Cortical Thickness of Native Tibetans in the Qinghai-Tibetan Plateau

W. Wei, X. X. Wang, Q. Gong, M. Fan, and J. Zhang

ABSTRACT

BACKGROUND AND PURPOSE: High-altitude environmental factors and genetic variants together could have exerted their effects on the human brain. The present study was designed to investigate the cerebral morphology in high-altitude native Tibetans.

MATERIALS AND METHODS: T1-weighted brain images were obtained from 77 Tibetan adolescents on the Qinghai-Tibetan Plateau (altitude, 2300–5300 m) and 80 matched Han controls living at sea level. Cortical thickness, curvature, and sulcus were analyzed by using FreeSurfer.

RESULTS: Cortical thickness was significantly decreased in the left posterior cingulate cortex, lingual gyrus, superior parietal cortex, precuneus, and rostral middle frontal cortex and the right medial orbitofrontal cortex, lateral occipital cortex, precuneus, and paracentral lobule. Curvature was significantly decreased in the left superior parietal cortex and right superior marginal gyrus; the depth of the sulcus was significantly increased in the left inferior temporal gyrus and significantly decreased in the right superior temporal gyrus, superior temporal gyrus, and insular cortex. Moreover, cortical thickness was negatively correlated with altitude in the left superior and middle temporal gyri, rostral middle frontal cortex, insular cortex, posterior cingulate cortex, precuneus, lingual gyrus, and the right superior temporal gyrus. Curvature was positively correlated with altitude in the left rostral middle frontal cortex, insular cortex, and middle temporal gyrus. The depth of the sulcus was negatively correlated with altitude in the left lingual gyrus and right medial orbitofrontal cortex.

CONCLUSIONS: Differences in cortical morphometry in native Tibetans may reflect adaptations related to high altitude.

ABBREVIATIONS: DMN = default mode network; HA = high altitude; PCC = posterior cingulate cortex; PPARA = peroxisome proliferator-activated receptor α

The Qinghai-Tibetan Plateau is one of the most extreme environments inhabited by humans. High-altitude (HA) natives have developed distinctive biologic characteristics in respiratory and circulatory functions, hemoglobin concentration, arterial oxygen saturation, energy metabolism, and genes to offset the stresses of HA environmental factors. Previous studies have revealed the adaptation of the cerebral glucose metabolic rate in HA Quechua natives and the adaptation of cerebral autoregulation in HA Himalayan natives and Ethiopian natives. However, existing studies provided no assessments of the cerebral structures in HA natives.

The brain is one of the organs in the body with the highest oxygen consumption and thus is particularly vulnerable to hypoxia. In contrast, cold weather at a HA may result in hypothermia, which has been shown to have a neuroprotective effect against hypoxic damage. Hypobaria at a HA could also be a factor contributing to brain lesions because it has been proved to induce white matter and cortical thickness impairment. Environmental ultraviolet rays can cause neuronal damage in the visual system and brain. Therefore, these HA environmental factors together could have exerted their effect on brain development.

Many present day native Tibetans on the Qinghai-Tibetan Plateau are the descendants of colonizers who arrived, at most, 25,000 years ago. Genetic adaptations at HA have been found in
the native Tibetans. Unique to Tibetans are the variants of genes within the hypoxia-inducible factor pathway, including Egl 9 homolog 1 (EGLN1), endothelial PAS domain protein 1 (EPAS1), and peroxisome proliferator-activated receptor α (PPARA), key genes in the oxygen homeostasis system at all altitudes. Among these genes, PPARA is involved in neuronal proliferation, differentiation, and apoptosis and neuroprotection against oxidative stress. Genetic variants may also play a role in brain development at a HA.

In previous studies, we have investigated the brain acclimatization to HA in the Han immigrant descendants on the Qinghai-Tibetan Plateau for several days to several years. We found that HA acclimatization was associated with brain structural and functional modifications. Therefore, we hypothesized that native Tibetans could have developed brain adaptations to HA under the combined actions of both environmental factors and genetic variants. To test this hypothesis, we investigated the cerebral morphology of 77 healthy Tibetan adolescents living at different altitudes, with 80 sea-level Han adolescents as controls.

