ABSTRACT

We present a new formula to numerically construct configurations in rotational equilibrium, which consists of multiple layers. Each layer rotates uniformly or differentially according to cylindrical rotation laws that are different from layer to layer. Assuming a different barotropic equation of state (EOS) for each layer, we solve the Bernoulli equation in each layer separately and combine the solutions by imposing continuity of the pressure at each boundary of the layers. It is confirmed that a single continuous barotropic EOS is incompatible with the junction condition. Identifying appropriate variables to be solved, we construct a convergent iteration scheme. For demonstration, we obtain two-layered configurations, each layer of which rotates rapidly with either an “Ω-constant law” or a “j-constant law” or a “v-constant law.” Other rotation laws and/or a larger number of layers can be treated similarly. We hope that this formula will be useful in studying the stellar evolution in multi-dimension with the non-spherical configuration induced by rotation being fully taken into account.

Key words: stars: evolution – stars: massive – stars: rotation
Online-only material: color figures

1. INTRODUCTION

It is well known that stars are generically rotating on the main sequence and, in particular, massive stars are rapid rotators (Fukuda 1982; Tassoul 2000). Although the distribution of angular momentum in the stellar interior is poorly known except for the sun, it is expected that the inner portion is rotating more rapidly than the outer part as the star evolves and the central part of the star contracts. In fact, some recent theoretical studies on the evolution of rotating stars have demonstrated that massive stars in their late evolutionary phases develop a central core that is rotating more rapidly than the outer envelopes (Heger et al. 2000; Hirschi et al. 2004; Limongi et al. 2000). Hence, the differential rotation is supposed to exist quite commonly in the stellar interior especially at the advanced stages of evolution.

The above-mentioned works on the evolution of rotating stars ignore non-spherical deformations of stars and the angle-averaged centrifugal force is added as a correction to the spherical models. This is not justified, however, if the star is rotating rapidly and the physical conditions on the rotation axis and on the equatorial plane are substantially different. Then the rotational equilibrium should be properly taken into account. This will be particularly important for the investigation of the progenitors of gamma-ray bursts (GRBs), since they are supposed to be driven by the gravitational collapse of very rapidly rotating massive stars (Woosley & Heger 2006).

Over the years, substantial effort has been made to numerically obtain configurations in rotational equilibrium in various contexts. Beginning with the pioneering works by Ostriker & Mark (1968), a robust iterating formula was developed by Hachisu (1986) and was extended to general relativistic and/or magnetized stars (Bocquet et al. 1995; Cook et al. 1994a; Kiuchi & Yoshida 2008b; Komatsu et al. 1989; Tomimura & Eriguchi 2005). The polytropic equation of state (EOS) was replaced by more generic ones (Cook et al. 1994b; Kiuchi & Kotake 2008a; Kiuchi et al. 2009). One of the limitations of these studies that hamper their application to the study of the evolution of rotating stars, putting aside the treatment of convections and meridional circulations, is the assumption that the whole star is rotating cylindrically, that is, the angular velocity is constant on each of the concentric cylinders and, as a result, the EOS is barotropic, that is, the pressure is a function of density alone (Tassoul 2000). On the contrary, the theoretical studies based on the spherical models indicate clearly that the stellar core and envelopes composed of different elements rotate independently of each other, since the steep gradient of mean molecular weight tends to suppress the transport of angular momentum beyond the boundary of elements. If one attempts to employ the rotational equilibrium configurations in the study of the post-main-sequence evolutions of massive stars, it is almost mandatory to treat multiple layers that obey different rotation laws.

Motivated by these facts, we present a new formulation to numerically construct nonrelativistic configurations in rotational equilibrium, which consists of multiple layers. We assume that each layer still rotates cylindrically but the rotation law, namely the angular velocity as a function of the distance from the rotation axis, can be different from layer to layer. This assumption allows us to employ the conventional formula based on the Bernoulli equation in each layer, a big advantage over the original partial differential equations. The EOS should accordingly be barotropic in each layer. We then introduce a junction condition, that is, the continuity of pressure at the boundary of the layers to combine them in such a way that the whole star is in rotational equilibrium. In this paper, mainly for demonstration purposes, we obtain two-layered configurations with each layer having different polytropic EOSs for three representative rotation laws: (1) Ω-constant law (rigid rotation), (2) j-constant law, and (3) v-constant law (see the next section for the exact definitions of these rotation laws). In principle, there is no problem in treating different rotation laws and/or a larger number of layers.

The paper is organized as follows. In Section 2, we describe the new formulation to obtain rotational equilibrium configurations with multiple layers, explaining numerical issues in detail. Section 3 is devoted to the demonstration of some model
computations. In Section 4, we give some discussions and summarize the paper.

