Drechslera rostrata
Eurotium tonophilum
Di-2-ethylhexyl phthalate
1,8-Dihydroxy-3-methoxy-6-methyl-anthraquinone
MTT assay
Human cancer cell lines

A B S T R A C T

Total extracts of Drechslera rostrata and Eurotium tonophilum in addition to two isolated compounds from their cultures [di-2-ethylhexyl phthalate (H1) and 1,8-Dihydroxy-3-methoxy-6-methyl-anthraquinone (H2)] were tested for their antitumor activity using four human carcinoma cell lines. Antitumor activity was assessed by performing MTT assay to check the % cell viability. The % viability of HCT-116 (colon carcinoma), HeLa (cervical carcinoma), HEP-2 (larynx carcinoma) and HepG-2 (hepatocellular carcinoma) cells decreased after treatment with Drechslera rostrata and Eurotium tonophilum extracts, these effects were ranged from 059.0 ± 0.1 to 217.0 ± 0.3 μg/ml on all types of cancer cells. The best activity was recorded for Eurotium tonophilum extract (054.5 ± 0.3, 059.0 ± 0.5 and 059.0 ± 0.1 for HEp-2, Hela, and HepG-2 respectively). The isolated compounds (H1&H2) were found to be responsible about the activities because they recorded the lowest IC_{50} on tested cell lines with range of 9.5–20.3 μg/ml. Vinblastine sulphate was used as a reference standard and showed in vitro antitumor activity. This study demonstrated that all extracts and isolated compounds have antitumor activity against HCT-116, HeLa, HEP-2 and HepG-2 cells.

1. Introduction

Cancer is a group of diseases involving abnormal cell growth with the potential to invade or spread to other parts of the body and has become the most important health problem due effect on morbidity and mortality (Martin et al., 2013). Normal cancer chemotherapy has multidrug resistance (MDR) caused by overexpression of integral membrane transporters, which can decrease drug buildup inside the cell. MDR cells are resistant to cytotoxic effects of various chemotherapeutic agents (Rueff et al., 2002; Shi et al., 2007). Developing new anticancer agents that are efficient to MDR cells is a reasonable approach to overcome MDR (Zhang et al., 2010).

Anticancer drugs can destroy tumors and arrest cancer progress but cancer treatment may damage healthy cells and tissues also (Liu et al., 2015). Thus, new anticancer agents from natural products are expected to play an important role in the development of more effective and safer drugs to inhibit the onset of cancer (Greenwell and Rahman, 2015).

Fungi contain some of the most unbelievable chemical factories known today. Accordingly, numerous bioactive agents such as mycotoxins, anticancer and antifungal agents have been reported in the literature (Frisvad, 2015; Frisvad et al., 2004). Despite there are many new compounds revealing many biological activities but still being discovered, including well-known metabolites such as griseofulvin (Panda et al., 2005; Rebacz et al., 2007; Ho et al., 2001; Ronnest et al., 2009). The Large combinatorial libraries of fungal active compounds have not provided the estimated number of new chemical entities in addition it couldn’t explains why the field of natural products is currently assuming new prominence (Barnes et al., 2016). It has been estimated that approximately 1.5 million or likely as many as 3 million fungal species exist on
Earth, of which only around 100,000 species have been described so far (Sharma et al., 2016; Hawksworth, 2012). A multitude of new species are likely to be discovered from miscellaneous habitats, such as soils and tropical forest plants, associated to insects and in the aquatic environment (Bladt et al., 2013).

Therefore, our aim was to study the antitumor activity of the extracts and isolated compounds from Drechslera rostrata and Eurotium tonophilum in human cancer cells.

2. Materials and methods

Fungi under investigation [Drechslera rostrata (DSM 62596) and Eurotium tonophilum (ATCC 16440)] were pushed from DSMZ (German Collection of Microorganisms and Cell Cultures). For culturing the fungal malt extract agar (MEA) medium (Zain et al., 2012) was used for cultivation of the fungal.

