Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Prevalence and associated influential factors of mental health problems among Chinese college students during different stages of COVID-19 pandemic: A systematic review

Abstract
This systematic review aims to take China as an example to determine the prevalence of mental health problems and associated influential factors of college students in different stages of the COVID-19 pandemic and provide a reference for effective intervention in the future. A systematic search was conducted on PubMed, Web of Science, Scopus, Science Direct, and Google scholar. A total of 30 articles were included. 1,477,923 Chinese college students were surveyed. In the early stage, the prevalence rates of depression, anxiety, stress, and PTSD ranged from 9.0% to 65.2%, 6.88% to 41.1%, 8.53% to 67.05%, and 2.7% to 30.8%, respectively. Major risk factors were being a female, a medical student, isolation or quarantine, having family members or friends infected with COVID-19, and challenges of online learning. During the normalization stage, depression, anxiety, and insomnia prevalence rates ranged from 8.7% to 50.2%, 4.2% to 34.6%, and 6.1% to 35.0%, respectively. The main risk factors were self-quarantined after school reopening, regular taking temperature, and wearing face masks. The prevalence rates of mental health problems and associated influential factors unveiled in both stages showed that the students' mental health status was greatly affected. Therefore, a combination of efforts from the government, universities, and families or communities is highly needed to alleviate the mental health sufferings of students.

Keywords: Mental health, college students, prevalence, depression, anxiety, stress
1. Introduction
Since the global pandemic of the novel coronavirus (COVID-19) from 2020, it has been an ongoing crisis for two years [1]. The pandemic has resulted in not only the risk of death but also psychological problems to people across the world [2]. Recent studies have revealed that mental health problems such as fear, anxiety, depression, insomnia, post-traumatic stress disorder (PTSD) were prevalent among various population such as the infected patients, psychiatric patients, children, pregnant women, healthcare workers, college students, and the general population during the pandemic [3-9]. As the first country reporting COVID-19 outbreak, 31 provinces and autonomous regions in China activated the level one public health emergency during the initial stage of the pandemic (January 2020) [10]. Strict epidemic control measures such as city lockdown, quarantine, suspension of social gatherings, closure of businesses and delayed starting schools were implemented [11, 12]. China had achieved great success in controlling the epidemic at late April, 2020. From May 2020, the newly confirmed cases per day kept at a low level with a clear downward trend nationwide. Since May 2020, the COVID-19 pandemic has been put under control in China. However, we can’t ignore another aspect about COVID-19. Imported cases and local outbreak often occur here and there, regularly prevention and control measures should be took at the normalization period for a long time [13, 14]. It has been a continuing crisis, which might influence the uncertainties of the pandemic and bring pervasive impacts on individual’s health [13, 14]

Previous studies revealed that COVID-19 has led to persistent negative psychological effects on various population. As a special group, college students’ physical and mental development is not mature, and they are more vulnerable to have distress and mental health problems during the epidemic [15]. Previous studies showed that college students have had higher prevalence of mental health problems during the different stages of COVID-19 epidemic. The prevalence of depressive symptoms is reported to range from 10.5 to 65.2% in the initial stage [16, 17] and 8.7 to 50.2% [18, 19] in the normalization stage in China. As the epidemic evolves, the mental health of college students may also change. In order to take timely and effective intervention measures accordingly, studies are needed to track the dynamic changes of the college students’ mental health status over time and find out the main problems and related influential factors at different stages of the epidemic. This systematic review aims to take China as an example to determine the prevalence and associated influential factors of mental health problems of college students in different stages of COVID-19 pandemic and provides reference for effective intervention in the future.

