Abstract

Background: Due to the short half-life of levodopa, immediate-release carbidopa-levodopa (IR CD-LD) produces fluctuating LD concentrations, contributing to a risk of eventual motor complications. IPX066 was designed to rapidly attain therapeutic LD concentrations and maintain them to allow a dosing interval of ~6 hours.

Objective: To extensively analyze the dosing data collected in IPX066 studies during open-label conversions from IR CD-LD alone or with entacapone (CLE) and identify patterns relevant for managing conversion in the clinical setting.

Methods: Patients had ≥2.5 hours/day of “off” time despite a stable IR or CLE regimen. Suggested initial dosing conversion tables based on prior LD daily dosage were provided.

Results: Of 450 patients previously treated with IR CD-LD and 110 with CLE, 87.3% and 82.7% completed conversion to IPX066, respectively. At the end of conversion, average IPX066 LD daily dosages were higher than pre-conversion dosages, with a mean conversion ratio of 2.1 ± 0.6 for IR CD-LD and 2.8 ± 0.8 for CLE; >90% of patients took IPX066 3 or 4 times/day, compared with a median of 5 times/day at baseline in both studies. After conversion, daily “off” time significantly decreased, with no significant increase in troublesome dyskinesia. The most common adverse event reported during conversion was nausea, with an incidence of 5.3% for conversion from IR and 7.3% from CLE.

Conclusions: Among PD patients with substantial “off” time, a majority were safely converted to IPX066. The sustained LD profile from the IPX066 formulation allowed an increase in LD dose accompanied by improved motor functions, without increased troublesome dyskinesia.

INTRODUCTION

Levodopa (LD) administered orally with the peripheral dopa-decarboxylase inhibitor carbidopa (CD) is a highly effective treatment of the motor symptoms of Parkinson’s disease (PD). However, levodopa has a short half-life resulting in fluctuating levodopa concentrations and a frequent requirement for dose adjustments. These fluctuations, along with the need for multiple daily doses, have led to significant patient burden and high risk of motor fluctuations and levodopa-induced dyskinesia. New formulations, such as IPX066, have been developed to achieve sustained levodopa delivery and allow for dosing every 6 hours, thereby improving patient adherence and potentially reducing the risk of motor complications.

Parkinson’s disease (PD) and is extensively used in all stages of the disease [1, 2]. However, the short half-life of LD, approximately 1.5 hours [3, 4], results in large peak-to-trough fluctuations in plasma concentrations even when LD is dosed frequently, with a consequent increase in risk of eventual motor complications [5, 6]. To prolong the half-life, the immediate-release (IR) formulation of CD-LD may be combined with a catechol-O-methyltransferase (COMT) inhibitor such as entacapone [7]. Alternatively, CD-LD may be administered as a controlled-release (CR) formulation. However, CR CD-LD has shown slow, sometimes unpredictable absorption [8–11], perhaps contributing to patient reports of delayed onset and decreased predictability of response [8, 9, 12, 13].

IPX066 (marketed as Rytary® [carbidopa and levodopa] extended release capsules) is an oral extended-release CD-LD formulation designed to rapidly achieve therapeutic LD plasma concentrations and maintain them for a prolonged duration [14], allowing dosing at 6-hour intervals in both early and advanced PD patients. Randomized, double-blind, active-comparator-controlled clinical trials have tested the efficacy and safety of IPX066 in advanced PD previously treated with IR CD-LD (ADVANCE-PD) [15] or with IR CD-LD plus entacapone (CLE, dosed separately or as combination tablets; ASCEND-PD) [16]. In both studies, the benefits of conversion to IPX066 included statistically significant decreases in daily “off” time and increases in daily “on” time without troublesome dyskinesia. In addition, a long-term open-label study [17] has demonstrated successful conversion to IPX066 from CR CD-LD taken alone or in combination with IR CD-LD for advanced PD. In this study, the identified benefits included patient preference for IPX066 and patient- and clinician-rated global improvement. In all 3 studies, IPX066 safety findings were consistent with those for standard CD-LD formulations.

