A Novel Fault Classification Scheme Based on Least Square SVM

H.C. Dubey\(^1\), A.K. Tiwari\(^2\), Nandita\(^3\), P.K. Ray\(^4\), S.R. Mohanty\(^5\) and Nand Kishor\(^2\)

Abstract—This paper presents a novel approach for fault classification and section identification in a series compensated transmission line based on least square support vector machine. The current signal corresponding to one-fourth of the post fault cycle is used as input to proposed modular LS-SVM classifier. The proposed scheme uses four binary classifier; three for selection of three phases and fourth for ground detection. The proposed classification scheme is found to be accurate and reliable in presence of noise as well. The simulation results validate the efficacy of proposed scheme for accurate classification of fault in a series compensated transmission line.

Index Terms—Digital relaying, distance relay, fault classification, least square-support vector machine, modular classifier, series compensated transmission line.

I. INTRODUCTION

Transmission lines are protected by digital relays which operate accurately and reliably as compared to their solid state counterparts. Digital relay are invariably based on signal processing techniques. Faults occurring in transmission lines need to be detected, classified, and located fastly and accurately for keeping faulty part isolated from the healthy part thereby, ensuring minimum damage and disturbance. The speed, accuracy and reliability of digital protective relays are dependent on underlying techniques used in design. Fault classification task is an important task after the detection of fault for isolating the faulty section from healthy one, thus reducing damages to power systems [1]-[2].

The FACTS employed in modern power system achieve enhancement in transmissible power, improvement in the system stability, reduction in transmission losses and more flexibility in power control. On the other hand, presence of FACTS devices like TCSC complicates the protection task because [1, 2]: the metal oxide varistor (MOV) is employed for protection of the series capacitor from over-voltage during faulty situations. However, it acts non-linearly during faults and increases the complexity of the protection problem. Due to resonance between the system inductance and series capacitor, non fundamental decaying components as well as decaying DC components are present in the voltage and current signals. Odd harmonics are due to MOV conduction during faults and sub-synchronous frequencies having frequency components varying around half the fundamental frequency value, high frequency components (which results from resonance between line capacitance and line inductance) are present in addition to fundamental components of the steady state fault current. Thus, these signals are not processed very accurately with conventional methods such as full cycle DFT/half cycle DFT (FCDFT/HCDFT) or least square error (LSE) technique; thereby cause large error in estimation of the fundamental phasor. In light of these issues, the fault classification task is complicated in the presence of TCSC [3]-[4]. Techniques based on fuzzy logic, adaptive Kalman filtering, neural network, wavelet transform and support vector machine have been addressed in research studies for fault classification task [5-14]. In [5], Kalman filtering based technique has been used for fault classification task. However, the validity of the proposed method had been tested on a limited number of test cases. Classification technique based on artificial neural network (ANN) in a series compensated transmission lines is addressed in [6]-[8]. However, ANN involves empirical risk minimization and suffers from drawbacks like over fitting and trapping in local minima. Further in [6]-[8], the performance of the classification schemes have not been investigated over extensive test cases and the compensation level was kept constant.

In [9]-[10], authors have suggested classification schemes based on wavelet transformation. Also, in [9]-[10], the proposed technique was validated only for limited cases. Some techniques based on fuzzy logic have also been presented for fault classification applications in [11]-[13]. A hybrid approach based on wavelet transform and fuzzy logic is proposed in [11]-[12]. Combination of fuzzy logic and higher order statistics (HOS) has been investigated in [13] for classification task considering a wide variation in the system conditions. Recently, support vector machine (SVM) based technique has been proposed for fault classification [14]-[17].

The presence of FACTS devices in transmission line influence pre-fault as well as post-fault current signals thereby making the task of fault classification a complicated one. In spite of research studies done, fault classification in series compensated transmission lines still remains a challenge in terms of accurate and reliable classification with reduced computational burden and number of data sets for sake of online implementation. One of the most promising approach used for fault classification applications in a transmission line as reported [13, 15] is SVM. SVMs are classifiers based on structural risk minimization. An improved version of SVM is least square SVM (LSSVM) that retains all advantages of SVM with lesser computational burden.

This paper proposes a novel scheme for accurate classification of faults in a series compensated transmission line based on LSSVM classifier using modular topology. The use of modular topology reduces the computational burden and time complexity of the proposed classification technique. The novelty of the work is three fold. First, the fault classification is studied in a series compensated transmission line rather a normal transmission line. Second, the introduction of LSSVM is new to fault classification task. Third, the modular topology of binary LSSVM classifier improves the performance. The proposed classifier is trained with input and output data-sets generated using Simulink model of studied power system in MATLAB environment.

