Reversible Thermochromic Polymeric Thin Films Made of Ultrathin 2D Crystals of Coordination Polymers Based on Copper(I)-Thiophenolates

Javier Troyano, Oscar Castillo, José I. Martínez, Vanesa Fernández-Moreira, Yolanda Ballesteros, Daniel Maspoch,* Félix Zamora,* and Salome Delgado*

1. Introduction

Luminescent films are very important for a wide variety of displays and optoelectronic devices, including light-emitting diodes, solar cells, photodetectors, flat-panel displays, and chemo/biosensors. Among the luminescent materials, those exhibiting thermochromism are particularly attractive because of their potential use as temperature sensors. A particular type of thermochromic materials is the family of \(^{10}\) transition metals complexes, due to the presence of metal–metal interactions with a closed-shell configuration. In these complexes, changes in color can be originated from an important shift of an emission band or the presence of two or more emission bands whose intensities fluctuate with temperature. In this context, coordination polymers (CPs) bearing closed-shell \(^{10}\) transition metals have recently been proposed as an alternative...
strategy to expand the variety of thermochromic materials.\textsuperscript{[4]} In particular, those CPs based on Cu(I) seem to be appropriate because of their wide structural variety combined with brightly luminescence emission varying from blue to red light.\textsuperscript{[5]} A specific type of robust CPs is built up from thiolates,\textsuperscript{[6]} those which made of Cu(I), [Cu(SR)]\textsubscript{n} (SR = thiolate), which have recently shown interesting electrical and/or optical properties.\textsuperscript{[7]} However, examples of Cu(I)-CPs based on thiolate ligands with thermochromic properties are still very scarce.\textsuperscript{[8]}

In addition, due to these special luminescence features and the increasing practical demand, efforts continue to expand industrial applications and the processing path of luminescent/thermochromic CPs. Particularly, the preparation of CPs as thin films is an area that has only recently been started but which can be relevant for many practical applications including chemical sensors, catalysis, and membranes.\textsuperscript{[10]} CP thin films are expected to show some distinctive and eye-catching properties for the fabricated luminophores. Despite complete fabrication of CPs–organic hybrids is known,\textsuperscript{[10]} integrating functional CPs as thin films is still very limited mainly due to their limited processability.\textsuperscript{[11]} Very recently, for example, the integration of CPs within organic polymeric matrices has been achieved using colloidal 2D nanosheets of CPs, opening up an elegant route for making CP thin films that show improved gas separation properties.\textsuperscript{[12]}

Following our research interest in the preparation of CPs based on organosulfur ligands and d\textsuperscript{10} metals ions,\textsuperscript{[13]} herein we show that the direct synthesis between Cu(BF\textsubscript{4})\textsubscript{2}·xH\textsubscript{2}O and 4-mercaptobenzoic acid (4-mba) in different organic solvents gives rise to the formation of two thermochromic CPs in the form of crystals with micrometer-size lateral dimensions and sub-micro-/nanometer thicknesses. The emission properties of these 2D CP crystals and their integration with polyvinylidene difluoride (PVDF) to form highly homogeneous composite thermochromic thin films have been studied. Theoretical calculations have been used in order to rationalize their emission.

