Measles re-emerged in a nationwide outbreak in Bulgaria from 2009 to 2011 despite reported high vaccination coverage at national level. This followed an eight-year period since the last indigenous cases of measles were detected. The Bulgarian National Centre of Infectious and Parasitic Diseases collated measles surveillance data for 2009–2011. We analysed data for age group, sex, ethnicity, diagnosis confirmation, vaccination, hospitalisation, disease complications, and death and describe the outbreak control measures taken. The outbreak started in April 2009 following an importation of measles virus and affected 24,364 persons, predominantly Roma. Most cases (73%) were among children <15 years old. Vaccination status was available for 52% (n = 12,630) of cases. Of children 1–14 years old, 22% (n = 1,769) were unvaccinated and 70% (n = 5,518) had received one dose of a measles-containing vaccine. Twenty-four measles-related deaths were reported. The Roma ethnic group was particularly susceptible to measles. The magnitude of the outbreak resulted primarily from the accumulation of susceptible children over time. This outbreak serves as a reminder that both high vaccination coverage and closing of immunity gaps across all sections of the population are crucial to reach the goal of measles elimination.

Introduction

One of the largest outbreaks of measles in the World Health Organization (WHO) European Region in recent years occurred in Bulgaria from 2009 to 2011 and mostly affected Roma communities. The outbreak was first detected in spring 2009 after an eight-year period since the last indigenous measles cases were reported in 2001 [1]. The last major outbreak in Bulgaria occurred in 1991–1992 affecting over 20,000 persons [2]. By December 2009, two preliminary reports on the outbreak were published in the scientific literature [3,4]. Here we provide an overview of the measles outbreak in Bulgaria by analysing measles surveillance data for the whole outbreak period of 2009–2011. We also describe the control measures taken and discuss lessons learnt in relation to the WHO European Regional goal of eliminating measles by 2015 [5].

The measles vaccine was introduced in Bulgaria in 1969 as a monovalent preparation [6]. A two-dose schedule began in 1983. The combined measles-mumps-rubella (MMR) vaccine has been given as the first dose at 13 months of age since 1993, and as the second dose at 12 years of age since 2001. For 2003–2008, the estimated national vaccine administrative coverage with the first MMR vaccine dose ranged from 94.7% to 96.2%, and for the second dose, from 89.4% to 94.3% [7].

Bulgaria forms part of the Balkan Peninsula in southeastern Europe and consists of 28 administrative regions. The latest census carried out in 2011 reported a population of 7,364,570, consisting of three main ethnic groups: Bulgarians (84.8%), Turks (8.8%) and Roma (4.9%). According to these official statistics, the Roma ethnic group numbers 325,343 persons distributed in all regions, but mainly in Montana (12.7% of population), Sliven (11.8%), Dobrich (8.8%) and Yambol (8.5%) [8].

Methods

Epidemiological data

The surveillance of measles in Bulgaria relies on passively reported cases. Measles has been a statutory notifiable disease since 1921 [9], and medical practitioners and medical laboratories are obliged to
immediately report suspected measles cases to the respective Regional Health Inspectorate (RHI) [10]. The RHIs are responsible for the epidemiological investigation of cases, tracing contacts of cases, undertaking control measures in affected families and communities and following up cases to register disease outcome. In 2005, the European Union case definition and case classification were adopted for reporting measles surveillance data [11].

During the outbreak period 2009–2011, case-based data were submitted by all 28 RHIs to the Department of Epidemiology and Communicable Disease Surveillance of the National Centre of Infectious and Parasitic Diseases (NCIPD) in Sofia. In October 2009, a web-based system for direct case-based data entry by the RHIs was implemented, gradually replacing previous manual methods of data collection and submission.

Case-based reports provided data for disease onset dates, date of birth, sex, diagnosis confirmation (i.e. laboratory-confirmed, epidemiologically linked and clinically compatible cases), vaccination, hospitalisation, complications and death. Information on vaccination status was obtained from patient immunisation cards whenever such cards were available. The investigators of the outbreak estimated the number of cases in Roma in parallel to routine data collection. We analysed surveillance data of cases with disease onset from 2009 until 2011 and separated the data by specified age groups.

