Abstract

In this work we investigate small clusters of bosons using the hyperspherical harmonic basis. We consider systems with \( A = 2, 3, 4, 5, 6 \) particles interacting through a soft inter-particle potential. In order to make contact with a real system, we use an attractive gaussian potential that reproduces the values of the dimer binding energy and the atom-atom scattering length obtained with one of the most widely used \(^4\text{He}-^4\text{He}\) interactions, the LM2M2 potential. The intensity of the potential is varied in order to explore the clusters’ spectra in different regions with large positive and large negative values of the two-body scattering length. In addition, we include a repulsive three-body force to reproduce the trimer binding energy. With this model, consisting in the sum of a two- and three-body potential, we have calculated the spectrum of the four, five and six particle systems. In all the region explored, we have found that these systems present two states, one deep and one shallow close to the \( A - 1 \) threshold. Some universal relations between the energy levels are extracted; in particular, we have estimated the universal ratios between thresholds of the three-, four-, and five-particle continuum using the two-body gaussian potential. They agree with recent measurements and theoretical predictions.
I. INTRODUCTION

Systems composed by few atoms having large value of the two-body scattering length, \(a\), with respect to the natural length, \(\ell\), fixed by the atomic potential, have been the object of an intense investigation both from a theoretical and experimental point of view (for recent reviews see Refs. [1–3]). In fact, they present universal properties: for example, the three-body system displays the Efimov effect \([4, 5]\), that means the appearance, in the limit \(a/\ell \to \infty\), of an infinite set of bound states accumulating toward the three-particle threshold; moreover, the three-body spectrum has a discrete-scale symmetry, with an universal ratio between the \(n\)-th and \(n+1\)-th levels \(E_{n+1}^3/E_n^3 = e^{-2\pi/s_0}\). The scaling factor depends only on the ratio between particle masses, and for identical bosons of mass \(m\) it reads \(e^{-2\pi/s_0} \approx 1/515.03\) (with \(s_0 \approx 1.00624\)). The finite value of \(\ell\) implies the existence of a three-body ground state \(E_0^3\) whose value reflects the short range physics, and that, together with the discrete-scale symmetry, completely determines the spectrum. In realistic cases the ratio \(a/\ell\) is large but finite; thus, the three-body spectrum reduces to a finite number of states.

A remarkable property in \(a \to \infty\) limit appears in the four-body system: two states \(E_{4,0}^0, E_{4,1}^0\) are attached to each trimer state \(E_n^3\), one deep and one shallow having universal ratios, \(E_{4,0}^0/E_n^3 \approx 4.6\) and \(E_{4,1}^0/E_n^3 \approx 1.001\) \([6–8]\); the two lowest four-body states, \(E_4^0 = E_{4,0}^0\) and \(E_4^1 = E_{4,1}^0\), are real bound states. These properties have been studied for large positive and large negative values of the scattering length in the \((a^{-1}, \kappa)\) plane, with \(\kappa = \text{sign}(E)[|E|/(\hbar^2/m)]^{1/2}\), constructing what is normally called an Efimov plot \([9]\).

There are very few studies of the spectrum of small bosonic clusters beyond \(A = 4\). In addition to the specific problems related to the solution of the Schrödinger equation for more than four particles, the atom-atom realistic potentials present a strong repulsion at short distances which makes the numerical problem more difficult. Specific algorithms have been developed so far to solve this problem: the Faddeev equation has been opportunely modified \([10]\), the Hyperspherical methods resorted either to the hyperspherical adiabatic (HA) expansion (for a review see Ref. \([11]\)), or to the correlated hyperspherical harmonic expansion (CHH) \([12]\). However, due to the difficulties in treating the strong repulsion, few calculations exist for systems with more than three atoms. For example, in Ref. \([13]\) the diffusion Monte Carlo method has been used to describe the ground state of \(^4\text{He}\) molecules.
up to 10 atoms, and in Ref. [14] a very extended calculation has been done in the four helium atom system. On the other hand, descriptions of few-bosons systems using soft-core potentials are currently operated (see for example Refs. [7, 15]).

The equivalence between hard- or soft-core-potential descriptions has been discussed in Refs. [16, 17], in which an attractive soft $^4$He-$^4$He gaussian potential has been used to investigate the three-atom system. The soft-two-body potential was designed to reproduce the helium dimer binding energy $E_2$, the $^4$He-$^4$He scattering length $a$, and the effective range $r_0$ of the LM2M2 potential [18], one of the most used $^4$He-$^4$He interactions. In this context the soft gaussian potential can be considered as a regularized-two-body contact term in an Effective Field Theory (EFT) approximation of the LM2M2 [19]; this is possible because of the scale separation between the $^4$He-$^4$He scattering length, $a = 189.41$ a.u., and the natural length $\ell = 10.2$ a.u., which is the van der Waals length calculated for the LM2M2 potential [1].