**MATERIALS AND METHODS**

**Subjects**

Seventy-seven healthy native Tibetans (34 males and 43 females, 14–18 years of age) living in the southeast Tibet Autonomous Region (southeast Nagqu, Xigaze, Lasa, Nyingchi, and Chamdo) (altitude, 2300–5300 m) were recruited. Their ancestors were all native Tibetans living on the Qinghai-Tibetan Plateau. They were without any prior descent to the lowlands or ascent to higher altitudes. All had a normal body mass index. They were all 10th grade students and had been enrolled in a high school at Chengdu (altitude, <400 m) for half a month. The control subjects were 80 (34 males and 46 females, 14–18 years of age) adolescents living at sea level (altitude, <50 m), matched with the native Tibetans by sex, age, and education. Subjects were excluded if they had a history of mountain sickness, neurologic disorder, or head injury. The experimental protocol was approved by the Research Ethics Review Board of Xiamen University. Procedures were fully explained, and all subjects provided written informed consent before participating in the study.

**MR Imaging Data Acquisition**

Brain images were obtained on the same model 3T Signa Excite MR imaging system (GE Healthcare, Milwaukee, Wisconsin) at the Huaxi Magnetic Resonance Research Center, West China Hospital, Chengdu, China, and at the MR Imaging Center, First Affiliated Hospital of Xiamen University, Xiamen, China. Parameters for the T1-weighted MPRAGE sequences were the following: TR/TE = 1900/2.48 ms, FOV = 25 × 25 cm², NEX = 1, matrix = 512 × 256, section thickness = 1.0 mm. Conventional 2D T1 and T2 images were also obtained and examined for any incidental findings. Data analyses were conducted by 2 researchers who were blinded to the status of subjects.

**FreeSurfer Analysis**

FreeSurfer (Version 5.1.0; http://surfer.nmr.mgh.harvard.edu) was used for cortical thickness, curvature, and sulcus analyses. The process consisted of the removal of nonbrain tissue, mapping to Talairach-like space, and segmentation of the gray/white matter and pial boundaries. These maps of measurements were obtained by reconstructing representations of the GM/white matter boundary and the white matter boundary to the GM/CSF boundary and then calculating the closest distance from those surfaces at each vertex on the tessellated surfaces. All subject data were resampled to the FreeSurfer default common surface template by using a high-resolution surface-based averaging technique that aligned cortical folding patterns. Finally, the surface data were spatially smoothed by using a Gaussian kernel of 10-mm full width at half maximum. Regional variations of the cortical thickness, curvature, and sulcus were compared by using an independent samples t test, with age, sex, and education as covariates.

The statistical parametric map was generated at $P < .05$ (false discovery rate–corrected for multiple comparisons).

**Correlation Analysis**

The correlations of cerebral structural measurements with altitude were analyzed, with age and sex as covariates. The false discovery rate of $P < .05$ was applied to correct for multiple comparisons.

**RESULTS**

**Cortical Thickness, Curvature, and Depth of the Sulcus**

Compared with controls, the significant changes of cerebral structural measurements in native Tibetans are shown in Fig 1. Cortical thickness was significantly decreased in the left posterior cingulate cortex (PCC), lingual gyrus, superior parietal cortex, precuneus, and rostral middle frontal cortex and the right medial orbitofrontal cortex, lateral occipital cortex, precuneus, and paracentral lobule (Table 1). Furthermore, curvature was significantly decreased in the left superior parietal cortex and right superior marginal gyrus. Finally, the depth of the sulcus was significantly increased in the left inferior temporal gyrus and significantly decreased in the right superior marginal gyrus, superior temporal gyrus, and insular cortex.

**Correlations**

The significant correlations of cerebral structural measurements with altitude in native Tibetans are shown in Fig 2. Cortical thickness was negatively correlated with altitude in the left superior and middle temporal gyri, rostral middle frontal cortex, PCC, precuneus, lingual gyrus, insular cortex, and right superior temporal gyrus (Table 2). Curvature was positively correlated with altitude in the left rostral middle frontal cortex, insular cortex, and middle temporal gyrus. The depth of the sulcus was negatively correlated with altitude in the left lingual gyrus and right medial orbitofrontal cortex.