**Laboratory data**

Laboratory confirmation of cases was carried out by detecting measles IgM antibodies in serum samples submitted mainly to the National Reference Laboratory of the NCIPD and, to a lesser extent, to the laboratories of three regional military hospitals. Clinical specimens of 20 laboratory-confirmed cases were submitted to the WHO European Regional Reference Laboratory for Measles and Rubella at the Robert Koch Institute in Berlin, Germany to determine the genotype of the measles virus (MV) circulating during the outbreak and to identify the likely origin of the virus. The specimens were taken from case-patients in different regions at various points in time (April 2009, May 2009, January 2010, June 2010 and January 2011). Serum was sent for confirmatory testing, and urine specimens and throat swabs were submitted for virus detection, sequencing and genotyping of the MV RNA following standard instructions [12]. IgM and IgG serology tests were carried out as described by Tischer et al. [13] and genotyping was performed according to the WHO recommendation [14]. Sequences were aligned using ClustalW [15] and further analysed using SeqScape 2.5 and MEGA 4.0 DNA analysis software [16]. Phylogenetic trees were constructed using the neighbour-joining method. Genotype assignment was performed by
Figure 2
Incidence of measles cases by region in Bulgaria, 2009–2011

A. 2009 (33.6/100,000 population)

B. 2010 (288.7/100,000 population)

C. 2011 (2.1/100,000 population)

Country incidence per 100,000 inhabitants is indicated in parentheses for each year.
The World Health Organization-named strains of MV genotype D4 (MVs/Enfield.GBR/14.07, MVs/Manchester.GBR/10.09 and MVs/Hamburg.DEU/03.09) circulating in Europe in the same period are also included. The unrooted tree is based on the 456 nt sequence encoding the C-terminus of the MV N gene. The phylogenetic distance scale bar indicates estimated changes per nucleotide.

Measles virus (MV) strains detected in Bulgaria are shown in bold. The obtained sequence data, genotype information and the official WHO MV sequence name and relevant epidemiologic data were submitted to the WHO database, Measles Nucleotide Surveillance (MeaNS) database [18] and GenBank.

Incidence and case-fatality calculations
Incidence was calculated with the number of measles cases as the numerator and the country and region population, obtained from the National Statistical Institute, as the denominator [19]. Unless otherwise specified, we expressed incidence per 100,000 inhabitants per year, and cumulatively for the three-year period 2009–2011. Case-fatality ratio (CFR) was expressed as the number of measles-related deaths per 100 cases for the three-year period 2009–2011.

Ethical approval or informed consent was not considered to be necessary for this analysis since the data were collated under the Ministry of Health’s Regulation 21 on epidemiological surveillance and control of communicable diseases in Bulgaria [10].

Results
Overall, 24,364 cases of measles were recorded between April 2009 and December 2011 corresponding to a cumulative incidence of 326 per 100,000 inhabitants over the three-year period. The outbreak reached its peak by March 2010 (monthly incidence: 73 per 100,000 inhabitants) when all 28 regions of Bulgaria were affected (Figure 1). Figure 2 shows the incidence of measles by region and by year, 2009–2011. During the three-year period of the outbreak, the highest incidence (>500 cases/100,000 inhabitants) was registered in the regions of Sliven (838.8/100,000 inhabitants), Montana (716.7), Yambol (689.5), Haskovo (681.8), Pazardjik (556.1) and the Sofia region (523.0).

Of the total, 3,958 cases (16%) were laboratory-confirmed by detecting measles IgM antibodies in serum samples, 8,233 (34%) cases were epidemiologically linked to a laboratory-confirmed case and 12,173 (50%) cases were classified as clinically compatible cases.

Of the total, 12,472 (51%) were males. The median age of the cases was seven years (range: one day to 71 years). Infants had the highest age-specific incidence per 100,000 inhabitants of 5,457 followed by 2,008 in children aged one to four years. Table 1 shows the age distribution of cases. Data on vaccination status were available for 52% (n=12,630) of all reported cases (Table 2). Of the cases vaccinated with one MMR vaccine dose (n=6,167; 49%), 11% (n=656) were vaccinated more than one year before the onset of disease.

Of the total, 21,821 (89.6%) cases were estimated to occur among Roma. Indeed, the outbreak was first detected in April 2009 among the Roma community in the north-eastern part of the country involving the regions of Razgrad, Shumen, Silistra and Dobrich. The index case was identified as member of the Roma community aged between 20 and 30 years, who fell ill in March 2009, a few days after returning home from Hamburg, Germany. Initial symptoms included high fever, cough, coryza and malaise followed by the development of a rash three days later. The clinical suspicion of measles was confirmed by serological tests. Three of the index case’s family members subsequently acquired laboratory-confirmed measles. At the outset, the detection of further cases was delayed.

Mortality, hospitalisation and complications
Measles-related deaths were recorded in 24 patients (14 laboratory-confirmed, five epidemiologically linked, and five clinical cases), corresponding to a CFR of 0.1 per 100 measles cases. The deaths occurred as a consequence of severe complications of measles: 19 cases (79%) suffered acute encephalitis. The median age at death was 1.71 years (range: 32 days–54 years). Infants and cases aged ≥25 years had a higher CFR (0.28% and 0.2%, respectively) compared with cases aged 1–24 years (0–0.09%). All deaths, with the exception of two cases of Bulgarian ethnicity aged between 40 and 49 years of age, occurred in Roma.

