse fibration in the formal neighborhood at first order.

5.4. Two fibrations in general position. The goal of this section is to show that there are many $(+1)$-neighborhoods with exactly two fibrations; surprisingly, they are easy to classify.

Suppose that the germ of $(+1)$-neighborhood $(S, C_0)$ admits two transverse fibrations $\mathcal{H}_1$ and $\mathcal{H}_2$, such that their tangent locus $T = Tang(\mathcal{H}_1, \mathcal{H}_2)$ is neither a leaf, nor $C_0$. Remember (see Proposition 5.2) that $T$ is smooth and intersects $C_0$ transversely in one point $p_0$, say $x = 0$. We say that $\mathcal{H}_1$ and $\mathcal{H}_2$ are in general position near $C_0$ if, moreover, the curve $T$ is transversal to $\mathcal{H}_1$ (and therefore $\mathcal{H}_2$). Note that, maybe translating to the neighborhood of a nearby fiber $C_\epsilon$, we can always assume $\mathcal{H}_1$ and $\mathcal{H}_2$ in general position. To state our result, denote

$$
Diff^{\geq k}(\mathbb{C}, 0) := \{\varphi(z) \in \mathbb{C}(z) ; \varphi(z) = z + o(z^k)\}
$$

the group of germs of diffeomorphisms tangent to the identity at the order $\geq k$ and denote $Diff^{k}(\mathbb{C}, 0) := Diff^{\geq k}(\mathbb{C}, 0) \setminus Diff^{\geq k+1}(\mathbb{C}, 0)$ the set of those tangent precisely at order $k$. The group

$$
A := \{\varphi(z) = az/(1 + bcz) : a \in \mathbb{C}^*, b \in \mathbb{C}\} = PGL_2(\mathbb{C}) \cap Diff(\mathbb{C}, 0)
$$

acts by conjugacy on each $Diff^{\geq k}(\mathbb{C}, 0)$ and therefore on $Diff^k(\mathbb{C}, 0)$.
Theorem 5.13. Germs of (+1)-neighborhoods \((S,C_0)\) that admit two transversal fibrations \(\mathcal{H}_1\) and \(\mathcal{H}_2\) in general position are in one to one correspondance with the quotient set
\[
\text{Diff}^1(\mathbb{C},0)/A.
\]

Proof. Like in the proof of Theorem 5.9 consider \(h_1,h_2 : S \to \mathbb{P}^1\) the first integrals of \(\mathcal{H}_1\) and \(\mathcal{H}_2\) whose restrictions on \(C_0\) coincide with the global parametrization \(x : C_0 \xrightarrow{\sim} \mathbb{P}^1\). Now, consider the map
\[
\pi : S \to \mathbb{P}^1 \times \mathbb{P}^1 ; \pi(p) = (h_1(p),h_2(p))
\]
and denote by \(\Sigma := \pi(T)\) the critical locus. One can check that, in the neighborhood of \(p_0\), \(\pi\) is a \((k+1)\)-fold cover ramifying over \(\Sigma\); indeed, the two fibers \(\{h_1 = 0\}\) and \(\{h_2 = 0\}\) have a contact of order \(k+1\) at \(p_0\) (see [24, Section 5] for details). In fact, we can extend this ramified cover over the neighborhood of \(\Delta \subset \mathbb{P}^1 \times \mathbb{P}^1\) and get
\[
\pi : (S,C_0 \cup C_1 \cup \cdots \cup C_k) \xrightarrow{(k+1):1} (\mathbb{P}^1 \times \mathbb{P}^1, \Delta)
\]
where \(C_0,\ldots,C_k\) are the preimages of \(\Delta\), that intersect transversely at \(p_0\). After selecting one of them, say \(C_0\), we get our initial map \(\pi : (S,C_0) \to (\mathbb{P}^1 \times \mathbb{P}^1, \Delta)\). From this point of view, it becomes clear that the lack of unicity comes from the choice \(C_0\) among \(C_0,\ldots,C_k\), and the corresponding neighborhoods might be not isomorphic: \((S,C_i) \neq (S,C_0)\).