2. Methods
2.1. Search process
The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) was employed to select studies assessing the mental health problems including prevalence and associated influential factors among college students during the COVID-19 pandemic. A comprehensive literature search on original articles in
electronic databases of PubMed, Web of Science, Scopus, Science Direct was conducted from inception until November 2021. An additional search on Google scholar was also included. Our search strategy was: ((mental health OR psychological health OR psychological distress OR depression OR anxiety OR PTSD OR psychological stress) AND (risk factors OR influencing factors) AND (university students OR college students OR higher education students) AND (novel coronavirus disease OR 2019 novel coronavirus OR COVID-19 OR 2019-nCOV)) on PubMed. ((TS=(mental health OR psychological health OR psychological distress OR depression OR anxiety OR PTSD OR psychological stress)) AND TS=(risk factors OR influencing factors)) AND TS=(university students OR college students OR higher education students)) AND TS=(novel coronavirus disease OR 2019 novel coronavirus OR COVID-19 OR 2019-nCOV)) on Web of Science; ((mental health OR psychological health) AND (university students OR college students) AND (risk factors OR influencing factors) AND (novel coronavirus OR COVID-19)) on Science Direct., and ((mental health* AND university students* AND risk factors* AND COVID-19*)) on Scopus. A time span from January 2020 to November 2021 for published articles was considered. The search was conducted by two independent researchers. Each article underwent three rounds of the screening process. In the first round, titles were screened, and the abstracts of relevant articles were further assessed in the second round. In the third round, selected articles were screened for full-text to examine their eligibility.

2.2. Study selection and eligibility criteria
The titles and abstracts of each article were screened for significance. After the first screening process, the full-text articles were assessed for eligibility. Studies were included if they: (i) used cross-sectional study design (ii) assessed the mental health status of the university students during the COVID-19 pandemic including prevalence and risk factors (iii) used scales for measurement of mental health problems (iv) conducted in China. Studies were excluded if they were: (i) reviews (ii) no abstract or incomplete information (iii) inaccessibility of full-text (iv) duplicate.

2.3. Data extraction process
Two independent researchers (I.C and K.S.D) conducted the data extraction and assessment of methodological quality. Periodical meetings were held to minimize the risk of errors at each step of the review process. In the case of any discrepancy, they were asked to reach a consensus. A data extraction form was used for included articles and covered the following areas: (i) first author and publication year (ii) survey time (iii) survey region (iv) study design (v) sample size (vi) sample characteristics (vii) prevalence of depression/anxiety/PTSD/psychological stress or other mental health problems (viii) associated risk and protective factors.

2.4. Study quality appraisal
The Newcastle-Ottawa Scale (NOS) commonly used for cross-sectional studies was used for study quality appraisal. The scale is divided into three sections: Selection,
Comparability, and Outcome. Overall, seven categories were included (assessment of sample representativeness, justification of sample size, comparison of respondents versus non-respondents, ascertainment of exposure, comparison according to study design or analysis, outcome assessment, and appropriateness of statistical analysis. A study that meets all of the criteria can be given a total score of ten stars. Selection gets a maximum of five stars, comparability gets two stars, and outcome gets three stars. A total of 9-10 stars (very good), 7-8 stars (good), 5-6 stars (satisfactory), and 0-4 stars (unsatisfactory) [20].

3. Results

3.1. Characteristics of the included studies
One thousand five hundred and sixty-four articles were identified through the database check. After screening for duplication and eligibility, 30 studies met the inclusion criteria and were included. A detailed workflow chart showing the study selection is presented in Fig. 1 and the characteristics of the included studies are displayed in Table 1. In total, twenty-four and six studies assessed the prevalence of mental health problems and their influential factors of college students in China during the early and normalization stage of COVID-19 pandemic respectively. The earliest survey time was January 31, 2020, and the latest survey time was December 19, 2020. All the included studies employed an online cross-sectional survey. The surveyed regions came from various part of China, such as Guangzhou, Wuhan, Chengdu or other cities across China (see details in Table 1). A total of 1,477,923 participants were surveyed in the 30 studies. The sample size varied greatly, from 478 to 746,217 participants. Except for 4 studies, the included studies surveyed more female students than male students.

3.2 Quality appraisal of included studies
Table 2 displayed the result of the quality appraisal using NOS. The overall quality of the selected studies was moderate with total stars ranging from five to seven. There were nine studies with five stars, eleven with six stars, and ten studies with seven stars.