In the two-body sector and in the low-energy limit, the two potentials predict similar phase shifts, therefore, even if their shape is completely different, they describe in an equivalent way the physical processes in that limit [19]. The equivalence is lost as the energy is increased, when the details of the potential become more and more important. When the soft interaction is used in the three-body sector, a new three-body-contact term is required to reproduce the ground-state-binding energy of the helium trimer given by the LM2M2 potential. This term is introduced by means of a gaussian-hypercentral three-body force, whose strength is tuned to reproduce the LM2M2 ground state binding energy of the three-atom system. In Ref. [16] the quality of this description has been studied for different ranges of the three-body force by comparing the binding energy of the excited Efimov state and the low-energy helium-dimer phase shifts to those obtained with the LM2M2 potential. In Ref. [17] the spectrum of small clusters of helium atoms has been investigated up to six particles maintaining however fixed the values of $a$ and $E_2$ as given by the LM2M2 potential.

In the present work we extend the analysis of the $A = 3 - 6$ bosonic spectrum to the $(a^{-1}, \kappa)$ plane. We have modified the strength of the LM2M2 potential in order to cover the region of negative values of $a$ up to $a_0^{-1}$, with this value indicating the threshold of having a three-body system bound. We have also increased the intensity of the interaction in order to extend the analysis to positive values of $a$ in which the universal character of the system starts to be questionable, i.e, when the ground-state $E_3^0$ approaches the natural
energy \( E_\ell = -\hbar^2/mL^2 \), which delimits the Efimov window.

Associate with the different values of \( a \) of the modified LM2M2 potential, we have constructed a set of attractive gaussian potentials with the strength fixed to reproduce the low-energy data of LM2M2. Moreover, the modifications of the LM2M2 produce different values of the \( A = 3 \) ground state energy \( E_3^0 \); accordingly, we introduce a soft three-body force devised to reproduce those values along the \( (a^{-1}, \kappa) \) plane. Within this model, consisting in the sum of a two- and three-body potentials, we have calculated the spectrum of the four, five and six particle systems.

Two different calculations have been performed in the present work. From one side we have calculated the \( A = 3 \) ground state and excited state, \( E_3^0 \) and \( E_3^1 \), using the LM2M2 potential and its modification, in order to construct the corresponding Efimov plot. Since this potential present a strong short-range repulsion we have used the CHH expansion as discussed in Ref. [12]. One the other side, when using the soft-core potential model in systems with \( A \geq 3 \), the numerical calculations were performed by means of the non-symmetrized hyperspherical harmonic (NSHH) expansion method with the technique recently developed by the authors in Refs. [17, 20–22]. In this approach, the authors have used the Hyperspherical Harmonic (HH) basis, without a previous symmetrization procedure, to describe bound states in systems up to six particles. The method is based on a particular representation of the Hamiltonian matrix, as a sum of products of sparse matrices, well suited for a numerical implementation. Converged results for different eigenvalues, with the corresponding eigenvectors belonging to different symmetries, have been obtained [22]. In the present work, since we are dealing with bosons, we only consider the symmetric part of the spectrum. Interestingly, we have observed that in all the region explored the \( A = 4, 5, 6 \) systems present two states, one deep and one shallow close to the \( E_{A-1}^0 \) threshold. To gain insight on the shallow state, for a selected value of \( a \), we have varied the range of the three-body force and we have studied the effect of that variation in the \( A = 4, 5, 6 \) spectrum. In the range considered, the variation produces small changes in the eigenvalues, but they are crucial to determine if the shallow state is bound or not with respect to the \( A - 1 \) threshold. This analysis confirms, at least in one zone of the Efimov plot, previous observations that each Efimov state in the \( A = 3 \) system produces two bound states in the \( A = 4 \) system, and extends this observation to the \( A = 5, 6 \) systems.

Finally, we have extended the calculations of the \( A = 4 \) and \( A = 5 \) systems up to the
four- and five-particle thresholds using the simple two-body-gaussian potential; the ratios between the thresholds are in agreement with previous theoretical results \cite{7, 23} and with experiments \cite{24, 27}.

The paper is organized as follows. In Section II we describe the two- and three-body forces we used in our calculations to reproduce the LM2M2 values. In Section III we discuss the Efimov plot for three particles. In Section IV the results for the bound states of the \( A = 3, 4, 5, 6 \) clusters are discussed whereas the conclusions are given in the last section.