However, in the case \(\mathcal{H}_1\) and \(\mathcal{H}_2\) are in general position, then \(k = 1\) and the covering, being of degree 2, is automatically galoisian: \((S,C_0) \simeq (S,C_1)\). Then we have a one-to-one correspondance between smooth curves \(\Sigma\) at \(q_0\) having a simple tangency with \(\Delta\) and (+1)-neighborhoods \((S,C_0)\) with \(\mathcal{H}_1,\mathcal{H}_2\) having a simple tangency at \(p_0 = \{x = 0\}\), up to isomorphism preserving the fixed parametrization \(x : C_0 \to \mathbb{P}^1\).

Finally, the change of parametrization induces a diagonal action of the group \(A\) on \(\mathbb{P}^1 \times \mathbb{P}^1\). Viewing \(\Sigma\) as the graph of a germ of diffeomorphism \(v = \varphi(u)\), we see that \(\varphi(u) = u + cu^2 + \cdots, c \neq 0\), and the diagonal action induced by \(A\) is an action by conjugacy on \(\varphi\), whence the result. \(\square\)

Remark 5.14. If we consider the very special (+1)-neighborhood \((S,C_0)\) studied along section 5.3 after specializing to the neighborhood of any deformation \(C_\varepsilon \neq C_0\), we get a new (+1)-neighborhood \((S,C_\varepsilon)\) with two fibrations in general position. This neighborhood does not depend on the choice of \(\varepsilon\) since \(\text{SL}_2(\mathbb{C})\) acts transitively on those rational curves; it is easy to check that it corresponds to the class of the diffeomorphism \(\varphi(u) = u/(1-u)\), i.e. to a curve \(\Sigma\) given by a bidegree \((2,2)\) curve (a deformation of \(\Delta\)).

5.5. Proof of Theorem 5.1. Before proving the theorem we make some considerations. First of all, recall (see Proposition 5.1) that there are normal forms
\[
\Phi = \left(\frac{1}{x} \frac{y}{x} + \sum_{V(-2,3)} b_{m,n} x^m y^n\right), \Phi_i = \left(\frac{1}{x} \frac{y}{x} + \sum_{V(-2,3)} b_{m,n}^i x^m y^n\right), i = 1,2,
\]
compatible with \(\mathcal{H}, \mathcal{H}_1\) and \(\mathcal{H}_2\) respectively, and denote by \(\vartheta_i = (\alpha_i, \beta_i, \gamma_i, 1)\) the parameter corresponding to the change of cocycle from \(\Phi\) to \(\Phi^i, i = 1,2\).

\[\begin{array}{c@{ }c@{ }c}
(\alpha_1, \beta_1, \gamma_1, 1) & \Phi & (\alpha_2, \beta_2, \gamma_2, 1) \\
\Phi_1 & \Phi_2
\end{array}\]

All along the section, we assume moreover \((\alpha_1, \beta_1, \gamma_1) \neq (\alpha_2, \beta_2, \gamma_2)\) and are both \(\neq (0,0,0)\) (otherwise two of the three fibrations coincide).

Lemma 5.15. If \(b_{-2,3} = 0\), \(\vartheta_1 = (\alpha, 0, 0)\) and \(\vartheta_2 = (0, \beta, 0)\), \(\alpha \beta \neq 0\), then \(b_{m,n} = 0\) for every \((m,n)\) and the neighborhood is linearizable.
Proof. From formula (17), we already get $0 = a_{-3,4} = ab_{-3,4}$ and $0 = a_{-2,4} = \beta b_{-2,4}$. Here, the notation $a_{n,m}^i$ stands for the $a$-coefficients of $b_i$ obtained by applying the change $\vartheta_i$ to a general cocycle $\Phi$. Assume by induction that $b_{m,k} = 0$ for every $k < n$. Then
\[
\Phi = \left( \frac{1}{x} y + \frac{b_{-2,n}}{x^2} y + \ldots + \frac{b_{1-n,n}}{x^{n-1}} y^n + \ldots \right).
\]
The change of coordinates sending $\Phi$ to $\Phi_1$ takes the form (see Proposition 4.4)
\[
\Psi_1^0 = \left( \frac{x}{1 + \alpha y} - ab_{-2,n} y^n + o(y^n), \frac{y}{1 + \alpha y} \right), \quad \Psi_1^\infty = (x + \alpha y, y),
\]
and we can check by direct computation that
\[
\Phi_1 = \left( \frac{1}{x} + \alpha \frac{b_{-3,n}}{x^2} y + \ldots + \frac{b_{1-n,n}}{x^{n-1}} y^n + o(y^n), \frac{y}{1 + \beta y} \right)
\]
so that we deduce $b_{m,n} = 0$ for $m \neq -2$. On the other hand
\[
\Psi_2^0 = (x + \beta y, y), \quad \Psi_2^\infty = \left( \frac{x}{1 + \beta y} + \beta b_{1-n,n} y^n + o(y^n), \frac{y}{1 + \beta y} \right),
\]
we see in a similar way that $a_{-3,7}^2 = \beta b_{-2,3} = 0$. We conclude by induction. \hfill \Box