3.3. Mental health problems and associated influential factors during different stages of COVID-19 pandemic
Depression, anxiety, stress, PTSD, and insomnia were major mental health problems reported among Chinese college students during different pandemic stages in the included studies. A few of these studies reported other mental health problems such as sleep problems, panic, mental distress, suicidal ideation, post-traumatic growth (PTG), and general psychological symptoms. Besides, relatively different protective factors were reported among the study subjects from a few studies (Table 1). The detailed prevalences and associated influential factors about mental health problems were outlined below:
3.4 Depression and associated influential factors

Fifteen studies conducted from January to April 2020 reported depression as a significant mental health problem among Chinese college students during the early stage of the COVID-19 pandemic [21-35]. The reported prevalence of depressive symptoms among the 15 studies ranges from 9.0% to 65.2%. Eight of the studies used the PHQ-9 scale [16, 26, 27, 29, 33, 35-37], four used SDS [17, 25, 30, 34], two used CES-D [28, 32], and one used the DASS-21 scale [31] to assess depressive symptoms. These studies’ findings were relatively similar in that depression was reported as a significant mental health problem among the study participants. However, except for being a female in three studies [17, 30, 35] and undergraduate in two studies [24, 30] observed as risk factors for depression, there were differences in risk factors for depressive symptom among the 15 studies. With regards to protective factors, nine studies [16, 17, 26, 28, 30, 32-35] identified protective factors for depression. Among these studies, two studies discovered that social support [26, 32], living with family members [33, 35], and physical activity [30, 34] as protective factors for depression. The rest reported on varying protective factors for depression. During the normalization stage, five studies carried out between September to December 2020 rated depression as a primary mental health problem among Chinese college students [18, 19, 38-40]. The prevalence of depressive symptoms among these studies ranges from 8.7% to 50.2%. PHQ-9 scale was the measurement tool used to assess depressive symptom in the five studies. Nevertheless, these studies reported several different risk factors leading to the development of depression. A study by Xu et al. [39] noticed frequent physical exercise as a protective factor for depression.

3.5 Anxiety and associated influential factors

A total of seventeen studies conducted from January to May 2020 reported anxiety as a fundamental mental health problem among Chinese college students during the early stage of the COVID-19 pandemic [23-26, 28-31, 34-36, 41-46]. The prevalence of anxiety symptoms reported by these studies range from 6.88% to 41.1%. Eight studies used GAD-7 scale [16, 26, 29, 35, 37, 41, 42, 45], five studies used SAS [25, 30, 34, 43, 46], two used Z-SAS [28, 36], and one used HAI [44] and DASS-21 [31] to measure anxiety symptoms among the students. Except for being a female student [35, 41, 43] and a senior student [23, 41] noticed as risk factors for anxiety in three studies and two studies respectively, different risk factors for anxiety symptoms were reported by the 17 studies. Among the 17 studies, 10 studies reported on protective factors for anxiety [16, 26, 28, 30, 34, 35, 42-45]. Varying protective factors for anxiety were disclosed by these studies. In the normalization stage, four studies assessed the anxiety symptom from September to December 2020 with a prevalence of 4.2% to 34.6% [18, 19, 38, 39]. Anxiety symptoms were measured by GAD-7 (n=3) [18, 19, 39] and SAS (n=1) [38]. The included studies also reported different risk factors for anxiety symptoms. Frequent physical exercise was revealed by Xu et al. [39] as a protective factor for anxiety.
3.6. Stress and associated influential factors
During the early stage, seven studies assessed the symptoms of stress from February to April 2020 among Chinese college students [23, 25, 26, 31, 45, 47, 48]. The prevalence of stress ranges from 8.53% to 67.05%. Measurement tools such as IES-6 (n=3) [26, 37, 49], CPSS (n=2) [25, 48], PSS-10 (n=1) [45], and DASS-21 (n=1) [31] were used by the included studies to measure stress. The included studies discovered different risk factors for stress. Moreover, among the seven studies, only one study [45] revealed higher frequency of daily news reading (4–7 times) and number of remaining masks (greater than 20) were protective factors for stress. In the normalization stage, a study conducted in June 2020 reported stress as a significant mental health problem among the students [18]. The prevalence of stress was 10.5%. The risk factors for stress were being a male student and living with siblings or in rural areas.