In advanced PD patients receiving a single dose of IPX066, the LD exposure (as measured by AUC, the area under the time curve of LD plasma level) averaged approximately 70% and the peak plasma LD concentration (Cmax) averaged approximately 30% of the values following a single dose of IR CD-LD [14]. Because the LD plasma profiles provided by IPX066 are substantially different from those of other LD products [18], changes in LD dose and dosing frequency are expected in patients switching to IPX066 from other LD products. Indeed, a recent review of IPX066 administration [19] emphasizes that its doses are not simply interchangeable with those of standard forms of CD-LD. The review urges clinicians to be familiar with proper dosing, have a plan in place for patients to provide feedback concerning treatment response, and be prepared to make regimen adjustments. Here we evaluate more extensively than in previous reports [15, 16, 20, 21] the dosing data collected during the conversion periods of the clinical studies of IPX066 versus IR CD-LD (ADVANCE-PD [15]) and versus CLE (ASCEND-PD [16]), with the aim of discerning patterns relevant for managing such conversions in the clinical setting.

**METHODS**

**Study designs**

ADVANCE-PD was a randomized, double-blind, double-dummy, parallel-group study of IPX066 versus IR CD-LD. Over a 3-week period, each patient’s pre-study IR CD-LD regimen was adjusted, based on clinical need. During the subsequent 6 weeks, patients were converted to IPX066 in an open-label fashion. Patients then received either the IPX066 regimen or the IR regimen for 13 weeks in a double-blind phase. ADVANCE-PD was a randomized, double-blind, double-dummy, crossover study of IPX066 versus CLE. Patients, who were required to be on a stable CLE regimen for at least 13 weeks in a double-blind phase, were converted from CLE to IPX066 over a 6-week period in an open-label fashion. This was followed by two 2-week, double-blind treatment periods in random order, one of them on IPX066, the other on each patient’s pre-study CLE regimen. The double-blind treatment periods were separated by a week of open-label IPX066 treatment. During both studies, patients were required to continue any use of amantadine, anticholinergics, selective monoamine oxidase type B inhibitors (e.g., selegiline, rasagiline), or dopamine agonists at dosages that had been stable for at least 4 weeks preceding screening, but were not permitted to initiate such agents or use any non-study LD preparations.

**Study participants**

In both studies, all patients were required to have a diagnosis of idiopathic PD by UK Parkinson’s Disease Brain Bank Criteria [22], identified at an age ≥ 30 years and at Hoehn & Yahr [23] stage 1 to 4 during an “on” state. All patients were also required to have been on a stable regimen of oral CD-LD for at least 4 weeks prior to study entry.
to screening, taken at least 4 times/day and totaling at least 400 mg/day of LD. In ADVANCE-PD, the prior LD therapy was from IR CD-LD; in ASCEND-PD, it was from IR CD-LD plus entacapone. Despite these treatments, all patients had at least 2.5 hours per day of “off” time during waking hours.

**Conversion to IPX066**

In both studies, each patient’s conversion to IPX066 was conducted during a 6-week open-label period. To help identify an appropriate initial IPX066 regimen, study investigators were given a conversion table based on the pre-study LD daily dosage (Table 1). The suggested initial IPX066 LD daily dosages were higher than in the pre-study LD regimens, based on pharmacokinetic studies demonstrating that IPX066 produces an LD AUC and C_{max} lower than those of an equal dose of IR CD-LD [14]. In addition, a study in advanced PD patients had demonstrated that the anticipated higher daily doses of IPX066 resulted in a reduction in “off” time without a significant increase in troublesome dyskinesia [14]. Entacapone increases the LD AUC, compared with IR CD-LD alone; hence, the suggested initial IPX066 doses were approximately 30% higher for conversion from CLE (Table 1, bottom) than for conversion from IR CD-LD (Table 1, top). Because IPX066 prolongs the duration of elevated LD concentrations [18], the suggested initial dosing frequency for all conversions was at 6-hour intervals during the waking day, regardless of a patient’s pre-study LD dosing frequency, resulting in either a t.i.d regimen (without bedtime dosing) or a q.i.d regimen (with bedtime dosing). During the conversion period, the regimen could be adjusted at the investigator’s discretion, but dosing more than 5 times daily or at less than 4-hour intervals was discouraged. The overall goal was to minimize “off” time without causing troublesome dyskinesia.