Lemma 5.16. If $b_{-2,3} = 0$ and $\vartheta_i = (\alpha_i, 0, 0)$ with $\alpha_1 \neq \alpha_2$ both non zero, then
\[
b_{m,n} = 0 \quad \text{for every} \quad (m,n), \quad \text{and the neighborhood is linearizable.}
\]
Proof. We prove by induction on $n$, in a very similar way, that $b_{m,n} = 0$ for $m \neq -2$, until $n = 7$: for instance, at each step, we get $a_{1,n}^1 = \alpha b_{1,m,n} (we use only two fibrations so far). Then, for $n = 8$, we find $a_{-3,8}^2 = \alpha_1 b_{-3,8} - \alpha_2 b_{-2,4} = 0$. Of course, since $\alpha_1 \neq \alpha_2$, we get both $b_{-3,8} = b_{-2,4} = 0$. For $n > 8$, the induction shows that $b_{3,2} = b_{3,3} = \ldots = b_{1-n,n} = 0$ and we get the result. \hfill \Box

Proof of Theorem 5.7: We consider the following cases.

Case 1: $\text{Tang}(\mathcal{H}, \mathcal{H}_1) \cap \text{Tang}(\mathcal{H}, \mathcal{H}_2) = \emptyset$. We change parametrization $x : C_0 \to \mathbb{P}^1$ so that $\text{Tang}(\mathcal{H}, \mathcal{H}_1) \cap C_0 = \{ x = 0 \}$ and $\text{Tang}(\mathcal{H}, \mathcal{H}_2) \cap C_0 = \{ x = \infty \}$, which implies $\beta_1 = \alpha_2 = 0$. Note that $\alpha_1 / \beta_2 \neq 0$ because we are not in the case of tangency along $C_0$.

If $b_{-2,3} \neq 0$, we can assume after change of coordinate $\vartheta = (0, 0, 0, \theta)$ that $b_{-2,3} = 1$. We consider the equations $a_{1,m}^1 = 0$ and $a_{1,n}^3 = 0$ for $n \leq 7$, we can solve and express all $b_{m,n}$, $n \leq 7$, in terms of $\alpha_1$, $\gamma_1$, $\beta_2$, and $\gamma_2$. We replace them in the remaining coefficients $a_{m,n}^i$ for $n \leq 7$, $m \neq 3$, and use Groebner basis in order to rewrite the ideal
\[
\langle a_{-4,5}^2, a_{-4,6}^2, a_{-5,6}^2, a_{-4,7}^2, a_{-5,7}^2, a_{-6,7}^2 \rangle = \langle \gamma_2, \alpha_1 \beta_2 \rangle
\]
but this implies that $\alpha_1 / \beta_2 = 0$, which is not possible.

If $b_{-2,3} = 0$ with a similar argument we arrive in $\gamma_1 = \gamma_2 = 0$ and thus we conclude by lemma 5.15.

Case 2: $\text{Tang}(\mathcal{H}, \mathcal{H}_1) \cap \text{Tang}(\mathcal{H}, \mathcal{H}_2) \cap C_0 = \{ x = 0 \}$. In this case we can assume $\vartheta_i = (\alpha_i, 0, \gamma_i, 1)$ with $\alpha_1 \alpha_2 \neq 0$. Suppose first $(\alpha_1, \gamma_1)$ not parallel to $(\alpha_2, \gamma_2)$.

If $b_{-2,3} = 1$, we use equations $a_{1,m}^1 = 0$, $3 \leq m < n \leq 7$, and $a_{2,3,5}^2 = a_{2,3,6}^2 = a_{2,3,7}^2 = 0$ in order to find all $b_{m,n}$ with $n \leq 7$ except $b_{-2,7}$ in terms of $\alpha_1$, $\gamma_1$, $\alpha_2$, and $\gamma_2$. Replacing them in $a_{-2,6}^2$, we obtain $\gamma_1 = 0$ or $\gamma_1 = 2$. The former case implies, by using $a_{-2,4}^2$, that $\gamma_1 = 2$ and this gives us the equation $a_{-4,6}^2 = 6 \alpha_1 = 0$, impossible.