2.1. Fungal extraction and isolation of compounds

The mycelia mat (800 g) of each fungus (D. rostrata and E. tonophilum) was separately harvested, washed with distilled water, and extracted by refluxing in boiled ethanol (2 liter) for 3 h and filtered off, this process was repeated for three times. The combined filtrates were centrifuged under reduced pressure at temperature not exceeding 35 °C. The obtained residues of D. rostrata (88 g) and E. tonophilum (90 g) were symbolized as D1 & E1.

The total extracts (22 g each) were separately dissolved in ethanol and applied on top of column (5 × 15 cm) packed with 100 g silica gel. Elution was carried out using chloroform - methanol (95:5 v/v), 150 fractions (100 ml each) were collected; each was concentrated under reduced pressure to a small volume. Similar fractions were collected together and re-applied on to other columns for final purification. H1 was isolated (Awaad et al., 2014).

The sub-fractions ET (9) were dissolved in ethanol and applied on the top of column (5 × 15 cm) packed with 360 g silica gel G. Benzenz: ethyl acetate: Methanol: Water (30: 5: 4 v/v/v), 110 fractions (100 ml each) were collected; each was concentrated under reduced pressure to a small volume. Similar fractions were collected together and re-applied on to other columns for final purification. H1 was isolated (Awaad et al., 2014).

2.2. Cell culture

The tested human carcinoma cell lines were obtained from the American Type Culture Collection (ATCC, Rockville, MD). The cells were grown on RPMI-1640 medium supplemented with 10% heat inactivated fetal calf serum, 1% L-glutamine, and 50 μg/ml gentamycin. The cells were maintained at 37 °C in a humidified atmosphere with 5% CO₂ incubator (Shel lab 2406, USA) and were sub-cultured two to three times a week.

2.3. Antitumor activity assay

For antitumor assays, the tumor cell lines were suspended in buffer and added to the medium at concentration 5 × 10⁴ cell/well in Corning® 96-well tissue culture plates, then incubated for 24 h. The tested compounds were then added into 96-well plates (six replicates) to achieve seven concentrations for each compound. Six vehicle controls with media or 0.5% DMSO were run for each 96 well plate as a control. After incubating for 24 h, the numbers of viable cells were determined by the MTT test. Briefly, the media was removed from the 96 well plate and replaced with 100 μl of fresh culture RPMI 1640 medium without phenol red then 10 μl of the 12 mM MTT (Sigma) stock solution (5 mg of MTT in 1 ml of PBS) to each well including the untreated controls. The 96 well plates were then incubated at 37 °C and 5% CO₂ for 4 h. An 85 μl aliquot of the media was removed from the wells, and 50 μl of DMSO was added to each well and mixed thoroughly with the pipette and incubated at 37 °C for 10 min. Then, the optical density was measured at 590 nm with the microplate reader (SunRise, TECAN, Inc, USA) to determine the number of viable cells.

The percentage of viability was calculated as:

\[
\text{% of viability} = \left( 1 - \frac{\text{ODt}}{\text{ODc}} \right) \times 100\%
\]

Where ODt is the mean optical density of wells treated with the tested sample and ODc is the mean optical density of untreated cells.

The relation between surviving cells and drug concentration is plotted to get the survival curve of each tumor cell line after treatment with the specified compound. The 50% inhibitory concentration (IC₅₀), the concentration required to cause toxic effects in 50% of intact cells, was estimated from graph plots of the dose response curve for each conc. using GraphPad Prism software (San Diego, CA, USA) (Mosmann, 1983; Elaesser et al., 2011).

2.4. Statistical analysis

Data were expressed as mean ± S. D. Statistical analysis was done by using GraphPad Prism 5 (San Diego, CA, USA).

3. Results and discussion

3.1. Isolated compounds

Two compounds were isolated from mycelial mat of D. rostrate (H1) and E. tonophilum (H2) using different spectroscopic analysis including ¹H-NMR, ¹³C-NMR, HMBC, HMQC and EI-MS (Fig. 1).

