PARTITION IDENTITIES FROM HIGHER LEVEL CRYSTALS OF $A_1^{(1)}$

JEHANNE DOUSSE, LEONARD HARDIMAN AND ISAAC KONAN

Abstract. We study perfect crystals for the standard modules of the affine Lie algebra $A_1^{(1)}$ at all levels using the theory of multi-grounded partitions. We prove a family of partition identities which are reminiscent of the Andrews–Gordon identities and companions to the Meurman–Primc identities, but with simple difference conditions involving absolute values. We also give simple non-specialised character formulas with obviously positive coefficients for the three level 2 standard modules.

1. Introduction and statement of results

The content of this paper lies within the intersection of combinatorics (in particular, the study of partition identities) and the representation theory of affine Kac–Moody algebras. Every since Lepowsky and Wilson’s foundational work [LW83, LW85] a productive relationship has been established between these two fields. We now recall some background and provide a brief description of the principal mechanism through which this interaction takes place.

A partition of a positive integer $n$ is a non-increasing sequence of natural numbers whose sum is $n$. For example, the partitions of 4 are (4), (3, 1), (2, 2), (2, 1, 1) and (1, 1, 1, 1). Among the most famous and ubiquitous partition and $q$-series identities are those of Rogers–Ramanujan [RR19]. In $q$-series form, they can be stated as follows:

Theorem 1.1 (The Rogers–Ramanujan identities). Let $i = 0$ or 1. Then

$$\sum_{n \geq 0} q^{n^2 + (1-i)n} (q; q)_n = \frac{1}{(q^2 -1; q^4)_\infty (q^3 + 1; q^6)_\infty}.$$\

Here and throughout the paper, we use the standard $q$-series notation: for $n \in \mathbb{N} \cup \{\infty\}$ and $j \in \mathbb{N}$,

$$(a_1; q) := \prod_{k=0}^{n-1} (1 - aq^k),$$

$$(a_1, \ldots, a_j; q)_n := (a_1; q)_n \cdots (a_j; q)_n.$$\

Interpreting the product side of the Rogers–Ramanujan identities as the generating function for partition with congruence conditions and the sum side as the generating function for partition with difference conditions yields the combinatorial identities:

Theorem 1.2 (Rogers–Ramanujan identities, combinatorial version). Let $i = 0$ or 1. For every natural number $n$, the number of partitions of $n$ such that the difference between two consecutive parts is at least 2 and the part 1 appears at most $i$ times is equal to the number of partitions of $n$ into parts congruent to $\pm (2i - 1) \mod 5$.

These identities were given many proofs and generalisations, see e.g. [And74, And89, Bre83, Cor17, GM81, Gor61, GOW16], including the famous Andrews–Gordon identities [And74].

Theorem 1.3 (Andrews–Gordon identities). Let $r$ and $i$ be integers such that $r \geq 2$ and $1 \leq i \leq r$. Let $G_{i,r}(n)$ be the number of partitions $\lambda = \lambda_1 + \lambda_2 + \cdots + \lambda_s$ of $n$ such that $\lambda_j - \lambda_{j+r-1} \geq 2$ for all $j$, and at most $i - 1$ of the $\lambda_j$ are equal to 1. We have

$$\sum_{n \geq 0} G_{i,r}(n) q^n = \frac{(q^{2r+1}; q^2)_{\infty} (q^2 r+1; q^2 r+1)_{\infty}}{(q; q)_{\infty}}.$$\

Note that the Rogers–Ramanujan identities correspond to the particular case $r = 2$ in Theorem 1.3.

In [Bre79], Bressoud found an even-moduli counterpart to the Andrews–Gordon identities.

Key words and phrases. integer partitions, Rogers–Ramanujan type identities, Kac-Moody Lie algebras, character formulas, crystal bases.
Theorem 1.4 (Bressoud). Let \( r \) and \( i \) be integers such that \( r \geq 1 \) and \( 1 \leq i \leq r \). Let \( B_{i,r}(n) \) be the number of partitions \( \lambda = \lambda_1 + \lambda_2 + \cdots + \lambda_s \) of \( n \) such that \( \lambda_j - \lambda_{j+r-1} \geq 2 \) for all \( j \), if \( \lambda_j \leq \lambda_{j+r-2} + 1 \) then \( \lambda_j + \cdots + \lambda_{j+r-2} \equiv i-1 \mod 2 \), and at most \( i-1 \) of the \( \lambda_i \) are equal to 1. We have

\[
\sum_{n \geq 0} B_{i,r}(n)q^n = \frac{(q^{2r}, q^{2r-1}; q^{2r})_{\infty}}{(q; q)_{\infty}}.
\]

We now explain how these partition identities have been related to representation theory. We assume that the reader is familiar with the notion of a Kac–Moody algebra, the standard reference text is [Kac90]. Let \( g \) be a affine Kac–Moody algebra with positive roots \( \Delta^+ \subset h^* \), where \( h \) is a Cartan subalgebra in \( g \). Let \( P \) (resp. \( P^+ \)) be the corresponding set of integral (resp. dominant integral) weights and let \( L(\lambda) \) an irreducible highest weight \( g \)-module of highest weight \( \lambda \in P^+ \). The character of \( L(\lambda) \) is defined as

\[
\text{ch } L(\lambda) = \sum_{\mu \in P} \dim L(\lambda)_{\mu} \cdot e^{\mu},
\]

where \( e \) is a formal exponential and \( L(\lambda)_{\mu} \) is the weight space corresponding to \( \mu \). A well studied problem within representation theory is the development of so-called character formulas i.e. explicit algebraic expressions for \( \text{ch } L(\lambda) \). An well-known example is provided by the Weyl–Kac character formula [Kac90, Proposition 10.10]

\[
\text{ch } L(\lambda) = \sum_{w \in W} \text{sgn}(w) e^{w(\lambda + \rho) - \rho} \prod_{\alpha \in \Delta^+} (1 - e^{-\alpha})^{\text{mult } \alpha},
\]

where \( W \) is the Weyl group and \( \rho \) is the Weyl vector. An important feature of the Weyl–Kac character formula is that it overcounts, i.e. the sum is alternating. Finding a non-overcounting character formula is a difficult task, partial results may be obtained using the theory of vertex operator algebras and equating the resulting formulas with the Weyl–Kac character formula gives rise to certain partition identities. This was the basic strategy employed by Lepowsky and Wilson [LW84, LW85] to derive the Rogers–Ramanujan identities from character formulas for level 3 modules over \( A_1^{(1)} \). Subsequently, other partition identities were obtained (some of which were previously unknown to the combinatorics community) using different levels and algebras, see, for example, [Cap93, MP87, MP99, MP01, Nan14, Pri94, PS16, Sil17]. More detail on the history of this interaction can be found in the introduction of [DK19a].