II. SOFT-CORE TWO- AND THREE-BODY POTENTIALS

As mentioned in the Introduction, we use the LM2M2 \(^4\text{He}-^4\text{He}\) potential as the reference interaction, with the mass parameter fixed to \( \hbar^2/m = 43.281307 \) (a.u.)\(^2\) K. In order to explore the Efimov-(\(a^{-1}, \kappa\)) plane, we have modified the LM2M2 interaction as following

\[
V_\lambda(r) = \lambda \cdot V_{\text{LM2M2}}(r) .
\] (1)

Examples of this strategy exist in the literature \cite{12, 28}. We have varied \( \lambda \) from \( \lambda = 0.883 \), where \( a = a_0 = -43.84 \) a.u., up to \( \lambda = 1.1 \) corresponding to \( a = 44.79 \) a.u., as shown in Fig. \ref{fig1}. The unitary limit is produced for \( \lambda \approx 0.9743 \). When \( \lambda = 1 \) the values of the LM2M2 are recovered: \( a = 189.41 \) a.u., \( E_2 = -1.303 \) mK and \( r_0 = 13.845 \) a.u..

Following Refs. \cite{11, 16, 17} we have constructed an attractive two-body gaussian (TBG) potential

\[
V(r) = V_0 \ e^{-r^2/R_0^2} ,
\] (2)

with range \( R_0 = 10 \) a.u., and we have varied the strength \( V_0 \) in order to reproduce the values of \( a \) given by \( V_\lambda(r) \), as shown in Fig. \ref{fig2}. For \( \lambda = 1 \) with the strength \( V_0 = -1.2343566 \) K we reproduce the LM2M2 low-energy data, \( E_2 = -1.303 \) mK, \( a = 189.42 \) a.u., and \( r_0 = 13.80 \) a.u.. The use of the TBG potential in the three-atom system produces a ground state binding energy appreciable deeper than the one calculated with \( V_\lambda(r) \). For example, at \( \lambda = 1 \) the LM2M2 helium trimer ground state binding energy is 126.4 mK whereas the one obtained using the two-body-soft-core potential in Eq. (2) is 151.32 mK. A smaller difference, though still appreciable, can be observed in the first excited state.

In order to have a closer description to the \( A = 3 \) system obtained with the modified LM2M2 potential, we introduce the following (repulsive) hypercentral-three-body (H3B)
FIG. 1. The scattering length $a$, in units of $\ell$, as a function of the parameter $\lambda$, calculated with the modified LM2M2 potential $V_\lambda(r)$. The range of variation of $\lambda$ is between $\lambda = 0.883$, which corresponds to the disappearance in the continuum of the excited three-body state, and $\lambda = 1.1$. The unitary limit is obtained for $\lambda \approx 0.9743$.

interaction

$$W(\rho_{123}) = W_0 \exp\left(-\frac{\rho_{123}}{\rho_0}\right),$$

with the strength $W_0$ tuned to reproduce the trimer energy $E_3^0$ obtained using $V_\lambda(r)$ for all the explored values of $\lambda$, as shown in Fig. 3. Here $\rho_{123}^2 = \frac{2}{3}(r_{12}^2 + r_{23}^2 + r_{31}^2)$ is the hyperradius of three particles and $\rho_0$ gives the range of the three-body force, or, in the spirit of EFT, the cut-off of the three-body-contact interaction; therefore, it is not independent of $R_0$, which is the cut-off of the two-body-contact force, and in fact it should be $\rho_0 = R_0$, as shown in [17], and so we fixed $\rho_0 = 10.0$ a.u. A different criterion to fix the three-body force was given in Ref. [23] in which the condition $\rho_0 \gg r_0$ has been used. In this case the (repulsive) three-body force is used to push the trimer spectrum high in energy in order to verify as
FIG. 2. The strength $V_0$ of the gaussian two-body-potential as a function of the parameter $\lambda$. The values are tuned to reproduce the scattering length $a$ given by the modified LM2M2 potential $V_\lambda(r)$. 

close as possible the universal ratios $E_3^{n+1}/E_3^n = e^{-2\pi/s_0}$ already at $n = 0$. With the LM2M2 interaction this relation is only approximate verified; for $\lambda = 1$ we have $E_3^0/E_3^1 \approx 56$, whereas at the unitary limit $E_3^0/E_3^1 \approx 525$, very close to the universal ratio.

