1006. Diagnostic accuracy of CSF cell index and corrected CSF white blood cell count in healthcare-associated ventilriculitis and meningitis after intracranial hemorrhage

Helena Jenkinson, MD; Onaizah Habib, MD; Lucrecia Salazar, MD; and Rodrigo Hashum, MD, MPH, MPhil. 1University of Texas McGovern Medical School at Houston. Houston, Texas, USA; 2Division of Infectious Diseases, University of Texas McGovern Medical School at Houston, Houston, Texas, USA; 3Division of Infectious Diseases, University of Texas Health Science Center at Houston, McGovern Medical School, Houston, Texas.

Session: 137. Adult Cns Infection
Friday, October 6, 2017: 12:30 PM

Background. The diagnosis of healthcare-associated meningitis and ventriculitis (HCAVM) in patients with intracranial hemorrhage (ICH) is challenging. The purpose of this study was to evaluate the diagnostic accuracy of routine cerebrospinal fluid (CSF) studies including a cell index and a corrected white blood cell (WBC) count.

Methods. Case control study of adult patients with the diagnosis of ICH and HCAVM at a large tertiary care hospital in Houston, Texas from 2003 to 2016. Cases were defined as patients with ICH and HCAVM as documented by a positive CSF culture. Controls were selected as patients with ICH without evidence of HCAVM, no previous antibiotic therapy and a negative CSF culture. Cases and controls were matched 1:2 by age, Glasgow Coma Scale (GCS) and Apache II scores. Cell index was calculated using the following formula: (CSF leukocytes / CSF erythrocytes) / (blood leukocytes / blood erythrocytes). Corrected WBC count was calculated using the following formula: CSF leukocytes - (CSF erythrocytes/1,000). Area under the curve of receiver operating characteristic (AUC-ROC) and 95% confidence interval (CI) for CSF cell index greater than or equal to absolute value of 1, corrected CSF WBC count greater than 5 K/µL, CSF lactate greater than 4 mM/L, and CSF glucose less than 40 mM/L, respectively, were calculated in order to determine the accuracy of these predictions.

Results. A total of 120 patients with ICH were included in this study; 40 patients had proven HCAVM whereas 80 patients had ICH with no evidence of HCAVM. Matching of cases and controls by age, GCS, and Apache II score was appropriate (p>0.05). The AUC-ROC values for CSF cell index, corrected CSF WBC count, CSF lactate, and CSF glucose were all low (0.609 (95% CI = 0.494 - 0.768), 0.731 (95% CI = 0.589 - 0.872), 0.719 (95% CI = 0.573 - 0.864), and 0.609 (95% CI = 0.449 - 0.768), respectively.

Conclusion. This study demonstrated poor accuracy of CSF cell index, corrected CSF WBC count, CSF lactate, and CSF glucose in diagnosis of HCAVM after ICH.

1007. Achieving Optimal Specialty Cerebrospinal Fluid (CSF) Testing: Are Electronic Medical Record Order Sets Helpful?

Jessica L. Abrantes-Figueiredo, MD; Virginia M. Bieluch, MD, FIDSA; and Michael D. Nair; PharmD, BCPS (AQ-ID). 1University of Connecticut Health Center, Farmington, Connecticut, USA; 2Medicine, Hospital of Central Connecticut, New Britain, Connecticut, USA; 3University of Connecticut School of Pharmacy, Storrs, Connecticut.

Session: 137. Adult Cns Infection
Friday, October 6, 2017: 12:30 PM

Background. Specialty PCR testing has become available for lumbar puncture to determine the cause of infectious meningitis and encephalitis. Testing with low pre-test probability may increase antimicrobial therapy while results are pending and create increased direct costs. We aim to describe the appropriateness of testing before and after the implementation of electronic medical record (EMR) order sets designed to reduce excessive testing of CSF by creating two lists of tests: (1) a routine panel for all patients and (2) a list of optional specialty tests designed to be utilized after the nucleated cells are reviewed.