2. Results and Discussion

2.1. Synthesis and Structural Characterization

Polycrystalline powder of [CuCT]\textsubscript{n} (I) was synthesized by a solvothermal reaction between Cu(BF\textsubscript{4})\textsubscript{2}·xH\textsubscript{2}O and 4-mba (1:2) in acetone (Scheme 1). Note here that the synthesis of 1, as micropowder, was also reported by refluxing Cu\textsubscript{2}O and 4-mba in ethanol.\textsuperscript{[7]} By replacing acetone by MeOH as the reaction media, we found the formation of polycrystalline [CuMCT]\textsubscript{n} (2) due to the in situ esterification of the carboxylic group of 4-mba (Figures S1 and S2, Supporting Information). This esterification was confirmed by elemental analysis and Fourier transform infrared (FTIR) spectroscopy (Figures S3 and S4, Supporting Information). The carbonyl stretching frequency of 2 showed a shift to a higher energy (1720 cm\textsuperscript{-1}) compared to the corresponding signal of the carboxyl group observed in 1 (1682 cm\textsuperscript{-1}). This in situ esterification was further corroborated by isolating the diester of the oxidized form of 4-mba, bis-p-methoxy carbonylphenyl disulfide [p-(CO\textsubscript{2}Me)PhS]\textsubscript{2}, as a by-product of this reaction (Table S1, Supporting Information). In fact, an analogous transition-metal-catalyzed esterification reaction\textsuperscript{[14]} under solvothermal conditions of the isonicotinic acid in the presence of Cul in EtOH as solvent was also recently reported by us.\textsuperscript{[15]}

Replacement of acetone by dimethylformamide (DMF) in the reaction of 1 allowed isolating crystals suitable for single-crystal X-ray analysis (Table S2, Supporting Information). Similarly, the solvothermal reaction (140 °C/20 h) between Cu(BF\textsubscript{4})\textsubscript{2}·xH\textsubscript{2}O and (p-(CO\textsubscript{2}Me)PhS)\textsubscript{2} (1:1) in DMF led to the formation of crystals of 2 by in situ cleavage of S–S bond in (p-(CO\textsubscript{2}Me)PhS)\textsubscript{2} (Table S2, Supporting Information). 1 and 2 are almost isstructural to previously reported compound [CuHT]\textsubscript{n} (HT = 4-hydroxy-thiophenolate). They consists of layers based on fused Cu\textsubscript{3}S\textsubscript{3} rings with the copper atoms adopting a slightly distorted trigonal planar geometry with three \(\mu_2\)-bridging S atoms of the thiolate ligands showing S–Cu–S bond angles in the range of 103°–130° (Figures 1 and 2, Table 1). The Cu–S distances are in the range of 2.24–2.30 Å, which are comparable with those of neutral polymeric homoleptic [Cu(SpH-p-X)]\textsubscript{n} (X = H, CH\textsubscript{3}, OCH\textsubscript{3}, NO\textsubscript{2}, OH) (2.24–2.35 Å).\textsuperscript{[7,k,e]} These layers are completed by the functionalized phenyl moieties placed above and below the layer. However, the presence of different functional groups in the phenyl ring induces significant modifications in the Cu\textsubscript{3}S\textsubscript{3} rings conformation (half-chair for 1 vs twist-boat for 2), the thickness of the inorganic core of the 2D sheet (2.037 vs 2.163 Å), the dihedral angle between the phenyl rings inside the sheet (parallel vs 50°), and the supramolecular interactions that held together the layers (hydrogen bonding vs weak van der Waals interactions). Note here that, although \(\pi\)-\(\pi\) stacking interactions are predominant in the packing of the layers in the analogous [CuHT]\textsubscript{n}, there is no experimental evidence of \(\pi\)-\(\pi\) stacking interactions between the phenyl rings in 1 and 2. Layers in 1 are connected through the well-known complementary double hydrogen bond between adjacent carboxylic groups. On the other hand, esterification of the carboxylic...
residue in 2 precludes these interactions, meaning that layers are only sustained by means of weak van der Waals interactions.

Overall, the lamellar structures of 1 and 2 are rather unusual since with the exception of the already mentioned [CuHT]ₙ, the only single crystals so far reported are a series of [Cu(p-SC₆H₄-X)]ₙ (X = CH₃, H, CH₃O, NO₂)[7c] showing extended ladder-like [Cu‒S] chains. In fact, the hexagonal bidimensional networks found in 1 and 2 based on Cu₃S₃ fused rings structurally resemble a single layer of β-phase antimony.[16] The crystal structures of 1 and 2 were also measured at 110 and 296 K in order to get some insight on the modification of the structural parameters, but only subtle changes were observed on the Cu‒S bond distances (≤0.01 Å), S‒Cu‒S angles (≤0.3°), and Cu‒Cu distances (≤0.01 Å).