3.7. PTSD and associated influential factors
An aggregate of three studies conducted between February to April 2020 investigated the symptoms of PTSD among students during the early stage [27, 36, 50]. According to these studies, the prevalence of PTSD symptoms ranges from 2.7% to 30.8%. Two studies used PCL [27, 36], and one study used IES-6 [50] to assess the symptoms of PTSD. The three studies’ risk factors leading to the development of PTSD were relatively different. However, in the normalization stage, a survey in June 2020 reported PTSD as a vital mental health problem among the students [39]. The prevalence of PTSD was 8.5%. The risk factors for PTSD were history of mental illness, positive history of family psychosis, changes in lifestyle, and distant relationship with parents. Also, protective for PTSD was frequent physical exercise.

3.8. Insomnia and associated influential factors
A survey conducted in February 2020 investigated insomnia as an essential mental health problem among Chinese college students during the early stage [48]. AIS was the tool used to measure insomnia. The prevalence of insomnia was 16.67%. The risk factors for insomnia included being a female student, living in an isolation unit, and general psychological symptoms. Amidst the normalization stage, four studies performed between June to December 2020 assessed insomnia among the study participants [18, 19, 39, 51]. As reported by these studies, the prevalence of insomnia ranges from 6.1% to 35.0%. Two studies used YSIS [18, 51] and ISI [19, 39]. The four studies identified independent risk factors for insomnia. Frequent physical exercise [39], and college senior degree and 7-8 hours’ sleep duration daily [51] served as protective factors for insomnia.

3.9. Other mental health problems and associated influential factors
Mental health problems such as post-traumatic growth (PTG = 66.9%) [36], sleep problems (13.5%) [45], panic (17.2%) [44], mental distress (47.1%) [33], suicidal ideation (7.3%) [35], and general psychological symptoms (5.8%) [48] were also reported during the early stage. These mental health problems were investigated...
between February to March 2020. The risk factors for PTG were higher subjective SES and knowing people who had been isolated [36]. According to Wang et al [45], the risk factors for sleep problems were high perceived stress and anxiety symptom. Also, protective factor for sleep problems was frequency of daily news reading (1–3 times). With reference to Zhou et al [35], having anxiety and depressive symptoms were risk factors for suicidal ideation. Additionally, the risk factors for mental distress were perceived infection risk or discrimination and having close contact with people who had visited Wuhan 2 weeks before the Chinese New Year [33]. In the normalization, a study performed in June 2020, reported that suicidal behavior with a prevalence of 2.0% is another mental health problem that affected students during the COVID-19 pandemic [39].

4. Discussion
This systematic review assessed the mental health problems, including prevalence and influential factors among Chinese college students during different stages of the COVID-19 pandemic. Depression, anxiety, stress, PTSD, and insomnia were the most common mental health problems reported. Main risk factors include isolation or quarantine, being a female or medical student, fear about COVID-19 infection, having family members or friends suspected or confirmed with COVID-19, and challenges of online learning were reported in the early stage. In the normalization stage, the identified risk factors were self-quarantined after school reopened, wearing face masks, and increased stress level. In both stages, frequent physical exercise, availability of social support, and staying with family members were significant protective factors for mental health problems.

Overall, the prevalence rates of depression, anxiety, stress, PTSD, and insomnia ranged from 8.7% to 65.2%, 4.2% to 41.1%, 10.5% to 67.05%, 2.7% to 30.8%, and 6.1% to 35.0% respectively. The prevalence rates of mental health disorders reported in this review were higher than the prevalence rates reported before the pandemic [52-56]. Nonetheless, these prevalence rates were higher than a multinational study that investigated the mental health status of participants who lived in seven middle income countries (MICs) in Asia (China, Iran, Malaysia, Pakistan, Philippines, Thailand, and Vietnam) during the pandemic [57]. In comparison with college students in other countries, these prevalence rates were higher than studies conducted in Bangladesh [58, 59] and Pakistan [60, 61]. The prevalence rates reported in this study were lowered than the prevalence rates reported in a systematic review that investigated the mental disorders of Bangladeshi students during the COVID-19 pandemic and noted depression (46.92% to 82.4%), anxiety (26.6% to 96.82%), and stress (28.5% to 70.1%) [62].