Let us state in detail a partition identity which was obtained by Meurman and Primc [MP99] through the study of vertex operator algebras for higher level modules of \( A_1^{(1)} \). An integer partition can equivalently be defined in terms of frequencies, i.e. by a sequence \( (f_1, f_2, f_3, ...) \) where for every natural number \( k \), \( f_k \) denotes the number of appearances of \( k \) in the partition. Meurman and Primc’s result reads as follows (slightly reformulated):

Theorem 1.5 (Meurman–Primc 1999). Let \( n \) and \( i \) be non-negative integers such that \( 0 \leq i \leq n \). Let \( M_{i,n}(m) \) denote the number of partitions of \( m \) in two colours, plain and underlined, such that their frequencies \( (f_1, f_2, f_3, ...) \) satisfy, for all \( k \geq 1 \):

\[
\begin{align*}
&f_{2k} = 0, \\
&f_{2k+1} + f_{2k} + f_{2k-1} \leq n, \\
&f_{2k} + f_{2k-1} + f_{2k-2} \leq n, \\
&f_{2k+1} + f_{2k+1} + f_{2k} \leq n, \\
&f_{2k+1} + f_{2k} + f_{2k-1} \leq n,
\end{align*}
\]

and

\[
\begin{align*}
f_1 &\leq i, \\
f_1 &\leq n - i.
\end{align*}
\]

Then we have the identity

\[
\sum_{n \geq 0} M_{i,n}(m)q^n = \frac{(q^{i+1}, q^{n-i+1}, q^{n+2}, q^{n+2})_{\infty}}{(q; q^2)_{\infty}(q; q)_{\infty}},
\]

Note that up to the factor \( 1/(q; q^2)_{\infty} \), the product side of (1.2) is exactly the product side of the Andrews–Gordon and Bressoud identities. Meurman and Primc’s identity is a great example of a partition identity for which it seems highly unlikely that guessing the identity using only the combinatorics of integer partitions would have been possible, and where representation theory plays a key role in the shape of the difference conditions.
An alternative approach to finding a non-overcounting character formula is provided by the theory of 
**crystal bases**, a good reference text for which is [HK02]. Said theory allows one to describe the character 
$\text{ch } L(\lambda)$ in terms of a **crystal** i.e. a directed graph $\mathcal{B}$ together with a weight function $w: \mathcal{B} \to P$ satisfying 
certain conditions (see, e.g. Definition 4.5.1 in [HK02]). In particular, the crystal graph $\mathcal{B}(\lambda)$ of a crystal 
basis of $L(\lambda)$ will satisfy 
$$
\text{ch } L(\lambda) = \sum_{b \in \mathcal{B}(\lambda)} e^{w(b)}.
$$

Kashiwara [Kas91] proved the existence and uniqueness of crystal bases. Therefore, understanding the 
structure of the corresponding crystal graph automatically grants one a non-overcounting character 
formula. Kashiwara et al. [KKM*92] then provided a description of $\mathcal{B}(\lambda)$ in terms of certain particularly 
well-behaved crystals for the associated classical algebra, called **perfect crystals**. As before, equating the 
resulting crystal character formula with the Kac–Peterson formula can lead to a partition identity. This 
was first accomplished by Primc [Pri99], using level 1 modules over $A_1$. 

It is also interesting to note that our difference conditions are very different from those of Theorem 1.5, 
and generalised to level 1 modules over $A_1$ by the first and third authors in [DK19a, DK19b], and generalised 
to other modules in [DK21] (more on this in Section 2). In this paper, we study different perfect $A_1$ 
crystals of arbitrarily high level and provide new partition identities and non-overcounting character 
formulas.

Our main result is a new family of partition identities which are companions (i.e. same infinite product 
structure) to the Meurman–Primc identity.

**Theorem 1.6.** Let $n$ and $i$ be non-negative integers such that $0 \leq i \leq n$. Let $C_{n,i}(m)$ be the number of 
$(n + 1)$-coloured partitions of $m$ in $C_n$ such that the last part is $0_i$, and the penultimate part has colour 
different from $c_i$. Let $C_{n,i} \geq(m)$ be the number of $(n + 1)$-coloured partitions of $m$ in $C_n \geq$ such that the 
last part is $0_i$, and the penultimate part is different from $0_i$. Then, we have the identities 

$$
\sum_{n \geq 0} C_{n,i}(m) q^m = \frac{(q^{i+1}, q^{n-i+1}, q^{n+2}; q^{n+2})_{\infty}}{(q^{i}, q)_{\infty}^{n+1}} q^{\lambda_i - \lambda_{i+1}} |u_i - u_{i+1}|. 
$$

(1.3)

$$
\sum_{n \geq 0} C_{n,i} \geq(m) q^m = \frac{(q^{i+1}, q^{n-i+1}, q^{n+2}; q^{n+2})_{\infty}}{(q^{i}, q^{n+1})_{\infty}^{2}} q^{\lambda_i - \lambda_{i+1}}. 
$$

(1.4)

Just like for the Meurman–Primc identity, up to the factor $1/((q; q^2)_{\infty}^{2} (q^2; q)_{\infty})$ (resp. $1/((q; q^2)_{\infty}^{2} (q^2; q)_{\infty})$), 
the product on the right-hand side of (1.3) (resp. (1.4)) is exactly the product side of the famous Andrews– 
Gordon and Bressoud identities. On the other hand, it is – at least to the extent of our knowledge – the 
first time in the literature that difference conditions involving absolute values arise in partition identities. 

It is also interesting to note that our difference conditions are very different from those of Theorem 1.5, 
and arguably more simple. This highlights the fact that the approaches via vertex operator algebras and 
crystal bases, though both in the realm of representation theory, are very different and give rise to very 
different results.

To prove Theorem 1.6, we use energy matrices for level $n$ perfect crystals of $A_1$ and the theory 
of grounded partitions introduced by the first and third authors [DK19b] to express the characters of standard 
modules as generating functions for coloured partitions, which gives the left-hand side of (1.3). 
The right-hand side of (1.3) comes from the principal specialisation of the Weyl–Kac character formula.

Building up on recent work of the first and third authors on multi-grounded partitions [DK21], we 
also give simple **non-specialised** character formulas with manifestly positive coefficients for all level 2 
standard modules of $A_1$.

Let $G = G(x_1, \ldots, x_n)$ be a power series in several variables $x_1, \ldots, x_n$. For $k \leq n$, we denote by 
$\mathcal{E}_{x_1, \ldots, x_k}(G)$ the sub-series of $G$ where we only keep the terms in which the sum of the powers of $x_1, \ldots, x_k$ 
is even. If $G$ has only positive coefficients, then for all $k$, $\mathcal{E}_{x_1, \ldots, x_k}(G)$ also has positive coefficients and
can be obtained easily from \(G\) via the formula
\[
\mathcal{E}_{x_1,\ldots,x_k}(G) = \frac{1}{2} \left( G(x_1,\ldots,x_k,x_{k+1},\ldots,x_n) + G(-x_1,\ldots,-x_k,x_{k+1},\ldots,x_n) \right).
\]
(1.5)

Our character formulas can be stated as follows,

**Theorem 1.7.** Let \(\Lambda_0,\Lambda_1\) be the fundamental weights and \(\alpha_0,\alpha_1\) be the simple roots of \(A_1^{(1)}\). Let \(\delta = \alpha_0 + \alpha_1\) be the null root. We have
\[
e^{-\langle\Lambda_0+\Lambda_1\rangle} \text{ch} L(\Lambda_0+\Lambda_1) = (-e^{-\alpha_0},-e^{-\alpha_1},-e^{-\delta},e^{-\delta})_\infty,
\]
(1.6)
\[
e^{-2\Lambda_0} \text{ch} L(2\Lambda_0) = \frac{1}{2} \left[ (-e^{-\frac{3}{2}\alpha_1},-e^{-\frac{1}{2}\alpha_1},-e^{-\frac{1}{2}\delta},e^{-\delta})_\infty + (e^{-\frac{3}{2}\alpha_1},e^{-\frac{1}{2}\alpha_1},e^{-\frac{1}{2}\delta},e^{-\delta})_\infty \right].
\]
(1.7)
\[
e^{-2\Lambda_1} \text{ch} L(2\Lambda_1) = \frac{1}{2} \left[ (-e^{-\frac{3}{2}\alpha_1},-e^{-\frac{1}{2}\alpha_1},-e^{-\frac{1}{2}\delta},e^{-\delta})_\infty + (e^{-\frac{3}{2}\alpha_1},e^{-\frac{1}{2}\alpha_1},e^{-\frac{1}{2}\delta},e^{-\delta})_\infty \right].
\]
(1.8)

Note that (1.7) and (1.8) are in the form of (1.5) and therefore have manifestly positive coefficients.