III. THREE-BODY EFIMOV PLOT

The calculations for $A = 3$ have been performed using the CHH expansion. Since $V_\lambda(r)$ is obtained multiplying the LM2M2 potential by a global factor $\lambda$, it inherits the strong short range repulsion; in this case, a direct use of the HH basis to compute the bound states is not feasible since it would be necessary to include an enormous number of basis elements in the expansion \cite{29}. The use of the CHH expansion circumvents this problem.
FIG. 3. The strength $W_0$ of the hypercentral three-body-potential as a function of the parameter $\lambda$. The values are tuned to reproduce the three-body ground state $E_3^0$ given by the modified LM2M2 potential $V_\lambda(r)$.

by the introduction of a correlation factor of the Jastrow type. The method is described in Ref. 12 and it allows to achieve similar accuracy as other techniques. As an example, in Table I we show the results for the ground state $E_3^0$ and the excited state $E_3^1$ at $\lambda = 1$ (in this case the results of the LM2M2 potential are recovered), and at the unitary limit ($\lambda = 0.9743$). These results have been obtained using the CHH basis up to a value of the grand-angular momentum $K = 160$.

As a byproduct of the tuning procedure of the three-body strength $W_0$, we have constructed, as was previously done for instance in Refs. 28, 30, the Efimov plot shown in Fig. 4. In the figure we report calculations of $E_3^0$ and $E_3^1$ as functions of $a$ done both with the $V_\lambda(r)$ and the TBG potential. When the TBG+H3B potential is used, the results coincide with those of $V_\lambda(r)$ and are not reported in the figure. In addition, we draw the dimer
potential & $E_0^3$ (mK) & $E_1^3$ (mK) \\
\hline
$\lambda = 1$ & & \\
$V_\lambda (r)$ & -126.4 & -2.27 \\
TBG & -151.3 & -2.48 \\
TBG+H3B & -126.4 & -2.31 \\
\hline
$\lambda = 0.9743$ & & \\
$V_\lambda (r)$ & -83.99 & -0.16 \\
TBG & -103.4 & -0.20 \\
TBG+H3B & -83.99 & -0.16 \\
\hline

TABLE I. The ground state $E_0^3$ and the excited state $E_1^3$ of the three-boson system calculated with the modified LM2M2 potential $V_\lambda (r)$, the TBG potential, and the TBG potential plus the H3B potential at $\lambda = 1$, that corresponds to the original LM2M2 potential, and in the unitary limit, $\lambda = 0.9743$.

energy $E_2$, calculated using the $V_\lambda (r)$ potential. In order to show these quantities together in the figure we have used the fourth root of the energy (in units of $E_\ell$) as a function of the square root of $a^{-1}$ (in units of $\ell$). In the region analyzed, the results are inside the Efimov window; in fact, the scattering length is still much larger than the natural length $\ell$, and the ground-state energy $E_0^3$ is above the natural value $E_\ell$.

Looking in Fig. [4] at negative values of $a$, it is possible to identify the value of the scattering length $a_+^1$ at which the excited state $E_1^3$ disappears. For $V_\lambda (r)$, this value is $a_+^1 \approx -975$ a.u., whereas using the TBG potential it results $a_+^1 \approx -752$ a.u.. The next interesting point appears at $a_0^1$, when the three-body cluster is no more bound, so that $E_0^3$ approaches zero. Using $V_\lambda (r)$ this happens at $a_0^1 \approx -48.1$ a.u., whereas using the TBG potential alone it is $a_0^1 \approx -43.3$ a.u..

The ratio $a_0^1/a_+^1$ has been predicted to have an universal value $(a_0^1/a_+^1)_{\text{theory}} = 22.7$ [1]; in the only experiment which measures the two thresholds, Ref. [24], the ratio is $(a_0^1/a_+^1)_{\text{experiment}} = 21.1$. In our case we obtain $(a_0^1/a_+^1)_{\text{TBG}} = 17.4$, and $(a_0^1/a_+^1)_{V_\lambda (r)} = 20.3$, which is closer to both theoretical and experimental values. The absolute position of $a_0^1$ is not predicted by the theory of Efimov physics and, in that sense it can be considered as not an universal
FIG. 4. (color online). Efimov plot for \( A = 3 \). We report the ground and excited state energies, \( E_0 \) and \( E_3 \), in units of \( E_\ell \), as a function of \( \ell/a \), both for the modified LM2M2 potential \( V_\lambda(r) \), and for the TBG potential. Following the literature, we really draw the fourth root of the scaled energies as a function of the square root of the scaled-inverse scattering length; using this trick, the ratio between excited and ground energies is greatly reduced, allowing for the graphical representation of both curves on the same scale. We also report the \( A = 2 \) binding energy.

quantity; however, it has been the subject of experimental measurements which give more or less the same value in units of mean scattering length \( \bar{\sigma} = 0.955978 \ell/2 \) for different atoms, \( a_0 = -(9 \pm 1) \bar{\sigma} \) \([31]\). In the present calculations we obtain \( (a^-_\lambda)_{TBG} = -8.9 \bar{\sigma} \) and \( (a^-_\lambda)_{V_\lambda(r)} = -9.9 \bar{\sigma} \).