Methods. A retrospective study of adult patients undergoing lumbar puncture with suspicion for CNS infection pre-and post-implementation of EMR order sets from January 2016–March 2017. Consecutive patients with complete charts were reviewed from a tertiary care center. Data collected included demographics, co-morbid conditions, clinical presentation, and lumbar puncture results. The primary outcome of interest was the frequency of CSF specialty testing in patients with ≤10 nucleated cells/µL in the CSF.

Results. Two hundred patients had ≤10 nucleated cells/µL in the CSF (n = 108 in pre-EMR group; n = 92 in post-EMR group). Of these patients 74% and 48.9% had Herpes Simplex Virus (HSV) PCR testing done pre and post EMR changes (P < 0.05). Enterovirus PCR testing remained similar among both groups (37% pre-EMR order sets vs. 36.9% post-EMR order sets, P = 0.99). Lyme PCR testing decreased between pre- and post-EMR order sets (9.7% vs. 2.6%, P = 0.005). Herpes encephalitis PCR testing also dropped significantly from 26.9% to 7.6% (P < 0.05). All specialty PCR testing that was performed on patients with ≤10 nucleated cells/µL in the CSF were negative. Paradoxically, HSV antibody testing increased post-implementation of EMR order sets (21.7% vs. 0%, P < 0.05). Total costs of tests on average decreased by $78.71 per patient post EMR changes.

Conclusion. In this cohort, CSF specialty testing was common but decreased after EMR changes. Laboratory stewardship can be improved with EMR changes but further education is needed to prevent unnecessary tests. Unwanted tests (HSV antibodies) may be increased as prescribers are unable to locate familiar tests.

1008. Brain Abscess Risk Associated with Genotypic Polymorphism of the Matrix Metalloproteinase-1, -2, -3, and -9 in North Indian Population

Priyanka Mishra, MSc; Kashi Nath Prasad, MD; Kamini Singh, PhD; Rabi Narayan Sahu, MS; Swayam Prakash, PhD; and Bal K Ojha, MS. 1Microbiology, Sanjay Gandhi Post Graduate Medical College, Lucknow, India; 2Microbiology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.; 3Neurosurgery, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.; 4Neurosciences, Lucknow, India.; 5Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.; 6Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Session: 137. Adult Cns Infection
Friday, October 6, 2017: 12:30 PM

Background. Brain abscess develops in response to a parenchymal infection due to pyogenic bacteria. MMPs (matrix metalloproteinases) play vital role in many infectious and central nervous system (CNS) diseases. The present study evaluated the association of specific alleles/ genotypes of MMP-1, -2, -3, and -9 with brain abscess.

Methods. A total of 100 brain abscess patients and 100 healthy controls were included in the study. Predisposing factors were identified in 70 brain abscess patients. Out of 100 brain abscess patients, 66 were culture positive. MMP-1: 1607 1G/2G, MMP-2: C-1306-T, MMP-3: -1171 5A/6A, and MMP-9 C-1562T genotypes were detected by PCR-RFLP. Levels of these MMPs were determined in patients’ sera by ELISA and correlated with different genotypes.

Results. The genotypes distributions of MMP-1:1607 1G/2G, MMP-2: C-1306-T, MMP-3: -1171 5A/6A, and MMP-9 C-1562T polymorphisms lead to increased production of these molecules, which appear to be a risk for the development of brain abscess in North Indian population.

Session: 137. Adult Cns Infection
Friday, October 6, 2017: 12:30 PM

Background. Acute febrile illness is a common reason for hospitalization in many developing countries, including Indonesia. While patients can often be categorized and managed based on clinical presentations, diagnostic capacity in these countries remains limited, leading to poor patient outcomes. For patients with central nervous system (CNS) infections, identifying the underlying etiologies is particularly important to prevent lifelong neurological complications and death.

Methods. As part of a study conducted at 8 top-referral hospitals across Indonesia from 2013 to 2016, 114 of 1,486 enrolled subjects presented with an acute fever and a CNS syndrome. To identify the etiologies and clinical manifestations of these infections, as well as the management of febrile patients at the hospitals, demographic and clinical data were collected at enrollment, and blood samples
were collected for diagnostic testing at enrollment, once during days 14–28, and at 3 months after enrollment.