The paper is organised as follows. In Section 2, we recall the necessary background on (multi-)grounded partitions. In Section 3, we study the energy matrices of level \(n\) perfect crystals of \(A_1^{(1)}\) and prove Theorem 1.6. Finally, in Section 4, we prove the non-specialised character formulas of Theorem 1.7 and notice an intriguing connection with Capparelli’s identity.

2. Background on perfect crystals and multi-grounded partitions

We start by briefly recalling the theory of perfect crystals. Let \(\mathfrak{g}\) be an affine Kac–Moody algebra with simple positive roots \(\alpha_0,\ldots,\alpha_n\) and with null root \(\delta = d_0\alpha_0 + \cdots + d_n\alpha_n\). For \(\lambda \in \bar{P}^+\), let \(B(\lambda)\) the crystal graph of a crystal basis of \(L(\lambda)\). For an integer level \(\ell \geq 1\) and a weight \(\lambda \in \bar{P}^\ell\), Kashiwara et al. [KKM+92b, Section 1.4] define the notion of a perfect crystal \(B\) of level \(\ell\), an energy function \(H : B \otimes B \to \mathbb{Z}\), and a particular element
\[
p_\lambda = (g_k)_{k=0}^\infty = \cdots \otimes g_{k+1} \otimes g_k \otimes \cdots \otimes g_1 \otimes g_0 \in B^\infty,
\]
called the ground state path of weight \(\lambda\) (see Section 1.4 of their paper for precise definitions). From this they consider all elements of the form
\[
p = (p_k)_{k=0}^\infty = \cdots \otimes p_{k+1} \otimes p_k \otimes \cdots \otimes p_1 \otimes p_0 \in B^\infty,
\]
which satisfy \(p_k = g_k\) for large enough \(k\). Such elements are called \(\lambda\)-paths; their collective set is denoted \(\mathcal{P}(\lambda)\). The crystal \(B(\lambda)\) can then be realised on the set of \(\lambda\)-paths, in particular the affine weight function is given by the following theorem.

**Theorem 2.1** ([KMN]² crystal base character formula [KKM+92a]). Let \(\lambda \in \bar{P}^\ell\), let \(H\) be an energy function on \(B \otimes B\), let \(\mathcal{P}(\lambda)\) be the set of \(\lambda\)-paths, and let \(p = (p_k)_{k=0}^\infty \in \mathcal{P}(\lambda)\). Then the weight of \(p\) is given by the following expressions:
\[
\text{wt } p = \lambda + \sum_{k=0}^\infty \left( \text{wt } p_k - \text{wt } g_k \right) - \delta \sum_{k=0}^\infty (k+1) \left( H(p_{k+1} \otimes p_k) - H(g_{k+1} \otimes g_k) \right),
\]
\[
e = \lambda + \sum_{k=0}^\infty \left( \text{wt } p_k - \text{wt } g_k \right) - \delta \sum_{k=0}^\infty (k+1) \left( H(p_{k+1} \otimes p_k) - H(g_{k+1} \otimes g_k) \right),
\]
where \(\text{wt}\) is the weight function of \(B\). As \(\mathcal{P}(\lambda) \cong B(\lambda)\), we obtain the character formula
\[
\text{ch} L(\lambda) = \sum_{p \in \mathcal{P}(\lambda)} e^{\text{wt } p}.
\]

In [DK19b], the first and third authors used bijections to transform the \((\text{KMN})^2\) crystal base character formula into a formula expressing characters as generating functions for so-called “grounded partitions”, in the case where the ground state path of the module considered was constant. In [DK21], they generalised their theory to treat the cases of all ground state paths, thereby introducing multi-grounded partitions. We directly explain this latter more general theory, which contains the former as a particular case.

First, recall the definition of multi-grounded partitions.
Definition 2.2. Let $\mathcal{C}$ be a set of colours, and let $\mathbb{Z}_\mathcal{C} = \{k_c : k \in \mathbb{Z}, c \in \mathcal{C}\}$ be the set of integers coloured with the colours of $\mathcal{C}$. Let $\succ$ be a binary relation defined on $\mathbb{Z}_\mathcal{C}$. A generalised coloured partition with relation $\succ$ is a finite sequence $(\pi_0, \ldots, \pi_s)$ of coloured integers, such that for all $i \in \{0, \ldots, s-1\}$, $\pi_i \succ \pi_{i+1}$.

In the following, if $\pi = (\pi_0, \ldots, \pi_s)$ is a generalised coloured partition, then $c(\pi_i) \in \mathcal{C}$ denotes the colour of the part $\pi_i$. The quantity $|\pi| = \pi_0 + \cdots + \pi_s$ is the weight of $\pi$, and $C(\pi) = c(\pi_0) \cdots c(\pi_s)$ is its colour sequence.

Definition 2.3. Let $\mathcal{C}$ be a set of colors, $\mathbb{Z}_\mathcal{C}$ the set of integers coloured with colours in $\mathcal{C}$, and $\succ$ a binary relation defined on $\mathbb{Z}_\mathcal{C}$. Suppose that there exist some colors $c_{g_0}, \ldots, c_{g_{t-1}}$ in $\mathcal{C}$ and unique coloured integers $u_{c_{g_0}}^{(0)}, \ldots, u_{c_{g_{t-1}}}^{(t-1)}$ such that

$$u^{(0)} + \cdots + u^{(t-1)} = 0,$$

$$u_{c_{g_0}}^{(0)} \succ u_{c_{g_1}}^{(1)} \succ \cdots \succ u_{c_{g_{t-1}}}^{(t-1)} \succ u_{c_{g_0}}^{(0)}.$$ 

Then a multi-grounded partition with colours $\mathcal{C}$, ground $c_{g_0}, \ldots, c_{g_{t-1}}$ and relation $\succ$ is a non-empty generalised coloured partition $\pi = (\pi_0, \ldots, \pi_{s-1}, u_{c_{g_0}}^{(0)}, \ldots, u_{c_{g_{t-1}}}^{(t-1)})$ with relation $\succ$, such that $(\pi_{s-t}, \cdots, \pi_{s-1}) \neq (u_{c_{g_0}}^{(0)}, \ldots, u_{c_{g_{t-1}}}^{(t-1)})$ in terms of coloured integers.

We denote by $\mathcal{P}^\succ_{c_{g_0}, \ldots, c_{g_{t-1}}}$ the set of multi-grounded partitions with ground $g_0, \ldots, g_{t-1}$ and relation $\succ$. We do not make the set of colours $\mathcal{C}$ explicit in the notation as it should be clear from the context.