On the other hand, the last case gives us $a_{-2,5}^2 = 12 (\alpha_1 \gamma_2 - \alpha_2 \gamma_1) = 0$, and this also contradicts our hypothesis. We conclude that we are never in this case.

If $b_{-2,3} = 0$, we use equations $a_{1,m}^1 = 0$, $3 \leq i < j \leq 7$, and $a_{2,3,5}^2 = a_{2,3,6}^2 = a_{2,3,7}^2 = 0$ in order to find all $b_{m,n}$ with $n \leq 7$ except $b_{-2,7}$ in terms of $\alpha_1$, $\gamma_1$, $\alpha_2$, and $\gamma_2$. Replacing them in $a_{-2,4}^2$, $a_{-2,5}^2$, and $a_{-2,6}^2$, we arrive in $\gamma_1 = \gamma_2 = 0$. We are in the hypothesis of lemma 5.15 and therefore we conclude the theorem.

Finally we consider the case $(\alpha_2, \gamma_2) = \lambda (\alpha_1, \gamma_1)$, for $\lambda \neq 0, 1$. 

If \( b_{-2,3} = 0 \), from \( a_{-3,4}^1 = a_{-3,4}^2 = 0 \) we obtain \( \gamma_1 = \gamma_2 = 0 \), and then we are able to apply lemma 5.16.

If \( b_{-2,3} = 1 \), again from \( a_{-3,4}^1 = a_{-3,4}^2 = 0 \), we obtain \( \gamma_1 = \gamma_2 = 0 \) and \( a_{-3,4}^1 = \alpha_1 b_{-3,4} = 0 \). Now, from \( a_{-3,5}^1 = a_{-4,5}^1 = 0 \) we also get \( b_{-3,5} = b_{-4,5} = 0 \). Therefore \( a_{-3,6}^1 = \alpha_1 (b_{-3,6} - \alpha_1) = 0 \) and \( a_{-3,6}^2 = \alpha_2 (b_{-3,6} - \alpha_2) = 0 \), which is a contradiction since \( \alpha_1 \neq \alpha_2 \).

6. Application to Painlevé equations

The Painlevé equations provide projective structures whose geodesics are the graphs of Painlevé transcendents. We provide the list of coefficients in table 1. They depend on coefficients \( \alpha, \beta, \gamma, \delta \in \mathbb{C} \).

| Equation | A | B | C | D |
|----------|---|---|---|---|
| PVI | \( 0 \) | \( 0 \) | \( 0 \) | \( 0 \) |
| PI | \( 0 \) | \( 0 \) | \( 0 \) | \( 0 \) |
| PII | \( 0 \) | \( 0 \) | \( 0 \) | \( 0 \) |
| PV | \( 0 \) | \( 0 \) | \( 0 \) | \( 0 \) |
| PIII | \( 0 \) | \( 0 \) | \( 0 \) | \( 0 \) |

Painlevé equations have been found by Painlevé more than one hundred years ago when he was looking for new second-order differential equations of the form \( y'' = f(x, y, y') \), with \( f \) polynomial, satisfying the Painlevé Property: there is a finite set \( S = \{ x_1, \ldots, x_n \} \subset \mathbb{C} \) such that any local solution can be meromorphically continued along any path avoiding the set \( S \). Linear differential equations have this property. Poincaré and Fuchs proved that first-order differential equations \( f(x, y, y') = 0 \) having that property either can be integrated by algebraic functions, or can be reduced by change of coordinates to Riccati or Weierstrass differential equations. Painlevé proved that a second-order differential equations \( y'' = f(x, y, y') \) with the Painlevé Property can be reduced to an equation of Table 1 if it is irreducible, i.e. if it cannot be reduced to previously known cases (linear, first-order, quadrature). In fact, due to some mistakes, he forgot some cases and the list was completed by R. Fuchs and Gambier. The Painlevé Property of these equations was proved by Okamoto by reducing the singularities of the Painlevé foliation by blow-ups. Painlevé equations can also be interpreted as differential equations for coefficients of isomonodromic deformations of linear differential systems. This has been proved by R. Fuchs in the Painlevé VI case, and later by Jimbo-Miwa-Ueno for all other cases, which turn out to be more complicated, because involving systems with irregular singular points with a study of Stokes matrices. It turns out that this isomonodromy property implies the Painlevé Property as shown by Malgrange. The proof of irreducibility is more recent. It is a transcendence result, that has been proved by Nishioka and Umemura in terms of non linear differential Galois theory (see also [13, 9]). The meaning of irreducibility is that Painlevé equations are as general as a second-order differential equation can be, and more complicated that first order. For instance, Painlevé foliations cannot be contained in a codimension one foliation (see for instance [13, 9]). This implies in particular that the corresponding projective structure on \( \mathbb{C}^2 \ni (x, y) \) cannot be globally foliated, defined by a Frobenius integrable Riccati equation on \( \mathbb{P}(T \mathbb{C}^2) \) (see section 3). We expect similar transcendent result even in restriction to smaller open sets. In that direction, we prove in many cases (see Propositions 6.1 and 6.2) that projective structures defined by Painlevé equations are not locally foliated, at the neighborhood of points \( (x, y) \equiv (x_0, y_0) \).

