TOWARDS COMBINATORIAL INVARIANCE FOR KAZHDAN-LUSZTIG POLYNOMIALS

CHARLES BLUNDELL, LARS BUESING, ALEX DAVIES, PETAR VELIČKOVIĆ, AND GEORDIE WILLIAMSON

Abstract. Kazhdan-Lusztig polynomials are important and mysterious objects in representation theory. Here we present a new formula for their computation for symmetric groups based on the Bruhat graph. Our approach suggests a solution to the combinatorial invariance conjecture for symmetric groups, a well-known conjecture formulated by Lusztig and Dyer in the 1980s.

1. Introduction

Kazhdan-Lusztig polynomials are important polynomials associated to pairs of elements $x, y$ in Coxeter groups. They appear throughout representation theory and related fields. Lusztig (ca. 1983) and Dyer (1987) independently conjectured that Kazhdan-Lusztig polynomials depend only on the poset of elements between $x$ and $y$ in Bruhat order. This is a fascinating conjecture. For example, it suggests that Kazhdan-Lusztig polynomials are providing subtle invariants of Bruhat order. This conjecture is known in several special cases ([Dye87, Bre04, Inc06, BCM06, Pat21, BLP21], see [Bre04] for an overview).

In this work we prove a new formula Kazhdan-Lusztig polynomials for symmetric groups. Our formula was discovered whilst trying to understand certain machine learning models trained to predict Kazhdan-Lusztig polynomials from Bruhat graphs (see [DVB+]). The new formula suggests an approach to the combinatorial invariance conjecture for symmetric groups.

Traditionally, Kazhdan-Lusztig polynomials are computed inductively based on the length. This means that in order to compute $P_{x,y}$ one might need to know $P_{u,v}$ where $u,v$ lies anywhere in $[\text{id}, x]$. Our new formula allows inductive calculation using only polynomials $P_{u,v}$ where $u,v$ belong to the Bruhat interval $[x, y]$—thus it “stays in the Bruhat interval”. Roughly speaking, we compute Kazhdan-Lusztig polynomials via induction over the rank of the symmetric group, rather than the length of a permutation.

As our new formula uses only information present in the Bruhat interval $[x, y]$ and thus might be useful for approaching the combinatorial invariance conjecture. However, the formula requires the knowledge of the intersection of $[x, y]$ with a coset $S_{n-1}x$, which is not combinatorially invariant information. It is not difficult to see that the intersection $[x, y] \cap S_{n-1}x$ forms a sub-interval $[x, c] \subset [x, y]$. We observe that the embedding $[x, c] \subset [x, y]$ has remarkable properties: the edges connecting any node $u \in [x, c]$ to a node $v \notin [x, c]$ possess a lattice-like quality which we call a hypercube cluster.
Abstracting the notion of hypercube cluster leads to the general notion of hypercube decomposition of which our sub-interval \([x, c] \subset [x, y]\) is an example. Hypercube decompositions appear to provide a nice general way of understanding Bruhat intervals in symmetric groups. We expect them to play a role in the solutions of other problems. In general, there may be many more hypercube decompositions than come from intersections with cosets of \(S_{n-1}\). Remarkably, our formula appears to give the right answer for any hypercube decomposition. We conjecture that this is always the case. We have checked our conjecture on all Bruhat intervals up to \(S_9\) (over a million Bruhat intervals, and many more hypercube decompositions!). Our conjecture implies the combinatorial invariance conjecture in more precise form.

1.1. Structure of this paper. We begin in §2 with an overview of Kazhdan-Lusztig polynomials and the combinatorial invariance conjecture. This is introductory, and can be skipped over by an experienced reader. In §3 we introduce hypercube clusters, and state our formula and conjecture. This section is purely combinatorial. In §4 and §5 we prove our formula; here geometric machinery (Schubert varieties, intersection cohomology, torus actions, weights . . . ) is needed. In §6 we outline a route to a proof of our conjecture in general, and explain that our conjecture would follow from the purity of a certain cohomology group, or the surjectivity of restriction map map in cohomology.

1.2. Acknowledgements. We are grateful to Erez Lapid, Matthew Dyer, Peter Fiebig, Leonardo Patimo and Joel Kamnitzer for useful discussions and/or correspondence. We are particularly grateful to Anthony Henderson for patiently listening to our incomplete explanations, and numerous helpful suggestions.

2. Kazhdan-Lusztig polynomials and combinatorial invariance

In this background section, we give some background on Coxeter groups, Bruhat graphs, Kazhdan-Lusztig polynomials and the combinatorial invariance conjecture. Excellent references for the following include [Hum90, Bre04, BB05, Soe97, EMTW20].

2.1. Coxeter groups and Kazhdan-Lusztig polynomials. Coxeter groups are an important class of groups, which arose out of H. S. M. Coxeter’s study of finite reflection groups in the 1930s. They are characterised by a presentation via generators and relations. In this presentation the generating set are called the simple reflections. An important example of a Coxeter group is the symmetric group \(S_{n+1}\) consisting of all permutations of 0, 1, . . . , \(n\), with simple reflections consisting of the set \(S = \{i, i + 1\}\) of adjacent transpositions.

In a seminal paper [KL79], Kazhdan and Lusztig associated to any pair of elements \(x, y\) in a Coxeter group a polynomial with integer coefficients

\[ x, y \in W \mapsto P_{x,y} \in \mathbb{Z}[q] \]

known as the Kazhdan–Lusztig polynomial. All that we say here concerning their definition is that it is highly inductive; one works one’s way “out” in the group, starting at the identity and applying generators from \(S\). At each step in the calculation one might need any of the previously computed polynomials. Thus, they are rather cumbersome to calculate by hand, but it is not difficult to compute billions
2.2. The Bruhat graph. To any Coxeter group one may associate its Bruhat graph. For the symmetric group, this is the graph with vertices corresponding to all elements of $S_n$, and an edge joining $x$ and $y$ if and only if they differ by multiplication by a transposition. (In other words, $x$ and $y$ are connected in the Bruhat graph if they agree on all but two elements of $0, 1, \ldots, n$.) Below, we will denote the transposition that exchanges $i$ and $j$ by $t_{(i,j)}$. The transpositions are precisely the conjugates of the simple reflections in $S_n$.

The symmetric group has a natural length function given by the number of inversions:

$$\ell(x) = \# \{ i < j \mid x(i) > x(j) \}.$$ 

We regard the length function as giving us a notion of “height” on the Bruhat graph. This allows us to orient the edges of the Bruhat graph via decreasing length. Figures 1 and 2 give pictures of the Bruhat graph for $n = 2, 3$ and $4$.

2.3. Bruhat order. The Bruhat graph allows us to define the Bruhat order, which is a partial order on $W$. It is defined as follows:

$$x \preceq y \iff \text{there exists a downward path from } y \text{ to } x \text{ in the Bruhat graph.}$$

(We include paths of length zero, so $x \preceq x$ always holds.) For example, in the symmetric group $S_{n+1}$ the minimal element is always the identity permutation, and the maximal element is the permutation $w_0$ which interchanges 0 and $n$, 1 and $n-1$ etc.

---

1The reader who wants to get a feeling for Kazhdan-Lusztig polynomials is encouraged to experiment with Joel Gibson’s LieVis software. For example, Kazhdan-Lusztig for an affine Weyl group of type $A_2$ are computed live here.

2Throughout this paper we use string notation for permutations. Thus $(2, 0, 3, 1)$ (or often simply 2031) denotes the permutation of 0, 1, 2 and 3 that sends 0 $\mapsto$ 2, 1 $\mapsto$ 0, 2 $\mapsto$ 3 and 3 $\mapsto$ 1.
The Bruhat order is remarkably complex, and it has long been suspected that Kazhdan-Lusztig polynomials reflect subtle properties of the Bruhat order. An elementary manifestation of this phenomenon (easy to prove) is that:

\[ P_{x,y} 
eq 0 \iff x \lessdot y. \]

Less elementary connections tend to involve the interval \([x, y]\) consisting of the full subgraph of the Bruhat graph between \(x\) and \(y\). (That is, this consists of all edges and vertices which may be reached from \(y\) on the way to \(x\), whilst progressing downwards.) For example, a much less obvious fact [Car94, Dye93] is that

\[ P_{x,y} = 1 \iff \text{the graph obtained from } [x, y] \text{ by forgetting edge orientations is regular } \]

\(\text{(i.e. all vertices have the same degree).}\)

(It is easy to see that the full Bruhat graph is regular, and in particular \(P_{id, w_0} = 1\).)
2.4. **First examples.** In $S_3$ all proper intervals are isomorphic to the following posets\(^3\) (as the reader may check easily, using Figure 1):

![Posets](image1)

All these graphs are regular (after forgetting edge orientations), and thus all Kazhdan-Lusztig polynomials are 1.

In $S_4$, almost all intervals $[x, y]$ are regular, and hence almost all Kazhdan-Lusztig polynomials $P_{x,y}$ are 1. There are four intervals which are not regular. Here we depict two intervals which are not: those between 0213 and 2301, and between 1032 and 3120:

![Intervals](image2)

In both cases, the interval is isomorphic to the following directed graph, known as the “4 crown”:

(2)

In both these cases the Kazhdan-Lusztig polynomials are equal:

\[
P_{0213,2301} = P_{1032,3120} = 1 + q.
\]

---

\(^3\)poset = partially ordered set
2.5. **The combinatorial invariance conjecture.** The following conjecture, formulated independently by Lusztig and Dyer in the 1980s, was a major motivation for the current work:

**Conjecture 2.1.** *The Kazhdan-Lusztig polynomial $P_{x,y}$ depends only on the isomorphism type of Bruhat graph of the interval $[x,y]$.***

For example, given only the ordered graph (2) (and not the labelling of its vertices) we should be able to predict the Kazhdan-Lusztig polynomial $1 + q$. The fact that (2) occurs in two different ways in the Bruhat graph of $S_4$ with equal Kazhdan-Lusztig polynomials, can be seen as an instance of this conjecture. Figures 3 and 4 shows two more examples of the assignment of Kazhdan-Lusztig polynomial to Bruhat intervals.

**Remark 2.2.** The combinatorial invariance conjecture is a central conjecture in the study of Bruhat intervals. The reader is referred to [Bre04] for more detail on known cases (see also [Dye87, Bre04, Inc06, Pat21, BLP21]). We do not discuss the various partial results towards the conjecture here, except to mention that it is known to hold for intervals starting at the identity [BCM06].

### 3. The new formula

In this section we describe our new formula. Before going into detail, let us give a rough idea of what the formula looks like. Recall that our goal is to compute the Kazhdan-Lusztig polynomial starting from the Bruhat graph. By induction,
we can assume that we can do this for any smaller graph. In particular, we can assume that all intermediate polynomials $P_{u,v}$ are known, for all $u,v \in [x,y]$ with $(u,v) \neq (x,y)$.

Our formula depends on the choice of an auxiliary structure on our graph, called a hypercube decomposition. Such a decomposition amounts to the choice of a subinterval $J \subset [x,y]$ satisfying certain concrete combinatorial conditions. (The reader is encouraged to skip ahead a few pages to Figure 6, where a typical hypercube decomposition is illustrated.) There always exists at least one hypercube decomposition, but in general there will be many. Any choice of hypercube decomposition determines two polynomials in $q$, the inductive piece and hypercube piece. Our formula is:

$$P_{x,y} = \text{inductive piece} + \text{hypercube piece}. \quad (4)$$

The left hand side is the $q$-derivative of the Kazhdan-Lusztig polynomial, from which the Kazhdan-Lusztig polynomial can be recovered. The calculation of the inductive piece (resp. hypercube piece) uses only the part of the graph which lies (resp. does not lie) in $J$. (Again, the reader is encouraged to glance at Figure 6. The nodes necessary for the computation of the hypercube and inductive piece are in blue (resp. red).)

3.1. The $q$-derivative of Kazhdan-Lusztig polynomials. We now introduce a new polynomial, whose knowledge is equivalent to knowledge of the Kazhdan-Lusztig polynomial, but which is easier to handle. Define

$$\partial P_{x,y}(q) = \frac{P_{x,y}(q) - q^{\ell(y)-\ell(x)}P_{x,y}(q^{-1})}{1-q}. $$
(One checks easily that the denominator always divides the numerator, so \( \partial P_{x,y} \) is always an integer valued polynomial.) We refer to \( \partial P_{x,y} \) as the \( q \)-derivative of the Kazhdan-Lusztig polynomial.\(^4\) Defining properties of Kazhdan-Lusztig polynomials\(^5\) ensure that \( \partial P_{x,y} \) determines \( P_{x,y} \).

**Example 3.1.** We give three examples of Kazhdan-Lusztig polynomials, and their corresponding \( q \)-derivatives:

1. \( P_{x,y} = 1, \ell(y) - \ell(x) = 3, \partial P_{x,y} = 1 + q + q^2, \)
   \[
   \begin{array}{c}
   \{0,1\} \\
   \{0,1\}
   \end{array}
   \]

2. \( P_{x,y} = 1 + q, \ell(y) - \ell(x) = 3, \partial P_{x,y} = 1 + 2q + q^2, \)
   \[
   \begin{array}{c}
   \{0,1\} \to \{0,2\} \to \{1,2\} \\
   \{0,1\} \to \{0,2\} \to \{1,2\}
   \end{array}
   \]

3. \( P_{x,y} = 1 + q^2, \ell(y) - \ell(x) = 6, \partial P_{x,y} = 1 + q + 2q^2 + 2q^3 + q^4 + q^5, \)
   \[
   \begin{array}{c}
   \{0,1\} \to \{0,2\} \to \{1,2\} \\
   \{0,1\} \to \{0,2\} \to \{1,2\}
   \end{array}
   \]

(We leave it up to the reader to determine the meaning of the box diagrams, as well as how to recover the Kazhdan-Lusztig polynomial from them.)

### 3.2. Hypercube clusters.

We work in the setting of directed acyclic graphs. Any such graph is a poset in natural way, where we declare \( x \leq y \) if there exists a directed path from \( y \) to \( x \).

For any finite set \( E \), the \( E \)-hypercube \( H_E \) is the directed acyclic graph with:

1. vertices consisting of subsets of \( E \);
2. an edge \( I \to J \) if \( J \) is obtained from \( I \) by removing one element.

**Example 3.2.** \( E \)-hypercubes \( H_E \) for \( E = \{0\}, \{0,1\} \) and \( \{0,1,2\} \):

\[
\begin{array}{c}
\{0\} \\
\{0\}
\end{array} \quad \begin{array}{c}
\{0,1\} \\
\{0,1\}
\end{array} \quad \begin{array}{c}
\{0,1,2\} \\
\{0,1,2\}
\end{array}
\]

\[
\begin{array}{c}
\{0\} \\
\{0\}
\end{array} \quad \begin{array}{c}
\{0,1\} \\
\{0,1\}
\end{array} \quad \begin{array}{c}
\{0,1,2\} \\
\{0,1,2\}
\end{array}
\]

Now suppose given a directed acyclic graph \( X \) (in our applications \( X \) will be a Bruhat graph) and a node \( x \in X \). We say that a subset \( E \) of edges with target \( x \) spans a hypercube if there exists a unique embedding (i.e. injection) of directed graphs

\[
\vartheta : H_E \to X
\]

sending the edge \( (\{\alpha\} \to \varnothing) \) in \( H_E \) to \( \alpha \), for all edges \( \alpha \) in \( E \). If \( E \) spans a hypercube, its crown is \( \vartheta(E) \).

---

\(^4\)In the related theory of Kazhdan-Lusztig-Stanley polynomials, this polynomial is often called the \( "H\)-polynomial".