**Outcome measures for dose conversion**

In each study, LD daily dosages and dosing frequencies were collected at baseline, and IPX066 dosages and dosing frequencies were collected at the end of the 6-week conversion period. IPX066 dose adjustments during conversion were recorded and the LD conversion ratios were estimated.

**Conversion-data analyses**

Baseline demographics and PD characteristics of all patients exposed to IPX066 were assessed descriptively for differences between patients who completed conversion and dropouts. For patients who completed conversion, mean conversion ratios were calculated for conversion from IR CD-LD and from CLE to IPX066. The proportion of patients who required adjustments.

### Table 1

| LD dosage at study entry, as IR CD-LD (mg/day) | Suggested initial LD dosage from IPX066 (mg/day) | Suggested initial IPX066 regimen |
|---------------------------------------------|-----------------------------------------------|----------------------------------|
| ADVANCE-PD                                  |                                               |                                  |
| 400–550                                     | 855                                            | 3 capsules × 95 mg t.i.d.*        |
| 551–750                                     | 1,140                                          | 4 capsules × 95 mg t.i.d.*        |
| 751–950                                     | 1,315                                          | 3 capsules × 145 mg t.i.d.*       |
| 951–1,250                                   | 1,755                                          | 3 capsules × 195 mg t.i.d.*       |
| 1,251–1,650                                 | 2,205 or 2,340                                 | 1 capsule × 245 mg t.i.d.* or     |
| >1,650                                      | 2,940                                          | 4 capsules × 245 mg t.i.d.*       |

| ASCEND-PD                                   |                                               |                                  |
| 400–550                                     | 1,140                                          | 4 capsules × 95 mg t.i.d.*        |
| 551–750                                     | 1,470                                          | 2 capsules × 245 mg t.i.d.*       |
| 751–950                                     | 1,755                                          | 3 capsules × 195 mg t.i.d.*       |
| 951–1,250                                   | 2,205                                          | 3 capsules × 245 mg t.i.d.*       |
| >1,250                                      | 2,940                                          | 4 capsules × 245 mg t.i.d.*       |

*At 6-hour intervals during the subject’s waking day. CD, carbidopa; IR, immediate-release; LD, levodopa; t.i.d., 3 times/day.
from their suggested initial IPX066 daily dosage, the extent of dosage adjustment, and the proportion of patients on various IPX066 dosing frequencies at the end of conversion were also assessed.

**Efficacy measures**

During the 3 days preceding the start and the 3 days preceding the end of the conversion period, patients in both studies maintained a home PD diary [24]. For each half-hour, patients recorded whether they had been asleep, “off,” “on” without dyskinesia, “on” with non-troublesome dyskinesia, or “on” with troublesome dyskinesia. For conversion completers, mean changes from baseline to the end of conversion in the 3-day averages for daily “off” time, “on” time without troublesome dyskinesia (“on” time without dyskinesia plus “on” time with non-troublesome dyskinesia), and “on” time with troublesome dyskinesia are presented.

**Safety/tolerability measures**

During the 6-week conversion period in each study, adverse events (AEs) and AEs leading to patient discontinuations were recorded, and were categorized using Medical Dictionary for Regulatory Activities (MedDRA) Version 12.1 Preferred Terms.

**Ethical conduct**

Both studies were conducted in accordance with Good Clinical Practice guidelines promulgated by the International Conference on Harmonisation, and were approved by appropriate institutional review boards. Prior to study procedures, all patients provided written informed consent.