**Results.** Subject ages ranged from 1 to 63.2 years old (median of 4.9 years old), and underlying diseases were reported in 35 (30.7%) subjects. Standard-of-care, molecular, and serological testing identified pathogens in 56 (49.1%) cases, as detailed in the table. Of the 19 subjects who died, 18 presented with decreased consciousness and 5 were infected with *Rickettsia typhi*, which was clinically misdiagnosed in each case.

**Conclusion.** The findings from this study will improve the diagnosis and treatment of patients presenting with CNS syndromes in Indonesia. Additionally, the discovery of misdiagnosed, fatal etiologies highlights the general need for greater diagnostic testing capacity to aid clinicians and inform public health policy makers.

---

**Table: Baseline characteristics and symptoms**

| Consciousness status (n) | Normal (61) | Decreased (53) |
|--------------------------|------------|---------------|
| End-of-study status (n)  | Discharged (60) | Died (1) | Discharged (33) | Died (18) |
| Etiology (n)             | Unknown (32) | Unknown (1) | Unknown (16) | Unknown (9) |
|                          | HHV-6 (9) | Dengue (5) | HHV-6 (3) | Dengue (1) |
|                          | Chikungunya (5) | Influenza (2) | Chikungunya (1) | S. pneumoniae (1) |
|                          | Influenza (3) | E. coli (2) | Leptospirosis spp. (1) |
|                          | K. pneumoniae (1) | S. pneumoniae (1) |
|                          | Amoeba (1) | R. typhi (1) |

1010. Viral Infections of the Central Nervous System in Qatar: Epidemiology, Pathogenesis and Clinical Outcomes
Fatma Ben Abd, MD; Mohammed Abukhattah, MD; Obada Salameh, MD; Ahmed Gohar, MD; Muna Al Masalmani, MD; Abdullatif Al-Khal, MD and Adeel Butt, MD, MS; Medicine, Hamad Medical Corporation, Doha, Qatar, ‘Hamad Medical Corporation, Doha, Qatar

**Session:** 137. Adult CNS Infection
Friday, October 6, 2017: 12:30 PM

**Background.** Viral central nervous system (CNS) infections are common causes of morbidity and most viral CNS infections in Gulf Cooperation Council countries. We conducted this study to determine the etiology, clinical and epidemiological characteristics, and outcomes of viral central nervous system infection in patients in Qatar.

**Methods.** We retrospectively evaluated all cerebrospinal fluid findings from January 2011–March 2015 at any of the 7 hospitals in the Hamad Medical Corporation. We included those with an abnormal CSF findings and excluded those with missing medical records, no clinical evidence of CNS infection and those with proven bacterial infection. Based on pre-defined clinical and CSF (lab, culture, PCR) criteria, patients were classified as having meningitis, meningoencephalitis, encephalitis or myelitis. We reviewed the laboratory results to determine the proportion of persons with confirmed viral etiology.

**Results.** Among 7690 patients with available CSF results, 550 cases met the case definition criteria for viral CNS infection (meningitis 75%; meningoencephalitis 16%; encephalitis 9%; myelitis 0.4%). Two-thirds (65%) were male and 50% were between 16-60 years old. The most common presenting signs and symptoms are listed in the table. Persons of Southeast Asian origin accounted for 39.6% of all infections. A definitive virologic etiologic agent was found in 38%, with enterovirus being the most common (44.3%) followed by Epstein-Barr virus (31%) and varicella-zoster virus (12.4%). The clinical outcome was overall good, only 2 cases died and the rest were discharged to home. Among those with confirmed viral etiology, 83.8% received ceftriaxone (mean duration 7.3 ± 5.2 days), 38% received vancomycin (mean duration 2.7 ± 5.4 days) and 38% received at least one other antibiotic.

**Conclusion.** Viral etiology is common among those evaluated for CNS infection in Qatar, and is most commonly seen in Southeast Asian immigrants. Clinical outcomes are generally excellent in this group of patients. Antibiotics are overly used even when a viral etiology is confirmed. There is a need for clinician education regarding etiology and treatment of CNS infections.