Grounded partitions, which were introduced in [DK19b], are a particular case of multi-grounded partitions where the ground is reduced to one colour $c_{g_0}$ (and therefore the smallest part has to be $0_{c_{g_0}}$).

We now recall the connection between multi-grounded partitions, ground state paths, perfect crystals and character formulas.

For $\ell \geq 1$, let $\mathcal{B}$ be a perfect crystal of level $\ell$ and let $\lambda \in \check{\mathcal{P}}^\ell_\mathcal{B}$ be a level $\ell$ dominant classical weight with ground state path $p_{\lambda} = (g_k)_{k \geq 0}$ (which is always periodic). Let us set $t$ to be the period of the ground state path, i.e. the smallest non-negative integer $k$ such that $g_k = g_0$. Let $H$ be an energy function on $\mathcal{B} \otimes \mathcal{B}$. Since $\mathcal{B} \otimes \mathcal{B}$ is connected, $H$ is uniquely determined by fixing its value on a particular $b \otimes b' \in \mathcal{B} \otimes \mathcal{B}$.

We now define the function $H_\lambda$, for all $b, b' \in \mathcal{B}$, by

$$H_\lambda(b \otimes b') := H(b \otimes b') - \frac{1}{t} \sum_{k=0}^{t-1} H(g_{k+1} \otimes g_k).$$

Thus we have

$$\sum_{k=0}^{t-1} H_\lambda(g_{k+1} \otimes g_k) = 0.$$ 

The function $H_\lambda$ satisfies all the properties of energy functions, except that it does not have integer values unless $t$ divides $\sum_{k=0}^{t-1} H(g_{k+1} \otimes g_k)$. With this new notation, we can rewrite the $(\text{KMN})^2$ formula for the weight of a $\lambda$-path in the following way. Let $m \geq 0$ and $p = (p_k)^m_{k=0} \in \mathcal{P}(\lambda)$ such that $p_{m't+i} = g_i$ for $m' \geq m$ and $i \in \{0, \ldots, t-1\}$. We have

$$\text{wt } p = \lambda + \sum_{k=0}^{mt-1} \text{wt } p_k + \frac{m}{t} \sum_{k=0}^{t-1} (k+1) H_\lambda(g_{k+1} \otimes g_k) - \frac{\delta}{d_0} \sum_{k=0}^{mt-1} (k+1) H_\lambda(p_{k+1} \otimes p_k).$$

Note that for any energy function $H$, we always have

$$\sum_{k=0}^{t-1} (k+1) H_\lambda(g_{k+1} \otimes g_k) = \sum_{k=0}^{t-1} (k+1) H(g_{k+1} \otimes g_k) - \frac{t+1}{2} \sum_{k=0}^{t-1} H(g_{k+1} \otimes g_k) \in \frac{1}{2} \mathbb{Z}.$$ 

The quantity above is an integer as soon as $t$ is odd, and is equal to 0 when $t = 1$. Thus we can choose a suitable divisor $D$ of $2t$ such that $DH_\lambda(\mathcal{B} \otimes \mathcal{B}) \subset \mathbb{Z}$ and $\frac{1}{2} \sum_{k=0}^{t-1} (k+1) DH_\lambda(g_{k+1} \otimes g_k) \in \mathbb{Z}$. For the entirety of this paper, $D$ always denotes such an integer.
Let us now consider the set of colours $C_B$ indexed by $B$, and let us define the relations $\succ$ and $\gg$ on $\mathbb{Z}_{C_B}$ by
\begin{align}
k_{c_b} \succ k'_{c_b} & \iff k - k' = DH_{\lambda}(b' \otimes b), \\
k_{c_b} \gg k'_{c_b} & \iff k - k' \geq DH_{\lambda}(b' \otimes b).
\end{align}
(2.3) (2.4)

We can define multi-grounded partitions associated with these relations, as can be seen in the next proposition.

**Proposition 2.4** ([DK21]). The set $\mathcal{P}^{\succ}_{c_{g_0}, \ldots, c_{g_t-1}}$ (resp. $\mathcal{P}^{\gg}_{c_{g_0}, \ldots, c_{g_t-1}}$) of multi-grounded partitions with ground $c_{g_0}, \ldots, c_{g_t-1}$ and relation $\succ$ (resp. $\gg$) is the set of non-empty generalised coloured partitions $\pi = (\pi_0, \ldots, \pi_s, u^{(0)}_{c_{g_0}}, \ldots, u^{(t-1)}_{c_{g_{t-1}}})$ with relation $\succ$ (resp. $\gg$), such that $(\pi_{s-1}, \ldots, \pi_s) \neq (u^{(0)}_{c_{g_0}}, \ldots, u^{(t-1)}_{c_{g_{t-1}}})$, and for all $k \in \{0, \ldots, t - 1\}$,
\[ u^{(k)} = -\frac{1}{t} \sum_{\ell=0}^{t-1} (\ell + 1)DH_{\lambda}(gt+1 \otimes gt) + \sum_{\ell=k}^{t-1} DH_{\lambda}(ge+1 \otimes ge). \]

In order to give a more general connection between multi-grounded partitions and character formulas, we use some further sets of multi-grounded partitions. For any positive integer $d$, let $d\mathcal{P}^{\succ}_{c_{g_0}, \ldots, c_{g_t-1}}$ denote the set of multi-grounded partitions $\pi = (\pi_0, \ldots, \pi_s, u^{(0)}_{c_{g_0}}, \ldots, u^{(t-1)}_{c_{g_{t-1}}})$ such that for all $k \in \{0, \ldots, s - 1\}$,
\[ \pi_k - \pi_{k+1} = DH_{\lambda}(p_{k+1} \otimes p_k) \in d\mathbb{Z}_{\geq 0}, \]
where $c(\pi_k) = c_{p_k}$ and $\pi_s = u^{(0)}_{c_{g_0}}$.

Finally, let $\mathcal{P}^{\gg}_{c_{g_0}, \ldots, c_{g_t-1}}$ (resp. $\mathcal{P}^{\succ}_{c_{g_0}, \ldots, c_{g_t-1}}$) denote the set of multi-grounded partitions of $d\mathcal{P}^{\gg}_{c_{g_0}, \ldots, c_{g_t-1}}$ (resp. $d\mathcal{P}^{\succ}_{c_{g_0}, \ldots, c_{g_t-1}}$) whose number of parts is divisible by $t$.

Now the character formulas connecting perfect crystals to multi-grounded partitions can be stated as follows.

**Theorem 2.5** (Dousse–Konan 2021). Setting $q = e^{-\delta/\langle da \rangle}$ and $c_b = e^{\frac{\Delta}{2\pi i}}$ for all $b \in B$, we have $c_{g_0}, \ldots, c_{g_t-1} = 1$, and the character of the irreducible highest weight $U_q(\mathfrak{g})$-module $L(\lambda)$ is given by the following expressions:
\[ \sum_{\mu \in \mathcal{P}^{\gg}_{c_{g_0}, \ldots, c_{g_t-1}}} C(\mu) q^{\vert \mu \vert} = e^{-\lambda} \text{ch } L(\lambda), \]
\[ \sum_{\pi \in \mathcal{P}^{\gg}_{c_{g_0}, \ldots, c_{g_t-1}}} C(\pi) q^{\vert \pi \vert} = \frac{e^{-\lambda} \text{ch } L(\lambda)}{(q^2;q^2)_{\infty}}. \]

This theorem will be used directly to prove Theorem 1.7 in Section 4 and the proof of Theorem 1.6 in Section 3 relies on a variant of these ideas.