During the early stage (January-May 2020) of the pandemic in China, the prevalence rates of depression, anxiety, stress, and PTSD ranged from 9.0% to 65.2%, 6.88% to 41.1%, 8.53% to 67.05%, and 2.7% to 30.8% respectively. Whereas only one study investigated the prevalence of insomnia (16.67%) during this stage. In the
normalization stage (June – current time) of the pandemic, the prevalence rates of depression, anxiety, and insomnia ranged from 8.7% to 50.2%, 4.2% to 34.6%, 6.1% to 35.0% respectively. While the prevalence rates of stress (10.5%) and PTSD (8.5%) were reported. The prevalence rates variations in this study could be attributed to different sample size, measurement tools and cut-off values, time periods and regions, and reporting styles utilized as demonstrated in Table 1. However, higher prevalence rates of mental health problems were reported in the early stage as opposed to the normalization stage. An essential reason could be the extensive implementation of prevention and control measures such as isolation, quarantine, lockdown, shutdown of educational institutions and businesses, closure of offices and public areas (clubs, restaurants, and shopping places etc), massive testing, and restriction of social movement and interaction across regions in China during the early stage. Moreover, students were locked down and urged to take online classes to keep the learning process going. These measures were revealed to have made students more prone to develop mental health problems. Despite the pandemic was controlled in the normalization stage, students also suffered from mental health issues and this might be the global spread of the virus which resulted in a pandemic and stringent actions were also implemented by the Chinese government to prevent the escalation of new and imported cases.

During the pandemic, studies also revealed that students’ mental health was greatly affected by a number of factors ranging from epidemic measures, gender, student category, information received, family support, geographic location, and online learning in the early and normalization stage. These factors were found to be associated with symptoms of mental health problems. The outbreak struck at a time when most Chinese citizens including college students stopped their work or academic activities to enjoy the Chinese New Year (CNY) which usually lasted for a month. Symptoms of mental health problems were expected to be lowered than previous periods but due to the occurrence of COVID-19 (early stage), epidemic-control measures were implemented across different regions in China and studies have found that such measures were significantly associated with higher risk of mental health problems. Students who were isolated at home for a long time faced a range of emotional stress responses [3]. Again, students having a history of quarantine were found to experience elevated levels of psychological distress and significantly at higher risk of anxiety and depression than those without [63, 64]. Prolong isolation can make people especially students to become bored and absorb excessive negative information, which also escalates possible risks of mental health disorders [65, 66]. Prolonged lockdown had caused diverse negative psychological impacts on people particularly students due to delays in school re-opening, postponement of examinations, and uncertainty about graduations [67].

With regards to gender, female students demonstrated an increased risk of developing symptoms of mental health problems than their male counterparts [3, 26, 29, 65, 68, 69].
Moreover, female gender is associated with depression in the world even before the pandemic [70]. A possible explanation could be females are considered to be more frequently, emotionally, and relatively exposed to tension which in tend to increase the occurrence of symptoms of depression as opposed to males [29]. Another reason could be that the stress reactions of females become extremely intense compared to males during epidemics. Physiologically, female hormones tend to swing and enhance very strong responses in the face of extremities than males. In addition, stress responses were also linked to the production of anxiety, tension, worry, or even emotions [71]. Again, studies found that medical students were at greater risk of developing anxiety and depressive symptoms compared to non-medical students [12, 72]. This could be explained due to perhaps medical students had an improved knowledge and understanding of COVID-19 and were more abreast of protective and preventive measures compared to non-medical students [19]. Another possible reason could be medical students encountered excessive study pressure, limited social activities, and vulnerability to death and sufferings in caring for patients which made them susceptible to higher risks of depression and anxiety. This could be explained due to perhaps medical students had an improved knowledge and understanding of COVID-19 and were more abreast of protective and preventive measures compared to non-medical students [63]. Another possible reason could be medical students encountered excessive study pressure, limited social activities, and vulnerability to death and sufferings in caring for patients which made them susceptible to higher risks of depression and anxiety [16].