H1: Colorless oil, (950 mg), Rₘ = 0.40 in system (n-hexane- benzene 30:70 v/v), b.p. = 385 °C; The ES-MS at m/z 413 [M + Na]+ (100%), 390 g/mol, [M + H]⁺ ion 391 (9.1), [M⁺] 390, [M⁺ 2 + Na⁺]+ 803 (5.4%). ¹H-NMR in CDCl₃: δ: 0.94 (3H, t, J = 7.2 Hz, H8, H8'), 0.93 (3H, t, J = 7.2 Hz, H10, H10'), 1.25–1.40 (6H, (H-5,5'), (H-6, 6' and (H-7,7'), 1.50–1.42 (4H, m, H-9,9'), 1.69 (2H, septet, J = 6 Hz, H-4, 4'), 4.10 (2H, dd, J_H3_H6 = 6.1 Hz and J_H3_H6 = 10.9 Hz, H-3',3'b), 4.26 (2H, dd, J_H5_H5' = 5.7 Hz and J_H5_H5' = 10.9 Hz, H-3,3'a), 7.6 (2H, m, H4,H5) and 7.74 (2H, m, H3, H6). ¹³C-NMR and DEPT in CDCl₃: δ: 10.97 (C-10,10') and 14.07 (C-8,8') δ: 22.97 (C-7,7'), 23.24 (C-9,9'), 28.90 (C-6,6') and 30.35 (C-5,5'), δ: 38.72 (C-4,4') δ: 128.83 (C-3,6) δ: 132.38 (C-1, C-2) δ: 168.10 (C-1'). Spectroscopic data analysis (¹H-NMR, ¹³C-NMR and DEPT COSY, HSQC and HMBC) was compared with published (Rao et al., 2000; Amade et al., 1994); this compound is identified as; di-2-ethylhexyl phthalate.
H2: Orange to yellow needle crystals (550 mg), Rf = 0.67 in system (Benzene-chloroform 80:20 v/v), m.p. = 204–205°C. 1H-NMR in CDCl3, showed at δ 2.45 (S, CH3) at δ (3.94, S, OCH3), at δ 6.73 (1H, d, J = 2.55 Hz, H-2), δ 7.1 (1H, S, H-7), δ 7.41 (1H, d, J = 2.55 Hz, H-4), δ 7.55 (1H, S, H-5) at 12.12, (S, 8-OH), at 12.32 (S, 1-OH). 13C-NMR and DEPT; the 13C-NMR in CDCl3, δ 22.20 (CH3-6) and δ 56.12 (OCH3-3) δ 106.76, 108.25, 121.32 and 124.53 δ 110.09, 113.93, 133.22, 135.23, 148.47, 162.49, 165.18, 166.53, 181.05, 190.78. By comparing the obtained spectroscopic data analysis with published (Jo et al., 2011), this compound is identified as 1,8-Dihydroxy-3-methoxy-6-methyl-anthraquinone.

3.2. Antitumor activity assay

The anticancer activity of Drechslera rostrata, Eurotium tonophilum extracts in addition to the isolated compounds H1 & H2 were evaluated on the basis of its protective effects on cell viability is shown in Figs. 2–5 & Table 1. The anticancer activity of Vinblastine sulphate as a reference standard was also studied and shown in Fig. 6 & Table 1.

Drechslera rostrata extract showed an IC50 value of 104.0 µg/ml, 78.7 µg/ml, 117.0 µg/ml and 217.0 µg/ml against colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells, respectively.

Eurotium tonophilum extract showed an IC50 value of 125.0 µg/ml, 59.0 µg/ml, 54.5 µg/ml and 59.0 µg/ml against colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells, respectively.