Figure 3 indicates the overlaps of brain between the regions showing decreases of cortical thickness and those showing correlation between cortical thickness and altitude. These regions included the left PCC, precuneus, lingual gyrus, and rostral middle frontal cortex.

**DISCUSSION**

Our study is the first to reveal the cerebral characteristics of native Tibetans living on the Qinghai-Tibetan Plateau. Adaptations of Tibetans to HA were associated with structural modifications in...
cortical thicknesses, curvature, and the sulcus. Mainly in the left hemisphere, the cortical structures were significantly correlated with altitude; moreover, with increasing altitude, native Tibetans had a decrease of regional cortical thickness, while they had an increase of cortical folding in terms of curvature. The regions showing decreases of cortical thickness and those showing correlations between cortical thickness and altitude overlapped in the left PCC, precuneus, lingual gyrus, and rostral middle frontal cortex.

The changed brain regions in the native Tibetans were in agreement with those found in our previous studies on Han immigrants living on the Qinghai-Tibetan Plateau. For example, Han immigrant descendants at HA showed decreases of cortical thickness in the paracentral lobule, PCC, and precuneus and increases of cortical thickness in the orbitofrontal cortex, superior parietal cortex, inferior temporal gyrus, and lingual gyrus. Moreover, compared with Tibetan adolescents who had lived at sea level for 4 years, the Tibetan adolescents who lived at a HA all the time showed decreases of GM volume in the superior parietal cortex and insular cortex.

### Table 1: Regional information of changed cortical thickness in native Tibetans

| Areas                                      | Volume (mm³) | MNI Coordinate | P (Peak) |
|--------------------------------------------|--------------|----------------|----------|
| *Left*                                     |              |                |          |
| Posterior cingulate cortex/lingual gyrus   | 1467         | −3.7           | −8.5     | 33.8     | 3.651 |
| Superior parietal cortex/precuneus         | 1815         | −8.6           | −68.1    | 56.0     | 2.571 |
| Rostral middle frontal cortex              | 1575         | −31.2          | 36.9     | 22.6     | 1.878 |
| *Right*                                    |              |                |          |
| Lateral occipital cortex                   | 2149         | 26.4           | −83.9    | 14.4     | 3.081 |
| Precuneus/paracentral lobule               | 2200         | 7.7            | −61.8    | 58.2     | 2.583 |
| Medial orbitofrontal cortex                | 1366         | 8.4            | 47.6     | −13.8    | 3.296 |

### Effects of Environmental Factors on Brain Structural Development

In native Tibetans, there were significant correlations between regional cortical measurements and altitude, suggesting that HA environmental factors influence brain development. The effects of HA environmental factors on brain development have been detected in Tibetan adolescents who were born and raised on the Qinghai-Tibetan Plateau compared with Tibetan adolescents who had lived at sea level during the past 4 years.

Cortical changes may be induced by hypoxia. For example, cerebral edema was found after acute exposure to normobaric hypoxia. In agreement with the present findings, damage of GM in the cingulate cortex, temporal gyrus, and insular cortex has been detected in patients with hypoxia with chronic obstructive pulmonary disease. The changed cerebral circulation may be attributed to temporal and posterior brain structural alterations shown in the present study. The vertebral artery supplies blood to...
these 2 parts of the brain. Willie et al\textsuperscript{29} found that with hypoxia, the relative increase in vertebral artery blood flow was 50\% greater than in the other vessels. Ogoh et al\textsuperscript{30} found that the internal carotid artery blood flow was unchanged, while the vertebral artery blood flow was significantly increased during acute hypoxia. Feddersen et al\textsuperscript{31} found that in mountaineers during ascent to 5050 m, the cerebral blood flow velocity was decreased in the posterior cerebral arteries. Moreover, hypoxia-induced alteration of cerebral blood flow patterns was found in the posterior brain in patients with hypoxia and obstructive sleep apnea, which included the lingual gyrus, parietal lobe, precuneus, temporal cortex, and insular cortex.\textsuperscript{32} Recently, Lawley et al\textsuperscript{33} found that 2 hours of hypoxia caused an expected increase in frontal cortical gray matter perfusion but unexpected perfusion decreases predominantly in the PCC. After 10 hours in hypoxia, the decreased blood flow became more pronounced and widespread. They further confirmed that these reductions in cerebral blood flow from hypoxia were related to vasoconstrictions.