In addition, we discuss the universal character of the shallow state \( E_3 \). Using the Efimov’s radial law \([5]\) it is possible to obtain an equation for this trimer binding energy as a function of \( a \). It reads

\[
E_3 + \frac{\hbar^2}{ma^2} = \exp \left[ \Delta(\xi)/s_0 \right] \frac{\hbar^2 \kappa^2}{m},
\]
where \( \kappa_* \) is the wave number corresponding to the energy \( E_{3}^{1} = \hbar^2 \kappa_*^2 / m = 0.156 \) mK at the resonant limit and \( \tan \xi = -(mE_{3}^{1}/\hbar^2)^{1/2}a \). The function \( \Delta(\xi) \) is universal and a parametrization in the range \([−π, −π/4]\) is given in Ref. [1]. It verifies \( \Delta(-\pi/2) = 0 \) and, from the very precise result \( \Delta(-\pi/4) = 6.02730678199 \) and \( \Delta(-\pi) \approx -0.89 \), it is possible to determine the values \( a^* \) (at which \( E_{3}^{1} = E_{2} \)) and \( a^1 \) (at which \( E_{3}^{1} = 0 \)). In order to analyze the universal character of the calculated energies \( E_{3}^{1} \) using the TBG and TBG+H3B potential models, in Fig. 5 we compare them to the values of Eq.(4). By construction the energies \( E_{3}^{1} \) at the resonant limit coincide with those of Eq.(4). It is possible to see that the calculated energies using the TBG potential, Fig. 5 upper panel, and TBG+H3B potential, Fig. 5 lower panel, reproduce the universal behaviour close to the resonant limit. The small differences observed at finite values of \( a \), especially close to the critical values \( a^* \) and \( a^1 \), are due to effective-range corrections which are automatically included in our approach. Moreover, \( E_{3}^{1} \) does not disappear in the atom-dimer continuum at \( a^* \) but follows very close the \( E_{2} \) curve from below.

To conclude, we further analyze the universality looking at the correlations between the three-body ground and excited states, as has been proposed in Ref. [32]. In Fig. 6 we trace the square root of the excited-trimer energy, measured from the two-body dimer, in units of the trimer-ground state energy, as a function of the dimer energy, always in units of trimer-ground state energy. The Efimov’s universal-radial law Eq. (4) gives the universal curve in this plot; we see that as far as the dimer is very shallow, the calculated points are very close to the universal curve. They depart from it when corrections due both to finite scattering length and to non-zero effective range become sizeable. This non-universal effect is more important for the TBG case, probably due to the lack of the three-body corrections.

IV. EFIMOV PLOT FOR \( A = 4, 5, 6 \) CLUSTERS

The calculations for the \( A > 3 \) systems are performed using NSHH basis. The method has been recently used to describe up to six nucleons interacting through a central potential [21, 22, 33] and six bosons using a two-body plus a three-body force [17]. The Hamiltonian matrix is obtained using the following orthonormal basis

\[
\langle \rho \Omega | m [K] \rangle = \left( \beta^{(\alpha+1)/2} \sqrt{\frac{m!}{(\alpha + m)!}} L_m^{(\alpha)}(\beta \rho) e^{-\beta \rho/2} \right) Y_M^{LM}(\Omega_N), \quad (5)
\]
FIG. 5. (color online). Comparison between the excited three-body energy $E_3^1$ and the theoretical universal value given by Eq. (4), using the TBG potential (upper panel), and the modified LM2M2 potential $V_\lambda(r)$ (lower panel). The two-body energy $E_2$ calculated with $V_\lambda(r)$ is also shown. The calculated and theoretical curves agree around the resonant limit, and the differences close to
FIG. 6. (color online). Correlations between the ground $E_3^0$ and excited $E_3^1$ states of the trimer. We compare the universal correlation, obtained by means of Eq. (4), to the calculations made using the full $V_\lambda(r)$ potential and the TBG potential. The agreement is good close to the unitary point, where the dimer energy $E_2$ is small. The deviations become significant when the finite effective-range effects become non-negligible.

where $L_m^{(\alpha)}(\beta \rho)$ is a Laguerre polynomial with $\alpha = 3N - 1$ ($N = A - 1$) and $\beta$ a variational non-linear parameter. The function $Y_{[K]}^{LM}(\Omega_N)$ are the HH functions with grand-angular momentum $K$, and total angular momenta $L$ and magnetic number $M$. The Hamiltonian matrix is not constructed, but using properties of HH is expressed as an algebraic combination of sparse matrices, allowing for an efficient research of the lowest eigenvectors/eigenvalues. A full discussion of the NSHH method is given in Refs. [17, 22].