3. Perfect Crystals for Standard $A_1^{(1)}$ Modules of Level $n$

The level $n$ perfect crystal $B_n$ of $A_1^{(1)}$ is shown on Figure 1 and for all $i$, the weights and null root are given, respectively, by
\[ \begin{aligned}
\widetilde{w} t b_i &= (2i - n) A_0 + (n - 2i) A_1 = \left(\frac{n}{2} - i\right) \alpha_1, \\
\delta &= \alpha_0 + \alpha_1,
\end{aligned} \]
(3.1)
where $\alpha_0$ and $\alpha_1$ are the simple roots [HK02, Example 10.5.2].

There are $n + 1$ standard $A_1^{(1)}$ modules of level $n$, namely whose highest weight is of the form
\[ \Lambda_{i,n} := i A_0 + (n - i) A_1, \]
for $i \in \{0, \ldots, n\}$. Their ground state paths are
\[ p_i := p_{\Lambda_{i,n}} = \cdots \otimes b_{n-i} \otimes b_i \otimes b_{n-i} \otimes b_i. \]
When $n$ is even, then there is a constant ground state path for $i = n/2$. Otherwise, all the ground state paths have period 2. By [KKM1923, Lemma 4.6.2], $B_n \otimes B_n$ is also a level $n$ perfect crystal, the corresponding energy function is given by the matrix below (where $H_n(b_i \otimes b_j)$ is given in column $i$, row $j$):

6
We can rewrite this more concisely, for all \( i, j \in \{0, \ldots, n\} \), as

\[
H_n(b_i \otimes b_j) = \max(i, n - j).
\]

While, to prove Theorem 1.6, we will not exactly use the theory of multi-grounded partitions explained in Section 2, we still need to consider a (pseudo) energy function \( H_\lambda \) such that the sum of its values on the ground state path of \( \lambda \) is 0. For this, we use (2.1).

Here, for all the ground state paths \( p_i \), we have

\[
H_n(b_{n-i} \otimes b_i) + H_n(b_i \otimes b_{n-i}) = n.
\]

Thus, for all standard modules \( \lambda \) of level \( n \), we have

\[
H_\lambda = H_n - \frac{n}{2},
\]

or in other words, for all \( i, j \in \{0, \ldots, n\} \):

\[
H_\lambda(b_i \otimes b_j) = \max(i - \frac{n}{2}, \frac{n}{2} - j).
\]

When \( n \) is even, \( H_\lambda \) is really an energy function. Otherwise, it has all the properties of an energy function, except that it has half-integral values.

To obtain the very simple difference conditions of Theorem 1.6, we perform yet another rewriting of \( H_\lambda \). For \( 0 \leq i, j \leq n \), we have

\[
H_\lambda(b_i \otimes b_j) = \frac{1}{2} \max(j + n - i, n - i - j) + \frac{1}{2}(i - j),
\]

\[
= \frac{1}{2} |n - i - j| + \frac{1}{2}(i - j). \tag{3.2}
\]

Thus

\[
H_\lambda(b_{n-i} \otimes b_i) + 2H_\lambda(b_i \otimes b_{n-i}) = H_\lambda(b_i \otimes b_{n-i}) = i - \frac{n}{2}. \tag{3.3}
\]
Let us consider the set of colours $\mathcal{C} = \{c_0, \ldots, c_n\}$ and define the difference condition $\Delta(c_a, c_b) = |a - b|$. Denote by $\mathcal{P}_{i,n}$ the set of grounded partitions with colours $\mathcal{C}$, grounded $c_i$ and relation $\succ$ defined by:

$$k_{c_a} \succ k_{c_b} \text{ if and only if } k - l = \Delta(c_a, c_b).$$

We shall now prove a key proposition which relates the partitions in $\mathcal{P}_{i,n}$ and the character of $L(\Lambda_{i,n})$.

**Proposition 3.1.** There exists a bijection $\Phi$ between $\mathcal{P}(\Lambda_{i,n})$ and $\mathcal{P}_{i,n}$ such that, if $\Phi(p) = \pi = (\pi_0, \ldots, \pi_s, 0_{c_i})$, then

$$\exp(wt\ p - \Lambda_{i,n}) = C'(\pi)q^{\pi},$$

where $x = \exp(-\frac{a_0 + a_1}{2})$, $c_k = \exp(k \cdot \frac{a_0 - a_1}{2})$, and

$$C'(\pi) = \prod_{a=0}^{s} (c_a)_{k}^{-1} \times \begin{cases} 1 & \text{if } s \text{ is odd} \\ c_i & \text{if } s \text{ is even} \end{cases}$$

Hence,

$$\sum_{\pi \in \mathcal{P}_{i,n}} C'(\pi)q^{\pi} = \exp(-\Lambda_{i,n}) \text{ ch } L(\Lambda_{i,n}).$$

**Proof.** In this proof, we set $\lambda = \Lambda_{i,n}$. Let $p = (b_{i,k})_{k \geq 0}$, with $i_k \in \{0, \ldots, n\}$ for all $k$, be a $\lambda$-path, and let $m$ be the unique non-negative integer such that $(i_{2m-2}, i_{2m-1}) \neq (i, n - i)$ and $(i_{2m}, i_{2m+1}) = (i, n - i)$ for all $m' \geq m$. We compute $wt\ p$, defined in (2.2), in terms of the roots $a_0$ and $a_1$. By (3.1), (3.2) and (3.3), we have

$$wt\ p = \lambda + \sum_{k=0}^{2m-1} \left( \frac{n}{2} - i_k \right) a_1 + m(a_0 + a_1) \left( i - \frac{n}{2} \right) + \frac{a_0 + a_1}{2} \sum_{k=0}^{2m-1} (k+1)(i_k - i_{k+1}) - \frac{a_0 + a_1}{2} \sum_{k=0}^{2m-1} (k+1)n - i_{k+1} - i_k.$$}

Using the fact that

$$\sum_{k=0}^{2m-1} (k+1)(i_k - i_{k+1}) = \sum_{k=0}^{2m-1} i_k - 2mi_{2m},$$

and that $i_{2m} = i$ because $p_{2m} = b_i$, we simplify and obtain

$$wt\ p = \lambda + \sum_{k=0}^{2m-1} \left( \frac{n}{2} - i_k \right) a_1 + m(a_0 + a_1) \left( i - \frac{n}{2} \right) - m(a_0 + a_1)i + \frac{a_0 + a_1}{2} \sum_{k=0}^{2m-1} i_k$$

$$= \lambda + \sum_{k=0}^{2m-1} \left( \frac{n}{2} - i_k \right) a_1 - \frac{a_0 + a_1}{2} \sum_{k=0}^{2m-1} (k+1)n - i_{k+1} - i_k.$$}

By setting $j_{2k+1} = n - i_{2k+1}$ and $j_{2k} = i_{2k}$, this reduces to

$$wt\ p - \lambda = \sum_{k=0}^{2m-1} (-1)^{k+1} j_k \cdot \frac{a_1 - a_0}{2} = - \frac{a_0 + a_1}{2} \sum_{k=0}^{2m-1} (k+1)j_{k+1} - j_k$$

$$= \sum_{k=0}^{2m-1} \left( (-1)^{k+1} j_k \cdot \frac{a_1 - a_0}{2} = - \frac{a_0 + a_1}{2} \sum_{l=k}^{2m-1} |j_{l+1} - j_l| \right).$$