2. BASIC EQUATIONS AND ITERATION SCHEME

2.1. Formulations

In this paper, the configurations in rotational equilibrium are assumed to be axisymmetric and steady with dissipative processes being neglected. Possible meridian flows are also ignored. Then the basic equations are

\[ \frac{1}{\rho(r, \theta)} \nabla_i p(r, \theta) = -\nabla_i \phi_g(r, \theta) + r \sin \theta \Omega^2(r, \theta) \nabla_i (r \sin \theta), \] (1)

where \( \phi_g \) refers to each component. The gravitational potential, mass density, pressure, angular velocity, and gravitational constant are denoted by \( \phi_g, \rho, p, \Omega \), and \( G \), respectively. For a barotropic EOS, i.e., \( p = p(\rho) \), which we assume for each layer throughout this paper, the left-hand side of Equation (1) can be integrated. The second term on the right-hand side of Equation (1), on the other hand, can also be integrated if the angular velocity is a function of the cylindrical radius, i.e., \( \Omega = \Omega(r \sin \theta) \). As representative cases, the following three rotation laws are chosen in this paper although there is no limitation in principle:

\[ \Omega(r \sin \theta) = \Omega_0 \] (rigid rotation),

(3)

\[ \Omega(r \sin \theta) = \frac{j_0}{r^2 \sin^2 \theta + A^2} \] (constant specific angular momentum in the limit of \( A \to 0 \)),

(4)

\[ \Omega(r \sin \theta) = \frac{v_0}{(r^2 \sin^2 \theta + A^2)^{1/2}} \] (constant rotational velocity in the limit of \( A \to 0 \)).

(5)

In these expressions, \( \Omega_0, j_0 \) and \( v_0 \) are constants that specify how fast the rotation is for each rotation law whereas \( A \) is a constant that gives a radius of the cylinder, inside which the rotation is almost rigid. The second and third rotation laws are referred to as the \( j \)-constant and \( v \)-constant laws, respectively, according to their limits of \( A \to 0 \). The first rotation law is also called \( \Omega \)-constant law. As already mentioned, the constants \( \Omega_0, j_0, v_0, \) and \( A \) can be different from layer to layer for multi-layered configurations. The values of these constants in the \( i \)th layer (see Figure 1) are represented by the subscript \( (i) \) in the following.

The integration of Equation (1) in each layer gives the so-called Bernoulli equation,

\[ H_i(\rho(\theta)) = -\phi_g(\theta) + h_{0(i)} + \phi_{\text{rot}}(r \sin \theta : A_{(i)}) + c_{(i)}, \] (6)

where \( H_i \) is a specific enthalpy defined by \( \int dP/\rho \) as a function of the mass density alone and \( c_{(i)} \) is called a Bernoulli constant. The second term on the right-hand side corresponds to the rotational potential and is given for each rotation law as

\[ h_{0(i)} = \Omega_{0(i)}, \quad \phi_{\text{rot}}(r \sin \theta : A_{(i)}) = \frac{1}{2} r^2 \sin^2 \theta \quad \text{(rigid rotation)}, \]

\[ = - \frac{1}{2(2\pi^2 \sin^2 \theta + A_{(i)}^2)} (j\text{-constant law}), \] (8)

\[ h_{0(i)} = v_{0(i)}, \quad \phi_{\text{rot}}(r \sin \theta : A_{(i)}) = \frac{1}{2} \ln (r^2 \sin^2 \theta + A_{(i)}^2) (v\text{-constant law}), \] (9)

where the amplitude, \( h_{0(i)} \), is expressed separately for later convenience. Note that the Bernoulli constants can be different from layer to layer. It is well known that the barotropic condition is equivalent to the requirement that the angular velocity be a function of the cylindrical radius alone, i.e., \( \Omega = \Omega(r \sin \theta) \) (Tassoul 2000). In this article, we assume a different rotation law for each layer, which means that the angular velocity is not a function of the cylindrical radius alone even if the rotation law is cylindrical in each layer. As a result, the EOS cannot be a single continuous barotropic one. In fact, the angular velocity is discontinuous across the layer boundary, which leads in general to the discontinuity in density as shown later. On the other hand, the pressure is continuous at the layer boundary, which can be understood as follows. Multiplied by the density, Equation (1) is written at the layer boundary as

\[ \nabla_i p = -\rho \nabla_i \phi_g + \rho r \sin \theta \frac{\Omega_i^2}{(r \sin \theta)} \nabla_i (r \sin \theta). \] (10)

The right-hand side of this equation contains step functions, that is, the density and angular velocity. Note that the gravitational potential, which is obtained by the integration of the density, is continuous. Then the pressure is also continuous because otherwise the left-hand side of Equation (10) would give a delta function. This in turn leads to the conclusion that a single continuous barotropic EOS cannot be applied across the layer boundary, since the pressure could not be continuous for the discontinuous density for such an EOS. Therefore, EOSs that are barotropic in each layer but different from layer to layer are required. As the simplest example, we employ in this article polytropic EOSs with a different polytropic constant and/or index in each layer. The essential points of our formula are summarized as follows: (1) the rotational equilibrium is locally ensured by the Bernoulli equation in each layer and (2) the layer boundary is the location where the layers are joined so that the pressure should become continuous.