The thermal stability of 1 and 2 was studied by thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). Both showed thermal stabilities higher than 300 °C (Figures S5 and S6, Supporting Information).

2.2. Morphological Studies

Field-emission scanning electron microscopy (FESEM) analysis of polycrystalline 1 revealed the formation of well-defined plate-like crystals with hexagonal habit and average lateral dimensions of 13 ± 6 μm (Figure 3a,b). The side-view image of some of these crystals showed that their thickness range from 100 nm to nearly 1 μm (Figure 3b, inset). In addition, as depicted in Figure S7 (Supporting Information), a higher magnification view confirmed the appearance of terraces on the crystal surface.

As in 1, FESEM images recorded for the polycrystalline form of 2 revealed the formation of aggregates of bidimensional crystals with lateral dimensions of 1–2 μm in width and 1–10 μm in length (Figure 3c). Side view of some of these crystals showed that their thickness is 40 ± 15 nm and that they could be folded meaning that they exhibit some flexibility (Figure 3d). In a similar manner, and as reported previously,[7b] morphological characterization of [CuHT]ₙ confirmed that it crystallizes as aggregated platy crystallites whose lateral dimensions are several micrometers in length with nanometer thickness (Figure S8, Supporting Information). Overall, since these CPs grow as 2D plate-like crystals, it is feasible to imagine a strong correlation between the macroscopic laminar shape of the crystals and their 2D crystal structures.

2.3. Switchable Luminescence Properties

Copper(I) complexes with thiolate ligands are well-known to present luminescence.[3a,17] Thus far, however, most of the investigations have focused on polynuclear compounds or clusters, formed by 2 to 6 Cu atoms, often with phosphines as coligands.[16,18] To this end, we evaluated the solid-state luminescence of the polymeric copper(I) thiolates 1, 2 and the previously described analogous [CuHT]ₙ.[7b]
In the case of [CuHT]ₙ, no emission upon UV excitation could be observed by naked eyes even under liquid nitrogen cooling. Emission spectrum of [CuHT]ₙ at room temperature was very close to that of the corresponding free ligand, 4-mercaptophenol (4-mp), as shown in Figure S9 (Supporting Information). These emissions could be assigned to ligand centered charge transfer transitions of the thiophenolate ligand (π→π*).[19]

Interestingly, inspection under UV-lamp of solid samples of 1 and 2 cooled to liquid nitrogen revealed a change in the color emission of 1, from pale yellow to green to orange, and a significant change in the color emission of 2, from pale orange to green, which was easily distinguished by the naked eye (Figures 4a and 5a). This thermochromism was reversible in both cases. To further investigate this thermochromic phenomenon, the temperature-dependent emissions of 1 and 2 together with the 4-mba and 4-mercaptometoxibenzoate (4-mmb) free ligands were measured to track their response to temperature.

The emission spectrum of 1 upon excitation at 350 nm at room temperature (Figure S10, Supporting Information) showed two strong bands, one narrow at 485 nm and a wide one at 523 nm. Additionally, weak bands at lower energies at 557 and 573 (sh) nm were observed. Upon cooling, the intensity of these bands increased (Figure 4b), reaching the higher intensity at 200 K where structured bands at 485 nm and broader, better-resolved bands at 514 (sh), 523, 557, and 573 (sh) nm were observed. From 200 to 80 K, the intensity of both bands slightly decreased, and a broadband centered at 650 nm was observed at 80 K (Figure 4c). The emission lifetimes were 0.34 ms at 280 K and 24 ms at 80 K for the high-energy band, and 1 ms for the low-energy band at 80 K.