\(^5\)more precisely, the fact that their degree is bounded above by \( (\ell(y) - \ell(x) - 1)/2 \)
**Example 3.3.** Consider the following directed graph (isomorphic to the Bruhat graph of $S_3$):

In the following we show some pairs of edges with common target with a colour. The pairs of red marked edges do not span hypercubes, whereas the blue edges do:

It should be clear that the first pair of red edges do not span a hypercube. In the second example, the issue is that there is not a *unique* way to map in a hypercube, with these specified base vertices.

We now come to a key definition. Suppose that $E$ is a set of arrows with target $x$ as above. We say that $E$ spans a hypercube cluster if every subset $E' \subseteq E$ consisting of arrows with pairwise incomparable sources spans a hypercube.$^6$

**Example 3.4.** Continuing the previous example, the pairs of blue arrows span hypercube clusters, whereas the red arrows do not:

In the first diagram, the sources of the blue arrows are comparable in $X$, so the condition to span a hypercube cluster reduces to each singleton spanning a hypercube, which is trivially the case.

Suppose that $E$ spans a hypercube cluster. Then the edges in $E$ form a partially ordered set by declaring that $\alpha \leq \beta$ if there exists a directed path from the source of $\beta$ to that of $\alpha$. Given a subset $F \subset E$, we define $F_{\text{max}}$ to be the subset of maximal elements with respect to this poset structure. Thus $F_{\text{max}} \subset F$ consists of incomparable elements. Define the hypercube map

$$\theta : F \mapsto \text{crown of the hypercube spanned by } F_{\text{max}}.$$ 

---

$^6$Elements $a$ and $b$ in a poset are *incomparable* if neither $a \leq b$ nor $b \leq a$ holds.
(Later we will see another rather different looking map arising from geometry, and finally see that both are equal. Later we will sometimes refer to $\theta$ as defined above as the combinatorial hypercube map.)

3.3. Diamonds. Given a directed graph $X$, a diamond in $X$ is a subgraph isomorphic to

![Diamond](image)

A full subgraph $J \subset X$ is diamond complete\(^7\) if whenever it contains two edges sharing a node, it contains the entire diamond. In other words, for all diamonds in $X$, if $J$ contains the red edges in any of the diagrams below, it necessarily contains the black edges as well:

![Diamonds](image)

3.4. Hypercube decompositions. Recall that $X = [x, y]$ denotes the Bruhat graph of the interval between $x$ and $y$. The following is the most important definition of this work. We say that a full subgraph $J \subset X$ is a hypercube decomposition if

1. $J = \{ v \in X \mid v \leq z \}$ for some $y \neq z \in X$, and $J$ is diamond complete;
2. for all $v \in J$, the set $E = \{ \alpha : u \rightarrow v \mid u \notin J \}$ spans a hypercube cluster.

Example 3.5. Continuing Example 3.3, here are some possible choices of $J$ (indicated by red):

![Hypercube Decompositions](image)

Only the middle choice of $J$ constitutes a hypercube decomposition. In the example on the left, the edges arriving at the base vertex do not span a hypercube cluster. In the example on the right, $J$ is not diamond complete. Here is the incomplete diamond:

![Incomplete Diamond](image)

\(^7\)This notion is due to Patimo [Pat21].
3.5. The hypercube piece. We are now ready to define the hypercube piece and inductive piece in our formula. We assume that $X$ is the Bruhat graph corresponding to the interval $[x, y]$ and that we have fixed a hypercube decomposition $J \subseteq X$. The set $E = \{ \alpha : v \rightarrow x \mid v \notin J \}$ spans a hypercube cluster by definition. In particular we have a hypercube map: $\theta : \text{subsets of } E \rightarrow X$

We consider the polynomial:

$$\tilde{Q}_{x,y,J} = \sum_{\emptyset \neq I \subseteq E} (q - 1)^{|I|-1} P_{\theta(I),y} \in \mathbb{Z}[q].$$

(Note that we may assume that all terms on the right hand side are known by induction.) We define the hypercube piece as follows:

$$Q_{x,y,J} = q^{\ell(y) - \ell(x) - 1} \tilde{Q}_{x,y,J}(q^{-1}).$$

3.6. The inductive piece. Let $J \subseteq X$ and consider the free $\mathbb{Z}[q]$-module:

$$M_J = \bigoplus_{x \neq v \in J} \mathbb{Z}[q] \delta_v.$$

This has a standard basis $\{ \delta_v \mid v \in J \}$. If we define

$$b_v = \sum_{x \neq w \in J} P_{w,v} \cdot \delta_w$$

then $\{b_v \mid x \neq v \in J\}$ is also a basis for $M$, which we call the Kazhdan-Lusztig basis. This basis is known by induction.

We may now define the inductive piece. Recall that $X$ is a Bruhat interval, with top node $y$. Define

$$r_{x,y,J} = \sum_{x \neq v \in J} P_{v,y} \cdot \delta_v \in M.$$  

(In other words we consider all inductively computed Kazhdan-Lusztig and “restrict” to $J$.) Now expand $r$ in the Kazhdan-Lusztig basis:

$$r_{x,y,J} = \sum_{x \neq v \in J} \gamma_v \cdot b_v.$$  

The inductive piece is defined as follows:

$$I_{x,y,J} = \sum_{x \neq v \in J} \gamma_v \cdot \partial P_{x,v}.$$  

3.7. A theorem. As above, $X = [x, y]$ denotes the Bruhat graph of the interval between $x$ and $y$.

Suppose for a moment that we know the labelling of the nodes of $X$ by permutations. (Note that this is forbidden information in the combinatorial invariance conjecture.) In this case, consider the full subgraph

$$L = \{ v \in X \mid v^{-1}(0) = x^{-1}(0) \} \subseteq X.$$

Remark 3.6. For any node $v \in L$, the “hypercube edges” (i.e. those edges with target $v$ and source $\notin L$) are those edges corresponding to swapping 0 and $i$ in $v$. These are precisely the edges which saliency analysis tell us are most important in our machine learning models (see Figure 3(a) in [DVB^+]). This was our initial motivation for considering $L$. 

We have:

**Theorem 3.7.** $L \subset X$ is a hypercube decomposition, and we have:

$$\partial P_{x,y} = I_{x,y,L} + Q_{x,y,L}.$$  

We will prove this formula in §4 and §5. This is a powerful new formula for Kazhdan-Lusztig polynomials for symmetric groups, and should have other applications. However, it does not solve the combinatorial invariance conjecture, as the node labellings are needed to define $L$.

### 3.8. A conjecture

Theorem 3.7 motivated us to consider more general hypercube decompositions. Remarkably, it seems that this combinatorial notion is exactly what is needed to make the above theorem hold:

**Conjecture 3.8.** For any hypercube decomposition $J \subset X$ we have

$$\partial P_{x,y} = I_{x,y,J} + Q_{x,y,J}.$$ 

Some remarks on this conjecture:

1. We have just seen that any interval admits a hypercube decomposition, and thus the conjecture implies the combinatorial invariance conjecture for symmetric groups.
2. The conjecture is equivalent to the statement that $I_{x,y,J} + Q_{x,y,J}$ is independent of the choice of hypercube decomposition.
3. We have considerable computational evidence for this conjecture. It has been checked for all hypercube decompositions of all Bruhat intervals up to $S_7$, and over a million non-isomorphic intervals in $S_8$ and $S_9$.

Positivity plays an important role in Kazhdan-Lusztig theory. Remarkably, both pieces $I_{x,y,J}$ and $Q_{x,y,J}$ in our formula should have positive coefficients:

1. The polynomials $Q_{x,y,J}$ have positive coefficients. (This can be shown directly, using the “unimodality of Kazhdan-Lusztig polynomials” [Ir88, BM01].)
2. Conjecturally, the polynomials $\gamma_v$ involved in the computation of the inductive piece have positive coefficients. This has also been checked in all the cases mentioned above, and is true for the hypercube decomposition $L$ discussed above.

**Remark 3.9.** It is interesting to ask whether our formula might solve the combinatorial invariance conjecture for Coxeter groups other than symmetric groups. It does not, as one can see by inspecting the 5-crown:

![5-crown diagram]

This occurs as a Bruhat graph of an interval in the group $H_3$ of symmetries of the icosahedron (see [BB05, §2.8]). One can check directly that it does not admit a hypercube decomposition.
3.9. **Two worked examples.** We give the reader two examples of our formula in action. These examples are illustrated in Figures 5 and 6.

**Figure 5.** The Bruhat graph for the interval between \( x = (0, 2, 1, 3) \) and \( y = (2, 3, 0, 1) \). The image of the hypercube map at \( x \) is shaded blue, and the inductive piece is shaded red. All Kazhdan-Lusztig polynomials \( P_{z,y} \) for \( z \neq x \) are 1. All hypercube decompositions of this interval are isomorphic to this one.

3.9.1. *The interval between* \( x = (0, 2, 1, 3) \) *and* \( y = (2, 3, 0, 1) \). This is the first non-trivial example of a Kazhdan-Lusztig polynomial. In several respects this example is “too simple”, but we discuss it anyway. The interval together with a choice of hypercube decomposition is illustrated in Figure 5. (The reader may check that in this example all hypercube decompositions are isomorphic.)

We have

\[
P_{x,y} = 1 + q \quad \text{and} \quad \partial P_{x,y} = 1 + 2q + q^2.
\]

In this case the polynomial \( \tilde{Q}_{x,y,J} \) is

\[
1 + 1 + (q - 1) = 1 + q
\]

and hence the hypercube piece is

\[
q^2(1 + q^{-1}) = q + q^2.
\]

The inductive piece is

\[
1 + q
\]

and we indeed we have

\[
\partial P_{x,y} = (1 + q) + (q + q^2).
\]
Figure 6. The Bruhat graph for the interval between $x = (1,0,2,4,3)$ and $y = (4,1,2,3,0)$ with a choice of hypercube decomposition. The image of the hypercube map at $x$ is shaded blue, and the inductive piece is shaded red. All Kazhdan-Lusztig polynomials $P_{z,y}$ for $z \neq x$ are 1 unless indicated.

3.9.2. The interval between $x = (1,0,2,4,3)$ and $y = (4,1,2,3,0)$. This is a more interesting case, and illustrates several features of the general case. The interval together with a choice of hypercube decomposition $J$ is illustrated in Figure 6.

The reader may check with a little work that we have

$$\tilde{Q}_{x,y,J} = 1 + 2q + q^2$$

and hence

$$Q_{x,y,J} = q^4(1 + 2q^{-1} + q^{-2}) = q^2 + 2q^3 + q^4.$$ 

We now turn to the inductive piece. We have

$$r_{x,y,J} = b_{14230} + q \cdot b_{10432}.$$ 

(In Figure 6, 10432 is the only node of length $\ell(x) + 2$ in the inductive piece with non-trivial Kazhdan-Lusztig polynomial.) In particular,

$$I_{x,y,J} = \partial P_{x,14230} + q \cdot \partial P_{x,10432} = 1 + 2q + 2q^2 + q^3 + q(1 + q)$$

$$= 1 + 3q + 3q^2 + q^3$$

and we deduce correctly that

$$\partial P_{x,y} = (1 + 3q + 3q^2 + q^3) + (q^2 + 2q^3 + q^4) = 1 + 3q + 4q^2 + 3q^3 + q^4.$$
Or in other words
\[ P_{x,y} = 1 + 2q + q^2. \]

4. Geometry of the New Formula

In this section we explain the proof of Theorem 3.7. This is a consequence of geometric techniques. We first recall fundamental results of Kazhdan and Lusztig and Bernstein and Lunts which connect Kazhdan-Lusztig polynomials to the geometry of Schubert varieties, and then proceed to the proof.

4.1. Geometric background. Given a complex \( d \)-dimensional complex algebraic variety \( X \), we denote by \( \text{IC}(X, \mathbb{Q}) \) the intersection cohomology complex on \( X \), with coefficients in \( \mathbb{Q} \), normalized so that its restriction to \( X \) is isomorphic to the constant sheaf without shift. Given a sheaf \( \mathcal{F} \) of \( \mathbb{Q} \) vector spaces on \( X \) we denote by \( H^\bullet(X, \mathcal{F}) \) its hypercohomology (a graded \( \mathbb{Q} \)-vector space). The intersection cohomology of \( X \) is by definition
\[ IH^\bullet(X, \mathbb{Q}) = H^\bullet(X, \text{IC}(X, \mathbb{Q})). \]

Because of our conventions, the intersection cohomology of a complex \( d \)-dimensional variety is concentrated in degrees between 0 and \( 2d \), as opposed to the more usual convention where it is concentrated in degrees between \(-d\) and \(d\).

Given a graded \( \mathbb{Q} \)-vector space \( H \) we define its Poincaré polynomial to be
\[ \sum_{i \in \mathbb{Z}} \dim H^i q^{i/2} \in \mathbb{Z}[q^{\pm 1/2}]. \]

Given a complex of \( \mathbb{Q} \)-vector spaces with finite-dimensional total cohomology we define its Poincaré polynomial to be that of its cohomology groups. In this paper, all Poincaré polynomials we consider are of vector spaces concentrated in positive even degrees. In this case the Poincaré polynomial is a polynomial in \( q \).

Throughout this section, we will work in the equivariant derived category (see [BL94]). Throughout \( T \) will denote an algebraic torus acting algebraically on a variety \( X \). By an equivariant sheaf we mean an object of \( D^b_T \mathcal{X}, \mathbb{Q} \). All sheaves considered will be constructible. On (equivariant) constructible categories we have the usual menagerie of functors \( f_*^e, f^e, f^! \) for equivariant maps \( f : X \to Y \) which all commute with the forgetful functor.

We will also need some arguments with weights. We will exploit the fact that \( \text{IC}(X, \mathbb{Q}) \) is a constructible complex underlying a mixed Hodge module, and hence so are all complexes obtained from \( \text{IC}(X, \mathbb{Q}) \) via standard functors (see e.g. [Sai89, Sch14]). In particular, each cohomology group \( IH^i(X, \mathbb{Q}) \) underlies a mixed Hodge structure, and we can talk about its weights. Our normalizations are such that \( \text{IC}(X, \mathbb{Q}) \) is pure of weight zero. When we say that a cohomology group \( H^i \) is pure of weight \( w \), we mean that \( H^i \) is pure of weight \( w + i \) for all \( i \). We can also talk about weights in equivariant cohomology, by taking appropriate resolutions in the category of algebraic varieties. Our demands on the theory of weights are modest, and the reader who prefers to work with étale cohomology and Frobenius weights will have no difficulty adapting the arguments.

4.2. Tools of the trade. The following techniques will be used repeatedly:

(1) (“Attractive Proposition”) Suppose that there exists a \( \mathbb{C}^* \)-action on \( X \) which retracts \( X \) equivariantly onto \( X^{\mathbb{C}^*} \). In other words, there exists a diagram
\[ a : \mathbb{C} \times X \to X \]
such that the restriction of $a$ to $\mathbb{C}^* \times X \to X$ agrees with the action map, and such that $\{0\} \times X$ maps into $X^{C^*}$. (Roughly speaking, this says that the $C^*$-action extends over 0, attracting $X$ onto $X^{C^*}$.) We can consider the inclusion and projection maps

$$
\begin{align*}
  X^{C^*} & \xrightarrow{i} X \\
  & \xleftarrow{p} X
\end{align*}
$$

where $p : X = \{0\} \times X \to X^{C^*}$ is induced by $a$. Given any $\mathbb{C}^*$-equivariant constructible sheaf $\mathcal{F}$ on $X$, we have canonical isomorphisms

$$
p_a \mathcal{F} \sim i^* \mathcal{F} \quad \text{and} \quad i^! \mathcal{F} \sim p_! \mathcal{F}.
$$

We have similar isomorphisms of $X$ is a $T$-space, and $C^*$ commutes with the $T$-action. This technique is fundamental to Geometric Representation Theory, for proofs and more detail see [Spr84], [Soe89, Proposition 1] and [FW14, §2.6].