2.2. HSCF Scheme for Single-layered Configurations

The problem is now reduced to the solution of Equations (6) and (2) and the search of the location where the pressures of the different layers coincide. Before discussing multi-layered configurations, we briefly review the Hachisu self-consistent field (HSCF) scheme (Hachisu 1986), which is known to be a very robust algorithm to solve iteratively Equations (6) and (2) for single-layered configurations in rotational equilibrium and on which our formula is based. In this scheme, we first introduce the following non-dimensional variables:

\[ \hat{\rho} = \rho/\rho_{\text{max}}, \]

(11)

\[ \hat{r} = r/r_e, \]

(12)

\[ \hat{h}_0^2 \hat{\phi}_{\text{tot}} = h_0^2 \phi_{\text{rot}}/4\pi G \rho_{\text{max}} r_e^2, \]

(13)
\[ \dot{c} = c / 4\pi GR_{\max} r_{\max}^2, \quad \] (14)

\[ \tilde{\phi}_g = \phi_g / 4\pi GR_{\max} r_{\max}^2, \quad \] (15)

\[ \tilde{p} = p / R_{\max} c^2, \quad \] (16)

\[ \tilde{H} = H / c^2, \quad \] (17)

where \( \rho_{\max}, p_{\max}, \) and \( c \) are the maximum density, pressure, and speed of light, respectively, and the subscript \( i \) is dropped in \( h_0, A, c, \) and \( \tilde{H}. \) The radius is normalized by the equatorial radius of the equilibrium configuration, \( r_e, \) which is unknown a priori and is expressed as \( r_e = \sqrt{\rho_{\max} / \tilde{\rho}_\text{max}} \) by the introduction of a new variable \( \beta. \) Then Equations (6) and (2) are reduced to

[\[ \frac{\beta}{\rho_{\max}} \tilde{H}(\tilde{\rho}(\tilde{r}, \theta)) = -\tilde{\phi}_g(\tilde{r}, \theta) + \tilde{h}_0^2 \tilde{\phi}_\text{rot}(\tilde{r} \sin \theta : A) + \dot{c}, (18) \]

In Equations (18) and (19), we have two unknown functions \( \tilde{\phi}_g(\tilde{r}, \theta) \) and \( \tilde{\rho}(\tilde{r}, \theta) \) and three constants \( \beta, h_0, \) and \( \dot{c} \) once the EOS and rotation law (Equations (7)–(9)) are specified. It is noted that the specific enthalpy \( H \) is a function of the density alone because of the barotropic condition. In the HSCF method, we give \( \rho_{\max}, \) the equatorial radius \( r_e, \) and polar radius \( r_p \) instead of \( \beta, h_0, \) and \( \dot{c} \) to specify the model and the latter three are treated as unknown variables to be solved. Note that \( r_e \) is unity by the definition of \( \beta \) (see Equation (12)). This choice of variables is essential for the HSCF scheme. Indeed, other choices such as \( \rho_{\max} \) and \( h_0 \) (and \( r_e = 1 \) fail to obtain convergence in the iteration (see below) more often if not.

The two unknown functions \( \tilde{\phi}_g(\tilde{r}, \theta) \) and \( \tilde{\rho}(\tilde{r}, \theta) \) and three unknown constants \( \beta, h_0, \) and \( \dot{c} \) are obtained iteratively in the HSCF method as follows. First, we give a trial density distribution \( \tilde{\rho} \) and solve Equation (19) to obtain \( \tilde{\phi}_g. \) As a second step, Equation (18) is evaluated at the following points: the stellar surfaces on the equator and on the rotation axis and the point of the maximum density, which are denoted as \( E, P, \) and \( C, \) respectively (see Figure 1):

\[ (E) \quad 0 = -\tilde{\phi}_g(1, \pi/2) + \tilde{h}_0^2 \tilde{\phi}_\text{rot}(1 : A) + \dot{c}, \quad (20) \]

\[ (P) \quad 0 = -\tilde{\phi}_g(r_p, 0) + \tilde{h}_0^2 \tilde{\phi}_\text{rot}(0 : A) + \dot{c}, \quad (21) \]

\[ (C) \quad \frac{\beta}{\rho_{\max}} \tilde{H}(\tilde{\rho}_{\max}) = -\tilde{\phi}_g(r_C, \pi/2) + \tilde{h}_0^2 \tilde{\phi}_\text{rot}(r_C : A) + \dot{c}, \quad (22) \]