H1 showed an IC50 value of 9.5 µg/ml, 17.5 µg/ml, 20.3 µg/ml and 10.4 µg/ml against colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells, respectively.
H2 showed an IC50 value of 18.6 μg/ml, 9.5 μg/ml, 16.1 μg/ml and 19.7 μg/ml against colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells, respectively.

Reference standard, Vinblastine sulphate showed an IC50 value of 3.5 μg/ml, 59.7 μg/ml, 21.2 μg/ml and 2.93 μg/ml against colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells, respectively.

Drechslera rostrate extract, Eurotium tonophilum extract, H1 and H2 showed a dose-dependent inhibitory effect on the growth of colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells.

4. Discussion and conclusion

Natural products have provided the most important successes in the chemotherapy of cancer. Most of the major anticancer compounds are obtained from natural products which includes plants and microorganisms (Olano et al., 2009). Earlier reports showed that the secondary metabolites from fungi provided an important group of new biological agents and having low toxicity on normal cells. Further, the secondary metabolites are low molecular weight compounds, exhibiting a potential anticancer activity. It is wondered that biological activity of the fungi extracts is associated with the endogenous environment of the plant (Engel and Evens, 2006). It is observed that the existing anticancer drugs have a limited selectivity and high toxicity.

Researchers in the molecular and cellular biology are regularly identifying novel potential targets, which are specific or selective for cancer cells (Kohn et al., 1996). The effect of the extracts of endophytic fungi isolated from mangrove plants on the cancer cells as well as their effects on topoisomerase was reported (Cai et al., 2010). The anticancer activity of compounds isolated from marine endophytic fungus Aspergillus terreus was reported (Suja et al., 2014). A new Topo I isomerase inhibitor, (+)-3, 3, 7, 7, 8, 8-hexahydroxy-5, 5-dimethylbianthraquinone was recently isolated from mangrove endophytic fungi (Tan et al., 2008).

The di-esters of 1, 2-benzenedicarboxylic acid (phthalic acid), commonly known as phthalates, are a group of man-made chemicals (Hauser and Calafat, 2005).

There are many researches reporting isolation of phthalates from bacterial strains, streptomycetes, fungi, algae and plants. These compounds seem to play an important role in many areas (Prabukumar et al., 2015).

Although these compounds are not novel isolates, it is the first time that their antitumor activity is described in colon carcinoma cells, cervical carcinoma cells, larynx carcinoma cells and hepatocellular carcinoma cells.

In our study, effects on cell viability/proliferation were assessed by an MTT assay and all extracts and compounds tested significantly decreased cell viability and proliferation in one or more of the cell lines tested. The anti-proliferative effect of the compounds could be due to induction of cell death and/or cell cycle arrest.

Hela (cervical carcinoma) cell line was the most sensitive line to Drechslera rostrata extract and H2. HEp-2 (larynx carcinoma) cell line was the most sensitive line to Eurotium tonophilum extract and HCT-116 (colon carcinoma) cell line was the most sensitive line to H1 and Vinblastine sulphate. In fact, almost all the extracts and compounds, proved to have an antitumor activity in a dose-dependent manner in these cell lines. The IC50 value of H1 and
Fig. 4. The antitumor activity of compound H1 on four cell lines.

Fig. 5. The antitumor activity of compound H2 on four cell lines.
H2 are found to be most promising compared to the extracts in all the four cell lines. The IC\textsubscript{50} value of H1 was found to be 9.5 µg/ml against colon carcinoma cells. The IC\textsubscript{50} value of H2 was found to be 9.5 µg/ml against cervical carcinoma cells.

This study demonstrates that the compounds H1 and H2 obtained from the fungus \textit{Drechslera rostrata} (DSM 62596) and \textit{Eurotium tonophilum} (ATCC 16440) have significant antitumor properties, as evaluated by performing MTT assay to check the % cell viability against HCT-116 (colon carcinoma), HeLa (cervical carcinoma), HEp-2 (larynx carcinoma) and HepG-2 (hepatocellular carcinoma) cells.