Table 1. Selected structural parameters (Å, °) S–Cu–S bond angles and Cu–S and Cu–Cu distances and their average value for compounds 1 and 2.

a)Symmetry codes: for compound 1: (i) x+1, y, z; (ii) x+2, y, z; for compound 2: 110 K: (i) x+1, y, z; (ii) x+2, y, z; (iii) x+2, y, z; (iv) x+3, y, z; (v) x+4, y, z; (vi) x+5, y, z.

b)Six nearest Cu–Cu distances.
The emission spectrum of 2 at room temperature (Figure S11, Supporting Information) displayed similar bands to that showed in 1, bands at 451 (sh), 465, and 529 nm, together with weak bands at 557 (sh) and 573 nm were observed. In addition, a very broadband at lower energy (629 nm) was registered. The emission spectrum of 2 revealed, upon cooling, a pattern very similar to 1 (Figure 5b). Thus, the intensity of the bands increases rapidly reaching the higher intensity at 80 K, where structured bands at 494, 530, and 570 nm were observed together with a broadband at 626 nm. Remarkably, the high-energy emission band at 465 was red-shifted to 494 nm at 80 K ($\Delta \lambda_{\text{max}} = 29$ nm). The emission lifetimes for the high-energy band were of 728 $\mu$s at 300 K and 32.8 ms at 80 K.

We then compared the emission spectra of 1 and 2 with those of the free ligands, 4-mba and 4-mmb, at variable temperature (Figures S12 and S13, Supporting Information). Upon cooling, 1 and 2 displayed similar vibronic structures to that found for 4-mba and 4-mmb. At room temperature, 1 exhibited a vibronic structure (Figure S10, Supporting Information). However, for 4-mba free ligand, a broad spectrum deprived of vibronic bands was observed (Figure S12, Supporting Information). In case of 2 and 4-mmb, at room temperature, the same vibronic structures were observed (Figures S11 and S13, Supporting Information). In both coordination polymers, the $\pi$-system of the benzene ring is only slightly perturbed when the coordination to copper take place, and a vibronic structure is observed. The difference between emission spectra of 1 and 4-mba can be explained in terms of possible conformational changes of the carboxylic group (−COOH) when it is incorporated in the coordination polymer.\[20\]

The long excited-state lifetime observed for 1 and 2 suggested that the emission is most likely associated with a spin-forbidden transition of triplet parentage, and that a ligand–metal charge transfer 3LMCT (S$^2$ $\rightarrow$ Cu) excited state governs the spectra. The lifetime observed for the high-energy band for 1 enhanced from 0.34 ms at 280 K to 24 ms at 80 K. In the case of 2, the lifetime observed for the similar band increased from 728 $\mu$s at 300 K to 32.8 ms at 80 K. These observations are consistent with a lower dissipative energy upon cooling, probably due to an increase of the medium rigidity. The weak bands centered at $\approx$650 and 626 nm at 80 K, respectively, could be tentatively assigned to a mixed 3LMCT/MC state.\[18c\]

In order to get a deeper insight into the reversible thermochromic behavior exhibited by 1 and 2, single-crystal X-ray analyses were performed for both CPs at 110 K. These experiments
Interestingly, although the temperature-dependent structural
and from 396.70 Å³ (296 K) to 395.68 Å³ (110 K) for 1.

The detailed crystal data, and selected bond lengths and bond
angles of 1 and 2 at 110 and 296 K are collected in Tables S3 and S4 (Supporting Information).

The thermochromic behavior of 2 at 296 and 110 K, associated
to the reduction of the unit-cell size, was also captured by
the first-principles density functional theory (DFT)-based calculations of their many-body excitation spectra (see the Supporting Information).