where we made use of the fact that the enthalpy vanishes on the stellar surface. Note that the radius, \( r_C, \) of point \( C \) is not known a priori. For the rigid rotation, \( \tilde{\phi}_\text{rot} \) is independent of \( A. \) We solve Equations (20) and (21) with respect to \( \dot{c} \) and \( h_0 \) for \( \tilde{\phi}_g(\tilde{r}, \theta) \) obtained in the first step. With these values of \( h_0 \) and \( \dot{c}, \) we then search for the location where the right-hand side of Equation (22) takes the maximum value. The maximum of the right-hand side of Equation (22) thus obtained gives \( \beta \) in turn. We are now in a position to update \( \tilde{\rho}(\tilde{r}, \theta), \) solving the Bernoulli equation (18) for \( \tilde{\phi}_g(\tilde{r}, \theta), \beta, h_0, \) and \( \dot{c} \) obtained so far. We then repeat the procedure until a sufficient convergence is achieved.

### 2.3. Extension to Multi-layered Configurations

#### 2.3.1. Choice of Variables

We move on to the multi-layered case. Although, for simplicity, we consider only two-layered structures in the following, the extension to configurations with a larger number of layers is straightforward. Then we have again two unknown functions \( \hat{\phi}_g(\hat{r}, \theta) \) and \( \hat{\rho}(\hat{r}, \theta) \) and this time five constants \( \beta, h_{0(1)}, h_{0(2)}, c_1, \) and \( c_2 \) in Equations (6) and (2). Another important function to be determined is the layer boundary expressed by a function \( \hat{r}_b(\theta). \) Just as in the single-layered case, the choice of variables and the iteration scheme are critically important to make the scheme convergent. We first write down the equations employed to obtain the unknown constants, which correspond to Equations (20)–(22) for the single-layered case. As explained above, the pressure should be continuous across the layer boundary. Employing this condition on the equator (point \( E_{12} \) in Figure 1) and on the rotation axis (point \( P_{12} \) in the same figure), we write down the Bernoulli equation for both sides of the layer boundary at these points:

- **Layer 1 side at \( E_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(1)}(p(r_{E_{12}}, \pi/2)) = -\hat{\phi}_g(r_{E_{12}}, \pi/2) + h_{0(1)}^2 \hat{\phi}_\text{rot}(r_{E_{12}} : A_{(1)}) + c_{(1)}, \]

- **Layer 2 side at \( E_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(2)}(p(r_{E_{12}}, \pi/2)) = -\hat{\phi}_g(r_{E_{12}}, \pi/2) + h_{0(2)}^2 \hat{\phi}_\text{rot}(r_{E_{12}} : A_{(2)}) + c_{(2)}, \]

- **Layer 1 side at \( P_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(1)}(p(r_{P_{12}}, 0)) = -\hat{\phi}_g(r_{P_{12}}, 0) + h_{0(1)}^2 \hat{\phi}_\text{rot}(0 : A_{(1)}) + c_{(1)}, \]

- **Layer 2 side at \( P_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(2)}(p(r_{P_{12}}, 0)) = -\hat{\phi}_g(r_{P_{12}}, 0) + h_{0(2)}^2 \hat{\phi}_\text{rot}(0 : A_{(2)}) + c_{(2)}, \]

where we omit * over the normalized variables for notational simplicity and \( r_{E_{12}}, r_{P_{12}} \) are the radii of points \( E_{12} \) and \( P_{12}, \) respectively. Note that \( H_{(1)}(p) \neq H_{(2)}(p) \) because the EOSs are different from layer to layer. We employ the previous conditions at points \( E, P, \) and \( C, \) which are written as

- **Layer 1 side at \( E_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(1)}(p(r_{E_{12}}, \pi/2)) = -\hat{\phi}_g(r_{E_{12}}, \pi/2) + h_{0(1)}^2 \hat{\phi}_\text{rot}(1 : A_{(1)}) + c_{(1)}, \]

- **Layer 2 side at \( E_{12} \)**
  \[ \frac{\beta}{\rho_{\max}} H_{(2)}(p(r_{E_{12}}, \pi/2)) = -\hat{\phi}_g(r_{E_{12}}, \pi/2) + h_{0(2)}^2 \hat{\phi}_\text{rot}(1 : A_{(2)}) + c_{(2)}, \]