(2) (“Attractive Weight Argument”) Let us stay in the setting of the previous point. We have seen that we have an isomorphism

$$
p_a \mathcal{F} \sim i^* \mathcal{F}.
$$

Now let us assume that $\mathcal{F}$ is pure (of weight 0, say). Then $i^* \mathcal{F}$ is of weights $\leq 0$, and $p_a \mathcal{F}$ is of weight $\geq 0$ because $i^*$ (resp. $p_a$) can only decrease (resp. increase) weights [Sai89, Proposition 1.7]. Thus $i^* \mathcal{F}$ is pure of weight 0. An identical argument establishes that $i^! \mathcal{F}$ is also pure of weight 0.

(3) (“Finite Stabilizer Argument”) Suppose that $C^*$ acts on $X$ with finite stabilizers with (geometric) quotient $X/C^*$. Then we have a full embedding

$$
D^b(X/C^*, \mathbb{Q}) \to D^b_{C^*}(X, \mathbb{Q})
$$

If $\mathcal{F}$ and $\tilde{\mathcal{F}}$ correspond under this embedding, we have a canonical isomorphism

$$
H^*_C(X, \mathcal{F}) = H^*(X/C^*, \tilde{\mathcal{F}}).
$$

We have analogous statements for equivariant cohomology and equivariant derived categories (i.e. when $X$ is a $T$-space). If we assume a free action, these facts are true very generally, and are known as the quotient equivalence [BL94, Proposition 2.2.5]. When we allow finite stabilizers the situation is a little more subtle, and coefficients of characteristic zero are essential [BL94, §9].

4.3. Geometric interpretation of Kazhdan-Lusztig polynomials. Let $G = GL_{n+1}(\mathbb{C})$, $B \subset G$ the Borel subgroup of upper triangular matrices and $T$ the maximal torus of diagonal matrices. We identify the Weyl group with permutation matrices, which is canonically isomorphic to $S_{n+1}$. We have the flag variety $G/B$ and its Bruhat decomposition into Schubert cells

$$
G/B = \bigsqcup_{y \in S_{n+1}} B y B / B.
$$

For any $y \in S_{n+1}$ we can consider the Schubert variety $\overline{B y B / B} \subset G / B$. On $\overline{B y B / B}$ we can consider the intersection cohomology complex $IC(\overline{B y B / B}, \mathbb{Q})$ (see §4.1 for
conventions). We have the following fundamental result of Kazhdan and Lusztig [KL80]:

**Theorem 4.1.** The cohomology sheaves $H^i(\mathcal{IC}(\overline{B_yB/B}, \mathbb{Q})_{xB/B})$ vanish in odd degree, moreover their Poincaré polynomial is given by the Kazhdan-Lusztig polynomial:

$$P_{x,y} = \sum_{i\geq 0} H^{2i}(\mathcal{IC}(\overline{B_yB/B}, \mathbb{Q})_{xB/B})q^i.$$ 

Let $U^-$ denote lower unitriangular matrices. For any $x \in S_{n+1}$ the product $BxB/B \times U^-xB/B$ is isomorphic to a $T$-stable affine neighbourhood of $x$ in $G/B$. Similarly, $BxB/B \times (U^-xB/B \cap B_yB/B)$ is isomorphic to a $T$-stable affine neighbourhood of $x$ in $B_yB/B$. Fundamental to everything below will be the space $S_{x,y} = U^-xB/B \cap B_yB/B$ which is a normal slice to the $B$-orbit through $xB/B$ in $B_yB/B$. We denote by point $xB/B$ in $S_{x,y}$ simply by $x$. Because $S_{x,y}$ is a normal slice, we deduce the following from Theorem 4.1:

**Proposition 4.2.** The cohomology sheaves $H^i(\mathcal{IC}(S_{x,y}, \mathbb{Q}x))$ vanish in odd degree, moreover their Poincaré polynomial is given by the Kazhdan-Lusztig polynomial:

$$P_{x,y} = \sum_{i\geq 0} H^{2i}(\mathcal{IC}(S_{x,y}, \mathbb{Q})_x)q^i.$$ 

**Remark 4.3.** There is no shift in the gradings between Theorem 4.1 and Proposition 4.2 because of our normalizations of $\mathcal{IC}$.

**4.4. Equivariance and the fundamental example.** Recall that $T$ denotes the maximal torus inside $GL_{n+1}$ consisting of diagonal matrices. Every $T$-fixed point $xB/B$ on $G/B$ is attractive in the sense that there exists a one-parameter subgroup $\lambda: \mathbb{C}^* \to T$ in $T$ such that

$$\lim_{z \to 0} \lambda(z) \cdot v = xB/B$$

for all $v$ in some neighbourhood of $xB/B$. (Equivalently and more algebraically: there exists $\lambda$ as above which acts with positive weights on functions on a $T$-stable affine neighbourhood of $xB/B$.) It follows that $x \in S_{x,y}$ is attractive and that (with $\lambda$ as above)

$$\lim_{z \to 0} \lambda(z) \cdot v = x$$

for all $v \in S_{x,y}$.

Because $\lambda$ acts with positive weights the geometric quotient

$$\mathbb{P}_\lambda S_{x,y} := \hat{S}_{x,y}/\lambda \mathbb{C}^*$$

exists and is a projective variety. Here “$/\lambda$” means that we consider the quotient by the $\mathbb{C}^*$-action given by $\lambda$. (One may establish the existence of this quotient by choosing a linear embedding $S_{x,y}$ inside an affine space $\mathbb{C}^n$ with linear $T$-action. Then $(\mathbb{C}^n \setminus \{0\})/\lambda \mathbb{C}^*$ exists, and is isomorphic to a weighted projective space. The chosen embedding $S_{x,y} \subset \mathbb{C}^n$ then provides a closed embedding of $\mathbb{P}_\lambda \hat{S}_{x,y}$ inside a weighted projective space.)
**Proposition 4.4.** The intersection cohomology groups $IH^i(P, \mathcal{S}_{x,y}, \mathbb{Q})$ vanish in odd degree, moreover their Poincaré polynomial is given by the $q$-derivative of the Kazhdan-Lusztig polynomial:

$$\partial P_{x,y} := \sum_{i \geq 0} IH^{2i}(P, \mathcal{S}_{x,y}, \mathbb{Q})q^i.$$ 

**Remark 4.5.** The following proof is standard in Geometric Representation Theory. For a detailed discussion of closely related ideas, the reader might enjoy [BL94, §14].

**Proof.** Note that $\mathcal{IC}(S_{x,y}, \mathbb{Q})$ is equivariant for $T$, and hence may be regarded as an element the equivariant derived category $D^b_c(S_{x,y}, \mathbb{Q})$. In this proof we always regard $S_{x,y}$ as a $\mathbb{C}^*$-variety via the action induced from $\lambda : \mathbb{C}^* \to T$.

Consider the closed/open decomposition

$$\{x\} \to S_{x,y} \to \hat{S}_{x,y}$$

where $\hat{S}_{x,y} = S_{x,y} - \{x\}$. This gives us a distinguished triangle

$$i! \mathcal{IC}(S_{x,y}, \mathbb{Q}) \to \mathcal{IC}(S_{x,y}, \mathbb{Q}) \to j_*j^* \mathcal{IC}(S_{x,y}, \mathbb{Q}) \quad [1]$$

Taking global sections (i.e. hypercohomology) we get a long exact sequence. We claim that all terms are pure of the same weight, and hence that the connecting homomorphism is zero. Indeed:

1. Consider the projection $p : S_{x,y} \to \{x\}$. We have

$$H^*_{\mathbb{C}^*}(\{x\}, p_* \mathcal{IC}(S_{x,y}, \mathbb{Q})) = H^*_{\mathbb{C}^*}(S_{x,y}, \mathcal{IC}(S_{x,y}, \mathbb{Q}))$$

by definition, and

$$H^*_{\mathbb{C}^*}(S_{x,y}, \mathcal{IC}(S_{x,y}, \mathbb{Q})) = H^*_{\mathbb{C}^*}(\{x\}, i^* \mathcal{IC}(S_{x,y}, \mathbb{Q}))$$

by the Attractive Proposition. By the Attractive Weight Argument,

$$H^*_{\mathbb{C}^*}(S_{x,y}, \mathcal{IC}(S_{x,y}, \mathbb{Q}))$$

is pure of weight zero as claimed.

2. By the Attractive Proposition again we have

$$H^*_{\mathbb{C}^*}(\{x\}, p! \mathcal{IC}(S_{x,y}, \mathbb{Q})) = H^*_{\mathbb{C}^*}(\{x\}, i^* \mathcal{IC}(S_{x,y}, \mathbb{Q}))$$

and the purity of both sides follows by the Attractive Weight Argument again.

3. Because $j^*$ is an open inclusion we have $j^* \mathcal{IC}(S_{x,y}, \mathbb{Q}) = \mathcal{IC}(\hat{S}_{x,y}, \mathbb{Q})$. Because $\mathbb{C}^*$ acts with finite stabilizers and our coefficients are $\mathbb{Q}$ we have

$$H^*_{\mathbb{C}^*}(\hat{S}_{x,y}, \mathcal{IC}(\hat{S}_{x,y}, \mathbb{Q})) = IH^*(P, \mathcal{S}_{x,y}, \mathbb{Q}).$$

The latter is pure of weight zero, as the intersection cohomology of a projective variety.

Thus we have a short exact sequence

$$(5) \quad H^*_{\mathbb{C}^*}(\{x\}, i^! \mathcal{IC}(S_{x,y}, \mathbb{Q})) \to H^*_{\mathbb{C}^*}(\{x\}, i^* \mathcal{IC}(S_{x,y}, \mathbb{Q})) \to IH^*(P, \mathcal{S}_{x,y}, \mathbb{Q}).$$

A similar argument to the one given above using the attractive proposition shows that non-equivariant cohomology groups

$$H^*(\{x\}, i^! \mathcal{IC}(S_{x,y}, \mathbb{Q})) \quad (\text{resp.} \quad H^*(\{x\}, i^* \mathcal{IC}(S_{x,y}, \mathbb{Q})))$$
are pure. Moreover, their Poincaré polynomials are given by
\[ q^{\ell(y) - \ell(z)} P_{x,y}(q^{-1}) \] (resp. \( P_{x,y}(1 - q) \)).
(The second is simply a restatement of Proposition 4.2, the first follows from it by
Verdier duality.) It follows that the equivariant cohomology groups are free over
\( H^*_C(pt, \mathbb{Q}) \) of graded ranks given by
\[ q^{\ell(y) - \ell(z)} P_{x,y}(q^{-1})(1 - q) \] (resp. \( P_{x,y}(1 - q) \)).
We deduce that the Poincaré polynomial of the last term in (5) is given by
\[ P_{x,y}(1 - q) - q^{\ell(y) - \ell(z)} P_{x,y}(q^{-1})(1 - q) = \partial P_{x,y} \]
which is what we wanted to show. \( \square \)

Example 4.6. Consider the first singular Schubert variety \( y = (2, 3, 0, 1) \) and \( x = (0, 2, 1, 3) \). We will keep this as a running example throughout. One can compute
directly (or wait until we discuss this example in more detail in Example 4.8) that
\( S_{x,y} \) may be identified with the following subvariety of \( 4 \times 4 \)-matrices:
\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
x & 1 & 0 & 0 \\
y & 1 & 0 & 0 \\
z & w & 1 & 0
\end{pmatrix}
\]
\( xw - yz = 0 \)
We can choose \( \lambda \) such that the attractive \( \mathbb{C}^* \)-action simply scales \( x, y, z \) and \( w \).
With this choice of \( \lambda \) the quotient \( \mathbb{P}^3 \) is simply
\( \{[x : y : z : w] \in \mathbb{P}^3 | xz - yw = 0\} \cong \mathbb{F}^1 \times \mathbb{F}^1 \).
This is smooth, thus its intersection cohomology and cohomology agree, and its
Poincaré polynomial is \( 1 + 2q + q^2 = \partial P_{x,y} \).

4.5. Where does the formula come from? We are now in a position to describe our
formula in more detail. Here we give an outline of the argument.
In the previous section we saw that the \( q \)-derivative of the Kazhdan-Lusztig polynomial
\( \partial P_{x,y} \) computes the Poincaré polynomial of the intersection cohomology of
the projective variety \( \mathbb{P} \lambda \mathcal{S}_{x,y} \). Now \( S_{x,y} \) has a natural stratification via intersections
with Schubert cells:
\[
S_{x,y} = \bigsqcup_{u \in \Pi(x,y)} S_{x,y}^u \text{ where } S_{x,y}^u = S_{x,y} \cap Bu/B.
\]
We will refer to this stratification as the Schubert stratification of \( S_{x,y} \). The Schubert stratification is \( T \)-invariant and induces a stratification of the quotient
\[
\mathbb{P} \lambda \mathcal{S}_{x,y} = \mathcal{S}_{x,y} / \mathbb{C}^* = \bigsqcup_{u \in \Pi(x,y)} S_{x,y}^u / \mathbb{C}^*
\]
(Note that \([x, y]\) has been replaced by \((x, y)\) because the point \( \{x\} = S_{x,y}^x = S_{x,y} \cap Bx/B \) has been removed in \( \mathcal{S}_{x,y} \).)
The pullback of the IC sheaf on \( \mathbb{P} \lambda \mathcal{S}_{x,y} \) to \( \mathcal{S}_{x,y} \) agrees with the IC sheaf on \( \mathcal{S}_{x,y} \),
which in turn agrees with the restriction of the IC sheaf on \( \mathcal{B}y/B \), because \( S_{x,y} \)
is a normal slice. In particular, all the Poincaré polynomials of the stalks of the IC sheaf
on \( \mathbb{P} \lambda \mathcal{S}_{x,y} \) are known. (To spell things out: the Poincaré polynomial of
\( \mathbb{IC}(\mathbb{P} \lambda \mathcal{S}_{x,y}, \mathbb{Q}) \) along the stratum \( S_{x,y}^u / \mathbb{C}^* \) is given by \( P_{u,y} \).) Thus it is reasonable,
perhaps, that we can compute the Poincaré polynomial of the global sections of $\text{IC}(\mathbb{P}_x \tilde{S}_{x,y}, \mathbb{Q})$ via some kind of long exact sequence.

We will define an open/closed decomposition

$$Z \xrightarrow{\iota} \mathbb{P}_x \tilde{S}_{x,y} \xrightarrow{j} U$$

with $U$ open and $Z$ closed. We have an associated long exact sequence:

$$\to H^*(Z, \iota^*\text{IC}) \to H^*(\mathbb{P}_x \tilde{S}_{x,y}, \text{IC}) \to H^*(U, j^*\text{IC}) \to$$

(where we have abbreviated $\text{IC} := \text{IC}(\mathbb{P}_x \tilde{S}_{x,y}, \mathbb{Q})$). The decomposition (7) has several very favourable properties:

1. $Z$ is isomorphic to a weighted projective space, the stratification induced by (6) courses its toric stratification, and $\iota^*\text{IC}$ is pure;
2. $U$ retracts $T$-equivariantly onto a space $Z'$ isomorphic to $\mathbb{P}_x \tilde{S}_{x,c}$, where $c$ denotes the maximal element in $[x, y]$ in the $S_n$-coset of $x$, and the restriction of $\text{IC}$ to $Z'$ is pure.