After solving the $A = 3$ problem for bound states, used to fix the strength of the H3B force, we have diagonalized the Hamiltonian for $A = 4, 5, 6$ bodies using the TBG and TBG+H3B potentials. The results are given in Fig. 7 in two scaled-$(a^{-1}, \kappa)$ plots, one obtained with the two-body potential alone (upper panel) and one with the two-body plus
three-body interactions (lower panel). In the first case, with only the TBG potential, we observe that the spectrum of the systems \( A = 4, 5, 6 \) presents two bound states, one deep and one shallow, for all values of \( a \) studied. When the repulsive three-body force is included, the spectrum moves up and we can observe that the excited state \( E_{3}^{1} \) disappears for \( A = 5, 6 \) for negative values of the scattering length as \( a \) approaches \( a_{\mathrm{1}}^{1} \). This fact is better shown in Fig. 8 where the differences \( E_{0}^{A} - E_{1}^{A+1} \) have been plotted as functions of \( \ell/a \). Whereas the differences \( E_{2}^{0} - E_{3}^{1} \) and \( E_{3}^{0} - E_{4}^{1} \) are positive along the whole range, indicating that the states \( E_{3}^{1} \) and \( E_{4}^{1} \) are bound, the differences \( E_{4}^{0} - E_{5}^{1} \) and \( E_{5}^{0} - E_{6}^{1} \) result negatives as \( a \) goes to the negative region, so at some value of \( a \) the excited states \( E_{5}^{1} \) and \( E_{6}^{1} \) are no more bound. The determination of the point where the transition happens can be determined by looking at the convergence of the states \( E_{3}^{1} \) and \( E_{6}^{1} \), as can be seen in Table II where we report the convergence pattern using the TBG+H3B potential for \( A = 4, 5, 6 \) at the point \( \lambda = 0.9 \) where both \( E_{3}^{1} \) and \( E_{6}^{1} \) are not bound. They remain above the \( E_{4}^{0} \) and \( E_{5}^{0} \) threshold respectively. In the table we have shown the three maximum values of \( K \) considered in the present calculations.

Moreover, the fact that the states \( E_{5}^{1} \) and \( E_{6}^{1} \) are bound or not depends also on the range of the three-body force \( \rho_{0} \). In order to analyze this relation, we have varied \( \rho_{0} \) at \( \lambda = 0.9 \) as well as at the unitary limit. For each value of \( \rho_{0} \) the strength of the three-body potential has been fixed to reproduce the trimer binding energy \( E_{3}^{0} \) as before. The results for \( A = 4, 5, 6 \) at \( \lambda = 0.9 \) are shown in Fig. 9. As can be seen, the excited states are recovered as bound states for values of \( \rho_{0} \approx 18 \) a.u.

To make contact with the analysis of Ref. [34] we have calculated \( \sqrt{|E_{4}^{1} - E_{3}^{0}| / |E_{4}^{0}|} = 0.070 \) and \( \sqrt{|E_{3}^{0}| / |E_{4}^{1}|} = 0.434 \) at the unitary limit. These two values correspond to a point in the plot given in Fig. 1 of that reference lying very close to line giving the relation of these two quantities at the unitary limit. In addition, in Fig. 10 we analyze the relation between \( E_{A+1}^{0} \) (upper panel) and \( E_{A+1}^{1} \) (lower panel) with \( E_{3}^{0} \) and \( E_{3}^{1} \) respectively, as a function of the scattering length for \( A = 4, 5, 6 \). We can observe a linear dependence in all cases except for a small curvature in the \( E_{4}^{1} \) vs. \( E_{3}^{0} \) and \( E_{4}^{1} \) vs. \( E_{3}^{1} \) curves close to the point in which \( E_{3}^{0} \) goes to zero. These curves display the universal character of these clusters as their spectrum is determined by two parameters, \( a \) and \( E_{3}^{0} \).