Note that in Equation (29) we do not know a priori in which layer the maximum density point \( C \) lies. Using Equations (23)–(29), we can determine for the given EOSs and rotation laws seven
unknown constants out of $\beta$, $h_{0(1)}$, $c_{i(1)}$, $c_{i(2)}$, $p_{Ei}$, $p_{Pi}$, $r_{pi}$, $r_{Ei}$, and $r_{Pi}$, in which $p_{Ei} \equiv p(r_{Ei}, \pi/2)$ and $p_{Pi} \equiv p(r_{Pi}, 0)$. This implies that one can give three constants to specify the model. As will be argued shortly, however, $p_{Pi}$ and $r_{Pi}$ as well as $p_{Ei}$ and $r_{Ei}$ cannot be specified independently. This can be understood by considering a non-rotating but two-layered configuration. In this case, one can construct an equilibrium configuration by integrating Equation (1) radially from the center to $r_{P1}$ with the use of the gravitational potential $\int_0^r 4\pi r^2 \rho \, dr / r^2$. Then, it is obvious that $p_{P1}$ depends on $r_{P1}$ and vice versa (note that the maximum density is also fixed). Going back to the multi-layered rotational case, we have found that the combination of $r_{pi}$, $p_{Pi}$, and $r_{Ei}$ is a good choice. The triplet of $r_{pi}$, $p_{Pi}$, and $p_{Ei}$ can be an alternative. Note that the inclusion of $r_{pi}$ seems to be mandatory as has been demonstrated by the HSCF scheme. To summarize, Equations (23)–(29) are used to obtain either $\beta$, $c_{i(1)}$, $h_{0(1)}$, $h_{0(2)}$, $p_{Ei}$, and $p_{Pi}$, for given $r_{pi}$, $r_{Ei}$, and $r_{P1}$ or $\beta$, $c_{i(1)}$, $c_{i(2)}$, $h_{0(1)}$, $h_{0(2)}$, $r_{Ei}$, and $r_{P1}$, for given $r_{pi}$, $p_{Ei}$, and $p_{Pi}$.

### 2.4. Iteration Scheme

Now, we proceed to the iteration scheme proposed in this paper. After solving the Poisson equation for the trial density distribution, Equations (23)–(29) are solved for the variables chosen in the previous section. The procedure is divided into the following three steps.

1. $h_{0(1)}$ and $c_{i(1)}$ are calculated from Equations (27) and (28) as

$$h_{0(1)}^2 = \frac{\phi_x(1, \pi/2) - \phi_x(r_{Pi}, 0)}{\phi_{rot}(1 : A_{(1)}) - \phi_{rot}(0 : A_{(1)})}.$$  

$$c_{i(1)} = \frac{-\phi_x(1, \pi/2) - \phi_{rot}(0 : A_{(1)}) + \phi_{rot}(r_{Pi}, 0) - \phi_{rot}(1 : A_{(1)})}{\phi_{rot}(1 : A_{(1)}) - \phi_{rot}(0 : A_{(1)})}.$$ 

2. For a trial value of $\beta$, $p_{Ei}$, and $p_{Pi}$ are obtained from Equations (23) and (25) and, combined with Equations (24) and (25), give $h_{0(2)}$ as

$$h_{0(2)}^2 = \frac{\phi_{rot}(r_{Ei} : A_{(1)}) - \phi_{rot}(0 : A_{(1)}) - h_{0(1)}^2}{\phi_{rot}(r_{Ei} : A_{(2)}) - \phi_{rot}(0 : A_{(2)})} + \frac{H_{(2)}(p_{Ei}) - H_{(1)}(p_{Ei}) + H_{(1)}(p_{Pi}) + H_{(2)}(p_{Pi})}{\phi_{rot}(r_{Ei} : A_{(1)}) - \phi_{rot}(0 : A_{(2)})} \frac{\beta}{p_{max}}.$$  

(32)

Then, $c_{i(2)}$ is obtained from Equation (24) or (26).

3. The point that gives the largest value to $-\phi_x(r, \pi/2) + h_{0(1)}\phi_{rot}(r : A_{(1)}) + c_{i(1)}$ is searched for in layer 1 and is referred to as point C1. The counterpart in layer 2 is then looked for and is called point C2. The point C is found by comparing C1 and C2 to $E_{12}$. The maximum value thus obtained is divided by $H_{(i)}(p_{max})/p_{max}$ with the appropriate $i$ and the updated value of $\beta$ is obtained. Steps (2) and (3) are repeated until the value of $\beta$ converges at a sufficient level.

#### 2.4.1. Layer Boundary

The final step of the iteration is the update of the density distribution and the location of the layer boundary. This is accomplished as follows. Regarding the specific enthalpy as a function of pressure alone, we first solve the Bernoulli equation, Equation (6), for each layer in the absence of the other layer and the layer boundary as a result:

$$p_{(1)}(r, \theta) = H_{(1)}^{-1}\left[\frac{(-\phi_x(r, \theta) + h_{0(1)}^2\phi_{rot}(r \sin \theta : A_{(1)})}{\beta} + c_{(1)}^1 \frac{p_{max}}{K_1}\right].$$  

(33)

$$p_{(2)}(r, \theta) = H_{(2)}^{-1}\left[\frac{(-\phi_x(r, \theta) + h_{0(2)}^2\phi_{rot}(r \sin \theta : A_{(2)})}{\beta} + c_{(2)}^2 \frac{p_{max}}{K_2}\right].$$  

(34)

where $H_{(i)}^{-1}$ is an inverse function of the specific enthalpy for layer $i$. Since the pressure should be continuous at the layer boundary as discussed in Section 2.1, we look for a point on the nonlinear ray (a line with $\theta = \text{const.}$), at which $p_{(1)}$ and $p_{(2)}$ coincide with each other. This gives the updated layer boundary as $r = r_{i}(\theta)$. On the other hand, $p_{(1)}(r, \theta)$ and $p_{(2)}(r, \theta)$ obtained above give the updated density distribution for each layer. This closes the iteration procedure. We go back to the Poisson equation and repeat all the steps until a sufficient level of convergence is reached.