By the Attractive Proposition our long exact sequence can be rewritten

$$\to H^*(Z, \iota'^*\text{IC}) \to H^*(\mathbb{P}_x \tilde{S}_{x,y}, \text{IC}) \to H^*(U, (\iota')^*\text{IC}) \to$$

where $\iota' : Z' \hookrightarrow \mathbb{P}_x \tilde{S}_{x,y}$ denotes the inclusion. Because everything is pure of weight zero, we conclude that our sequence is in fact short exact. Thus, taking Poincaré polynomials (and using that the $q$-derivative of the KL polynomials is the Poincaré polynomial of the middle term) we deduce

$$\partial P_{x,y} = Q + I$$

where $Q$ (resp. $I$) is the Poincaré polynomial of the left-most (resp. right-most) term in (8). We can compute $Q$ via a simple formula (yielding the hypercube piece), and $I$ is computed by induction (yielding the inductive piece).

**Example 4.7.** We continue our running example. We have seen that $\tilde{S}_{x,y}/_\lambda \mathbb{C}^*$ is isomorphic to $\mathbb{P}^1 \times \mathbb{P}^1$. The torus $T/\lambda(\mathbb{C}^*) \cong \mathbb{C}^* \times \mathbb{C}^*$ still acts on this quotient, and one may check that this is the standard action, i.e.

$$(z, z') \cdot ([u : v], [u' : v']) = ([u : zv], [u' : z'v']).$$

There are $4 + 4 + 1 = 9$ orbits of $(\mathbb{C}^*)^2$ on $\mathbb{P}^1 \times \mathbb{P}^1$, and these orbits coincide with the image of the Schubert stratification. (It is nice to notice that the closure patterns of these orbits nicely match the vertices $\neq x$ in the interval $[x, y]$:

---

\[\text{See §4.11 for the definition of “toric stratification”}\]
Thus the four vertices are height 1 correspond to the 4-fixed points on $\mathbb{P}^1 \times \mathbb{P}^1$, the four vertices at height 2 correspond to the 4 invariant $\mathbb{C}^*$'s, and the unique vertex at height 3 corresponds to the open orbit.)

Our decomposition has $Z$ equal to a torus invariant $\mathbb{P}^1 \subset \mathbb{P}^1 \times \mathbb{P}^1$, and $U$ its complement, which retracts equivariantly onto the “opposite” $\mathbb{P}^1$ which yields $Z'$. The short exact sequence

$$0 \to H^\bullet(Z, i^! \mathbb{Q}_{\mathbb{P}^1 \times \mathbb{P}^1}) \to H^\bullet(\mathbb{P}^1 \times \mathbb{P}^1, \mathbb{Q}) \to H^\bullet(Z', i^! \mathbb{Q}_{\mathbb{P}^1 \times \mathbb{P}^1}) \to 0$$

gives the unsurprising identity

$$1 + 2q + q^2 = (q + q^2) + (1 + q)$$

coming from the Poincaré polynomial of the left hand term (resp. right hand term) in the short exact sequence.

### 4.6. Slices and their subvarieties in the flag variety.

Our eventual goal is to make the sketch provided in the previous section precise. We will need an explicit description of the slice $S_{x,y}$ in the case of $\mathrm{GL}_n^\mathbb{C}$. Most of this is rather standard, for more information, see [Ful92], [WY08, §3.2] and [WY12, §2.2]. The experienced reader can probably skim over this subsection and the next.

Recall that $B \subset \mathrm{GL}_n^\mathbb{C}$ denotes the subgroup of upper triangular matrices, $U_-$ denotes the subgroup of lower uni-triangular matrices and that we identify permutations in $\mathcal{S}_n$ with the corresponding permutation matrices in $\mathrm{GL}_n^\mathbb{C}$.

Because the multiplication $U_- \times B \to \mathrm{GL}_n^\mathbb{C}$ is an open immersion, $U_-$ provides an open neighbourhood of $B/B$ in $G/B$. It follows that $xU_-$ provides an open neighbourhood of the point $xB/B$ in $G/B$. We have

$$xU_- = \{ (\gamma_{i,j}) \mid \gamma_{x(i),i} = 1, \gamma_{x(i),j} = 0 \text{ if } j > x(i). \}$$

That is, “zero if right of a 1”. Here is a picture for $x = (1, 0, 3, 2) \in S_4$:

$$xU_- = \begin{pmatrix} * & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ * & * & * & 1 \\ * & * & 1 & 0 \end{pmatrix}$$

In this chart, the $B$-orbit through $xB/B$ consists of “zero if not above a 1”.

In particular, a normal slice to the $B$-orbit through $xB/B$ is given by

$$S_x = \{ (\gamma_{i,j}) \mid \gamma_{x(i),i} = 1, \gamma_{i,j} = 0 \text{ if } j > x(i) \text{ or } i < x^{-1}(j) \}$$

That is, “zero if right or above a 1”. A picture for $x = (1, 0, 3, 2) \in S_4$:

$$S_x = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ * & * & 0 & 1 \\ * & * & 1 & 0 \end{pmatrix}$$

Throughout an important role will be played by

$$m := x^{-1}(0)$$

This is the column in which the 1 occurs in the top row in $x$. Consider the subvarieties

$$S_x^H = \{ \gamma \in S_x \mid \gamma_{i,j} = 0 \text{ unless } (i,j) = (x(j), j) \text{ or } j = m \},$$

$$S_x^I = \{ \gamma \in S_x \mid \gamma_{i,j} = 0 \text{ unless } (i,j) = (x(j), j) \text{ or } j \neq m \}.$$
That is, “zero if not in column number $m$” and “zero if in column number $m$” respectively. A picture for $x = 1032 \in S_4$ (so $m = 1$):

$$S^H_x = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & * & 0 & 1 \\ 0 & * & 1 & 0 \end{pmatrix} \quad \text{and} \quad S^I_x = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ * & 0 & 0 & 1 \\ * & 0 & 1 & 0 \end{pmatrix}$$

4.7. Equations defining slices to Schubert varieties. Let $g \in G = \text{GL}_{n+1}(\mathbb{C})$ be a matrix. By a lower left corner we mean the submatrix:

$$g^{< (p, q)} = \{(g_{ij})_{i \geq p, j \leq q}\}$$

Given a matrix, its corner rank matrix is the matrix which at position $(p, q)$ records the rank of $g^{< (p, q)}$. These matrices will be particularly important for permutation matrices. For example, if $y = (1, 2, 3, 0)$ then

$$y = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix} \quad \text{and} \quad \text{corner rank matrix} = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 2 & 3 & 3 \\ 0 & 1 & 2 & 2 \\ 0 & 0 & 1 & 1 \end{pmatrix}$$

Suppose that $g'$ is obtained from $g$ by a scaling rows or columns, upwards row operation, or a rightwards column operation, then the rank of any lower left corner remains unchanged. In particular, any matrix $g \in B \sigma B$ satisfies

$$\text{rank}(g^{< (p, q)}) = \text{rank}(\hat{y}^{< (p, q)}) = (p, q)^{th} \text{ entry in corner rank matrix of } \hat{y}$$

for all $p, q$. It is not difficult to see that $g \in B \sigma B$ if and only if these conditions are met.

In fact, $B \sigma B$ is cut out by the equations:

$$\text{(10)} \quad \text{rank}(g^{< (p, q)}) \leq \text{rank}(\hat{y}^{< (p, q)}) \quad \text{for all } p, q.$$ 

Intersecting with the slices $S_x, S^H_x$ and $S^I_x$ defines subvarieties

$$S_{x,y} := S_x \cap B \sigma B,$$

$$S^H_{x,y} := S^H_x \cap B \sigma B,$$

$$S^I_{x,y} := S^I_x \cap B \sigma B$$

which are cut out of the respective affine spaces by rank conditions.

**Example 4.8.** We continue our running example (see Examples 4.6 and Example 4.7). The corner rank matrix $y = (2, 3, 0, 1)$ is

$$\hat{y} = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \text{corner rank matrix} = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 2 & 2 & 3 \\ 1 & 2 & 2 & 2 \\ 0 & 1 & 1 & 1 \end{pmatrix}$$

Recall that $x = (0, 2, 1, 3)$ and hence the slice $S_x$ is:

$$S_x = \begin{pmatrix} 1 & 0 & 0 & 0 \\ a & 0 & 1 & 0 \\ b & 1 & 0 & 0 \\ c & d & e & 1 \end{pmatrix}$$
In this case, the equations cutting out $S_{x,y} \subset S_x$ reduce to rank $g^{(3,0)} \leq 0$, i.e. $c = 0$, and rank $g^{(1,2)} = 1$, i.e. $ae + bd = 0$. This recovers the description claimed in Example 4.6.

4.8. Decomposition of the projectivized slice. In this section we make the outline in §4.5 precise. In particular, we define the subvarieties $U$, $Z$ and $Z'$. As in §4.5 we denote

$$\text{IC} := \text{IC}(\mathbb{P}_\lambda \hat{S}_{x,y}, \mathbb{Q}).$$

Given a $T$-stable closed subvariety $X \subset \hat{S}_{x,y}$ we denote by $\mathbb{P}_\lambda X$ the closed subvariety obtained as the image of $X := X \setminus \{x\}$ in $\mathbb{P}_\lambda \hat{S}_{x,y}$. It is a closed subvariety. Set

$$Z := \mathbb{P}_\lambda \hat{S}^H_{x,y}, \quad U := \mathbb{P}_\lambda \hat{S}_{x,y} - \mathbb{P}_\lambda \hat{S}^H_{x,y}, \quad Z' := \mathbb{P}_\lambda \hat{S}^I_{x,y}$$

and denote by $i, j, i'$ the inclusions of $Z, U, Z'$ into $\mathbb{P}_\lambda \hat{S}_{x,y}$.

Let

$$L = \{z \in [x, y] \mid z^{-1}(0) = x^{-1}(0)\} \subset [x, y].$$

In order to carry out the program outlined in §4.5 we need to check the following statements:

**Theorem 4.9.** $U$ retracts $T$-equivariantly onto $Z'$, $(i')^*\text{IC}$ is pure, and the Poincaré polynomial of $H^\bullet(Z', (i')^*\text{IC})$ is given by $I_{x,y,L}$.

We prove this in §4.9 and §4.10 below.

**Theorem 4.10.** $i^*\text{IC}$ is pure, and the Poincaré polynomial of $H^\bullet(Z, i^*\text{IC})$ is given by $Q_{x,y,L}$.

We prove this in §4.14 below, using an alternative (geometric) definition of the hypercube map. In §5 we check that these two definitions agree.

**Example 4.11.** In the setting of our running example (see Examples 4.6, 4.7 and 4.8) we have

$$S^H_x = \begin{pmatrix} 1 & 0 & 0 & 0 \\ * & 0 & 1 & 0 \\ * & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad S^I_x = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & * & 1 \end{pmatrix}$$

which produce two $T$-stable “opposite $\mathbb{P}^1$’s” in $\mathbb{P}^1 \times \mathbb{P}^1$ discussed in Example 4.7.

4.9. The inductive piece: geometry. The results for the inductive piece follow essentially because everything is nicely compatible with restriction to the fixed points of a particular choice of $\gamma : \mathbb{C}^* \to T$ whose centralizer is $\text{GL}_1 \times \text{GL}_n$. This is a common theme in Geometric Representation Theory: much information can be gained from Levi subgroups via torus localization. Now we give the details.

Recall from above that we have fixed a one-parameter subgroup $\lambda : \mathbb{C}^* \to T$ which acts attractively on $S_{x,y}$. It is this $\lambda$ that we used to form the quotient

$$\mathbb{P}_\lambda \hat{S}_{x,y} = \hat{S}_{x,y}/\lambda \mathbb{C}^*.$$ 

**Remark 4.12.** It will not be important to fix a particular choice of $\lambda$. However, the reader might like to check that we could take

$$\lambda : z \mapsto \text{diag}(1, z, z^2, \ldots, z^n).$$
Below another one-parameter subgroup will be important. Consider
\[ \gamma : \mathbb{C}^* \to \text{GL}_{n+1} \]
\[ z \mapsto \text{diag}(1, z, z, \ldots, z). \]
Because we have two \( \mathbb{C}^* \)'s at play, we will use \( \lambda \) and \( \gamma \) to distinguish them. For example, if we refer to the \( \mathbb{C}^*_\lambda \)-action we mean the \( \mathbb{C}^* \)-action provided by \( \lambda \), and \( S_{x,y}^\gamma \) denotes the \( \mathbb{C}^* \)-fixed points on \( S_{x,y} \), with \( \mathbb{C}^* \)-action given by \( \gamma \).

Firstly, note that \( \mathbb{C}^*_\gamma \) acts naturally on \( p_{n+1}^\gamma \hat{p}_{n+1}^\gamma \) matrices via conjugation.

The action is via scaling block matrices as follows
\[
\begin{pmatrix}
1 & z^{-1} \\
z & 1
\end{pmatrix}
\]

In particular,
\[ G^\gamma = \text{GL}_1(\mathbb{C}) \times \text{GL}_n(\mathbb{C}). \]

This subgroup will play an important role below. We give it its own notation:
\[ G_n = \text{GL}_1(\mathbb{C}) \times \text{GL}_n(\mathbb{C}) \subset G. \]

This is a Levi subgroup of \( G \). We denote by \( S_n \) its Weyl group. It consists of the subgroup of \( S_{n+1} \) consisting of those permutations which fix 0. We let \( B_n = G_n \cap B \) denote the Borel subgroup of upper triangular matrices in \( G_n \).

\textit{Remark 4.13.} We caution the reader that the inclusion of \( G_n \hookrightarrow G \) is via block \( 1 \times n \)-matrices, not \( n \times 1 \) as it more common. Similarly, our inclusion \( S_n \hookrightarrow S_{n+1} \) via permutations fixing 0 is slightly non-standard.

\textbf{Proposition 4.14.} \((G/B)^\gamma\) is a disjoint union of flag varieties for \( G_n \). More precisely,
\[ (G/B)^\gamma = \bigsqcup_{x \in S_n \setminus S_{n+1}} G_n \cdot x \]
and each \( G_n \cdot x \) orbit is isomorphic to \( G_n/B_n \).

\textit{Proof.} This is a standard result, so we will be brief. Firstly, \( G_n = G^\gamma \) certainly acts on the \((G/B)^\gamma\). If \( z \) denotes a minimal coset representative of \( S_n \setminus S_n \) (i.e. \( z(l) = 0 \) for some \( 0 \leq l \leq n \) and \( z \) maps the remainder \( 0, 1, \ldots, l-1, l+1, \ldots, n \) monotonically to \( 1, \ldots, n \)) then the stabilizer of \( G_n \) acting on \( zB/B \) is
\[ z^{-1}G_nz \cap B = B_n \]
as follows from an easy calculation. Thus action on the points given by minimal coset representatives gives an inclusion
\[ (G/B)^\gamma \]

A similar computation to that establishing \( G^\gamma = G_n \) above shows that on each of the \( xU \) for \( G/B \), the \( \gamma \)-action is via scaling the free variables in \( 0^{th} \)-row by \( z^{-1} \), and scaling the entries in the \( x^{-1}(0)^{th} \)-column by \( z \). Thus the fixed points in this chart have zeroes in the \( 0^{th} \)-row and \( x^{-1}(0)^{th} \)-column, except the 1 in position \((0, x^{-1}(0))\). It follows that
\[ (xU)^\gamma \subset G_n \cdot xB/B \]
As the charts \( xu \) cover \( G/B \), we deduce that the inclusion in (11) is an equality. □

Consider a \( T \)-fixed point \( xB/B \). We can consider the slice \( S_x \subset G/B \) to the \( B \)-orbit through \( xB/B \). On the other hand, if \( z \in S_{x} \) denotes the minimal coset representative then we have seen that \( g \mapsto g \cdot zB/B \) yields an embedding

\[
\phi : G_n/B_n \hookrightarrow G/B
\]

of flag varieties. If we set \( x' := xz^{-1} \) then \( x' \in S_{x} \), and \( x'B_n/B_n \) maps to \( xB/B \) under this inclusion. We denote by \( S_{x,n} \) the image under this inclusion of the slice \( S_{x'} \) to the \( B_n \)-orbit through \( x' \) in \( G_n/B_n \).