Observe that when $i_{2m} = n - i$, we have $|j_{2m+1} - j_{2m}| = |i - i| = 0$. Furthermore, $(i_{2m-2}, i_{2m-1}) \neq (i, n - i)$ if and only if $(j_{2m-2}, j_{2m-1}) \neq (i, i)$. Thus, for $k \in \{0, \ldots, 2m - 1\}$, we set $$\pi_k = \left( \sum_{l=k}^{2m-1} |j_k - j_{k+l}| \right)_{c_{i_k}}.$$
and

\[ \Phi(\pi) = \begin{cases} (\pi_0, \ldots, \pi_{2m-2}, 0_{c_i}) & \text{if } j_{2m-1} = i \\ (\pi_0, \ldots, \pi_{2m-1}, 0_{c_i}) & \text{if } j_{2m-1} \neq i. \end{cases} \]

Hence, for all \( 0 \leq k \leq 2m - 2 \), we have \( \pi_k - \pi_{k+1} = [j_k - j_{k+1}] \), i.e. \( \pi_k \gtrdot \pi_{k+1} \). Finally, when \( j_{2m-1} = i \), we instead have \( j_{2m-2} \neq i \), so \( \pi \) is a grounded partition with ground \( c_i \). When \( j_{2m-1} \neq i \), \( \pi \) is also a grounded partition with ground \( c_i \), as \( \pi_{2m-1} = |j_{2m-1} - j_{2m}| = |j_{2m-1} - i| \) and then \( \pi_{2m-1} \geq 0_{c_i} \).

Therefore, \( \pi \) always belongs to \( \mathcal{P}_{i,n} \), and (3.6) becomes

\[ \text{wt } p - \Lambda_{i,n} = \frac{\alpha_1 - \alpha_0}{2} \left( \sum_{k=0}^{2m-1} (-1)^{k+1} j_k \right) - \frac{\alpha_0 + \alpha_1}{2} |\pi|, \]

where \( |\pi| \) denotes the size of \( \pi \).

Let us now give the inverse bijection. Let \( \pi = (\pi_0, \ldots, \pi_s, 0_{c_i}) \in \mathcal{P}_{i,n} \), with \( c(\pi_k) = j_k \) for all \( 0 \leq k \leq s+1 \). In particular, \( j_{s+1} = i \). Then set \( m = \left\lceil \frac{s+1}{2} \right\rceil \),

\[ (i_{2k}, i_{2k+1}) = \begin{cases} (j_{2k}, n - j_{2k+1}) & \text{if } k \leq m - 1 \\ (i, n - i) & \text{if } k \geq m, \end{cases} \]

and \( \Phi^{-1}(\pi) = p = (b_{i_k})_{k \geq 0} \). Since \( j_s \neq i \) and \( s \in \{2m-2, 2m-1\} \), we then have \( (j_{2m-2}, j_{2m-1}) \neq (i, i) \), so that \( m \) is the unique non-negative integer satisfying \((i_{2m-2}, i_{2m-1}) \neq (i, n - i) \) and \( (i_{2m'}, i_{2m'+1}) = (i, n - i) \) for all \( m' \geq m \). Hence, \( p \in \mathcal{P}(\Lambda_{i,n}) \). Moreover, as \( j_{s+1} = i \) and \( s + 1 \in \{2m - 1, 2m\} \), setting \( j_{2m} = i \) yields

\[ \pi_k = \sum_{i=k}^{s} |j_i - j_{i+1}| = \sum_{i=k}^{2m-1} |j_i - j_{i+1}|, \]

\[ |\pi| = \sum_{k=0}^{m} \pi_k = \sum_{k=0}^{2m - 2m-1} \sum_{i=k}^{2m-1} |j_i - j_{i+1}|, \]

and applying (3.6) to \( p \) gives

\[ \text{wt } p - \Lambda_{i,n} = \frac{\alpha_1 - \alpha_0}{2} \left( \sum_{k=0}^{2m-1} (-1)^{k+1} j_k \right) - \frac{\alpha_0 + \alpha_1}{2} |\pi|. \]

The uniqueness of the relations between \( s \) and \( m \), as well as the definition of the sequences \((i_k)_{k \geq 2m-1}\) and \((j_k)_{k \geq 0}\), imply that \( \Phi \) and \( \Phi^{-1} \) are inverses of each other. The relation (3.4) comes from the fact that, for \( \pi = \Phi(p) \),

\[ \text{wt } p - \Lambda_{i,n} = \frac{\alpha_1 - \alpha_0}{2} \left( \sum_{k=0}^{2m-1} (-1)^{k+1} j_k \right) - \frac{\alpha_0 + \alpha_1}{2} |\pi|. \]

We now consider the set \( \mathcal{P}_{i,n}^\ast \) of grounded partitions with colours \( C \), ground \( c_i \) and relation \( \gtrdot \) defined by:

\[ k_{c_s} \gtrdot l_{c_s} \text{ if and only if } k - l \geq \Delta(c_a, c_b). \]

Denote by \( \mathcal{P} \) the set of classical partitions.

**Proposition 3.2.** There exists a bijection \( \Psi \) between \( \mathcal{P}_{i,n}^\ast \) and \( \mathcal{P}_{i,n} \times \mathcal{P} \) such that \( \Psi(\pi) = (\mu, \nu) \) implies \( |\pi| = |\mu| + |\nu| \).

**Proof.** Here we only describe the bijection \( \Psi \). The proof of its well-definedness is analogous the proof of Proposition 3.6 in [DK1995]. Let \( \pi = (\pi_0, \ldots, \pi_{s-1}, 0_{c_i}) \in \mathcal{P}_{i,n}^\ast \), and set

\[ r = \max \{k \in \{0, \ldots, s\} : c(\pi_{k-1}) \neq c_i\}. \]

We set \( \mu := (\mu_0, \ldots, \mu_{r-1}, 0_{c_i}) \), where the part \( \mu_k \) is coloured \( c(\pi_k) \) and has size

\[ \sum_{l=k}^{r-1} \Delta(c(\pi_l), c(\pi_{l+1})). \]
We now build $\nu = (\nu_0, \ldots, \nu_{t-1})$. If $r < s$, then $t = s$ and

$$\nu_k := \begin{cases} 
\pi_k - \mu_k & \text{for } k \in \{0, \ldots, r-1\}, \\
\pi_k & \text{for } k \in \{r, \ldots, s-1\}.
\end{cases}$$

Otherwise $r = s$, in which case we set

$$t = \min\{k \in \{0, \ldots, s\} : \pi_k = \mu_k\},$$

and $\nu_k := \pi_k - \mu_k$ for all $k \in \{0, \ldots, t-1\}$. □

We are now ready to prove our main theorem.