Additionally, given that the most important computed electronic transitions correspond to the VB, the CV, and states close
to them, we have computed the valence and conduction band
orbital electron 3D isodensities for the different compounds
studied (Figure S16, Supporting Information) in order to check their spatial morphology. In this figure, it is possible to observe
that the valence band for all the compounds is mostly located
in the metallic chains with some minor contribution within the aromatic rings of the ligands, while the conduction band shows a substantial depletion in the metallic chain being mostly located in the ligands.
Overall, comparison of the optical properties of 1 and 2 clearly indicated that the presence of substituents with different electronic properties in the para position of the phenyl ring has a clear influence in their emission spectra. This could be explained in accordance with the significant modifications observed in some of the structural parameters of the Cu3S3 rings conformation (half-chair for 1 vs twist-boat for 2), the thickness of the inorganic core of the 2D sheet (2.037 Å for 1 vs 2.163 Å for 2), the dihedral angle between the phenyl rings inside the sheet (parallel for 1 vs 50° for 2), and the supramolecular interactions that held together the layers (hydrogen bonding for 1 vs weak van der Waals interactions for 2).

2.4. Composites Films

Recently, it has been suggested that nanoscale plate-like crystals of porous MOFs can be integrated into polymers in a more homogeneous way, allowing the fabrication of mixed matrix membranes with effective separation properties.[21] Following this idea, we considered that the plate-like crystals of 1 and 2 could also be used for the fabrication of homogeneous thin films that exhibit reversible thermochromic responses.

Figure 6a shows a schematic illustration of the process followed to fabricate these composite thin films. The preparation started with the dispersion of crystals of 1 or 2 in a DMF solution of polyvinylidene difluoride (PVDF). This homogenous suspension was drop-casted on a glass substrate and dried at 85 °C. After solvent removal, a homogeneous film was formed and detached from the substrate upon immersion in water. Figure 6b shows the resulting 1@PVDF and 2@PVDF thin films with a CP content of 50% (wt%). Notably, they were completely freestanding, free of macroscopic defects and robust under mechanical bending stress (Figure 6c). The cross-section FESEM images of 1@PVDF and 2@PVDF revealed a film thickness of 75 and 35 μm, respectively (Figure 6d). This difference between both films could tentatively be explained by the smaller thickness and higher flexibility of crystals of 2, allowing better packing during the evaporation process and resulting in a higher densification of the composite film.

The XRPD patterns confirmed that the crystallinity of both CPs was retained after the fabrication process (Figure 6e). Energy-dispersive X-ray spectrum (EDS) revealed that crystals of 1 and 2 are homogeneously distributed along the plane of the fabricated thin films (Figure 6f). However, detailed analysis of FESEM images showed a different distribution of CP crystals between the two sides of the films (Figure S17, Supporting Information).
Information). In them, the side against the glass substrate presented a higher PVDF content, whereas the other side was richer in crystals. This effect was already observed in the preparation of MOF-based mixed matrix membranes by drop casting.[21a]

To evaluate that the fabricated 1@PVDF and 2@PVDF films retained the thermochromic properties of 1 and 2, we examined them under UV irradiation (Figure 7). Remarkably, 1@PVDF exhibited thermochromism upon cooling down from 300 to 77 K, changing its color from pale yellow (room temperature) to green (200 K) to orange (77 K) (Figure 7a). This thermochromic behavior was fully reversible upon warming, as illustrated in Figure 7b. Similarly, 2@PVDF also exhibited a marked reversible chromic response upon changing the temperature, switching from pale orange (room temperature) to green (77 K) (Figure 7c). The emission spectra of both films were registered at variable temperature. Both show similar thermochromic behavior than 1 and 2 (Figure S18, Supporting Information).

We have also analyzed the effect of reducing the amount of CP crystals on the optical properties of the composite films. To this end, we prepared 1@PVDF thin films with a CP content ranging from 50 to 9 wt% by following the same methodology. Characterization of the lower content composite film 1@PVDF (9 wt%) is shown in Figure S19 (Supporting Information). These films showed a thermochromic luminescent response similar to 1@PVDF (50 wt%), although the emission intensity decreases as the CP content diminishes. Besides, the transparency of the films increases with decreasing of the CP content as shown in Figure S20a (Supporting Information). Remarkably, the generated 1@PVDF film with a 9 wt% displayed a reasonable transparency (40–80%) in the visible range (Figure S20b, Supporting Information). In addition, it shows a satisfactory thermochromic luminescent response (Figure S19d, Supporting Information).