**Proposition 4.15.** We have \( S_x = S_{x,n} \) as subvarieties of \( G/B \).

**Proof.** Recall the subvariety \( S_{x} \) defined in §4.6. A simple computation shows

\[
S_x = S_{x,n}.
\]

On the other hand, the slice to \( x' \) in \( G_n/B_n \) has the form:

\[
\begin{pmatrix}
1 & 0 \\
0 & S_{x'}
\end{pmatrix}
\]

Right multiplication by \( z \) produces exactly \( S_{x} \), and the result follows. □

Finally, one checks easily that \( \gamma \) has positive weights on the slice \( S_x \). The following is immediate:

**Lemma 4.16.** For any \( p \in S_x - S_x^{H} \) we have

\[
\lim_{z \to 0} \gamma(z) \cdot p \in S_x^{I}.
\]

4.10. **The inductive piece: sheaves.** In this section we prove Theorem 4.9. We keep the notation of previous sections, in particular §4.8. Note first that Lemma 4.16 implies that \( U = \mathbb{F}_{\lambda} S_{x,y} - \mathbb{F}_{\lambda} S_{x,y}^{H} \) retracts equivariantly onto \( \mathbb{F}_{\lambda} S_{x,y}^{I} \). Hence, by the Attractive Proposition and the Attractive Weight Argument, we conclude:

- \((i')^{*}\text{IC}\) is pure;
- \( H^{*}(U, j^{*}\text{IC}) = H^{*}(Z', (i')^{*}\text{IC}) \), and both are pure.

All that remains is to check that the Poincaré polynomial of \( H^{*}(Z', (i')^{*}\text{IC}) \), is given by \( Q_{x,y,L} \). This will take a little more work, and uses in a more substantial way the results of the previous section.

Consider the embedding

\[
\phi : G_n/B_n \hookrightarrow G/B
\]

of flag varieties considered in the previous section, whose image is the \( G_n \)-orbit through \( xB/B \in G/B \).

**Proposition 4.17.** \( \phi^{*}\text{IC}(\overline{B y B}/\overline{B}, \mathbb{Q}) \) is pure.

**Proof.** Consider the Bialynicki-Birula decomposition with respect to \(-\gamma\).9 Because \(-\gamma\) has positive weights on \( B \), the attracting sets are unions of Bruhat cells. In

\[9\text{i.e. } z \mapsto \text{diag}(1,z^{-1},\ldots,z^{-1}).\]
particular, the attracting set \( Z^+ \subset G/B \) for the component \( Z = \phi(G_n/B_n) \) of 
\((G/B)^\gamma\) is given by

\[
Z^+ = \bigcup_{u \in S_n} BuB/B
\]

and the attracting map \( \pi \) realizes \( Z^+ \) as an affine bundle over \( Z \). We have a diagram

\[
\begin{array}{ccc}
Z^+ & \xrightarrow{\phi'} & G/B \\
\downarrow{\iota} & \downarrow{\pi} & \downarrow{\phi} \\
G_n/B_n & \xrightarrow{\iota} & G/B
\end{array}
\]

By Braden’s theorem on hyperbolic localization \cite[Theorems 1 and 2]{Bra03} we know that

\[
\pi_!(\phi')^* \IC(ByB/B, \mathbb{Q})
\]

is pure. (It is a summand of the hyperbolic localization of \( \IC(ByB/B, \mathbb{Q}) \) to the fixed points of \(-\gamma\).) On the other hand, we know that this is equal to

\[
\iota^!(\phi')^* \IC(ByB/B, \mathbb{Q})
\]

by the Attractive Proposition. Finally, \( Z^+ \) is stratified by Bruhat cells, and \( \iota \) is a normally non-singular inclusion for this stratification. Hence \( \iota^* \equiv \iota^*[-2m] \), where \( m \) is the complex dimension of the fibres. We deduce that the above complexes are equal (up to a shift) to

\[
\iota^!(\phi')^* \IC(ByB/B, \mathbb{Q}) \cong \phi^* \IC(ByB/B, \mathbb{Q}).
\]

The latter complex is the one for which we wished to establish purity. \( \square \)

As \( \phi^* \IC(ByB/B, \mathbb{Q}) \) is pure, it decomposes as a direct sum of shifts of intersection cohomology complexes. We now describe how to compute some of these multiplicities. First some notation: given a polynomial \( p = \sum a_i q^i \) with positive coefficients and an object \( \mathcal{F} \) in a derived category, write

\[
p \cdot \mathcal{F} := \bigoplus \mathcal{F}^a \cdot [-2i].
\]

Because \( \phi^* \IC(ByB/B, \mathbb{Q}) \) is pure and its stalks have no cohomology in odd or negative degree, we can certainly write

\[
(12) \quad \phi^* \IC(ByB/B, \mathbb{Q}) = \bigoplus_{v \in S_n} \gamma'_v \cdot \IC(BvB/B).
\]

for certain \( \gamma'_v \in \mathbb{Z}_{\geq 0}[q] \).

Recall that in \( \S 3.6 \) we defined certain polynomials \( \gamma_v \) as part of the definition of the inductive piece:

**Proposition 4.18.** For \( x \neq v \in L \) we have \( \gamma_v = \gamma'_v \).

**Proof.** Taking Poincaré polynomials of stalks on both sides of (12) for any \( x \neq v \in L \). We deduce the relations:

\[
P_{v,y} = \sum_{x \neq u \in L} \gamma'_v \cdot P_{u,v}.
\]

These are (a repackaging of) the relations that determine the \( \gamma_v \) in \( \S 3.6 \). The proposition follows. \( \square \)
We now reach the goal of this section:

**Theorem 4.19.** The Poincaré polynomial of \( H^*(Z', (i')^*IC) \) is given by \( I_{x,y,L} \).

**Proof.** Consider the commutative diagram

\[
\begin{array}{c}
G_n/B_n \xrightarrow{\phi} G/B \\
\downarrow \quad \downarrow \quad \downarrow \\
\check{S}_{x,n} \xrightarrow{i''} \check{S}_x \\
\downarrow \quad \downarrow \\
P_\lambda \check{S}_{x,n} \xrightarrow{i'} P_\lambda \check{S}_x
\end{array}
\]

where we have used Proposition 4.15 to identify \( S_I^x \) with \( S_{x,n} \). Because \( C^* \) acts (via \( \lambda \)) on \( \check{S}_x \) with finite stabilizers we can apply the Finite Stabilizer Argument. We have

\[
H^*(Z', (i')^*IC) = H^*_{C^*}(\check{S}_{x,n}, (i'')^*IC(\check{S}_{x,y}, Q)) = H^*_{C^*}(\check{S}_{x,n}, (i'')^*k^*IC(\check{B}yB/B, Q))
\]

where for the second equality we have used that \( k \) is a normally non-singular inclusion. Using the above commutative diagram, we can rewrite this as:

\[
H^*_{C^*}(\check{S}_{x,n}, k_n^*\phi^*IC(B\check{B}/B, Q)) \cong \bigoplus_{x \neq v \in L} H^*_{C^*}(\check{S}_{x,n}, \gamma_v \cdot k_n^*IC(BvB/B, Q))
\]

We used Proposition 4.18 for the first step, and the normal nonsingularity of \( S_{x,n} \to G_n/B_n \) and the Finite Stabilizer Argument again for the second step. Taking Poincaré polynomials (and using Proposition 4.4) we deduce that its Poincaré polynomial is

\[
\sum_{x \neq v \in L} \gamma_v \cdot \partial P_{x,v} = I_{x,y,L}.
\]

4.11. **Geometry of weighted projective space.** We now turn to the hypercube piece, which comes from a sheaf on \( S_x^H/_{C^*}. \) We will see that this space is isomorphic to a weighted projective space. In this section we discuss some preliminaries on weighted projective spaces with torus action.

Suppose that a torus \( T \) acts diagonally on \( V = \bigoplus_{i=1}^p C e_i \). Assume moreover:

1. the weights of \( T \) on \( V \) are linearly independent;
2. we have fixed a cocharacter \( \lambda : C^* \to T \), all of whose weights on \( V \) (with respect to the action induced by \( T \)) are positive.

Note that (1) implies:

3. \( T \) has finitely many orbits on \( V \). Moreover, \( T \)-orbits on \( V \) are classified by subsets of \( \{1, \ldots, p\} \); given such a subset \( I \) the corresponding \( T \)-orbit is

\[
V_I = \left\{ \sum \lambda_i e_i \bigg| \lambda_i \in C^* \right\}.
\]

The stratification by the \( \{V_I\} \) will be called the toric stratification of \( V \).
(4) For any subset $I \subset \{1, \ldots, n\}$ we can find a cocharacter $\lambda_I : \mathbb{C}^* \to T$ such that the induced action fixes each $e_i$ for $i \in I$ and has positive weights on the rest. In particular
\[
\lim_{z \to 0} \lambda_I(z) \cdot v \in \sum_{i \in I} \mathbb{C}e_i
\]
for all $v \in V$.

Denote the weighted projective space obtained as the quotient by $\mathbb{P}_\lambda V := (V - \{0\})/\lambda \mathbb{C}^*$.

Statements (3) and (4) for $V$ imply the following for $\mathbb{P}_\lambda V$:

(5) $T$ has finitely many orbits on $\mathbb{P}_\lambda V$. Moreover, these orbits are classified by non-empty subsets of $\{1, \ldots, p\}$. Given such a subset $I$ the corresponding $T$-orbit is $O_I$, given by the image of $V_I$ in $\mathbb{P}_\lambda V$. We will refer to this stratification as the toric stratification of $\mathbb{P}_\lambda V$.

(6) For any $\emptyset \neq I \subset \{1, \ldots, p\}$ we set
\[
U_I = \bigcup_{J \subset I} O_J = \{[\lambda] | \lambda = \sum \lambda_i e_i, \lambda_i \neq 0 \text{ if } i \in I\}.
\]

Note that $U_{\{1\}}, \ldots, U_{\{p\}}$ form an open covering of $\mathbb{P}_\lambda V$ by finite quotients of $\mathbb{C}^{p-1}$.

Also, (4) above implies that, for all $\emptyset \neq I \subset \{1, \ldots, p\}$,

(13) $U_I$ retracts equivariantly onto $O_I$.

4.12. Equivariant sheaves on vector spaces. Let $T$ and $V = \bigoplus \mathbb{C}e_i$ be as above. (In applications, $V$ will be a slice to a stratum in weighted projective space. Hence, it will not be the “same $V$” as in the previous section. We hope that this does not lead to too much confusion.) In particular, the weights of $T$ on $V$ are linearly independent and we have the stratification $V_I$ by subsets of $\{1, \ldots, p\}$ (so $V_{\emptyset} = \{0\}$ and $V_{\{1, \ldots, p\}}$ consists of vector all of whose coordinates are non-zero.)

The aim of this section is to prove the following:

**Proposition 4.20.** Consider $\mathcal{F} \in D^b_T(V, \mathbb{Q})$. Suppose that:

1. The stalks of $\mathcal{F}$ are pure of weight zero.
2. The restriction of $\mathcal{F}$ to each stratum is isomorphic to a direct sum of even shifts of constant sheaves.
3. For any $I$ the restriction map
\[
H^*_T(V, \mathcal{F}) \to H^*_T(V_I, \mathcal{F}|_{V_I})
\]
is surjective.

Then $\mathcal{F}$ is pure of weight zero.

**Remark 4.21.** This is close to several results in the literature. As the reader will see, it uses in a crucial way in the proof that all subvarieties $V_I$ are smooth. The analogue of this theorem for a general attractive fixed point is false.

**Proof.** Consider the truncation functors $\tau_{\leq k}$ and $\tau_{> k}$ associated to the standard (i.e. not the perverse!) $t$-structure on $D^b_T(V, \mathbb{Q})$. We first argue that each sheaf in the distinguished triangle

(14)
\[
\tau_{\leq k} \mathcal{F} \to \mathcal{F} \to \tau_{> k} \mathcal{F}^{[1]}
\]
satisifies the conditions (1), (2) and (3) of the theorem. (1) and (2) are clear, as \( \tau_{\leq k} \) and \( \tau_{> k} \) have a predictable effect on stalks. For (3), note that from the existence of an attractive cocharacter we know by the Attractive Proposition that the restriction map

\[ H^*_T(V, \mathcal{F}) \rightarrow H^*_T(\{0\}, \mathcal{F}_0) \]

is an isomorphism. Hence we have a commutative diagram:

\[
\begin{array}{cccccc}
0 & \rightarrow & H^*_T(\{0\}, (\tau_{\leq k} \mathcal{F})_0) & \rightarrow & H^*_T(\{0\}, \mathcal{F}_0) & \rightarrow & H^*_T(\{0\}, (\tau_{> k} \mathcal{F})_0) & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & H^*_T(\{0\}, (\tau_{\leq k} \mathcal{F})_{V_1}) & \rightarrow & H^*_T(\{0\}, \mathcal{F}_{V_1}) & \rightarrow & H^*_T(\{0\}, (\tau_{> k} \mathcal{F})_{V_1}) & \rightarrow & 0
\end{array}
\]

(The rows are short exact by parity vanishing of \( T \)-equivariant cohomology of \( T \)-orbits). The middle arrow is a surjection, hence so are the left and right arrows by the 5-lemma\(^{10}\). Thus (1), (2) and (3) are true for each term in (14).

If we know the theorem for the left and right terms in (14), then each term is isomorphic to a direct sum of even shifts of constant sheaves on the closure of the strata \( V_I \), by purity. In particular, \( \text{Hom}(\tau_{> k} \mathcal{F}, \tau_{\leq k} \mathcal{F}[1]) = 0 \) and hence (14) splits, and the theorem is true for \( \mathcal{F} \) too. In particular, it is enough to show the proposition for the left and right terms. By induction, we may assume that \( \mathcal{F} \) is concentrated in degree zero.

Fix a stratum \( \mathcal{O} := V_I \) which is maximal (i.e. open) in the support of \( \mathcal{F} \). (Of course \( \mathcal{O} \) may not be unique, but this won’t worry us.) We will argue that a choice of summand \( Q_\mathcal{O} \subset \mathcal{F}_\mathcal{O} \) leads to a summand \( Q_\mathcal{O} \subset \mathcal{F} \).