Hypobaria at HA could be another important factor contributing to brain alterations. Acute mountain sickness scores were higher,\textsuperscript{34} and visual sensitivities were lower\textsuperscript{35} in hypobaric than in normobaric hypoxia. Studies on U-2 pilots showed that hypobaria was associated with a change of white matter hyperintensity\textsuperscript{14,36} and with the reduction of cortical thickness.\textsuperscript{15} Moreover, exposure to hypobaria after traumatic brain injury worsened brain function.\textsuperscript{37}

Cold ambient temperature at a HA may result in hypothermia. Mild hypothermia is associated with decreased ventricular function, oxygen extraction, and microvascular flow.\textsuperscript{38} During hypoxia, hypothermia has been shown to have a neuroprotective effect against hypoxic encephalopathy.\textsuperscript{12} Moreover, hypothermia treatment in an animal stroke model reduced infarct size and improved neurologic behavior.\textsuperscript{11}

The decrease of visual cortical thickness in the present study may be an outcome of ultraviolet radiation at HA. Ultraviolet light has been shown to alter neuronal activity in the cortical structures involved in visual processing.\textsuperscript{39} Environmental doses of ultraviolet rays can induce apoptosis in the retina and lamina ganglionaris within the visual system and in the brains of invertebrate crustaceans.\textsuperscript{16-18}

Effects of Genes on Brain Structural Development

The results of the present study obtained from native Tibetans showed some differences from those found in the Han immigrant descendants, which suggest that genes may play a role in Tibetan brain development. A recent study discovered genetic selection on the PPARA in HA native Tibetans on the Qinghai-Tibetan Plateau through comparing them with Chinese and Japanese lowland populations. PPARA is expressed in the brain and involved in neuronal proliferation, differentiation, and apoptosis. PPARA encodes the fatty acid–activated transcription factors and fatty acid oxidation regulators; thus, it may affect brain structure through control of energy homeostasis. Moreover, during hypoxia, PPARA supports a role in neuroprotection against oxidative stress.

Gene or Environment: Which One Determines Brain Structure?

Reduced psychomotor speed has been tested in the subjects (6–16 years of age) of mixed-ethnic background (including Native American, European, or African ancestries who immigrated to HA during different periods) who were born and raised at HAs. For the proportion of Native Americans, Europeans, and Africans, genetic admixture with reduced psychomotor speed was comparable across altitude groups; therefore, chronic hypoxic exposure rather than genetic inheritance appears to affect brain change.
function development at HA. However, pulmonary function (forced expiratory volume and forced vital capacity) measures were greater in the HA natives compared with the lowland natives born and raised at HAs; this finding suggests a genetic effect. In contrast, these 2 pulmonary measures were similar in HA natives and sea-level natives at lowland; this finding suggests that the genetic potential for larger lung volumes at HA depended on the developmental exposure to HA. In summary, results from these studies emphasized the importance of developmental adaptations to HA.

**Implications for the Changes in Cortical Structural Measurements**

In our study, decreases of cortical thickness in the medial orbitofrontal cortex, PCC, lingual gyrus, and precuneus; a decrease of curvature in the superior parietal cortex; and a decrease of the depth of the sulcus in the temporal cortices were detected. These regions are core areas of the resting-state brain default mode network (DMN) in humans. The impairment of GM structures may contribute to reduced neuronal activity. Previous multimodal neuroimaging studies have shed light on this functional-structure association, underlining cognition, aging, disease, and behavior. The changed activity within the DMN in response to chronic stress exposure has been found in humans and animals. The impairment of cortical structures in HA Tibetans is likely to reflect the stress-induced atrophic effects in cortical regions. Cortical atrophy within the DMN may reduce the brain response to HA environmental stress. Because regions within the DMN exert forebrain modulation over visceral responses mediated via the hypothalamus and brain stem, structural and functional changes within these circuits may contribute to modulations in autonomic and neuroendocrine functions associated with HA adaptations.