But let us recall first the case of linearisability. One can check that only the sixth one PVI with parameters \( (\alpha, \beta, \gamma, \delta) = (0, 0, 0, \frac{1}{2}) \) is locally linearizable, and it
corresponds to the Picard parameter for Painlevé equation (see [12]). In fact, if we apply the criterium of Liouville (see Proposition 2.12), then we see that $L_2 = 0$ for all Painlevé equations, and $L_1 = 0$ only for the Picard one.

**Proposition 6.1.** The first two Painlevé equations are not locally foliated.

*Proof.* We use Proposition 3.8 and prove that we cannot find functions $f, g$ satisfying equations (12) with the coefficients given by the first two rows of table 1. Because $C = D = 0$, the last equation $g_y = -g^2$ gives

$$g(x, y) = \frac{1}{y + \psi(x)}$$

for a function $\psi$. Then, using moreover $B = 0$, the second equation $f_y = g_x - 2fg$ gives

$$f(x, y) = \frac{\psi(x) - y\psi'(x)}{(y + \psi(x))^2}$$

for a function $\varphi$. Finally, the first equation yields

$$f_x - f^2 - Ag + Ay = \frac{h(x, y)}{(y + \psi(x))^4}$$

where $h$ is a polynomial in $y$ with coefficients in $x$ (depending on $\varphi$, $\psi$ and their derivatives). But the dominant term of $h$ is $6g^5$ and $4g^6$ for Painlevé equations I and II respectively. Therefore, whatever are $\varphi$ and $\psi$, $h$ cannot vanish identically. □

Similar computations seem out of reach for all cases, especially Painlevé VI case. Instead of this, we will use our results proved along the paper to provide an alternate and more geometric approach to prove non existence of foliated structure in the case of Painlevé VI. In fact, we will use the monodromy representation that we now explain.

The projective structure defined by Painlevé VI equation is holomorphic on

$$(x, y) \in \Omega = \mathbb{C}^2 \setminus \{xy(x-1)(y-1)(y-x) = 0\}.$$ Consider the geodesic (or Painlevé) foliation in the open chart $\Omega \times \mathbb{C} \ni (x, y, z)$ by setting $z = \frac{dy}{dx}$. One easily check that $\Sigma := \{x = x_0\} \subset \Omega$ defines a cross-section for the foliation, for any $x_0 \neq 0, 1$. The Painlevé Property of the equation allows us to continue meromorphically each local solution along any loop $\gamma : [0, 1] \to \Omega$, $\gamma(0) = \gamma(1) = x_0$, and therefore define a monodromy map $\phi_\gamma : \Sigma \to \Sigma$. This return map is only defined outside of an analytic set, but can be inverted. One can built a larger fiber bundle $x : \Omega \to (\mathbb{C} \setminus \{0, 1\})$ with respect to which the foliation has a well-defined holonomy, therefore providing a representation

$$\pi_1(\mathbb{C} \setminus \{0, 1\}, x_0) \to \text{Bihol}(\Sigma)$$

into the group of biholomorphisms of a larger transversal $\Sigma := \{x = x_0\} \subset \Omega$ (see [14, 16, 29, 9]). Precisely, Okamoto constructed in [14] a partial compactification $\hat{\Omega}$ with the lifting path property to provide a geometric counterpart to Painlevé Property. The transversal $\Sigma$ in this larger space is usually called Okamoto’s space of initial conditions. The monodromy representation has been defined by Dubrovin-Mazzocco in [16] for special parameters, and was generalized to all parameters by Iwasaki (see [29, 9] for a global picture). It turns out that the monodromy group corresponds via the Riemann-Hilbert correspondence with an action of the Mapping-Class-Group of the 4-punctured sphere on the character variety for $\text{SL}(2, \mathbb{C})$. Some dynamical properties have been studied by Dubrovin-Mazzocco, Iwasaki-Uehara and Cantat using this later point of view. We will use a result obtained in [9].