#### 3. RESULT

To demonstrate that the new formula described above really works, we will apply it to two-layered configurations for some representative rotation laws. For simplicity, we employ two polytropic EOSs, $p_{(i)}(\rho) = K_i\rho^{1/n_i}$, in which $K_i$ and $n_i$ are the polytropic constants and indices for layer $i$. We take rather arbitrarily $K_1 = 1.015 \times 10^{12}$ and $K_2 = 5.14 \times 10^{14}$ in cgs unit and $n_2 = n_1 = 3$. Note that the specific enthalpy is given as $H_{(i)} = (n_i + 1)K_i\rho^{1/n_i}$, so that $K_i^{n_i/n_1}p_{(1)}^{1/n_1}p_{(2)}^{1/n_1}$ for layer $i$. Adopting $p_{max} = 5.629 \times 10^9$ g cm$^{-3}$, we obtain white dwarf-like configurations.
We work with the normalized variables (Equations (11)–(17)), and the numerical domain covers a quadrant of the meridian section, $0 \leq r \leq 1$ and $0 \leq \theta \leq \pi/2$, under the assumption of equatorial symmetry. We typically deploy 1000 mesh points on the $r$-coordinate and 200 grid points on the $\theta$-coordinate to obtain an acceptable accuracy, which is confirmed by the equatorial symmetry. We typically deploy 1000 mesh points identical with each other. Then, Equation (32) gives the second term is also zero because $c_{12}$ be noted that the density is continuous across the boundary. To check this, we show the pressure profiles are continuous in the same region. From Figure 4 plots the values of $\Omega_{c1}$ for each layer. It is clear that the density is discontinuous at the layer boundary because rotations tend to flatten equilibrium configurations in general. In fact, we find that the solutions for such cases have a negative centrifugal force, which is, of course, unphysical. We thus confirm that the inner layer is still oblate in the multi-layered configurations.

### 3.1. Non-rotational Case

As a mandatory step, we first construct a non-rotational configuration with two layers according to the present formula and compare it with the solution obtained by the ordinary and much simpler method, that is, the radial integration. Setting $r_p = 1$ and $r_E12 = r_P12$, we obtain $h_{(1)} = 0$ from Equation (30) and $p_{E12} = p_{P12}$ from Equations (23) and (25) that are actually identical with each other. Then, Equation (32) gives $h_{(2)} = 0$ because the first term vanishes owing to $h_{(1)} = 0$ and the second term is also zero because $p_{E12} = p_{P12}$. As a consequence, Equation (24) becomes identical with Equation (26). It should be noted that $c_{12} \neq c_{22}$ even in the non-rotational case, since the EOSs are different between two layers.

Table 1 summarizes the comparison of the non-rotating configuration obtained by the new formulation, which is referred to as “2D” in the table, with the solution of the one-dimensional hydrostatic equation obtained by the radial integration from center to surface, which is called “1D.” The radius, mass, and the Bernoulli constants in 2D, which characterize the configurations, agree with the 1D counter parts. Indeed, the relative errors in these quantities are less than 1% and the normalized virial is of the order of $10^{-5}$, both of which indicate that the present method can reproduce the non-rotational configuration.

### 3.2. $\Omega$-constant Case

We now proceed to the rotational cases. In this section we deal with the simplest one, that is, the combination of two rigid rotations ($\Omega$-constant laws in Equation (3)). We have constructed two configurations with $(r_p, r_E12, r_P12) = (0.9, 0.5, 0.5)$ and $(0.8, 0.5, 0.433)$. In Table 2, we show some key quantities that characterize the configurations. As expected, the angular velocities are different between the layers. Note that in the present formula, the angular velocity is not specified but solved. It is $r_{E12}$ and $r_{P12}$ that dictate the angular velocities. If one wants to construct a configuration for particular angular velocities, another iteration is needed for shooting. Incidentally, we can impose in principle the combinations that satisfy $r_{E12} \leq r_{P12}$, which is intuitively unlikely because rotations tend to flatten equilibrium configurations in general (Hachisu 1986). In fact, we find that the solutions for such cases have a negative centrifugal force, which is, of course, unphysical. We thus confirm that the inner layer is still oblate in the multi-layered configurations.