Let \( j \) denote the open inclusion of all strata above \( V_I \) into \( V \). (This subvariety was called \( U_I \) in §4.11.) By the Attractive Proposition we have

\[ \text{Hom}(Q_\mathcal{O}, \mathcal{F}) = H^0_T(\mathcal{O}, j^* \mathcal{F}) = H^0_T(\{0\}, \mathcal{F}_0) = H^0_T(V, \mathcal{F}) \]

Because we have a surjection

\[ H^0_T(V, \mathcal{F}) = \text{Hom}(Q_\mathcal{O}, \mathcal{F}) \rightarrow \text{Hom}(Q_\mathcal{O}, \mathcal{F}_\mathcal{O}) = H^0_T(\mathcal{O}, \mathcal{F}_\mathcal{O}) \]

we may find a map \( \beta : Q_\mathcal{O} \rightarrow \mathcal{F} \) whose restriction to \( \mathcal{O} \) is the inclusion of our summand. On the other hand, our chosen projection \( \mathcal{F}_\mathcal{O} \rightarrow Q_\mathcal{O} \) corresponds (via adjunction) to a morphism

\[ \mathcal{F} \rightarrow j_* Q_\mathcal{O} \]

which restricts to our chosen map on the open stratum. Applying \( \tau_{\leq 0} \) we get a morphism

\[ \alpha : \tau_{\leq 0} \mathcal{F} = \mathcal{F} \rightarrow \tau_{\leq 0} j_* Q_\mathcal{O} = Q_\mathcal{O} \]

which still agrees with our chosen projection on the open stratum. Composing we get \( \alpha \circ \beta : Q_\mathcal{O} \rightarrow Q_\mathcal{O} \) which is the identity on the open stratum. As

\[ \text{Hom}(Q_\mathcal{O}, Q_\mathcal{O}) \rightarrow \text{Hom}(Q_\mathcal{O}, Q_\mathcal{O}) \]

is an isomorphism, we deduce that \( \alpha \circ \beta \) is an isomorphism everywhere. In other words, we have found \( Q_\mathcal{O} \) as a summand of \( \mathcal{F} \). Continuing in this way, we deduce that we can find an isomorphism:

\[ \mathcal{F} = \bigoplus_{I \in \{1, \ldots, p\}} Q^\mathcal{O}[m_I]_V \]

\(^{10}\text{or more precisely the 4-lemma...}\)
As each $\nabla_I$ is smooth, $Q_{\nabla_I}$ is pure of weight zero, hence so is $\mathcal{F}$ and we are done. $\square$

Recall the notation of the previous subsection on weighted projective spaces. The previous statement has the following corollary, which will be important below:

**Corollary 4.22.** Suppose that $\mathcal{F}$ is a sheaf on weighted projective space $\mathbb{P}_V$. Suppose that:

1. The stalks of $\mathcal{F}$ are pure.
2. The restriction of $\mathcal{F}$ to each toric stratum $\mathcal{O}_I$ is isomorphic to a direct sum of even shifts of constant sheaves.
3. For $i \in \{1, \ldots, p\}$ and any $J \subset \{1, \ldots, p\}$ containing $i$ the restriction map
   \[ H^*_I(U_{(i)}, \mathcal{F}_{U_{(i)}}) \to H^*_I(\mathcal{O}_I, \mathcal{F}_{\mathcal{O}_I}) \]
   is surjective.

Then $\mathcal{F}$ is pure.

**Proof.** It is enough to prove that the restriction of $\mathcal{F}$ to each $U_{(i)}$ is pure. This then follows (using the Finite Stabilizer Argument) from Proposition 4.20. $\square$

The following allows us to compute Poincaré polynomials of global sections from Poincaré polynomials of stalks:

**Proposition 4.23.** Suppose that $\mathcal{F} \in D^b(\mathbb{P}_V, \mathbb{Q})$ is a pure sheaf whose restriction to each toric stratum is a direct sum of constant sheaves in even degrees. Then the Poincaré polynomial of $H^*_I(\mathbb{P}_V, \mathcal{F})$ is given by

\[ \sum_{\emptyset \neq I \subset \{1, \ldots, p\}} (q - 1)^{|I| - 1} P(\mathcal{F}_{x_I}) \]

where $x_I$ denotes a point in the toric stratum $\mathcal{O}_I$, and $P(\mathcal{F}_{x_I})$ denotes the Poincaré polynomial of the stalk.

**Proof.** If the formula is true for $\mathcal{F}_1$ and $\mathcal{F}_2$, then it is true for their sum. Hence (using our purity assumption on $\mathcal{F}$ to deduce that $\mathcal{F}$ is a direct sum of IC-sheaves, and then our assumptions on the restriction to each stratum to deduce that only constant sheaves show up) it is enough to check the formula when

\[ \mathcal{F} = IC(\mathcal{O}_I, \mathbb{Q}) = Q_{\nabla_I}. \]

In this case, $\mathcal{O}_I$ is a weighted projective space of dimension $|I| - 1$ and its Poincaré polynomial is

\[ 1 + q + \cdots + q^{|I| - 1}. \]

Our formula predicts that this should equal

\[ \sum_{\emptyset \neq J \subset I} (q - 1)^{|J| - 1} = \sum_{0 \neq k \leq |I|} \binom{|I|}{k} (q - 1)^{k - 1} \]

This is easily checked.$^{11}$

---

$^{11}$For example, by a) multiplying both terms by $(q - 1)$, then adding 1 and using the binomial theorem, or b) considering the toric stratification of projective space and counting points.
4.13. **The hypercube piece: geometry.** In §4.14 and §5 we establish Theorem 4.10, which describes the Poincaré polynomial for hypercube piece. Here we begin by describing the (rather simple) geometry involved in the hypercube piece.

**Remark 4.24.** The simple geometry of the hypercube piece reminds one of the importance of the “miraboic subgroup” in type $A$. This suggests that generalization of these results to other types might need new ideas.

Recall that $S^H_x$ denotes subvariety of $S_x$ where all coordinates are zero, except for those below the 1 in the $0^{th}$ column. For example, if $x = 210345$ then

$$S^H_x = \begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & * & 1 & 0 & 0 \\
0 & 0 & * & 0 & 1 & 0 \\
0 & 0 & * & 0 & 0 & 1
\end{pmatrix}$$

It will be useful for the reader to keep the explicit form of $S^H_x$ in mind below.

Recall that in §4.7 we gave equations cutting out $S_{x,y}$ inside the affine space $S_x$. In general these equations are complicated. However in simple situations one can be lucky:

**Proposition 4.25.** $S^H_{x,y} \cong \mathbb{C}^p$ for some $p$.

**Proof.** Consider an $(l \times l)$-matrix of the form

$$P = \begin{pmatrix}
& x_1 \\
& \vdots \\
& x_l
\end{pmatrix}
\begin{pmatrix}
P & \\
\vdots
\end{pmatrix}$$

where $P$ is an $(l - 1) \times l$-matrix of 0’s and 1’s having at most one 1 in each row and column. Then its determinant is either 0 or $\pm x_i$ for some $1 \leq i \leq l$, as one sees easily by expanding the determinant from left to right. Applying this observation to the above equations implies that $S^H_{x,y} \subset S^H_x$ is cut out by the vanishing of certain coordinates in the $m^{th}$-column. The proposition follows.

Denote by $\varepsilon_i$ the character of the torus given by $\text{diag}(\lambda_0, \lambda_1, \ldots, \lambda_n) \mapsto \lambda_i$. The following is an easy direct calculation:

**Lemma 4.26.** The $T$-weights on $S^H_x$ are all distinct, and belong to $\{e_i - e_0\}_{i=1}^n$. In particular, $T$ has finitely many orbits on $S^H_x$.

Recall that $Z = \mathbb{P}_\lambda \hat{S}_{x,y}$ where $\lambda$ is a cocharacter acting attractively on the slice $S_{x,y}$. We deduce from the above that $Z$ is a weighted projective space, and hence results of §4.11 and S4.12 apply.

**Proposition 4.27.** $Z = \mathbb{P}_\lambda S^H_{x,y}$ is isomorphic to a weighted projective space, and $T$ has finitely many orbits on $Z$. Moreover, each toric stratum in $Z$ is the intersection with a unique Schubert stratum $\mathbb{P}_\lambda \hat{S}_{x,y}$ for $u \in (x, y)$. 

Proof. The only statement not clear from the above is the one starting “Moreover, . . .”. However, note that the intersection of $Z$ with the image of any Schubert stratum is $T$-stable, and hence a union of $T$-orbits. The statement follows because $T$ has finitely many orbits on $Z$. □

Let $\mathcal{X}$ denote the $T$-weights occurring in $S^H_{x,y}$. (Note that the weights in $\mathcal{X}$ are linearly independent and the $S^H_{x,y}$ are $\mathbb{C}$-stable, and hence a union of $T$-orbits. The statement follows because $T$ has finitely many orbits on $Z$.)

4.14. The hypercube piece: sheaves. In this section, we prove that $i^*\text{IC}$ is pure, and that its Poincaré polynomial is given by the hypercube piece in our formula, where we use the geometric hypercube map in place of its combinatorial version. All that then remains is to check that the geometric $\theta_{\text{geom}}$ (defined above) agrees with the combinatorial hypercube map $\theta$ (defined in §3.5). This we do in the subsequent section.

Proposition 4.28. $i^*\text{IC}$ is pure.

Proof. We will check the conditions of Corollary 4.22. As $i^*\text{IC}$ is the restriction of a pointwise pure sheaf, its stalks are pure, and so (1) is satisfied. Moreover, the restriction of $\text{IC}(\mathcal{B}_B, \mathbb{Q})$ to each Bruhat stratum is a direct sum of shifts of constant sheaves in even degrees. As the stratification of $Z$ is via intersections with Bruhat cells, it follows that (2) is satisfied. We now turn to (3) which is the most subtle. Denote by $T' = T/\lambda(\mathbb{C}^*)$ the torus which acts on $\mathbb{P}_\lambda S_{x,y}$. We want to check that for each $i$, the restriction map

$$H^*_T(U_{\{i\}}, (i^*\text{IC})_{U_{\{i\}}}) \to H^*_T(Z_{\{i\}}, (i^*\text{IC})_{\{i\}})$$

is surjective, for all subsets $J$ containing $i$. Now, via the attractive proposition we can rewrite this as the restriction map

$$H^*_T(Z_{\{i\}}, (i^*\text{IC})_{Z_{\{i\}}}) \to H^*_T(Z_{\{i\}}, (i^*\text{IC})_{\{i\}})$$

We already know that both are isomorphic to direct sums of (even) shifts of $H^*_T(Z_{\{i\}})$ and $H^*_T(Z_{\{i\}})$ respectively. In particular, when we reduce modulo the maximal ideal of $H^*_T(pt, \mathbb{Q})$ (i.e. elements of positive degree) we obtain a map

$$H^*(\{p\}, (i^*\text{IC})_p) \to H^*(\{p'\}, (i^*\text{IC})_{p'})$$

where $p$ (resp. $p'$) denotes the unique (resp. a choice of) point in the stratum $Z_{\{i\}}$ (resp. $Z_{\{i\}}$). By Nakayama’s lemma we are done if we know that this map is surjective. However, by definition of the geometric hypercube map, this map may be identified with the map

$$H^*(\{u\}, \text{IC}(\mathcal{B}_B/\mathbb{B})_u) \to H^*(\{v\}, \text{IC}(\mathcal{B}_B/\mathbb{B})_v)$$

considered in [BM01, §3.5]. This map is surjective by [BM01, Theorem 3.6]. □
Remark 4.29. We briefly recall why [BM01, Theorem 3.6] holds. The key point is that in the case of flag varieties the natural restriction map
\begin{equation}
(15) \quad IH^*(B_Y B/B, \mathbb{Q}) \to H^*(\{u\}, IC(B_Y B/B, \mathbb{Q}_u))
\end{equation}
is surjective, for any point \(u \in G/B\). Indeed, by equivariance it is enough to check this for \(T\)-fixed points, and then this follows because all fixed points on \(G/B\) are attractive. (Once one has the surjectivity in (15) it is easy to deduce that one has a surjection \(H^*(\{u\}, IC(B_Y B/B, \mathbb{Q}_u)) \to H^*(\{v\}, IC(B_Y B/B, \mathbb{Q}_v)\) whenever \(v\)'s stratum contains \(u\) in its closure.) Braden and MacPherson use [BM01, Theorem 3.6] to deduce the unimodality of Kazhdan-Lusztig polynomials.

By definition of the hypercube map, the Poincaré polynomial of \(i^*IC\) on the toric stratum \(O_I \subset Z\) agrees with the Kazhdan-Lusztig polynomial \(P_{\theta_{geom}}(t,y)\). Hence we can use Propositions 4.28 and 4.23 to deduce the following:

**Proposition 4.30.** The Poincaré polynomial of \(H^*(Z, i^*IC)\) is given by
\[
\tilde{Q}_{geom} := \sum_{\emptyset \neq I \subset \{1, \ldots, p\}} (q - 1)^{|I| - 1} P_{\theta_{geom}}(t, z).
\]

**Corollary 4.31.** The Poincaré polynomial of \(H^*(Z, i^*IC)\) is given by
\[
Q_{geom} = q^{\ell(y) - \ell(x) - 1} \tilde{Q}_{geom}(q^{-1}).
\]

**Proof.** The Poincaré polynomial of the dual of \(H^*(Z, i^*IC)\) is given by \(\tilde{Q}_{geom}(q^{-1})\). Because Verdier duality interchanges \(i^!\) and \(i^*\) we deduce that \(\tilde{Q}_{geom}(q^{-1})\) agrees with the Poincaré polynomial of
\[
H^*(Z, i^! DIC) = H^*(Z, i^! IC)[2(\ell(y) - \ell(x) - 1)].
\]

We use that \(DIC(X, Q) = IC(X, \mathbb{Q})[2d]\), where \(d = \dim_C X\), and the fact that \(P_{\lambda, \sigma} S(x, y)\) has dimension \(\ell(y) - \ell(x) - 1\). Hence the Poincaré polynomial of \(H^*(Z, i^! IC)\) is \(q^{\ell(y) - \ell(x) - 1} \tilde{Q}_{geom}(q^{-1})\) as claimed. \(\square\)

**Remark 4.32.** The formula for the Poincaré polynomial of \(H^*(Z, i^*IC)\) agrees with the hypercube piece, with the only difference being that the former involves the geometric hypercube map, whereas the later involves the combinatorial hypercube map. Thus to prove our formula it is enough to show that the two hypercube maps agree.

5. Combinatorics of the hypercube map

In the previous section we almost finished the proof of our formula. The only missing piece is the following theorem, that compares the “geometric” and “combinatorial” hypercube maps. Here the arguments are of a different flavour, hence the new section. The goal of this section is the following:

**Theorem 5.1.** The set
\[
L = \{z \in [x, y] \mid z^{-1}(0) = x^{-1}(0)\}
\]
provides a hypercube decomposition of the Bruhat interval \([x, y]\). Moreover, we have \(\theta = \theta_{geom}\), thus the geometric and combinatorial hypercube maps agree.
5.1. **Explicit description of the hypercube map.** Recall that $S^H_x$ denotes subvariety of $S_x$ where all coordinates are zero, except for those below the 1 in the $0^{th}$ column. For example, if $x = 210345$ then

$$S^H_x = \begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & * & 1 & 0 & 0 \\
0 & 0 & * & 0 & 1 & 0 \\
0 & 0 & * & 0 & 0 & 1
\end{pmatrix}$$

We can compute the geometric hypercube map explicitly by taking any subset of the $*$-variables, setting the remaining $*$-variables to zero, and then describing in which Schubert cell we lie. (It is a consequence of Proposition 4.27 that the resulting Schubert cell only depends on which $*$-variables are non-zero.) In any specific example this is easily decided by performing row and column operations.