**Proof of Theorem 1.6.** First observe that the quantity $C_{i,n}(m)$ counts the partitions of $m$ in $P_{i,n}$, and thus

$$\sum_{m \geq 0} C_{i,n}(m) q^m = \sum_{\pi \in P_{i,n}} q^{\abs{\pi}}.$$  

The principal specialisation of the character, which consists in performing the transformations $e^{-\alpha_0}, e^{-\alpha_1} \mapsto q$, is denoted by 1. In Proposition 3.1, it implies the transformations $x \mapsto q$ and $c_k \mapsto 1$. Hence, we obtain that $C'(\pi) = 1$ for all $\pi \in P_{i,n}$, and the equality (3.5) becomes

$$\sum_{m \geq 0} C_{i,n}(m) q^m = 1 \left(\exp(-\Lambda_{i,n}) \text{ch} L(\Lambda_{i,n})\right).$$

Finally, we deduce the right-hand side of (1.3) from the principal specialisation of the Weyl–Kac character formula (1.1) for the type $A^{(1)}_1$:

$$1 \left(\exp(-\Lambda_{i,n}) \text{ch} L(\Lambda_{i,n})\right) = \prod_{\alpha \in \Delta^\vee_{+}} \left(\frac{1 - q^{(\Lambda_{i,n} + \rho, \alpha)}}{1 - q^{(\rho, \alpha)}}\right)^{\text{mult } \alpha},$$

with

$$\rho = \Lambda_0 + \Lambda_1,$$

$$\Delta^\vee_{+} = \{k\alpha_0^\vee + (k-1)\alpha_1^\vee, (k-1)\alpha_0^\vee + k\alpha_1^\vee, k\alpha_0^\vee + k\alpha_1^\vee : k \in \mathbb{Z}_{\geq 1}\},$$

$$\text{mult } \alpha = 1 \text{ for all } \alpha \in \Delta^\vee_{+},$$

$$\langle \Lambda_u, \alpha_v^\vee \rangle = \chi(u = v).$$

To prove (1.4), we similarly remark that $C'_{i,n}(m)$ counts the partitions of $m$ in $P_{i,n}$, so that by Proposition 3.2

$$\sum_{m \geq 0} C'_{i,n}(m) q^m = \sum_{\pi \in P_{i,n}} q^{\abs{\pi}} = \frac{1}{(q; q)^\infty} \sum_{\pi \in P_{i,n}} q^{\abs{\pi}}.$$  

□

4. NON-SPECIALISED CHARACTER FORMULAS FOR LEVEL 2 STANDARD MODULES

In this section, we focus in more detail on the level 2 standard module of $A^{(1)}_1$ and prove the non-specialised character formulas of Theorem 1.7.

![Figure 2. The level 2 perfect crystal of $A^{(1)}_1$](image)
Here, we have three highest weights of level 2:
- \( \Lambda_0 + \Lambda_1 \), with ground state path \( \cdots \otimes b_1 \otimes b_1 \),
- \( 2\Lambda_0 \), with ground state path \( \cdots \otimes b_0 \otimes b_2 \otimes b_2 \otimes b_2 \),
- \( 2\Lambda_1 \), with ground state path \( \cdots \otimes b_2 \otimes b_0 \otimes b_0 \otimes b_0 \).

Note that \( H_2 \) is exactly the non-dilated matrix of difference conditions for Capparelli’s identity reformulated by the first author [Dou20]. Unfortunately, this doesn’t allow us to directly connect Capparelli’s identity to perfect crystals, as the connection is actually made with energy functions whose sum is zero on the ground state paths.

In order to compute our character formulas, we define the energy function satisfying that property:

\[
H = b_1 \begin{pmatrix}
  b_0 & b_1 & b_2 \\
  1 & 1 & 2 \\
  0 & 1 & 2
\end{pmatrix}.
\]

We now use the theory of grounded and multi-grounded partitions to prove Theorem 1.7.

4.1. The module \( L(\Lambda_0 + \Lambda_1) \). The highest weight \( \Lambda_0 + \Lambda_1 \) has a constant ground state path. We can thus apply the theory of grounded partitions directly to the energy matrix \( H \) to prove (1.6) of Theorem 1.7.

**Proof of (1.6) of Theorem 1.7** We set \( q = e^{-\delta}, c_0 = e^{\alpha_1}, c_1 = 1, c_2 = e^{-\alpha_1} \), and let \( \mathcal{P}_{\geq} \) denote the set of grounded partitions with colour set \( \{c_0, c_1, c_2\} \), ground \( c_0 \) and relation \( \geq \) given by

\[
k_{c_0} \geq l_{c_1} \iff k - l \geq H(b_j \otimes b_i).
\]

Then by Theorem 2.5 we have

\[
\sum_{\pi \in \mathcal{P}_{\geq}} C(\pi) q^{||\pi||} = \frac{e^{-(\Lambda_0 + \Lambda_1)} \mathrm{ch} L(\Lambda_0 + \Lambda_1)}{(q; q)_\infty}.
\]

(4.1)

Thus to compute the non-specialised character of \( L(\Lambda_0 + \Lambda_1) \), we only need to find a nice expression for the generating functions of grounded partitions in \( \mathcal{P}_{\geq} \). To do this, we note that the difference conditions given by the matrix \( H \) correspond to the partial order

\[
\cdots \ll 0_{c_1} \ll 1_{c_0} \ll 1_{c_1} \ll 2_{c_0} \ll 2_{c_1} \ll 3_{c_0} \ll 2_{c_2} \ll \cdots.
\]

By definition, the grounded partitions in \( \mathcal{P}_{\geq} \) must have \( 0_{c_1} \) as the last part, and the penultimate part should be different from \( 0_{c_1} \). The parts \( k_{c_0} \), can repeat arbitrarily many times because \( H(b_1 \otimes b_1) = 0 \). Thus, including the last part \( 0_{c_1} \) generated by \( c_1 \), the parts coloured \( c_1 \) are generated by

\[
\frac{c_1}{(c_1 q; q)_\infty}.
\]

Now the parts coloured \( c_0 \) and \( c_2 \) can also appear several times, but always in sequences of the form

\[
\cdots \ll k_{c_0} \ll (k - 1)_{c_2} \ll k_{c_0} \ll (k - 1)_{c_2} \ll \cdots.
\]

The generating function of such a sequence for a fixed integer \( k \geq 1 \) is given by

\[
\frac{(1 + c_0 q^k)(1 + c_2 q^{k - 1})}{(1 - c_0 c_2 q^{2k - 1})},
\]

where the denominator generates pairs \( (k_{c_0}, (k - 1)_{c_2}) \) that can repeat arbitrarily many times, and the numerator accounts for the possibility of having an isolated \( (k - 1)_{c_2} \) on the left end of the sequence, or an isolated \( k_{c_0} \) on the right end of the sequence. Multiplying this over all integers \( k \geq 1 \) gives the generating function for the parts coloured \( c_0 \) and \( c_2 \):

\[
\frac{(-c_0 q; q)_{\infty}(-c_2 q; q)_{\infty}}{(c_0 c_2 q; q^2)_{\infty}}.
\]

(4.1)
Thus the generating function for the grounded partitions in $\mathcal{P}_{c_1}^{\gg}$ is

$$
\sum_{\pi \in \mathcal{P}_{c_1}^{\gg}} C(\pi)q^{\|\pi\|} = \frac{e^{c_1(-c_0; q)_\infty(-c_2; q)_\infty}}{(c_1; q)_\infty(c_0c_2q; q^2)_\infty}.
$$

Substituting the correct values of $q, c_0, c_1, c_2$ into (4.1), and using that $1/(q; q)_\infty = (-q; q)_\infty$, we obtain

$$
e^{-(\lambda_0 + \lambda_1)} \text{ch} L(\lambda_0 + \lambda_1) = (-e^{-c_0}; q)_\infty(-e^{-c_1}; q)_\infty(-e^{-\delta}; q)_\infty,
$$

and (4.6) of Theorem 1.7 is proved. \[\square\]

It is interesting to note that in the purely combinatorial proof of Capparelli’s identity given by Lovejoy and the first author in [DL10], itself inspired by the combinatorial proof of Alladi, Andrews and Gordon [AAC95], they actually also compute the generating function for coloured partitions with difference $\gg$, and the first author in [DL19], itself inspired by the combinatorial proof of Alladi, Andrews and Gordon [AAC95], they actually also compute the generating function for coloured partitions with difference $\gg$, but with other initial conditions. Indeed, while in the present paper, the last part needs to be $0_{c_1}$ in their work, the smallest part could be any non-negative integer, which gave rise to the generating function

$$
(-c_0; q)_\infty(-c_2; q)_\infty,
$$

and $(-c_1; q)_\infty(c_0c_2q; q^2)_\infty$.