Finally, we have evaluated the mechanical properties of the composite films by submitting the 1@PVDF and 2@PVDF films with a CP content of 9 and 50 wt% to tensile test (Figure S21, Supporting Information). Mechanical behavior is summarized in Figure S22 (Supporting Information). 1@PVDF and 2@PVDF at 9 wt% films show an almost negligible change in ultimate tensile strength and elastic modulus to that observed for naked PVDF (Figures S23 and S24, Supporting Information), whereas both strength and modulus are significantly reduced for the films at 50 wt%. Additionally, Figure S25 (Supporting Information) shows that an increase of the amount of CPs in the composite films produces a decrease in the material ductility. However, the flexibility of the composite films is still remarkable.

3. Conclusions

Two new CPs based on Cu(I) and thiophenolate ligands with general formula [Cu(p-SPhCOO-X)]n (X = H, 1 and Me, 2) have been synthesized by direct one-pot reaction between Cu(BF4)2·xH2O and 4-mba using different solvents. The so-formed materials consist of 2D crystals of sub-micro- (for 1) and nanometric (for 2) thicknesses, and large lateral dimensions, in the micrometer range. X-ray diffraction studies on single crystals confirm that 1 and 2 display rather similar layered structures. 1 and 2 show reversible thermochromic luminescence, with changes from pale yellow to green and from pale orange to green for 1 and 2, respectively, upon cooling down to 77 K. Variable temperature experiments indicate that there is direct evidence that luminescent thermochromism of these compounds is caused by a higher rigidity and even a more efficient packing of the ligands, according to the decrease in volume of the unit cell observed at 110 K.
Interestingly, the simple processability of 1 and 2 as plate-like crystals and their high dispersibility in DMF enable their integration with PVDF to form homogeneous thin film composites retaining the reversible thermochromic response of these CPs and the mechanical properties of the PVDF matrix. Importantly, the transparency of the composite films can be tuned with the quantity of CP nanosheets while their mechanical behavior is only significantly affected upon high CP content, as previously reported for similar MOF composite films.[21b]

This simple fabrication procedure enables practical application as thermal stimuli-responsive thin films potentially useful for electronic and optoelectronic devices, including light emitting diodes, solar cells, photodetectors, flat-panel displays, and chemical and biological sensors.[14]

4. Experimental Section

Materials and Methods: All the reagents were purchased from Sigma-Aldrich and used as received. FTIR spectra (KBr pellets) were recorded on a Perkin-Elmer 1650 spectrophotometer. C, H, N, S elemental analyses were performed by the Microanalysis Service of the Universidad Autónoma de Madrid on a Perkin-Elmer 240 B microanalyser. Powder X-ray diffraction experiments were carried out on a Diffractometer PANalytical X’Pert PRO θ/2θ primary monochromator and detector with fast X’Celerator. The samples were analyzed with scanning θ/2θ. FESEM images were collected on a FEI Magellan 400L scanning electron microscope at an acceleration voltage of 2.0 kV and FEI Quanta 650F scanning electron microscope with EDX Inca 250 SSD XMax20 at an acceleration voltage of 20.0 kV, using aluminum as support. Steady-state photoluminescence spectra were recorded on a Jobin-Yvon Horiba Fluorolog FL-3-11 spectrometer using band path ways of 3 nm for both excitation and emission. Phosphorescence lifetimes were recorded with an IBH 5000F coaxial nanosecond flashlamp. The lifetime data were fitted with the Jobin-Yvon software package. Measurements at variable temperature were done with an Oxford Cryostat Optistat DN. The lifetime data were fitted with the Jobin-Yvon IBH software DAS6 v6.1.