**Example 5.2.** Here we give two examples when $n = 3$:

1. Suppose that $x = (0, 1, 2, 3)$ is the identity. Consider a general element of $S^H_x$:

$$\begin{pmatrix}
1 & 0 & 0 & 0 \\
a & 1 & 0 & 0 \\
b & 0 & 1 & 0 \\
c & 0 & 0 & 1
\end{pmatrix}$$

If $c \neq 0$, then by rescaling the last row and performing row operations upwards followed by column operations rightwards we see that

$$\begin{pmatrix}
1 & 0 & 0 & 0 \\
a & 1 & 0 & 0 \\
b & 0 & 1 & 0 \\
c & 0 & 0 & 1
\end{pmatrix} \sim \begin{pmatrix}
0 & 0 & 0 & -c^{-1} \\
0 & 1 & 0 & -ac^{-1} \\
0 & 0 & 1 & -bc^{-1} \\
1 & 0 & 0 & c^{-1}
\end{pmatrix} \sim \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
1 & 0 & 0 & 0
\end{pmatrix}$$

all lie in the same Bruhat cell. In particular $\theta(I) = t_{0,3}$ if $3 \in I$ (i.e. if $c \neq 0$). Similar arguments show that when $x = 0$ the hypercube map only depends on the last non-zero element in the first column. In other words

$$\theta(I) = t_{i(0, \max I)} \text{ for all } I.$$

2. Consider the case $x = (0, 3, 2, 1)$. Again, by upwards row and rightwards column operations we see:

$$\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
c & 1 & 0 & 0
\end{pmatrix} \sim \begin{pmatrix}
0 & -c^{-1} & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
c & 1 & 0 & 0
\end{pmatrix} \sim \begin{pmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
1 & 0 & 0 & 0
\end{pmatrix}$$

Thus $\theta(\{3\}) = (3, 0, 2, 1) = t_{(0,3)x}$. On the other and if $a, b$ and $c$ are all non-zero then

$$\begin{pmatrix}
1 & 0 & 0 & 0 \\
a & 0 & 0 & 1 \\
b & 0 & 1 & 0 \\
c & 1 & 0 & 0
\end{pmatrix} \sim \begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0
\end{pmatrix}$$
One can check this by hand. A more efficient way is to notice that the corner rank matrices of both matrices are given by

\[
\begin{pmatrix}
1 & 2 & 3 & 4 \\
1 & 2 & 3 & 3 \\
1 & 2 & 2 & 2 \\
1 & 1 & 1 & 1 \\
\end{pmatrix}
\]

and hence both belong to the same Schubert cell by the results of §4.7. Thus \(\theta(\{1, 2, 3\}) = w_0\).

We now give an explicit general description of the hypercube map. We will make the following simplifications:

1. The subvariety \(SH_{x,y}\) can be viewed as a coordinate subspace inside \(SH_x\). In particular, the geometric hypercube map for \(SH_{x,y}\) is the restriction of that for \(SH_x\). Thus it is enough to describe the hypercube map for \(SH_x\).

2. Recall that \(m = x^{-1}(0)\). The free variables in \(SH_x\) can be identified with the set \(x(m+1), x(m+2), \ldots, x(n)\). (In this indexing, the variable \(i\) corresponds to the unique free variable in \(SH_x\) which occurs in the \(i^{th}\)-row. These are exactly the free variables which have a 1 to their right in \(SH_x\).)

Thus, from now on we regard the hypercube map as a map

\[\theta_{\text{geom}} : \left\{ \text{subsequences of } x(m+1), x(m+2), \ldots, x(n) \right\} \rightarrow [x, w_0]\]

which maps the empty subsequence to \(x\). Note that the elements of the set \(x(m+1), x(m+2), \ldots, x(n)\) are distinct, subsequences and subsets are the same thing. However, in the following the order in which entries occur in the subsequence will play an important role in determining the map.

Consider a non-empty subsequence \(I\) of \(x(m+1), x(m+2), \ldots, x(n)\). Define a sequence \(i'_1, i'_2, \ldots\) inductively as follows:

- \(i_1 = \) maximum of the entries in \(I\),
- \(i_{k+1} = \) maximum of the entries right of \(i_k\) in \(I\).

For some \(l\), the set of entries right of \(i_l\) is empty, in which case \(i_{l+1}\) is undefined. We let

\[I_{\text{decr}} = (i_1, i_2, \ldots, i_l)\]

denote the resulting subsequence.

**Remark 5.3.** One may consider \(I \rightarrow I_{\text{decr}}\) as the extraction of a “greedy decreasing subsequence”: first choose the maximal element of \(I\), then choose a maximal element right of it, etc.

Now consider the \(k+1\)-cycle \(\sigma_I\) which sends:

\[i_l \rightarrow i_{l-1} \rightarrow \ldots i_2 \rightarrow i_1 \rightarrow 0 \rightarrow i_l\]

We define

\[\theta'_{\text{geom}}(I) := \sigma_I x.\]

If \(I\) is empty, we set \(\theta'_{\text{geom}}(I) := x\). We obtain in this way a map

\[\theta'_{\text{geom}} : \left\{ \text{subsequences of } x(m+1), x(m+2), \ldots, x(n) \right\} \rightarrow S_{n+1}.\]
The following shows that this explicit description does indeed describe the geometric hypercube map.

**Theorem 5.4.** \( \theta_{\text{geom}} = \theta'_{\text{geom}}. \)

*Proof.* In the discussion below we make use of the description of Schubert cells in terms of the corner rank matrix recalled in §4.7. In particular, we will use the notation \( g_{\leq (p,q)} \) introduced there.\(^{12}\)

Consider the permutation matrix \( x \). Its corner rank matrix is given by

\[
\text{rank } x_{\leq (p,q)} = \#\{\text{elements in } x(0), x(1), \ldots, x(q) \text{ which are } \geq p\}.
\]

On the other hand, if \( g \) denotes an element of the stratum \( (S^H)^I \) (so that \( I \) is a subset of \( \{x(m + 1), \ldots, x(n)\} \)), its corner rank matrix is computed as follows:

\[
(16) \quad \text{rank } g_{\leq (p,q)} = \begin{cases} 
\text{rank } x_{\leq (p,q)} & \text{if } q < m, \\
\text{rank } x_{\leq (p,q)} & \text{if } I \cap \{\geq p\} \subset \{x(0), x(1), \ldots, x(q)\}, \\
\text{rank } x_{\leq (p,q)} + 1 & \text{otherwise}.
\end{cases}
\]

(Indeed, \( x \) and \( g \) differ only at the \( m \)-th column. This column is not contained in \( g_{\leq (p,q)} \) if \( q < m \). Otherwise, the condition \( I \cap \{\geq p\} \subset \ldots \) expresses whether this new column is in the span of the others in \( g_{\leq (p,q)} \).)

Now consider the permutations \( x \) and \( \sigma_I x \) in string notation (i.e. as the sequences \( (x(0), x(1), \ldots, x(n)) \) and \( (\sigma_I x(0), \sigma_I x(1), \ldots, \sigma_I x(n)) \)). In the passage from \( x \) to \( \sigma_I x \) the elements \( I_{\text{dec}} \) move left, and 0 moves all the way to the right, to the position occupied by the final element of \( I_{\text{dec}} \). In particular, if we consider the elements which are larger than \( p \), then those belonging to \( I_{\text{dec}} \) move to the left. It follows that:

\[
(17) \quad \text{rank } (\sigma_I x)_{\leq (p,q)} = \begin{cases} 
\text{rank } x_{\leq (p,q)} & \text{if } q < m, \\
\text{rank } x_{\leq (p,q)} & \text{if } I_{\text{dec}} \cap \{\geq p\} \subset \{x(0), x(1), \ldots, x(q)\}, \\
\text{rank } x_{\leq (p,q)} + 1 & \text{otherwise}.
\end{cases}
\]

We claim that if \( q \geq m \), then

\[
(18) \quad I \cap \{\geq p\} \subset \{x(0), x(1), \ldots, x(q)\} \Rightarrow I_{\text{dec}} \cap \{\geq p\} \subset \{x(0), x(1), \ldots, x(q)\}.
\]

The implication \( \Rightarrow \) is obvious, as \( I_{\text{dec}} \) is a subset of \( I \). For the other direction, assume that \( I \cap \{\geq p\} \not\subset \{x(0), x(1), \ldots, x(q)\} \) and let \( j \) belong to \( I \cap \{\geq p\} \) but not to \( \{x(0), x(1), \ldots, x(q)\} \). Then, by definition of \( I_{\text{dec}} \), there exists some element \( j' \) in \( I_{\text{dec}} \) which occurs to the right of \( j \) in \( x \), and is larger than \( j \). Thus \( j' \) belongs to \( I_{\text{dec}} \cap \{\geq p\} \) but not to \( \{x(0), x(1), \ldots, x(q)\} \). Thus (18) holds.

Thus the corner rank matrices described by (16) and (17) coincide. We deduce that \( g \) and \( \sigma_I x \) belong to the same Schubert cell. Thus

\[
\theta_{\text{geom}}(I) = \theta'_{\text{geom}}(I)
\]

which proves the theorem. \( \square \)

**Example 5.5.** The extreme examples of the hypercube map are the following:

\(^{12}\)We are grateful to A. Henderson for suggesting the proof below. All inaccuracies are ours!
(1) If \( x = (0, 1, \ldots, n) \) is the identity then \( m = 0 \) and for any sequence of \( (1, \ldots, n) \), \( I = (\max I) \) because \( x \) contains no descending sequences whatsoever. Hence
\[
\theta_{\text{geom}}(I) = t_{0, \max I}.
\]
In this case the image of \( \theta_{\text{geom}} \) is isomorphic to the totally ordered set
\[
t_{(0,1)} \leq t_{(0,2)} \leq \cdots \leq t_{(0,n)}.
\]
The image of \( \theta_{\text{geom}} \) is illustrated (for \( n = 3 \)) in Figure 5.1. This example matches the explicit calculation in Example 5.2(1).

(2) If \( x = (0, n, \ldots, 2, 1) \) then \( m = 0 \) and for any subsequence \( I \) of \( (n, \ldots, 2, 1) \), we have \( I_{\text{decr}} = I \) in descending order. Hence each \( \sigma_I \) is distinct and
\[
\theta : \text{subsequences of } (n, \ldots, 1, 0) \to S_n
\]
is injective. It identifies the lattice of subsets \( \{1, \ldots, n\} \) with the lattice between \( x \) and \( w_0 \) in \( S_n \). The image of \( \theta \) is illustrated (for \( n = 3 \)) in Figure 5.1. (This example generalizes the explicit calculations in Example 5.2(2).)

That such a nice lattice is present in Bruhat order might come as a surprise to the reader. It is less surprising when one realizes that \( c = w_0 x = (n, 0, 1, \ldots, n-1) \) is a Coxeter element, and hence \( w_0 \) gives an order reversing bijection between the interval \([x, w_0]\) and the interval \([\text{id}, c]\). The interval \([\text{id}, c]\) is easily seen to be isomorphic to a \( \{0, \ldots, n\} \)-hypercube.

5.2. The hypercube map and Bruhat graph. In this section we prove that the geometric hypercube map is determined by what it does to subsequences of \( (x(m + 1), \ldots, x(n)) \) of length 0 and 1. In particular, we will see that the edges
\[
\{\theta(i) \to x \mid i \in (x(m + 1), \ldots, x(n))\}
\]
in the Bruhat graph of the interval \([x, y]\) span a hypercube cluster, and that the geometrical hypercube map and combinatorial hypercube maps (defined in §3.5) agree.

In the following, the following standard fact on Bruhat order for the symmetric group will be indespensible (see e.g. [Bil98, Lemma 2.1]):

**Proposition 5.6** ("Subword Condition"). Suppose that \( u \) and \( v \) are permutations in \( S_{n+1} \) such that \( u(i) = v(i) \) except in positions \( i_1 < i_2 < \cdots < i_m \). Consider the permutations \( u' \) (resp. \( v' \)) of the set \( \{u(i_j) \mid 1 \leq j \leq m\} \) (with its natural increasing ordering) given in string notation by \( (u(i_1), u(i_2), \ldots, u(i_m)) \) (resp. \( (v(i_1), v(i_2), \ldots, v(i_m)) \)). Then \( u \leq v \) if and only if \( u' \leq v' \).

Recall that \( x \) and \( y \) are fixed permutations in \( S_{n+1} \), and that
\[
\theta_{\text{geom}} : \left\{ \text{subsequences of } x(m + 1), x(m + 2), \ldots, x(n) \right\} \to [x, w_0]
\]
denotes the geometric hypercube map. The combinatorial characterisation of the hypercube map discussed above will be a consequence of two simple propositions:

**Proposition 5.7.** Suppose that \( i \) occurs to the left of \( j \) in \( I \).

1. If \( i > j \) then \( \theta_{\text{geom}}(\{i\}) \) and \( \theta_{\text{geom}}(\{j\}) \) are incomparable.
2. If \( i < j \) then \( \theta_{\text{geom}}(\{i\}) < \theta_{\text{geom}}(\{j\}) \)
Figure 7. The image of the hypercube map based at $x = 0123$.
The reader can check that the red dots form a subposet isomorphic
to a chain $3 \rightarrow 2 \rightarrow 1 \rightarrow 0$.

Proof. The hypercube map in question only disturbs $0, i$ and $j$. Hence, by the
Subword Condition, we can assume $x = (0, i, j)$ viewed as a permutation of $\{0, i, j\}$.
In both cases we have
$$\theta_{\text{geom}}(\{i\}) = (i, 0, j) \quad \text{and} \quad \theta_{\text{geom}}(\{j\}) = (j, i, 0)$$

If $i < j$ then $(j, i, 0) < (i, 0, j)$ establishing (2). If $i > j$ then $(i, 0, j)$ and $(j, i, 0)$ are
distinct and both of length 2, and hence incomparable, establishing (1). \hfill \square

Remark 5.8. We could have also deduced this proposition from the $n = 2$ case of
Example 5.5.

Proposition 5.9. Suppose that $I$ is a subsequence of $(x(m + 1), \ldots, x(n))$ such that
$I_{\text{decr}} = I$. (That is, $I_{\text{decr}}$ is decreasing.) Then $\theta_{\text{geom}}$ gives the unique embedding of
directed graphs
$$H_I \to [x, w_0]$$
such that $\emptyset \mapsto x$ and $\{i\} \mapsto \theta_{\text{geom}}(\{i\})$ for all $i \in I$.

Proof. Let $I = (i_1, \ldots, i_l)$. By the Subword Condition we can work with permutations of the (ordered) set $0, i_l, \ldots, i_0$, and assume that
$$x = (0, i_0, \ldots, i_l).$$
Figure 8. The image of the hypercube map based at $x = 0321$. The reader can check that the red dots form subposet isomorphic to the 1-skeleton of a $t_{0123}$-hypercube. However we have seen in Example 5.5(2) that the interval between $\theta_{\text{geom}}(\mathcal{X}) = x$ and $\theta(I) = (i_0, \ldots, i_t, 0)$ is isomorphic to an $I$-hypercube. The proposition follows, as any morphism between $I$-hypercubes is uniquely determined by what it does on the base vertex and vertices of height 1.

We are now ready to give:

Proof of Theorem 5.1. We first need to show that the edges $\{z \to x \mid z \notin L\}$ span a hypercube, and that the combinatorial and geometric hypercube maps agree. First note that $tx \in L$ if and only if $t(0) \neq 0$, in other words that $t = (0, l)$ for some $l$. In order for $tx > x$ we must have $x^{-1}(l) > x^{-1}(0)$. Thus the edges incident to $x$ in both the combinatorial and geometric hypercube may be identified with the set $E = \{tx \to x \mid t = (0, l) \text{ for some } l \in \{x(m + 1), \ldots, x(n)\}, \text{ such that } x < tx \leq y\}$. It will be convenient to consider $E' = \{l \in \{x(m + 1), \ldots, x(n)\} \mid x < t_{(0, l)}x \leq y\}$. Of course, $E$ and $E'$ are obviously isomorphic, and we let $\phi : E \to E'$ denote the obvious isomorphism.