**RESULTS**

**Patient disposition**

Of the 560 PD patients who underwent conversion to IPX066, 87.3% of those who had been taking IR CD-LD (393 of 450) and 82.7% of those who had been taking CLE (91 of 110) completed conversion (Fig. 1). Patient characteristics for conversion completers and for dropouts during conversion are provided in Table 2.

**Concomitant medications**

The use of other anti-parkinsonian medications and antidepressants at study entry is summarized in Table 2. Overall, the proportions of patients taking each class of medication were similar in conversion completers and dropouts.

**Dosage adjustments**

For conversion completers, LD dosages and dosing frequencies prior to the start of conversion and at the end of conversion to IPX066 are presented in Table 3. At the end of conversion from IR CD-LD, 24.9% of completers were on the dose recommended by the study’s conversion table, 59.5% were on a higher dose, and 15.5% were on a lower dose. The median percent change in IPX066 dosage from the initial recommended dosage was +14.5% (mean, +21.0%). Of the 393 completers, 165 (42.0%) increased their dosage by \( \leq 50\% \) from the initial recommended dosage, and 32 (8.1%) increased it by >75%.

At the end of conversion from CLE, 30.8% of completers were on their initial recommended IPX066 dosage, 56.0% were on a higher dose, and 13.2% were...

*In IR CD-LD prior to start of conversion; in IPX066 at end of conversion. CD, carbidopa; CLE, immediate-release carbidopa-levodopa plus entacapone; IR, immediate-release; LD, levodopa; SD, standard deviation.
on a lower dose. The median percent change in IPX066 dosage from the initial recommended dosage was +8.3% (mean, +19.7%). Of the 91 completers, 38 (41.8%) increased their dosage by ≤50% from the initial recommended dosage, and 7 (7.7%) increased it by >75%.

**Dosing frequencies**

At the end of conversion, the mean (SD) IPX066 dosing frequency was 3.6 (0.7) times/day among patients converted from IR CD-LD and 3.5 (0.6) times/day among patients converted from CLE (see Table 3). The median in both studies was 3 times/day. Among patients converted from IR CD-LD, 52.2% were taking IPX066 3 times/day and 39.7% were taking it 4 times/day. Among patients converted from CLE, the proportions were 57.1% and 37.4%, respectively. Prior to the start of conversion, the mean LD dosing frequency had been 5.1 (1.5) times/day for IR CD-LD and 5.0 (1.2) times/day for CLE. The median for both had been 5 times/day.

**Conversion ratios**

Figure 2 charts the LD daily doses of IPX066 versus IR CD-LD (Panel A) or versus CLE (Panel B) for all conversion completers. For conversion from IR CD-LD, the mean (SD) conversion ratio, denoted by the slope of a line in the chart, was 2.1 (0.6), and the median was 1.9. For conversion from CLE, the mean ratio was 2.8 (0.8) and the median was 2.9. The ratios were generally similar throughout the range of LD daily dose and therefore were largely independent of pre-conversion LD dosage.

**Efficacy**

From pre-conversion to end of conversion from IR CD-LD or from CLE, mean changes in diary data among conversion completers showed a statistically significant reduction of daily “off” time, a statistically significant increase in daily “on” time without troublesome dyskinesia, and no significant change in daily “on” time with troublesome dyskinesia (Table 4). In both studies, the improvements were also significant at the end of double-blind IPX066 treatment [15, 16].

**Safety**

The overall incidence of reported AEs was 45.8% during conversion from IR CD-LD and 30.9% during conversion from CLE (Table 5). The only AE with an incidence ≥5.0% in both studies was nausea, at 5.3% during conversion from IR CD-LD and 7.3% during conversion from CLE. The highest severity of most AEs during the conversion periods was mild or moderate. During the double-blind treatment period of each study, no AE had an incidence ≥5% [15, 16].