The rest of the paper is presented as follows; the LSSVM is briefly described in section II, proposed scheme is discussed in section III, followed by simulation and results in section IV. Finally, conclusions based on simulation results are given in section V.

II. LEAST SQUARE SUPPORT VECTOR MACHINE

Support vector machines (SVMs) are statistical learning systems based on structural risk minimization used for pattern recognition. But, the computational complexity of SVMs is related to the number of training samples. As the sample size increases, the solution of the corresponding quadratic programming problem becomes complex resulting in slow computing speed. Least square SVM (LSSVM) is an improvement over SVM without losing its advantages [18]-[19]. LSSVM technique for classification and non-linear regression are characterized by linear Karush-Kuhn-Tucker (KKT) systems [19]. Sparseness can be imposed in LSSVM using pruning as known in NNs. Non-linear SVM for classification and regression problems involves convex quadratic programming. The LSSVM as a classifier differs from conventional SVM in two ways; firstly it uses equality constraints and secondly, a squared loss function is taken as error variable [19].

The optimal separation of hyperplane is shown in Fig.1. LSSVM aims to build a classifier which is characterized by following optimization problem:

\[ \min_{w, b, \varepsilon} J_{LS} = \frac{1}{2} w^T w + \gamma \sum_{k=1}^{N} e_k^2 \]

Subject to the equality constraints

\[ y_k = w^T x_k + b + e_k, k = 1, 2, ..., N \]

Where \( e_k \) are slack variable and \( \gamma \) is a positive real constant known as regularization parameter. The parameter \( \gamma > 0 \) determines the trade-off between fitting error minimization and smoothness.

![Fig.1 The optimal hyperplane of the binary classifier](image)

The lagrangian involved in the optimization problem is

\[ \mathcal{L}(w, b, \alpha) = w^T w + \gamma \sum_{i=1}^{N} \sum_{k=1}^{2} \alpha_k (w^T \phi(x) + b + \varepsilon_i - y) \]

Where \( \alpha_i \in \mathbb{R}^+ \), \( i = 1, 2, ..., n \) are Lagrange multipliers. The conditions for optimality are given by:

\[
\begin{cases}
\frac{\partial \mathcal{L}}{\partial w} = \sum_{i=1}^{N} \alpha_i \phi(x_i) & \text{for} \ \alpha_i \geq 0 \\
\frac{\partial \mathcal{L}}{\partial b} = \sum_{i=1}^{N} \alpha_i & \text{for} \ \alpha_i \geq 0 \\
\frac{\partial \mathcal{L}}{\partial \varepsilon_i} = \gamma \phi(x_i) & \text{for} \ i = 1, 2, \ldots, n \\
\frac{\partial \mathcal{L}}{\partial \varepsilon_i} = \gamma & \text{for} \ i = 1, 2, \ldots, n \\
\frac{\partial \mathcal{L}}{\partial \alpha_i} = w^T \phi(x_i) + b + \varepsilon_i - y & \text{for} \ i = 1, 2, \ldots, n \\
\frac{\partial \mathcal{L}}{\partial \alpha_i} = 0 & \text{for} \ \alpha_i = 0 \\
\end{cases}
\]
The solution of eqn. (5) is obtained as:

$$
\begin{bmatrix}
0 \\
1
\end{bmatrix} \begin{bmatrix}
x \\
y
\end{bmatrix} = 
\begin{bmatrix}
0 \\
y
\end{bmatrix}
$$

(6)

$$
\Omega = \phi(x)^T \phi(x) = K_j(x_i, x_j); i,j = 1,2,3,..., n
$$

(7)

$$
\sum_{i=1}^{n} e_i^2
$$

(9)

The feature vector $\phi(x)$ is known by means of the positive definite kernel function. The kernel function is required to satisfy Mercer’s condition, which implies that

$$
K_j(x_i, x_j) = \Phi(x_i)^T \Phi(x_j)
$$

(10)

The classifier based on LS-SVM model is then constructed as follows:

$$
\min_{w, \gamma} \frac{1}{2} w^T w + \gamma \frac{1}{2} \sum_{i=1}^{n} e_i^2
$$

such that $e_i = y_i - (w^T \phi(x_i) + b)$,

The outputs of four modules of binary classifiers are used for deciding fault type as according to Table 1. Here, $+1$ represents the involvement of phase or ground in fault and -1 represents its absence. The binary LS-SVM classifier are combined to form a modular network of four binary classifier, thus forming a multi-class classifier to discriminate between R-G, RY, RY-G, RYB and RYB-G faults.

### A. LSSVM for section identification

Identification of faulty section is also necessary with fault classification in a series compensated transmission line. Due to presence of FACTS devices the apparent impedance of the transmission changes and hence just after the midpoint and just before that there is a significant change in current, so the section having fault must be identified.