The reason to distinguish these two sets is to compare two partial orders on them. Consider a partial order on $E$ given by $\alpha \leq \beta$ of their are $\leq$ in Bruhat order.
On the other hand, say $i < j$ in $E'$ if $i$ occurs to the left of $j$ and $i < j$ (in the usual sense, i.e. as numbers!). Now Proposition 5.7 tells us that

$$\alpha < \beta \iff \phi(\alpha) < \phi(\beta).$$

In other words, $E$ and $E'$ are isomorphic as posets.

Now consider a subset $F$ of $E$. To compute the image of $F$ under the combinatorial hypercube map we first form the subset $F_{\text{max}} \subset F$ consisting of maximal elements, and then define

$$\theta(F) = \text{crown of hypercube spanned by } F_{\text{max}}.$$

On the other hand, consider a subset $I \subset E'$. To compute the image of $I$ under the geometric hypercube map we first form the subset $I_{\text{decr}} \subset I$ consisting of a greedy decreasing subsequence. Thanks to Proposition 5.9 we may describe the image of $I$ as

$$\theta_{\text{geom}}(I) = \text{crown of hypercube spanned by } \{\theta_{\text{geom}}(\{i\}) \to x \mid i \in I\}$$

Via the isomorphism $\phi$ the formation of $F_{\text{max}} \subset F$ and $I_{\text{decr}} \subset I$ correspond to each other. We conclude that the combinatorial and geometric hypercube maps agree. It also follows from Proposition 5.9 that the edges $E$ span a hypercube cluster.

Finally, note that there was nothing special about $x$ in the above argument. In particular, for any $z \in L$ the set

$$\{u \to z \mid u \notin L\}$$

spans a hypercube cluster. In particular, $L \subset [x, y]$ is a hypercube decomposition, and the theorem is proved. \hfill \Box

### 6. Geometry of the Conjecture

Despite considerable effort we are unable to prove Conjecture 3.8. Our conjecture is motivated by Theorem 3.7, and hence it is tempting to imitate its proof. In this section we discuss the obstacles remaining in doing so.

#### 6.1. Subvarieties of slices

In this section, we explain the natural generalizations (for any hypercube decomposition) of the subvarieties $S^H_{x,y}$ and $S^I_{x,y}$ of the slice $S_{x,y}$ (see §4.6).

Recall the coordinate characters $\varepsilon_i$ of our torus defined in §4.13 and let $R^+ = \{\varepsilon_i - \varepsilon_j \mid i < j\}$ denote positive roots with respect to $B$. Recall that we have a bijection between reflections $t_{(i,j)}$ in $S_{n+1}$ and negative roots $\varepsilon_j - \varepsilon_i$. We use this to relabel the edges of our Bruhat graph with negative roots.

As above, let $S_{x,y}$ denote the standard slice through $xB/B$ inside the Schubert variety $ByB/B$. Because we are in type $A$, we have a $T$-equivariant embedding

$$\iota : S_{x,y} \to T_x(S_{x,y}) = \bigoplus_{u \sim x \in E} C_\alpha$$

where $T_x$ denotes the tangent space at $x$, $E$ denotes the edges with target $x$ in the Bruhat graph $[x, y]$, and $C_\alpha$ denotes the one-dimensional $T$-module on which $T$ acts via the character $\alpha$.\footnote{Indeed, any attractive fixed point $z$ has an affine neighbourhood that may be embedded inside the tangent space at $x$, see [Br98, Proof of Theorem 17]. In type $A$ it is known [LS84] that this tangent space is spanned by its $T$-invariant curves. Hence the statement.}
Suppose fixed a choice of hypercube decomposition $J \subset [x, y]$. This breaks the set $E$ into two “inductive” and “hypercube” pieces $E = E_{\text{ind}} \sqcup E_{\text{hyp}}$ where

$$E_{\text{ind}} = \{ u \to x \in E \mid u \in J \} \quad \text{and} \quad E_{\text{hyp}} = \{ v \to x \in E \mid v \notin J \}.$$ 

To simplify notation we denote by

$$V = \bigoplus_{u \to x \in E} C_\alpha$$

the vector space with $T$-action into which $S_{x, y}$ embeds. Our decomposition of $E$ leads to a direct sum decomposition

$$V = V_{\text{ind}} \oplus V_{\text{hyp}}$$

and it is tempting to consider the subvarieties

$$S^I_{x, y} := S_{x, y} \cap V_{\text{ind}} \quad \text{and} \quad S^H_{x, y} := S_{x, y} \cap V_{\text{hyp}}.$$ 

Recall that $J = \{ \leq z \} \cap [x, y]$ for some $\in [x, y]$. The following is the analogue of Proposition 4.15:

**Proposition 6.1.** We have $S^I_{x, y} = S_{x, z}$.

The proof is satisfying, and neatly explains the “diamond complete” condition in the definition of a hypercube decomposition. We give it in §6.3.

The following should be the analogue of Proposition 4.27:

**Conjecture 6.2.** We have $S^H_{x, y} = V_{\text{hyp}}$. Moreover, each toric stratum (corresponding to a subset $I \subset E_{\text{hyp}}$) is the intersection of $S^H_{x, y}$ with a unique Schubert cell $BuB/B$ and we have

$$\theta(I) = u$$

where $\theta$ is the hypercube map associated to our hypercube decomposition $J$.

We believe we have a proof of this conjecture. However the argument is unsatisfying and long. We are willing to try to write it down if the obstacle to be discussed in §6.2 can be overcome.

**Remark 6.3.** Two remarks of a hygienic nature:

1. The $(T$-equivariant) embedding $\iota$ inside the tangent space involves a choice of $(T$-equivariant) sections of the quotient map

$$m_x \twoheadrightarrow m_x/m_x^2$$

where $m_x$ denotes the maximal ideal at $x$. Thus, although the right-hand side of (19) is canonical, the embedding isn’t in general. Thus we need to be careful with constructions based on $\iota$. For example, it is not clear a priori that $S^H_{x, y}$ and $S^I_{x, y}$ are well-defined. It turns out that they are, as follows from some considerations in equivariant geometry which we omit.

2. The embedding $\iota$ is not the same as the embedding of $S_{x, y}$ considered in §4.6. One can get a choice of embedding $\iota$ by composing the embedding considered in §4.6, with a projection to those coordinates which span one-dimensional orbits in $S_{x, y}$. This gives a canonical $\iota$ which is useful in examples.
6.2. The main obstacle. In this section we explain the main difficulty in generalizing our proof. We assume that Conjecture 6.2 is known. To simplify notation, let

$$X = \mathbb{P}_\lambda \hat{S}_{x,y}$$

and let $Z$ and $Z'$ denote closed subvarieties of $X$ given by the images of $\hat{S}^H_{x,y}$ and $\hat{S}^l_{x,y}$ respectively. We have the following diagram of inclusions:

As above, we denote by $\text{IC}$ the intersection cohomology complex on $X$, and by $T' = T/\lambda(\mathbb{C}^*)$ the torus acting on $X$.

We have a commutative diagram of cohomology groups:

$$
\begin{array}{ccc}
H^*_{T'}(X, j^* \text{IC}) & \xrightarrow{\alpha} & H^*_{T'}(X, \text{IC}) \\
\downarrow{\xi} & & \downarrow{\beta} \\
H^*_{T'}(Z, i^* \text{IC}) & \xrightarrow{\beta} & H^*_{T'}(Z', (i')^* \text{IC})
\end{array}
$$

(Here $H^*_{T'}(X, j^* \text{IC}) = H^*_{T'}(X, j_! j^* \text{IC})$ denotes compactly supported cohomology.) We know:

(1) The diagonal

$$H^*_{T'}(Z, i^* \text{IC}) \xrightarrow{\alpha} H^*_{T'}(X, \text{IC}) \rightarrow H^*_{T'}(X - Z, j^* \text{IC})$$

and anti-diagonal

$$H^*_{T'}(X - Z, j^* \text{IC}) \rightarrow H^*_{T'}(X, \text{IC}) \xrightarrow{\beta} H^*_{T'}(Z', (i')^* \text{IC})$$

are part of the long exact sequence for the pair $(X, X - Z)$ (resp. $(X, Z')$).

(2) The groups $H^*_{T'}(Z, i^* \text{IC})$ and $H^*_{T'}(Z', (i')^* \text{IC})$ are pure. (For the first group, this follows from Conjecture 6.2, and for the second this may be assumed by induction.)

It will be useful to recall the magic that happened where our theorem holds. In that case $X - Z$ retracts equivariantly onto $Z'$ (using the character $\gamma$ in \S 4.9) and hence: $\zeta$ is an isomorphism, $H^*_{T'}(X - Z, i^* \text{IC})$ is pure, and

$$H^*_{T'}(Z, i^* \text{IC}) \xrightarrow{\zeta} H^*_{T'}(X, \text{IC}) \xrightarrow{\beta} H^*_{T'}(Z', (i')^* \text{IC})$$

is a short exact sequence. Thus, both $\xi$ and $\zeta$ are isomorphisms in this case and (20) collapses to a single short exact sequence.

We do not know whether $\zeta$ and $\xi$ are isomorphisms in general. However, if one is, then so is the other one, and our conjecture holds. Recall that we say that $H^*_{T'}(X, F)$ is equivariantly formal if it is free as a $H^*_{T'}(pt, \mathbb{Q})$-module. The following are easily seen to be equivalent:

(1) $\beta$ is surjective,
Similarly, we have equivalences between the following statements:

1. \( \alpha \) is split injective (or equivalently, its non-equivariant analogue is injective),
2. \( H^*_T, c(X - Z, j^*IC) \) is pure and equivariantly formal.

It seems that one could use equivariant localization to reduce to rank 2 and deduce equivalences between:

1. \( H^*_T, c(X - Z, j^*IC) \) is pure and equivariantly formal,
2. \( \xi \) is an isomorphism.

Similarly, localization techniques should show equivalences between:

1. \( H^*_T, c(X - Z, j^*IC) \) is pure and equivariantly formal,
2. \( \zeta \) is an isomorphism.

Thus it seems likely that (1)–(8) are all equivalent, and any one of them implies our conjecture.

6.3. Bruhat polytopes and the inductive piece. In this final section we prove Proposition 6.1. We include this proof because we think it is enlightening, and explains neatly why the “diamond complete” condition in the definition of a hypercube decomposition arises. Recall that \( z \) denotes the crown of the inductive piece, i.e. \( J = \{ \leq z \} \). We want to show:

**Proposition 6.4.** \( S_{x,y} \cap V_{\text{ind}} = S_{x,z} \).

We will need some results from the beautiful paper [GfS87] before turning to the proof. Let us fix throughout a regular dominant weight \( \lambda \). In the following we will identify \( W \) with its image in the \( \lambda \) orbit, i.e. \( x \) is identified with \( x(\lambda) \in h^* \), where \( h^* \) denotes the realification of the character lattice of \( T \). We also consider \( G/B \) as embedded by the Plücker embedding:

\[
\text{Plücker} : G/B \hookrightarrow \mathbb{P}(V_{\lambda}).
\]

Take a point \( p \in G/B \). Consider its \( T \)-orbit closure \( \overline{T \cdot p} \). Gelfand and Segal prove the following:

1. The set \( \{ u \mid u \in (\overline{T \cdot p})^T \} \subset h^* \) are the vertices of a convex polytope \( \text{Poly}(p) \subset h^* \).
2. \( \text{Poly}(p) \) agrees with the moment map image of \( \overline{T \cdot p} \);
3. \( x \in \text{Poly}(p) \) if and only if the \( x \)-coordinate of the Plücker coordinate is non-zero. (The \( x(\lambda) \)-weight space in \( V_{\lambda} \) is one-dimensional, so this statement makes sense.)

Let us call a polytope that occurs in this way (with \( \lambda \) fixed as always) a flag polytope. The theory of toric varieties also produces the important fact (also proved in [GfS87]) that:

\[
\text{(21)} \quad \text{Any face of a flag polytope is a flag polytope.}
\]

From (21) we deduce (by considering one-dimensional faces) that:

\[
\text{(22)} \quad \text{Any edge of Poly}(p) \text{ is parallel to a root.}
\]
We also need the classification of 2-dimensional flag polytopes. They are the following, together with their horizontal flips:

(The gray edges in the last diagram indicated edges in the Bruhat graph which are not edges of the polytope.) Note that these pictures represent conformal equivalence classes of polytopes: we can stretch edge lengths, but angles must be preserved.

For example, there is no need for the hexagon above to be regular, but all angles between edges (including gray edges) must be as displayed.

**Proof of Proposition 6.4.** The inclusion \( S_{x,y} \cap I \supset S_{x,z} \) is immediate. The tricky bit is to establish that \( S_{x,y} \cap I \subset S_{x,z} \).

Choose \( p \in S_{x,y} \cap I \). It is enough to show that if \( u \in \text{Poly}(p) \) then \( u \leq z \).

(Note \( \lim_{z \to \infty} \lambda(z) \cdot p = u' \) for some \( u' \in \text{Poly}(p) \), where \( \lambda \) is our anti-dominant cocharacter as always. Thus \( p \) belongs to \( Bu'B/B \cap U^{-x}B/B \) which is contained in \( S_{x,z} \) if \( u' \leq z \).)

Consider the vertices of \( \text{Poly}(p) \). We can divide these into those edges contained in inductive piece (which we will call blue vertices) and those which are not (which we will call red vertices). We will show the contrapositive to the statement of the last paragraph: namely we will show that if the set of red vertices in \( \text{Poly}(p) \) is non-zero, then \( p \notin S_{x,y} \cap I \).

So let us assume that red vertices exist. We can certainly find a red vertex \( u \) which is connected to a blue vertex \( v \) by an edge in \( \text{Poly}(p) \). Note that the edges in \( \text{Poly}(p) \) inherit a direction from the Bruhat graph (equivalently, from \( \lambda \)). Because \( v \to v' \) implies that \( v' \) is also blue, we know that the orientation of the edge joining \( u \) to \( v \) has to be \( u \to v \).

If \( v = x \), then the \( u \)-coordinate of Plücker\((p)\) is non-zero, and hence \( p \notin S_{x,y} \cap I \) and we are done. Otherwise, there exists an edge \( v \to w \) in the polytope. Now consider the 2-dimensional face \( F \) of \( \text{Poly}(p) \) containing \( u, v \) and \( v' \). From our knowledge of the 2-dimensional flag polytopes, and forgetting conformal structure (i.e. just remembering isomorphism type of directed graph) we see that there are 5 possibilities:
We claim the last possibility is impossible. Indeed, because the blue nodes are closed under the Bruhat order, the following nodes must be blue:

Now diamond completeness forces all six nodes to be blue, which is a contradiction.

In the remaining four cases, consider the green edge below:

We claim that the source of each green arrow is red: in the first and last cases this follows from diamond completeness of the blue vertices; in the second case this is clear; in the third case this follows because the blue nodes are closed under Bruhat order.

Now the green arrow gives us a new edge $u' \rightarrow v'$ of our polytope, with $u'$ blue, $v'$ red, and $v' < v$. Continuing in this way we eventually produce an edge $u'' \rightarrow x$ with $u''$ red, and we deduce that $p \notin S_{x,y} \cap I$ as above (i.e. because then the $u''$-Plücker coordinate is non-zero), and we are done. □