Theoretical Methodology: All the DFT-based calculations were carried out by the accurate and efficient plane-wave code QUANTUM ESPRESSO.[25] Within this atomistic simulation package, the Kohn–Sham equations were solved using a periodic supercell geometry. The exchange-correlation (XC) effects were accounted through the generalized gradient approximation (GGA) within the Perdew–Burke–Ernzerhof (PBE) parameterization.[26] To model the ion–electron interaction in the H, C, O, S, and Cu atoms, Rabe Rappe Kaxiras Joannopoulos (RRKJ) ultrasoft pseudopotentials was used.[24] The Brillouin zone (BZ) was sampled by means of a [6 × 6 × 1] Monkhorst–Pack grid[23] (where the Cartesian XY plane corresponds here to the lamina plane) for 1 and 2. The one-electron wave-functions were expanded in a basis of plane-waves with energy cutoffs of 400 and 500 eV for the kinetic energy and for the electronic density, respectively, which were adjusted to be plane-wave sufficient accuracy to guarantee a full convergence in energy and density. For the computation of the many-body excitation spectra, the aforementioned standard DFT formalism was used combined with many-body perturbation theory via the quasi-particle approximation GW correction[20] to conventional DFT, combined with the Bethe–Salpeter equation (BSE).[27] For the calculation of the excitation spectrum implemented within the YAMBO code.[28] The BSE was solved for coupled electron–hole excitations, thereby accounting for the screened electron–hole attraction and the unscreened electron–hole exchange.

X-Ray Data Collection and Crystal Structure Determination: The X-ray diffraction data collections and structure determinations were done on a Bruker Kappa Apex II diffractometer using graphite-monochromated Mo-Kα radiation (λ = 0.71073 Å). The cell parameters were determined and refined by a least-squares fit of all reflections. A semi-empirical absorption correction (SADABS) was applied for all cases. All the structures were solved by direct methods using the SIR92 program[29] and refined by full-matrix least-squares on F² including all reflections (SHELXL97).[30] All calculations were performed using the WINGX crystallographic software package.[31] All nonhydrogen atoms were refined anisotropically. The hydrogen atoms were included in their calculated positions and refined riding on the respective parent atoms. Relevant data acquisition and refinement parameters are gathered in Tables S1 and S2 (Supporting Information).

Mechanical Testing: The mechanical test of the samples were carry out in an Universal Testing Machine IBTH 500 (SAE ibertest) equipped with a 500 N load cell. The measurements of load and displacement were acquired using a crosshead speed of 0.5 mm min⁻¹ and the stress–strain curves for each specimen were obtained. Three different measurements were carried out for each composite sample. The values shown in Table S5 and Figures S23–S25 (Supporting Information) correspond to an average of three measurements for each sample and the bars indicate the standard deviation. Specimens for tensile testing were prepared with composite films of 100 mm long, 25 mm wide, and 0.1 mm thick. In order to avoid the clamping jaws cause a damage in the samples, a VHB tape of 1 mm (3M) was used (Figure S21, Supporting Information). The length between tapes was 30 mm, as well as the initial separation between clamping jaws.

Synthesis of [CuCT]ₙ (1): A mixture of Cu(BF₄)₂·xH₂O (0.118 g, 0.50 mmol) and 4-mercaptobenzoic acid (0.154 g, 1.00 mmol) in 20 mL of acetone was sealed in a 23 mL Teflon-lined stainless steel autoclave. The reactor was heated at 120 °C for 48 h and then allowed to cool to room temperature. A pale yellow powder was obtained, washed with DMF and diethyl ether, and then dried in a vacuum line at 60 °C for 4 h (0.085 g, 78% yield based on Cu). Anal. calcd (%) for C₃₆H₃₈CuO₅S: C, 40.39; H, 3.29; S, 14.13. Found (%): C, 40.42; H, 3.31; S, 14.18. IR (KBr): 3450 (m), 2950 (w), 1682 (s), 1583 (m), 1480 (w), 1435 (m), 1392 (m), 1290 (m), 1128 (w), 1082 (w), 841 (m). Colorless plate crystals of 1 suitable for single-crystal X-ray diffraction were obtained following the procedure above-mentioned except that DMF (4 mL) was used as solvent and the reactor was cooled down to room temperature at a rate of 3 °C h⁻¹.