Figure 2 displays the contour plots of the density and angular velocity in the meridian section for the model with $(r_p, r_E12, r_P12) = (0.9, 0.5, 0.433)$. The thick curve in the figure represents the layer boundary. To check this, we show in Figure 3 the density and pressure profiles along the radial lines with $\theta = 0$, $\pi/4$, and $\pi/2$. It is clear that the density is discontinuous at $1.2 \times 10^8$ cm whereas the pressure profiles are continuous in the same region. From this, we can understand again why different EOSs are needed for each layer.

The values of $VC$ in Table 2 are of the same orders of magnitude, ~$10^{-5}$, as in the non-rotational case. This implies that the configurations we have constructed by the new formula are in rotational equilibrium to the same accuracy as the spherical configuration in the previous section is in hydrostatic equilibrium.

### 3.3. $j$-constant and $v$-constant Cases

We move on to the combinations of other rotation laws. In the following configurations, each layer is rotating differentially. Although various combinations are actually possible, only those in the same rotation law are considered here just for simplicity. Thus, the $j$-constant case refers to

### Table 1

| Dimension | $R$ (cm) | $M (M_\odot)$ | $c_{12}$ | $c_{22}$ | $VC$ |
|-----------|---------|--------------|---------|---------|------|
| 1D        | 3.218E+08 | 4.292E+00 | $-3.622E-03$ | $-8.579E-03$ | ... |
| 2D        | 3.224E+08 | 4.291E+00 | $-3.601E-03$ | $-8.533E-03$ | 2.815E-05 |

**Notes.** The radius, mass in cgs unit, and normalized virial are denoted by $R$, $M$, and $VC$, respectively. For this model, we adopt $r_{E12} = r_{P12} = 1.718 \times 10^{-2}$.

### Table 2

| $(r_p, r_E12, r_P12)$ | $R$ (cm) | $M (M_\odot)$ | $\Omega_{c1} (\text{rad} \text{s}^{-1})$ | $\Omega_{c2} (\text{rad} \text{s}^{-1})$ | $c_{12}$ | $c_{22}$ | VC |
|-----------------------|---------|--------------|-------------------------------|-------------------------------|--------|--------|------|
| $(0.9, 0.5, 0.5)$     | 2.802E+08 | 1.554E+00 | 1.441E+00 | 1.087E+00 | $-2.207E-03$ | $-2.911E-03$ | 2.120E-05 |
| $(0.8, 0.5, 0.433)$   | 3.116E+08 | 1.585E+00 | 1.854E+00 | 2.910E+00 | $-1.838E-03$ | $-2.453E-03$ | 1.499E-05 |
the configurations in which each layer obeys the \( j \)-constant law in Equation (4) although \( h_0 \) and \( A \) are different between the layers. The same is true of the \( v \)-constant case. For each case, we have constructed two configurations that have \((r_p, r_{E12}, r_{P12}, A_{(1)}, A_{(2)}) = (0.6, 0.5, 0.32, 0.1, 0.05)\) and \((0.6, 0.5, 0.5, 0.1, 0.1)\). Note again that \( h_0(i) \), or how fast each layer is rotating, are not specified but solved, and \( r_{E12} \) and \( r_{P12} \) are the control parameters. On the other hand, the degree of differential rotations or \( A_{(i)} \) can be specified freely.

Table 3 summarizes the quantities that characterize the configurations whereas Figures 5 and 6 display the contour plots of the density and angular velocity for the models in the \( j \)-constant and \( v \)-constant cases, respectively. As expected and shown in these figures, the differentially rotating models are more deformed than the one presented in the previous section, in which each layer rotates rigidly. The values of \( VC \) in Table 3 are of the same order, \( \sim 10^{-5} \), as in the non-rotational and \( \Omega \)-constant cases; that fact indicates our formulation’s capability of constructing configurations with strongly differential rotations. This may be important in dealing with the progenitors of GRB (Woosley & Heger 2006).

### 4. SUMMARY AND DISCUSSIONS

Bearing in mind the application to the study of rotational massive stars in their late evolutionary phase, in this paper we have proposed a new formula to construct multi-layered configurations in rotational equilibrium. This is an extension of the HSCF scheme that is based on the Bernoulli equation and meant originally for single-layered configurations that are rotating cylindrically with a barotropic EOS. In our method, on the other hand, each layer is assumed to rotate still cylindrically with a barotropic EOS but the rotation laws and EOSs are different from layer to layer. We have shown that the pressure...
should be continuous at the layer boundary whereas the density is in general discontinuous across the boundary, which is an alternative demonstration that the EOS cannot be identical for the adjacent layers. We have identified the variables that are appropriate to make the iteration scheme convergent. This is indeed a crucial ingredient in our formula. For demonstration, we have actually constructed several configurations with two layers for three representative rotation laws if we deploy 1000 × 200 mesh points, and we have also demonstrated that the error is reduced as the number of mesh points is increased. Incidentally, it has been confirmed that a non-rotational configuration is also reproduced by the present scheme. From these results, it is obvious that our method works well and is robust indeed. The application of the present formula to more realistic problems will be published elsewhere (H. Nagakura et al. 2010, in preparation).