During conversion from IR CD-LD, 23 patients (5.1%) discontinued due to AEs. The AEs leading to discontinuation of more than one patient were dyskinesia (in 5 patients, or 1.1%); anxiety, dizziness, and on and off phenomenon (each in 3 patients, or 0.7%); and nausea and visual hallucinations (each in 2 patients,
Table 4

| Variable                          | Conversion from IR CD-LD | Change, p-value* | Conversion from CLE | Change, p-value* |

| Upper respiratory tract infection, n (%)  | 5 (1.1)                  | 3 (2.7)             |

*p-values are those reported in ≥2.0% of patients who began conversion to IPX066 in either study, and are listed by Medical Dictionary for Regulatory Activities Version 12.1 Preferred Term. AE, adverse event; CD, carbidopa; CLE, immediate-release carbidopa-levodopa plus entacapone; IR, immediate-release; LD, levodopa.

DISCUSSION

In this large sample of patients with advanced PD and ≥2.5 hours/day of daily "off" time despite stable regimens of standard CD-LD formulations, a large majority—overall, 86.4%—were successfully converted from IR CD-LD, either taken alone or with adjunctive entacapone, to a stable IPX066 dosage within a 6-week conversion period. Although their end-of-conversion LD dosages, taken as IPX066, were substantially higher than their previous LD dosages (taken as IR CD-LD or as CLE), mean changes in diary data showed a significant decrease in daily "off" time with no significant increase in troublesome dyskinesia. In addition, during IPX066 treatment, patients took a median of 3 doses/day, compared with 5 doses/day during IR CD-LD or CLE treatment. More than 90% of patients were taking IPX066 either 3 or 4 times/day (see Table 3).

The observed increases in daily LD dosage and decreases in dosing frequency likely reflect pharmacokinetic differences between IPX066 and the patients’ prior LD regimens [18]. In a crossover study of individualized IPX066 treatment versus IR CD-LD in patients with advanced PD, plasma LD levels remained above 50% of Cmax for a mean (SD) of 4.0 (2.0) hours for IPX066, compared with 1.4 (0.7) hours for IR CD-LD [14]. Furthermore, following repeated dosing, the mean Cmax/Cmin ratio during a 12-hour period was significantly lower for IPX066 than for IR CD-LD, at 12.0 versus 82.2 [14]. The fluctuation index, calculated as (Cmax – Cmin)/Caverage, was also significantly lower, at 1.5 for IPX066 versus 3.2 for IR CD-LD [14]. IPX066 was designed to rapidly attain and sustain therapeutic plateau concentrations of plasma LD, in effect “filling in” the troughs in LD concentration between doses of standard oral LD formulations. In the present studies, the observed IPX066-related LD dose increases may also have helped rectify previous under-treatment. For inclusion, all of the patients had at least 2.5 hours/day of "off" time, and in fact averaged 6 hours/day despite their stable regimens of standard LD formulations.
formulations. In both studies, conversion to IPX066 yielded a significant decrease in daily “off” time, an increase in “on” time without troublesome dyskinesia, and no significant increase in troublesome dyskinesia relative to pre-conversion values. These improvements were maintained during double-blind IPX066 use. Overall, the results of these studies suggest that the IPX066-initiation tables guiding conversion from IR CD-LD (Table 1, top) or CLE (Table 1, bottom) are appropriate starting points for achieving an effective IPX066 regimen. Patients taking CLE may need to be started on a higher dose of IPX066 than patients taking IR CD-LD, to account for the loss of entacapone, which acts to increase LD exposure [7]. In Table 1, the suggested initial IPX066 doses are approximately 30% higher for the ASCEND-PD trial compared with the ADVANCE-PD trial, reflecting this expectation. The higher mean conversion ratio among conversion completers who had been using CLE as opposed to those who had been using IR CD-LD—2.8 versus 2.1—is also consistent with this expectation. Responses during dose conversion are likely to vary from patient to patient, warranting tailored adjustments after the initial conversion to IPX066. Indeed, while more than half of both studies’ patients required an increased IPX066 dosage, more than a tenth required a decrease, highlighting the importance of frequent monitoring and individualized adjustments. Responses during dose conversion are likely to vary from patient to patient, warranting tailored adjustments after the initial conversion to IPX066. Indeed, while more than half of both studies’ patients required an increased IPX066 dosage, more than a tenth required a decrease, highlighting the importance of frequent monitoring and individualized adjustments. In all patients, initial follow-up should take place soon after initiation, e.g., within 1 week.