**Proposition 6.2.** The Painlevé VI equation is not locally foliated, except for the Picard parameter $$(\alpha, \beta, \gamma, \delta) = (0, 0, 0, \frac{1}{2}).$$

*Proof.* If it is foliated at some point $p \in \Omega$, then Corollary 3.11 allows us to extend meromorphically the foliated structure along any path inside $\Omega$. Assume first that it is uniform, i.e. that we have a global meromorphic foliated structure on $\Omega$. Then
we can apply results of [9] about the monodromy of the Painlevé VI equation. It is shown in [9, Theorem D] that the monodromy cannot preserve a foliation, and we get a contradiction. Therefore, the foliated structure cannot be uniform. In fact, if it has finitely many determinations, then it defines a web which is invariant under the monodromy, and again [9, Theorem D] gives a contradiction. Finally, if it has at least 3 determinations, then this implies by our Theorem [5,1] that the projective structure is linearizable, and therefore that we are in the case of Picard parameters as in the statement.

Example 6.3. In [28], Hurtubise and Kamran provide linking formulae between Cartan invariants for projective structures, and coefficients $a_{m,n}$ and $b_{m,n}$ of normalized cocycle in Theorem 4.2 up to order $n = 7$. In a similar way, one can easily compute the normalized cocycle of Painlevé I equation up to order $n = 11$ with Maple:

\[ \Phi_{Pi} = (a(x, y), b(x, y)) \]

where

\[
\begin{align*}
a(x, y) &= \frac{1}{2} + 63 \frac{y}{x^2} - \frac{5311}{2} \frac{y^2}{x^2} + \frac{209939}{154} \frac{y^3}{x^2} + o(y^{11}) \\
b(x, y) &= \frac{1}{2} - 14 \frac{y}{x^2} + \frac{489}{7} \frac{y^2}{x^2} - \frac{1243}{7} \frac{y^3}{x^2} - \frac{8137}{9} \frac{y^4}{x^2} + o(y^{11})
\end{align*}
\]

This corresponds to the cocycle of $U^\vee$ dual to the projective structure induced by $y'' = 6y^2 + x$ at $(\mathbb{C}^2, 0)$. However, it is difficult to compute many other examples as complexity increases fastly with the size of entries.

7. Concluding remarks

7.1. Coordinates on $C$. In the classification, we have fixed a coordinate $x : C \to \mathbb{P}^1$. One could consider the action of Moebius transformations on $C$ and therefore on $x$. For instance, the action of homotheties $x \mapsto \lambda x$ on normal forms is easy:

\[ a_{m,n}' = \lambda^{m-1} a_{m,n} \quad \text{and} \quad b_{m,n}' = \lambda^{m-1} b_{m,n}. \]

If we add this action to the 4-parameter group $\Gamma$, then orbits correspond to the analytic class of $(S, C \supset \{p_0, p_\infty\})$ where we have fixed two points $p_i = \{x = i\}$ without fixing the coordinate on $C$. If we blow-up $p_0$ and $p_\infty$, and then contract the strict transform of $C$, then we get a germ $(\hat{S}, C_0 \cup C_\infty)$ of neighborhood of the union of two rational curves $C_0$ and $C_\infty$ (exceptional divisors) with self-intersection $C_1 \cdot C_1 = 0$, that intersect transversally at a single point $p = C_0 \cap C_\infty$ (the contraction of $C$). In fact, we can reverse this construction and have a one-to-one correspondance

\[ (S, C \supset \{p_0, p_\infty\}) \leftrightarrow (\hat{S}, C_0 \cup C_\infty) \]

so that analytic classifications are the same. We note that the action of other Moebius transformations on normal forms $\Phi$ are much more difficult to compute.