Regarding regions, studies conducted in Guangdong, Hubei, and Shangdong province reported higher prevalence rates of mental health problems [17, 19, 37-39, 73]. Wuhan, the capital of Hubei province, known to identify the first case of COVID-19 and the worst-hit region in China, was completely lockdown, and face mask as well as social distancing were made mandatory in order to curb the spread of the virus. Similarly, Guangzhou, the capital of Guangdong province, was the second worst-hit region after Wuhan. It is the largest industrial and trade hub in China. To curtail the spread of the virus, lockdown and travel restrictions were also implemented and massive COVID-19 testing was carried out across the region following the detection of the second variant (Delta) of the new coronavirus [74]. Shangdong being the second largest population in China set up an epidemic prevention and control task force groups and various cities also created a command system to respond to public health emergencies. The level one public health emergency was also implemented following the high incidence of COVID-19 and all educational institutions shutdown, businesses and social gatherings suspended to slow down the spread of the virus [75]. The severity of the disease and wide implementation of epidemic prevention and control measures in these regions could have greatly impacted the mental health status of students. Furthermore, students who lived in provinces where the total number of infected cases span from 1000 to 9999 were 0.25 times at risk of anxiety and depressive symptoms in comparison with those living in provinces where the total number of infected cases span from 1 to 49 [76]. Additionally, students living in
urban areas were at higher risk of anxiety or depressive symptoms contrary to those in rural areas [63, 77]. This situation happened due to the severe and robust actions to curb the spread and transmission of the virus in urban areas as opposed to rural areas [78].

As most students lived with their family members or relatives during the pandemic, studies have shown that there was an association between living with family members and mental health status. According to Wang et al [28] and Li et al. [79] students whose family members were suspected, confirmed, or died of COVID-19 were significantly at risk of developing symptoms of PTSD and depression, and further developed extreme levels of panic and uncertainty. Also, students whose family members (or persons staying together with them) went outside for recreational activities during the quarantine period were reported to have severe symptoms of depression than those whose family members stayed at home [63, 80]. Consequently, these students might have been worried about their own health, family health status, spread of the virus to other members, and mortality rate, which in tend increased their risk of mental health disorders [81]. Further, some studies have shown that economic instability might increase anxiety among university students, particularly during epidemic situations. College students having lower economic status were reported to be at greater risk of developing anxiety symptoms in contrast with those of higher economic status [3]. Similarly, low social support was also found to be a risk factor for developing depression and anxiety symptoms among students [3, 10].

In February 2020, China Ministry of Education (MoE) postponed all educational activities and urged schools including higher educational institutions to use online medium as an alternative to face-to-face teaching in order to restore the normal teaching process and prevent the spread of the virus [82]. The introduction of online learning was perceived by many students as a good idea but studies have revealed that students who participated in online learning were at risk of developing symptoms of mental health problems as opposed to students who did not participate [32, 50, 83]. A study by Albagmi et al revealed that university students encountered the greatest level of anxiety in contrast to other professions, this was linked to the suspension of traditional (face-to-face) forms of learning and switched to online learning during the COVID-19 pandemic [84]. Also, students were more prone to develop anxiety or depressive symptoms in the face of online learning due to the increased demand for new technological skills and use of electronic gadgets, efficiency, and excessive information and workload [85].

Despite the mental health status of most students being greatly affected during the pandemic, a number of studies have outlined some protective factors against mental health issues. Knowledge about infectious diseases and moderate or high satisfaction with prevention and control measures [17], use of face masks [86], frequent physical exercise [39], positive about projections of COVID-19 trends and effectively adhering to COVID-19 preventive and control measures [35], hope and availability of huge personal income [87], mindfulness and perceived social support [88], resilience [21],
extraordinary sense of control [83], and positive preventive behaviors and attitudes [77], were among the protective factors of mental health problems.