Data on hospitalisation status were available for 92% (n=22,296) of cases, of whom 86% (19,167) were hospitalised. Among those hospitalised, 88% (16,854) were aged <19 years. Information on measles-related complications was reported in 86% (21,039) of cases, of whom 38% (8,074) reported complications (Table 3).
were offered a dose of MMR vaccine, irrespective of their immunisation status or age. Between April 2009 and December 2010, 188,700 MMR vaccine doses were administered free of charge by the Ministry of Health (MoH) through routine immunisation services.

Special outreach teams composed of local epidemiologists and health inspectors in collaboration with Roma health mediators (RHM) were deployed to vaccinate Roma communities. RHM are usually young adult members of the Roma community who are specially educated in the health field and trained to liaise between the community and healthcare facilities [23]. RHM assisted vaccination teams by improving communication between the team members, and leaders and members of the Roma community; by informing Roma leaders and parents of the benefits of vaccinations and by facilitating the transport of children to immunisation centres.

The MoH recommended that patients with measles living in crowded households be admitted to hospital to ensure better conditions for treatment and care and to minimise the spread of the disease in the poor neighbourhoods.

Outbreak communication
Activities to increase awareness of the outbreak among the public and healthcare professionals were undertaken. When the outbreak started spreading beyond the north-eastern part of Bulgaria, the MoH issued a press release on the emerging outbreak, and provided information on the surveillance and immunisation activities. The MoH website also provided regularly updated information. Information leaflets were also distributed to the general population, and specifically to Roma, via their religious and community leaders. Information packages including a description of measles, updates on the status of the outbreak and a call to the public to be vaccinated were also regularly supplied to the media.

The MoH distributed official circular letters to medical professionals in April 2009, August 2009 and February 2010. Medical professionals were requested to pay special attention to patients presenting with rash and fever, to reach out to parents to explain the benefits of vaccination, and to ensure timely routine MMR vaccination of children.

Additional measures
The MoH regularly informed the WHO Regional Office for Europe and the European Centre for Disease Prevention and Control (ECDC) on the outbreak situation and measures taken to mitigate it. In February 2010, experts from both organisations worked closely with the Bulgarian public health authorities to assess the outbreak and potential risk for further spread beyond the country, to review the current vaccination strategies and MMR vaccine supplies in the country for efficient control measures and to provide guidance on long-term strategies that address vaccination among

### Table 1
Age distribution of measles cases (n = 24,364) and measles-related deaths (n = 24), Bulgaria, 2009–2011

| Age group (years) | No. of cases (n = 24,364) (% of total reported cases) | Deaths (n = 24) | Case-fatality ratio % |
|------------------|------------------------------------------------------|----------------|-----------------------|
| <1               | 3,891 (16)                                           | 11             | 0.28                  |
| 1–4              | 5,858 (24)                                           | 5              | 0.09                  |
| 5–9              | 3,473 (14)                                           | 2              | 0.06                  |

|                   | ≥20 years (n = 245) | 63 | 25.7% | |
| Vaccinated with single dose | 19 | 0.6% | 2,085 | 58.7% |
| Vaccinated with at least two doses | 3 | 101 | 151 | 7.4% |

* Of the cases vaccinated with one MMR vaccine dose (n = 6,167), 11% (n = 656) were vaccinated within 14 days before onset of measles.

vulnerable populations. Timely communication through these organisations alerted other countries to respond to any imported cases. In spring 2010, Bulgaria used the opportunity of the 2010 European Immunisation Week to advocate for and gain high-level political commitment to immunisation.

Discussion
Our assessment of the outbreak relied on data collected though routine surveillance based on passively reported cases. Such systems are notorious for under-reporting and incompleteness of data. On the other hand, some over-estimation of cases may have occurred since half of these were not confirmed by laboratory testing or were epidemiologically linked, and patients with other rash- and fever-like illnesses may have been wrongly reported as measles cases. Furthermore, since there are no provisions for data collection by ethnicity, the investigators could only estimate the number of Roma cases based on their observations. Moreover, our analysis on vaccination status was limited to the 48% of cases with data on this variable. Despite these limitations, the data we present strongly indicate that the Roma ethnic group was particularly susceptible to measles. Measles outbreaks have also emerged in Roma communities in other European countries [24–27]. As in Bulgaria, their vulnerability was brought to light when the MV was imported from abroad.

Similar to the measles outbreak in neighbouring Greece in 2005–2006 [25], sub-optimal immunisation coverage among Roma children largely contributed to this outbreak. A cross-sectional survey of coverage with routine immunisations in children born in 2006 in the region of Sofia showed that out of 324 Roma children eligible for immunisation, only 68.8% (n = 223) received the first MMR vaccine dose [28].