Besides, the universal ratios \( E_{A}^{0} / E_{3}^{0} \) and \( E_{A+1}^{1} / E_{A}^{0} \) can be studied at \( \lambda = 1 \). They are: \( E_{4}^{0} / E_{3}^{0} = 4.5, E_{5}^{0} / E_{3}^{0} = 10.4, E_{6}^{0} / E_{3}^{0} = 18.4 \) and \( E_{4}^{1} / E_{3}^{0} = 1.020, E_{5}^{1} / E_{4}^{0} = 1.009, E_{6}^{1} / E_{5}^{0} = 1.009 \).
1.016. These ratios are in close agreement to those obtained in the literature \cite{23}. At the unitary limit the ratios $E_A^0/E_3^0$ move a little bit from the universal values showing some dependence on the form of the soft potential whereas the ratios $E_{A+1}^1/E_A^0$ show stability. At $\lambda = 0.9743$ they are: $E_4^0/E_3^0 = 5.3$, $E_5^0/E_3^0 = 13.0$, $E_6^0/E_3^0 = 23.4$ and $E_4^1/E_3^0 = 1.026$, $E_5^1/E_4^0 = 1.004$, $E_6^1/E_5^0 = 1.006$.

Finally, using the TBG potential, we have extended the calculations for $A = 4$ and $A = 5$ systems up to the four- and five-particle thresholds in order to calculate the ratios between the different thresholds and to compare our results to previous calculations and experimental outcomes. Our results are summarized in Fig. 11. Denoting with $a_{4,0}^{4,0}$ and $a_{4,1}^{4,1}$ the four-particle thresholds of the ground and excited state respectively, we have $a_{4,1}^{4,1} \approx -39.8$ a.u., and $a_{4,0}^{4,0} \approx -19.6$ a.u.; equivalently, with respect to the three-particle threshold $a_0^0$ we get $(a_{4,1}^{4,1}/a_0^0)_{TBG} \approx 0.92$ for the excited state, and $(a_{4,0}^{4,0}/a_0^0)_{TBG} \approx 0.45$ for the ground states. These values agree very well with what measured in the experiments \cite{24,26} and with what predicted by the theory \cite{7,23,35}. The five-particle thresholds read $a_{5,0}^{5,0} \approx -12.5$ a.u. for the ground state and $a_{5,1}^{5,1} \approx -18.7$ a.u. for the excited state. Equivalently, the ratios with respect the four-particle threshold are $(a_{5,0}^{5,0}/a_{4,0}^{4,0})_{TBG} \approx 0.64$ and $(a_{5,1}^{5,1}/a_{4,0}^{4,0})_{TBG} \approx 0.95$, still in agreement with previous theoretical prediction \cite{23} and with recent experiments \cite{27}.

V. CONCLUSIONS

In the present paper we have discussed the spectrum of bosonic systems up to six particles interacting through a two-body potential having a large two-body scattering length (with respect to the effective range). The three-body scale has been fixed using a scaled Helium-Helium potential. The scope was to extend previous studies on the Efimov physics done in the three- and four-body systems. We have observed that, similarly to the four-body system, the five- and six-body systems present two bound states, one deep and one shallow. It seems that this type of spectrum is to some extend universal depending only on the condition $a \gg r_0$ in the two-body system. This condition produces a geometrical series of bound states in the three-body system and, attached to each of these states, a two-level spectrum has been showed to appear in the four-body system \cite{6,8}. However they are true bound states only in correspondence to the lowest trimer level. The other states appear as resonances embedded in the continuum of four particles. It is possible to introduce a
FIG. 7. (color online). Energies of the $A = 3-6$ ground and excited states, $E_A^0, E_A^1$, as a function of $a^{-1}$, using the two-body gaussian potential (upper panel), and using the two-body plus the hypercentral three-body force (lower panel). In both panels we also give the two-body ground-state energy $E_2$ calculated with the LM2M2 potential.
FIG. 8. The difference $\Delta E = E^0_A - E^1_{A+1}$ for the indicated cases as a function of the inverse of $a$ for the TBG+H3B potential. The particular cases at $\lambda = 1$ and 0.9 as well as at the unitary limit are indicated as vertical lines.

A repulsive three-body force that eliminates all the trimer states below one specific level. In this way, the two-level spectrum of the four-body system attached to this trimer ground state will become true bound states. Also, the universal character of the spectrum will be more evident as the repulsive three-body force will push more and more the particles faraway.