#### Fig. 2 Proposed LSSVM based classification scheme

### TABLE I

FAULT TYPE IDENTIFICATION

| S.No. | Output of LS SVM_R | Output of LS SVM_Y | Output of LS SVM_B | Output of LS SVM_G | Type of fault |
|-------|--------------------|--------------------|--------------------|--------------------|--------------|
| 1     | 1                  | -1                 | -1                 | 1                  | R-G          |
| 2     | -1                 | 1                  | -1                 | 1                  | Y-G          |

| Fault | Kernel | Parameter Value | Classification |
|-------|--------|-----------------|----------------|
| RY fault at 25%, FIA=135°, LA=40°, R_f=60 ohm | Poly | 1.3269 | 1 |
| RB-G fault at 30%, FIA=175°, LA=30°, R_f=80 ohm | Poly | 1.322 | 1 |
| RYB-G fault at 75%, FIA=120°, A=65°, R_f=80 ohm | Poly | 1.440 | 1 |
| YB-G fault at 90%, FIA=95°, LA=55°, R_f=100 ohm | Poly | 1.389 | 1 |
Section identification is accomplished by training the LSSVM to build an optimized classifier. The current samples corresponding to one-fourth cycle of post fault current are fed as input to the LSSVM and the output is +1 (before series capacitor) or -1 (after series capacitor). The training is done using 208 data sets and the accuracy of identification is tested over 916 datasets. The average classification rate for section identification for 916 data sets is found to be 97.25% for all fault types which is reasonably good. Table II depicts the results for section identification with proposed approach. Also, misclassification is observed for the RYB-G fault at 75%, FIA=120°, LA=65°, Rf=80 ohm, Poly misclassifies showing the output as 1. Other cases shown in Table II shows correct identification.

IV. SIMULATION STUDIES

A three phase transmission line of 250 km length, 230 kV, 50 Hz connecting two systems with MOV and series capacitor kept at midpoint of line as shown in Fig.3 is used for testing of proposed scheme. The model of transmission system with TCSC shown in Fig.3 has been simulated using MATLAB/Simulink environment. The various parameters of transmission line used for simulation are given in Table III. The post-fault current signal is retrieved at the relaying end bus A and used for recognition of fault events. The sampling rate used is 1.0 kHz at nominal frequency 50 Hz, thus giving 20 samples per cycle.

![Fig.3 Series compensated transmission line](image321to570x241)

**TABLE III**

PARAMETERS OF THE SIMULATED TRANSMISSION LINE

| Parameter                  | Value                  |
|---------------------------|------------------------|
| System voltage            | 230 kV                 |
| System frequency          | 50 Hz                  |
| Voltage of source 1       | 1.0 0 degree pu        |
| Voltage of source 2       | 1.0 <= 20 degree pu    |
| Transmission line length  | 250 km                 |
| Positive sequence         | R = 0.0368 (ohm/km), L = 0.55 (mH/km), C = 0.028 (uF/km)  |
| Zero sequence             | R = 0.0328 (ohm/km), L = 1.722 (mH/km), C = 0.024          |

To demonstrate the potential of the proposed approach, all ten cases of fault event are simulated. The data-set consists of 916 test cases comprising all the ten types of faults with varying fault resistances, different fault inception angles, different source impedance values, different fault positions, different percentage compensation levels for validation of proposed approach. Fig.4 shows the current signals of three phases in case of R-G fault with fault resistance 50 ohm and fault inception angle of 50 degree with 50% compensation level.

V. RESULTS AND DISCUSSIONS

The classification accuracy of LSSVM-R classifier with RBF kernel as function of two parameters is shown in Fig.6. There is no significant change observed in accuracy as these parameters are varied. The proposed LSSVM based classifier performs consistently well and gives accurate classification for all fault types. This suggests the efficacy of proposed technique. The classification accuracy indicates the average performance obtained by different types of kernel functions used in the proposed scheme. Fig.6 shows overall classification accuracy of the proposed technique which again supports its utility in fault classification task.

VI. CONCLUSION

The present paper investigates a novel approach for fault classification and section identification in a series compensated transmission line. The proposed scheme is based on a modular network consisting of four binary LSSVM classifiers. The proposed classifier has been tested under various system changing conditions. One-fourth cycle of post-fault current samples are used as input by classification scheme. Simulation result validates the consistency and accuracy of proposed scheme. It is found that LSSVMs require lesser training sets for most optimized classification with less number of training samples compared to the neural network and neuro-fuzzy systems. Hence the proposed method is comparatively fast, accurate and robust for the protection of transmission line.