In general, conversion to IPX066 from IR CD-LD or from CLE was well tolerated. The most frequently reported AEs during the 6-week conversion period were AEs associated with dopaminergic therapy. Nausea had a reported incidence of 5.3% to 7.3%. Despite the higher LD exposure after switching to IPX066, the incidence of dyskinesia as a reported AE was low, at 0.9% to 5.6% across studies. Small numbers of patients (0.9% to 5.1%) discontinued their conversion because of AEs.

The present report is limited by the requirement in each study that patients maintain stable dosages of adjunctive PD drugs. The studies therefore did not explore the extent to which the use of IPX066 might permit simplification of a patient’s overall PD regimen. Additionally, the studies did not investigate long-term post-conversion outcomes; however, a 9-month open-label extension study is now completed and has reported encouraging findings [25]. The experience gained in the studies reported here suggests that patients taking standard CD-LD formulations for control of motor symptoms in advanced PD can achieve a stable, tolerable IPX066 regimen with a dosing frequency less than that of their prior LD treatment, with associated improvements in motor symptoms [15, 16].

ACKNOWLEDGMENTS

These studies were funded by Impax Laboratories, Inc. Impax participated in the study design, data collection, interpretation and analysis, writing and editing the manuscript, and submission of the manuscript for publication. Medical writing support was provided by Michael Feirtag of The Curry Rockefeller Group, LLC, supported by Impax Laboratories, Inc.

CONFLICTS OF INTEREST

PAN has received honoraria from Impax Laboratories, Inc., for consulting services and as an investigator. He has spoken on behalf of Novartis, UCB, Inc., and Teva Pharmaceuticals. He has held stock in the following companies Abbott Laboratories, Bristol-Myers Squibb, Celgene, Dox Chemical, DuPont, Durata Therapeutics, Eli Lilly, Gilead, GlaxoSmithKline, Humana, Impax Laboratories, Inc., Johnson and Johnson, Neogen, PhytoPharm plc, Roche Holding, Sigma-Aldrich, and Teva Neuroscience. Lastly, he has received financial support from Adams Pharmaceuticals, Aurora Health Care Foundation, Biste Therapies, Greater Milwaukee Foundation, Helen Bader Foundation, Icon Clinical Research, Impax Laboratories, Inc., Milwaukee County Department of Family Care, Pharmasset LLC, PRA International, Quintiles Inc., Schwarz Biosciences/UCB, Wisconsin Parkinson Association, and XenoPort.

AH was an employee of Impax Laboratories, Inc., when the studies were conducted and owns Impax stock.

LE has received honoraria for speaking engagements from Lundbeck, Novartis, UCB Pharma, and Teva Neuroscience; has served as a paid consultant for Teva Neuroscience and UCB Pharma; has received honoraria as a member of advisory boards for Lundbeck, Teva Neuroscience, and UCB Pharma; and has received unrestricted educational grant support from Teva Neuroscience.

RAG has received honoraria from Impax Laboratories, Inc., for consulting services, advisory board services, and as an investigator. He also has received honoraria for speaking engagements from Allergan, Impax, US WorldMeds, Ipsen, and Merz.

JS has indicated that he has nothing to disclose.

CS has received honorarium from US WorldMeds. He also has obtained grants from UCB, Allergan, Teva, and Prana.
SKanna, RR, SKell, NBM, and SG are employees of Impax Laboratories, Inc., and own Impax stock and/or stock options.