7.2. The case of general positive self-intersection $C \cdot C > 1$. Mishustin gave in [40] a normal form for $(d)$-neighborhood for arbitrary $d \in \mathbb{Z}_{>0}$ and the story is similar to the case $d = 1$. More geometrically, we can link the general case to the case $d = 1$ as follows. Let $d > 1$ and $(S, C)$ a $(d)$-neighborhood. Then, maybe shrinking $S$, the topology of $(S, C)$ is the same than the topology of $(N_C, 0)$, in particular:

\[ \pi_1(S \setminus C) \simeq \mathbb{Z}/ < d > \]

i.e. the fundamental group of the complement of $C$ is cyclic of order $d$. We can consider the corresponding ramified cover

\[ (\hat{S}, \hat{C}) \xrightarrow{k} (S, C) \]

totally ramifying at order $d$ over $C$, and inducing the cyclic cover of order $d$ over the complement $S \setminus C$. If we do this with $S$ being the total space of $\mathcal{O}_{\mathbb{P}^1}(k)$, then $\hat{S}$ will be the total space of $\mathcal{O}_{\mathbb{P}^1}(1)$, the neighborhood of a line in $\mathbb{P}^2$. Likely as in the linear case, the lifted curve $\hat{C}$ will have self-intersection $\hat{C} \cdot \hat{C} = 1$ and we are back to the case $d = 1$. Moreover, $\hat{S}$ is equipped with the Galois transformation, of order $d$, which has $\hat{C}$ as a fixed point curve.
Proposition 7.1. Isomorphism classes \((S,C)\) of germs of \((d)\)-neighborhoods of the (parametrized) rational curve \(x : C \to \mathbb{P}^1\) are in one-to-one correspondence with isomorphism classes of germs of \((+1)\)-neighborhoods \((\tilde{S}, \tilde{C})\) equipped with a cyclic automorphism of order \(d\) fixing \(C\) point-wise.

We can also see a \((d)\)-neighborhood \((S,C)\) from the following point of view.

Proposition 7.2. Given \(p_1, \ldots, p_{d+1}\) distinct fixed points on \(C\). Then, there exists a one-to-one correspondence between \((d)\)-neighborhoods \((S,C)\) and neighborhood germs \((V,D)\) of a bouquet \(D = D_1 \cup \ldots \cup D_{d+1}\) of rational curves of zero self-intersection intersecting transversely at one point.

![Figure 5. 0-Neighborhood](image)

Proof. After blowing up \((d+1)\) points on \(C\), we get a neighborhood of \(C' \cup E_1 \ldots \cup E_{d+1}\) where \(C'\) is the strict transform of \(C\) and \(E_i\)'s are the exceptional divisors. Moreover, all these \(d + 2\) rational curves have self-intersection \(-1\). After contracting \(C'\), we get a neighborhood \(V\) of \(d + 1\) rational curves \(D_1 \cup \ldots \cup D_{d+1}\) intersecting at one point and having self-intersection \(0\). We obtain like this a neighborhood of \(D = D_1 \cup \ldots \cup D_{d+1}\) and this process can be reversed. □

Remark 7.3. The germ of surface \((V,D)\) is obtained by gluing \((0)\)-neighborhoods \((V_i, D_i)\), which are trivial by [48], by elements of \(\text{Diff}(\mathbb{C}^2, 0)\).

7.3. Open questions.

- **Riemannian metrics**: projective structures arising from holomorphic metrics are rare, there are infinitely many obstructions (see [6]). Can we characterize these Riemannian projective structures, or their dual surfaces \(U^v\), in a geometric way?

- The linear projective structure is Riemannian for several metrics (arbitrary constant curvature). For a generic Riemannian projective structure, is the Riemannian metric determined up to a scalar?

- **Algebraic dimension**: generic \((+1)\)-neighborhoods \(U^v\) do not carry non constant meromorphic functions (see [22]). Does there exist examples with with function field having transcendence dimension one over \(\mathbb{C}\)?
• Painlevé equations: what can be said about those $U^\gamma$ associated to a Painlevé equation? We know that they are rarely Riemannian (see [14]). Do they provide explicit examples without non constant meromorphic functions? Our Propositions [11] and [12] are first step towards this direction.

• Singularities: global projective structures on compact surfaces have been classified in [31], they impose strong constraints on the surface. It would be interesting to investigate a singular version of projective structure, for instance defined by a logarithmic affine connection (see [5, 24]), in view of examples of orbifold uniformization in dimension 2. In this direction, logarithmic singularities of affine structures are studied in [37].