Synthesis of [CuMCT]ₙ (2): 2 was synthesized by a method similar to that for 1, except that methanol (20 mL) was used as solvent. A yellow powder was obtained, washed with hot methanol, DMF, and diethyl ether, and then dried under vacuum at 60 °C for 4 h (0.085 g, 74% yield based on Cu). Anal. calcd (%) for C₄₂H₄₄CuO₅S: C, 41.64; H, 3.06; S, 13.89. Found (%): C, 41.67; H, 3.16; S, 13.78. IR (KBr cm⁻¹): 2900 (w), 1720 (s), 1589 (m), 1485 (w), 1435 (m), 1392 (m), 1277 (s), 1180 (m), 1171 (s), 1111 (m), 825 (m), 752 (m), 683 (w). Bright yellow crystals of 2 suitable for single-crystal X-ray diffraction were obtained by mixing Cu(BF₄)₂·xH₂O (0.024 g, 0.10 mmol) with bis-p-methoxy carbonyl-phenyl disulfide (0.034 g, 0.10 mmol) in 4 mL of DMF. The reactor was heated at 140 °C for 20 h and then slowly cooled down to room temperature at a rate of 4 °C h⁻¹.

Synthesis of [p-(CO₂Me)PhS₂]: Bis-p-methoxy carboxyl-phenyl disulfide was obtained as a subproduct during the synthesis of 2. In this synthesis, a white solid was obtained after the hot methanol washing solution was joined to the mother solution and the solvent was removed under reduced pressure. This solid was washed with diethyl ether and dried under vacuum (0.101 g, 60% yield based on 4-mba). Recrystallization from diethyl ether afforded the product as white crystals suitable for X-ray analysis.[32] ¹H NMR (300 MHz, CD₂OD): δ = 7.97 (4H, m), δ = 7.64 (4H, m), δ = 7.39 (4H, s) ppm. IR (KBr cm⁻¹): 2997 (s), 2947 (w), 1716 (s), 1589 (m), 1485 (w), 1435 (m), 1396 (m), 1277 (s), 1180 (m), 1107 (s), 1076 (m), 1011 (m), 845 (w), 825 (w), 756 (w), 686 (w).

Synthesis of 4-Mercaptotetoxbenzoate: 4-Mercaptobenzoic acid (0.308 g, 2.00 mmol) was dissolved in 50 mL of methanol and 1 mL of hydrochloric acid (37%) was added. The mixture was refluxed overnight under stirring and then evaporated to dryness. The residue was washed with distilled water and recrystallized in diethyl ether (0.302 g, 90% yield). ¹H NMR (300 MHz, CDCl₃): δ = 7.95 (2H, d), δ = 7.66 (2H, d).

Synthesis of [CuHT]n. For this synthesis, an analogous method to that
reported previously was used,[7h] with a soluble metal precursor. Thus, a
mixture of Cu(BF4)2·2H2O (0.118 g, 0.50 mmol) and 4-mercaptopentanol
(0.127 g, 1.00 mmol) in 20 mL of ethanol was heated under reflux with
stirring for 24 h under an argon atmosphere. The yellow precipitate
was filtered off, washed with ethanol and diethyl ether, and then dried in
a vacuum line at 60 °C for 4 h (0.053 g, 56% yield based on Cu).

Preparation of CP@PVDF Thin Films: CPs and PVDF were mixed in
different proportions and were dispersed in DMF with sonication until
total solution of the polymer. The resulting homogeneous suspension was casted
on microscope slide and dried at 85 °C to remove the DMF. The resulting
CP@PVDF films were delaminated via immersion in water and dried in air.