As commented in Section 2, it is straightforward to extend our scheme to the configurations with more than two layers though the procedure becomes a bit more involved. Although we have combined the rotation laws of the same family but with different parameters for simplicity in this paper, two rotation laws of different families can be treated in the same way. The implementation of more realistic EOSs will pose no problem in principle as long as they are barotropic. We may employ the idea by Jackson et al. (2005) and MacGregor et al. (2007) that the pressure, density, and temperature are assumed to be functions of the effective potential alone. Moreover, the present formula will be able to treat configurations with a topology of torus by relaxing the assumption that the surface extends itself to the symmetry axis and by choosing appropriate points on the equator to impose the conditions corresponding to Equations

| Table 3 | Radius, Mass, Specific Angular Momenta/Rotational Velocities, Bernoulli Constants, and Virial for j-constant and υ-constant Cases |
|--------|---------------------------------------------------------------------------------|
|  | j-constant case                                                                 |
| $r_{E12}$, $r_{E12}$, $A_{(1)}$, $A_{(2)}$ | R(cm) | $M(M_\odot)$ | $j_{(1)}(cm^2 s^{-1})$ | $j_{(2)}(cm^2 s^{-1})$ | $c_{(1)}$ | $c_{(2)}$ | VC |
| (0.6,0.5,0.32,0.1,0.05) | 2.405E+08 | 1.739E+00 | 2.683E+16 | 1.435E+16 | −3.501E−03 | −4.956E−03 | 4.969E−05 |
| (0.6,0.5,0.5,0.1,0.1) | 2.555E+08 | 1.711E+00 | 2.748E+16 | 2.074E+16 | −2.870E−03 | −4.042E−03 | 4.404E−05 |
|  | υ-constant case                                                                 |
| $r_{E12}$, $r_{E12}$, $A_{(1)}$, $A_{(2)}$ | R(cm) | $M(M_\odot)$ | $v_{(1)}(cm s^{-1})$ | $v_{(2)}(cm s^{-1})$ | $c_{(1)}$ | $c_{(2)}$ | VC |
| (0.6,0.5,0.32,0.1,0.05) | 3.037E+08 | 1.823E+00 | 4.094E+08 | 4.709E+08 | −1.837E−03 | −2.434E−03 | 2.204E−05 |
| (0.6,0.5,0.5,0.1,0.1) | 3.057E+08 | 1.654E+00 | 4.506E+08 | 3.412E+08 | −1.632E−03 | −2.295E−03 | 1.326E−05 |
In our formula, the layer boundary is determined from the condition that the pressure be continuous there. In reality, however, the layers in the stellar interior correspond to the regions of different chemical compositions and their boundaries are determined by the thermodynamical conditions for nuclear burnings. This difference originates from the fact that we have imposed piecewise cylindrical rotation laws. In the actual stellar interior, each layer obeys a toroclinic EOS and, as a result, rotates non-cylindrically. Moreover, the gas motions in the meridian section such as convections and meridional circulations are likely to exist generically. Then, the original partial differential equations should be solved somehow, which is a formidable task and will need an entirely new approach. Our formula, therefore, is admittedly a rather crude approximation to the reality but, hopefully, a not so bad one if one chooses an appropriate rotation law for each layer. In fact, it will be much better than any approximate configurations with only a single layer.

The real challenge will be to somehow implement chemical evolutions to the sequence of rotational configurations. One possibility may be an extension of the idea employed in most of the current one-dimensional evolution models of rotational massive stars (Heger et al. 2000; Hirschi et al. 2004; Limongi et al. 2000). Under the assumption that the thermodynamical conditions as well as the chemical abundances are uniform on each surface of constant effective potential, we solve the nuclear network locally and then transfer generated energy on the multidimensional mesh. The transport of angular momentum may be also approximated by diffusion. Since the resultant distributions of thermodynamical quantities and elements will in general be non-uniform on the surface of constant effective potential, we will take their angular averages on the surface and solve the new rotational equilibrium for the obtained equations of state and rotation law. This completes the single cycle, and the iteration of this process will give the temporal evolution of rotational stars. We hope that this procedure is feasible and that the formulation presented in this paper will contribute to the study of the influences of non-sphericity on the evolution of rapidly rotating massive stars.

Numerical computations were in part carried out on XT4 and the general common-use computer system at the center for Computational Astrophysics, CfCA, the National Astronomical Observatory of Japan, and on NEC-SX8 at Yukawa Institute for Theoretical Physics in Kyoto University. This study was supported in part by Grants-in-Aid for Scientific Research from the Ministry of Education, Science and Culture of Japan (nos. 80251403 and 19104006).