The high prevalence rates and risk factors of mental health problems uncovered in this study depicted that the mental health of students was largely affected during the early and normalization stage and therefore collective actions from different entities are needed to relieve the mental health sufferings of students. Firstly, students should be encouraged to adapt to healthy lifestyles like regular physical exercise and recreational activities. Regular physical exercise has been reported to lower mental health distress by improving sleep quality. Recreational activities can provide rest and relaxation resulting in a reduction in stress levels during pandemic [89]. Secondly, universities should provide psychosocial support and mental health services to students, particularly those who were at greater risk of developing mental health issues. Special consideration should be given to students who were infected with COVID-19, had family members or relatives infected, and lost loved ones during the pandemic [10]. The most evidence-based treatment is cognitive behaviour therapy (CBT), especially Internet CBT that can prevent the spread of infection during the pandemic [90-92]. Online psychotherapy should be adopted by mental health providers [67]. Also, universities should organize health education programs and mental health services. Greater attention should be given to females, junior and medical students in the health education and promotion programs [93]. Thirdly, governments should continue to strengthen public health education required for the circulation of information on preventive and control measures during the COVID-19 pandemic [94]. Again, governments should continue to give out more prevention and control services to the student population to increase their knowledge and promote their levels of confidence and trust to help fight against the COVID-19 pandemic [22]. Finally, families and communities should provide adequate care and support to students to assist them in suppressing negative psychological problems of COVID-19 or any other emerging epidemic diseases [95].

5. Strength
To the best of our knowledge, this is the first systematic review to assess and summarize previous studies that investigated the mental health status, including the prevalence and associated influential factors of mental health problems among Chinese college students amid the early and normalization stage of the COVID-19 pandemic.

6. Limitations
Studies were conducted at different stages and time periods of the pandemic resulting in variations in prevalence rates and risk factors affecting the mental health of students. All included studies used an online cross-sectional study design and therefore causal conclusions could not have been established. The collection of data via an online survey by the included studies may have created different objectives among respondents in the absence of a trained and qualified psychiatrist or researcher,
and this might caused bias and inconsistencies in the professional assessment of psychiatric symptoms.

This study mainly used self-reported questionnaires to measure psychiatric symptoms and did not make clinical diagnosis. The gold standard for establishing psychiatric diagnosis involved structured clinical interview and functional neuroimaging should be applied in the future face-to-face research after COVID-19 restrictions are removed [96-98]. Another possible limitation is the larger number of female participants reported over males in most studies resulting in over-representation and selection bias. Most included studies may not be a good representative of the actual population due to over representation and selection bias.

7. Conclusion
This systematic review presents an overview of prevalence rates of symptoms of mental health disorders particularly depression, anxiety, stress, PTSD, and insomnia including associated influential factors that affected students amid the early and normalization stage of the pandemic. Higher prevalence rates of mental health disorders were reported in the early stage as compared to the normalization stage. In general, the prevalence rates of mental health problems were reported to be increased as opposed to before the pandemic. A combination of efforts from the government, universities, families or communities together with students is highly needed to alleviate the mental health sufferings during the pandemic or future outbreaks of any epidemic disease. Hence, future research is needed to assess the current mental health problems of students due to the fact that included studies were only conducted during the early and normalization stage of the pandemic.

**Notes:**
- Anxiety: Senior students and those who smoked
- Anxiety and depression: confirmed or suspected cases in one’s community or village, low perceived social support, and prior mental health problems
- Stress: >3 h exposure to media coverage of the COVID-19 each day
- Good: Satisfactory
under quarantine, fever or cough, and
mask usage, need
ways to regulate
emotions, professional and
psychological hotline, and
psychiatric visits provided by schools

**Depression:**
Married, undergraduate and
postgraduate, non-medical, and
urban students, COVID-19-related
factors, such as a fever or cough, and
hours spent browsing COVID-
19-related information, needed ways
to regulate their emotions, used
professional and psychological
hotlines, and had psychiatric visits
provided by schools.

Highlights

- Evaluate the mental health status of college students during the early and normalization stage of the COVID-19 pandemic.
- Depression, anxiety, stress, and PTSD were the major mental health problems reported in the early stage. The prevalence rates of them ranged from 9.0% to 65.2%, 6.88% to 41.1%, 8.53% to 67.05%, and 2.7% to 30.8% respectively.
- Depression, anxiety, and insomnia were the main mental health problems reported in the normalization stage. The prevalence rates of them ranged from 8.7% to 50.2%, 4.2% to 34.6%, and 6.1% to 35.0% respectively.
- Higher prevalence rates of mental health problems were reported in the early stage compared to the normalization stage.