Tibetan college students were found to have higher levels of negative emotional expressivities such as fear, sadness, and anger in comparison with Han, Uighur, Hui, and Mongolian students. The Cattell 16 Personality Factor Questionnaire revealed that Tibetan adolescents had lower stability, persistence, independence, and self-discipline and higher extraversion and excitability than Han adolescents. The findings of the Eysenck Personality Questionnaire and Trait Coping Style Questionnaire suggested that Tibetan adolescents had higher neuroticism, introversion, and psychoticism and lower concealment than Han adolescents.

In humans, the DMN is thought to support a variety of self-referential functions and mind-wandering. Anxiety disorders and high trait anxiety are associated with decreased functioning of the DMN. The precuneus is implicated in social and emotional functions, especially among individuals with neuroticism. The left posterior and middle cingulate cortices and precuneus were found to be negatively correlated with neuroticism. The ventral medial prefrontal (orbitofrontal) cortex of the DMN functions as a sensory-visceromotor link concerned with social behavior, mood control, and motivational drive, all of which are important components of an individual’s personality. Therefore, a changed DMN may explain why Tibetan adolescents had personality traits distinct from those of the Han adolescents.

The decreases of cortical thickness in the PCC and lingual gyrus may be related to visual deficits at HA. The poor visual performances were consistent and prominent problems in the HA immigrants, such as the sea-level college students after 7 months of study at moderate altitudes, and in the HA Han immigrant descendants. The PCC and lingual gyrus have direct anatomic connectivities with the visual striate cortices. The PCC lies at the parietomedial temporal visual stream pathway. It is activated by visual perception, attention, and motion. The lesions of the PCC produce an impairment in visual discrimination learning and a decrease of resting-state functional connectivity in the PCC, which is indicated by severe myopia. The lingual gyrus is a part of the occipitotemporal pathway that engages in object drawing and is activated by visuospatial navigation and angle discrimination tasks. GM volume in the right lingual cortex has been proved to have a positive correlation with visual reproduction, while GM atrophy in this area was associated with visual hallucinations.

The decreased depth of the anterior insular sulcus and damage to the ventral medial prefrontal cortex in the present study support the hypothesis that these 2 regions are needed to process the perturbation of the homeostatic balance in extreme environments. Because the lesions in the insular cortex have been proved to disrupt representation of internal states that underpin motivation, the changes of the anterior insular cortex may also be related to the blunted hypoxic ventilatory response in HA residents.

**Limitations**

There are several limitations to our study. First, brain images were obtained by using 2 MR imaging scanners. However, several studies have confirmed that the MR imaging scanner field strength, manufacturer, machine upgrade, and pulse sequence and the different postprocessing algorithms applied to the images acquired from different MR imaging systems have little effect on the reliability of cortical thickness measurements.

Second, the Tibetan subjects had moved to the lowlands for 1–15 days, which would have an influence on cerebral blood flow. However, given the previous investigations, this effect may be slight after residing at sea level for such a short time. For example, when HA adult natives descended to sea level for several weeks, their cardiac functions remained unchanged.

Third, the interethnic difference of brain structure can be large. Brain morphologic differences between populations of different origins have been found in whole-brain and region-specific volume. Future study should compare the interethnic difference of brain structures between Tibetans and Han populations at lowland.

Fourth, Tibetans have been living on the Qinghai-Tibetan Plateau and have developed a unique culture and language. The lifestyle of the Tibetans was different from that in the lowlands, for example, in the absence of crowds, which could have affected the subjects’ emotional well-being. Moreover, diet was likely to be an important factor for the observed brain changes.

**CONCLUSIONS**

Native Tibetans have developed brain structural adaptations that enable their successful existence in the HA environment. The al-