According to a seroprevalence survey that included 1,666 individual samples collected in 2001–2004, Bulgaria was one of several European countries that had not met the WHO targets for measles susceptibility [29]. For the 2–4 and 5–9 year-old age groups, 30.4% and 25.9% respectively, were seronegative for measles. The WHO susceptibility targets for these consecutive age groups are <15% and <10% [30]. A seroprevalence survey on 249 hospitalised non-measles patients aged ≤ 65 years conducted in 2008 by NCIPD in Burgas, Bulgaria, revealed that 51 patients (20.5% (95% CI 15.6–27.0%)) were measles IgG-negative [31]. These results suggest that the population susceptibility to measles at national level is probably higher than that indicated by the reported minimum of 94.7% immunisation coverage for the first dose of routine measles vaccination for 2003–2008 [7]. In Bulgaria, immunisation coverage is estimated using the administrative method as a proportion of the number of routinely administered vaccine doses by eligible birth cohorts of the previous year. An overestimation of the coverage may have resulted if the denominator did not include all the population targeted for vaccination. Lack of registration of Roma children with a healthcare facility has, indeed, been documented [32].

The magnitude of the outbreak underlined the substantial number of susceptible children that had accumulated gradually since the last major nationwide outbreak in 1991–1992. During the health reforms of the 1990s there were a number of challenges in ensuring access to quality child health services, including immunisation, to the Roma minority [33]. In addition, since primary vaccine failure is reported to occur in 2–5% of vaccinated children after the first measles-containing vaccine (MCV) dose given at 12 months of age [34], the accumulation of non-responders to the first MCV dose probably also contributed to the pool of susceptible individuals. This also explains, at least in part, the relatively large proportion (49%, n = 6,167) of cases reported having received one MCV dose, since in Bulgaria, the second dose is not given until 12 years of age. Other potential contributing factors may include incorrect documentation on vaccination status and issues with the cold chain. Nonetheless, 11% (n = 656) of these cases developed measles within 14 days of vaccination, which was probably administered as part of the outbreak control measures while they were in the incubation period following infection with MV.

Roma communities are often separated from the mainstream of social and economic life in segregated, often crowded, neighbourhoods; however, there is intensive contact between the different communities.
The RHIs played a key role in executing control measures despite financial and human resource limitations. Supplementary immunisation activities were instigated to first target Roma in the affected regions and later the general population. Concurrently, healthcare workers emerged as a group at risk of acquiring measles. This necessitates clear recommendations to adhere to infection control measures in healthcare settings and to ensure healthcare workers are adequately protected.

The Bulgarian health authorities implemented the necessary control measures with coordination, support and directives from the MoH. Regular communication with the WHO Regional Office for Europe and the ECDC allowed transparency, dialogue and advice to be sought. The large number of reported cases posed a major challenge to the surveillance system that relied on time-consuming manual methods of data collection and submission. With the support of the WHO Regional Office for Europe these methods of data collection were replaced by a web-based system allowing direct and timely case-based data entry by the RHIs.

The outbreak in Bulgaria has served as another reminder to all countries of the WHO European Region of their commitment to eliminate measles [43]. To reach this goal every country needs to ensure that their immunisation programmes achieve and maintain high vaccination coverage (≥ 95%) with two MCV doses, while also identifying and closing immunity gaps across all population segments.

In conclusion, a nationwide outbreak of measles in Bulgaria during 2009–2011 resulted from the accumulation of a large susceptible population despite reported high measles vaccination coverage at national level. The outbreak particularly highlighted the vulnerability of Roma communities in Bulgaria to measles. In addition to low coverage among Roma, accumulation of non-responders to the first MCV dose could have also contributed to the pool of susceptible individuals. The development and implementation of strategies to identify susceptible individuals and close immunity gaps across all segments of the population are of vital importance in relation to reach the measles elimination goal.

Acknowledgements

We thank all epidemiologists from the Bulgarian Regional Health Inspectorates of all the 28 regions of Bulgaria for providing essential epidemiological data. We extend our gratitude to Nino Khetsuriani (Centers for Disease Control and Prevention, Atlanta, Georgia, USA) for her valuable comments and suggestions, Myriam Ben Mamou (WHO Regional Office for Europe) for her assistance with providing references, and Catharina de Kat-Reynen (WHO Regional Office for Europe) for editorial suggestions and the WHO Regional Office for Europe for funding and supporting the development of the Bulgarian measles, mumps and rubella web-based system.
for data entry and analysis. We are also grateful to Ajay Goel and Henrik Bang (Statens Serum Institut, Denmark) for assisting with data management.

Conflict of interest
None declared

Authors’ contributions
LM co-ordinated the measles surveillance activities in Bulgaria, collated data and with MM, analysed data and reviewed literature. MM had the primary responsibility of writing the manuscript. AM and SS performed molecular characterisation of the measles virus and produced the related graphic. NG, ZM, AK and MK provided valuable comments and suggestions at various stages in the preparation of this manuscript.