Though the analysis of the bosonic spectrum can follow the strategy illustrated above, in the present paper we follow a different one based on the physics introduced by the two-body potential. In nuclear systems as well as in many atomic systems the two-body interaction has a sharp repulsion at short range followed by a very weak attractive part that produces very shallow dimers as for example the deuteron or the two-helium molecule. The particles are located in the asymptotic region and do not feel the details of the interaction. Therefore, we can introduce a soft potential to be considered as a regularized-two-body contact.
The universal character of the structure of these clusters has been studied using Tjon lines, that means the relation between $E_{A+1}^{0}$ and $E_{A}^{0}$, and between $E_{A+1}^{1}$ and $E_{A}^{1}$. As illustrated...
FIG. 10. Relation between $E_{A+1}^0$ and $E_A^0$ (upper panel), and between $E_{A+1}^1$ and $E_A^1$ (lower panel) for the indicated cases obtained with the TBG+H3B potential along the $(a^{-1}, \kappa)$ plane.
FIG. 11. (color online). Energies of the states $E_3^0$, $E_4^1$, $E_4^0$, $E_5^1$, and $E_5^0$ as a function of $a^{-1}$ for negative values of the scattering length close to the continuum threshold obtained using the TBG potential. The four-particle thresholds are $a_{4,0}^{-1} \approx -19.6$ a.u., and $a_{4,1}^{-1} \approx -39.8$ a.u. The five-particle thresholds are $a_{5,0}^{-1} \approx -12.5$ a.u., and $a_{5,1}^{-1} \approx -18.7$ a.u.

In Fig. 10 we have obtained an almost linear relation between $E_{A+1}^0$ and $E_A^0$ (upper panel) and between $E_{A+1}^1$ and $E_A^1$ (lower panel) in the region from $\lambda = 1$ to 0.9. As the energy of the cluster, $E_A^0$ or $E_A^1$, tends to zero the linear relation is lost.

Since we are describing the lowest bound states, some universal ratios are only approximately verified, though not very far from the values quoted by other groups in $A = 3, 4$. However, in the simple case of TBG we have extended our calculations for $A = 4$ and $A = 5$ up to the four- and five-particle continuum threshold in order to calculate the ratios between the thresholds: the values we obtain in the four-body case, $(a_{4,1}^{-1}/a_0^{-1})_{TBG} \approx 0.92$ and $(a_{4,0}^{-1}/a_0^{-1})_{TBG} \approx 0.45$, and in the five-body system $(a_{5,0}^{-1}/a_4^{-1})_{TBG} \approx 0.64$ and $(a_{5,1}^{-1}/a_4^{-1})_{TBG} \approx 0.95$, are in accord with the ratios that have been previously predicted \cite{36} and measured \cite{27}.
TABLE II. Convergence of the binding energies as a function of the grand angular quantum number $K$ using the TBG+H3B potential at $\lambda = 0.9$, $R_0 = 10$ a.u., and $\rho_0 = 10$ a.u., for clusters of $A$ particles. We also report the number $N_{HH}$ of hyperspherical basis elements corresponding to a given $K$.

| $A$ | $K$ | $N_{HH}$ | $E^0_A$ (mK) | $E^1_A$(mK) |
|-----|-----|---------|--------------|-------------|
| 4   | 36  | 33649   | -166.25945   | -6.55041    |
| 4   | 38  | 42504   | -166.25949   | -6.79163    |
| 4   | 40  | 53130   | -166.25951   | -6.99574    |
| 5   | 26  | 448800  | -532.75811   | -161.96737  |
| 5   | 28  | 724812  | -532.75828   | -162.98374  |
| 5   | 30  | 1139544 | -532.75834   | -163.79689  |
| 6   | 18  | 709410  | -1063.8276   | -513.50956  |
| 6   | 20  | 1628328 | -1063.8311   | -516.42712  |
| 6   | 22  | 3527160 | -1063.8322   | -518.25341  |

Another interesting aspect is the uncertainty introduced by the cutoff in the hypercentral three-body force. We have observed that with the most natural choice $\rho_0 = R$ the shallow states $E^1_5$ and $E^1_6$ result unbound in the last part of the curves. They cross the respective threshold $E^0_5$ and $E^0_6$. Increasing $\rho_0$ they result bound again around $\rho_0 \approx 18$ a.u.. Increasing further $\rho_0$ they become again unbound. This last analysis is somehow inconclusive as to really understand the cutoff dependence we need to vary both cutoff $R_0$ and $\rho_0$ in a coherent way; the dependence on the cutoff will eventually reflect the leading order nature of the potential we are using, pointing to the necessity of going to a higher order in the EFT expansion [19]. Studies along this line are at present under consideration as well as the analysis of the two-level spectrum for cluster with more than six particles.