Then, adding a staircase (i.e. a partition $1 + 2 + 3 + \cdots$) to such a partition – which adds 1 to all the differences between consecutive parts and therefore transforms $H$ into $H_0$ – transforms it into a partition satisfying the difference conditions of Capparelli’s identity. The proof concludes with some $q$-series computations to show the generating function that one obtains is an infinite product, and therefore the generating function for partitions with congruence conditions.

Again, our hope of finding a direct proof of Capparelli’s identity via the theory of perfect crystals is not really fulfilled, because on the one hand the proof of Capparelli’s identity uses the “correct” energy function but with the “wrong” initial conditions, and on the other hand, if we start from the “correct” energy function and initial conditions, then adding a staircase gives a generating function which is not an infinite product. However, it is still interesting and intriguing that a purely combinatorial proof, with no connection or background in crystal base theory, naturally leads to the study of the exact energy matrix that is meaningful in the theory of perfect crystals and grounded partitions. This hints yet again at a deeper connection between the approaches in combinatorics and number theory, and between Capparelli’s identity (which originally comes from vertex operator algebras) and crystal base theory.

### 4.2. The module $L(2\Lambda_0)$

We now turn to the module $L(2\Lambda_0)$, whose ground state path $\cdots \otimes b_0 \otimes b_2 \otimes b_0 \otimes b_2$ is of period 2. Thus, we need the theory of multi-grounded partitions to prove (1.7) of Theorem 1.7.

**Proof of (1.7) of Theorem 1.7.** As explained in Section 2, we need to choose a suitable divisor $D$ of 4 such that $DH (B_2 \otimes B_2) \subseteq \mathbb{Z}$ and $\frac{1}{2} DH (b_0 \otimes b_2) + 2DH (b_2 \otimes b_0) \in \mathbb{Z}$. We have $H (b_2 \otimes b_0) = -H (b_0 \otimes b_2) = 1$, so we can choose $D = 2$, and define the relation $\gg$ as

$$
k_{c_0} \gg l_{c_1} \iff k - l \geq DH (b_j \otimes b_i).
$$

We want to study the multi-grounded partitions in $\mathcal{P}_{c_0}^{\gg}$. Using Definition 2.3 or Proposition 2.4, we obtain that the two fixed last parts of such partitions are $(1_{c_2}, 1_{c_0})$.

Applying Theorem 2.5 with $d = 2$ and $D = 2$ gives

$$
\sum_{\pi \in \mathcal{P}_{c_0}^{\gg}} C(\pi)q^{\|\pi\|} = \frac{e^{-2\lambda_0} \text{ch} L(2\Lambda_0)}{(q^2; q^2)_\infty},
$$

where $q = e^{-\delta/2}, c_0 = e^{\alpha_1}, c_1 = 1, c_2 = e^{-\alpha_1}$.

Recall that $\mathcal{P}_{c_0}^{\gg}$ is the set of multi-grounded partitions $\pi = (\pi_0, \ldots, \pi_{2s-1}, -1_{c_2}, 1_{c_0})$ with relation $\gg$ and ground $c_2, c_0$, having an even number of parts, such that for all $k \in \{0, \ldots, 2s - 1\}$,

$$
\pi_k - \pi_{k+1} - 2H (b_{k+1} \otimes b_k) \in 2\mathbb{Z}_{\geq 0}.
$$

where $c(\pi_k) = c_{k+1}$ and $\pi_{2s} = -1_{c_2}$.

Note that by (4.3) and the fact that $u^{(0)} = -1$, the multi-grounded partitions of $\mathcal{P}_{c_0}^{\gg}$ only have parts with odd sizes, as the differences between consecutive parts are even. Thus we can compute the generating function for partitions in $\mathcal{P}_{c_0}^{\gg}$ similarly to the last section, by noticing that, combined with (4.3), $\gg$ is the following partial order on the set of coloured odd integers:
\[ \cdots \ll 1_{c_0} \ll -1_{c_2} \ll 1_{c_1} \ll 3_{c_0} \ll 1_{c_2} \ll 3_{c_1} \ll 5_{c_0} \ll 3_{c_2} \ll \cdots. \]

At first, let us temporarily forget the condition that the number of parts must be odd, and let us compute the generating function.

The parts \((2k + 1)_{c_1}\) can repeat arbitrarily many times because \(2H(b_1 \otimes b_1) = 0\). Thus the parts coloured \(c_1\) are generated by

\[ \frac{1}{(c_1 q; q^2)_\infty}. \]

Now, as in the previous section, the parts coloured \(c_0\) and \(c_2\) can also appear several times, but always in sequences of the form

\[ \cdots \ll (2k + 1)_{c_0} \ll (2k - 1)_{c_2} \ll (2k + 1)_{c_0} \ll (2k - 1)_{c_2} \ll \cdots. \]

The generating function for such sequences for \(k \geq 1\) is given by

\[ \frac{(-c_0 q^2; q^2)_\infty(-c_2 q^2; q^2)_\infty}{(c_1 q; q^2)_\infty(c_0 c_2 q^2; q^4)_\infty}. \]

Moreover, the fixed tail of the multi-grounded partitions under consideration is \((-1_{c_2}, 1_{c_0})\), so that for \(k = 0\), only an isolated \(1_{c_0}\) can appear, but not \(-1_{c_2}\), otherwise our partition would end with \((-1_{c_2}, 1_{c_0}, -1_{c_2}, 1_{c_0})\), which is forbidden. Thus we should still multiply our generating function by

\[ c_0 c_2 (1 + c_0 q). \]

Combining all this, we obtain the generating function

\[ \frac{c_0 c_2 (-c_0 q^2; q^2)_\infty(-c_2 q^2; q^2)_\infty}{(c_1 q; q^2)_\infty(c_0 c_2 q^2; q^4)_\infty}. \]

Now, to take back into account the fact that there must be an even number of parts, we use (1.5). Thus the multi-grounded partitions in \(\mathbb{Z} P_{c_0 \otimes c_0}\) are generated by:

\[ \sum_{\pi \in \mathbb{Z} P_{c_0 \otimes c_0}} C(\pi) q^{||\pi||} = c_{c_0, c_1, c_2} \left( \frac{c_0 c_2 (-c_0 q^2; q^2)_\infty(-c_2 q^2; q^2)_\infty}{(c_1 q; q^2)_\infty(c_0 c_2 q^2; q^4)_\infty} \right) \]

\[ = \frac{c_0 c_2}{(c_0 c_2 q^2; q^4)_\infty} \left( \frac{(-c_0 q^2; q^2)_\infty(-c_2 q^2; q^2)_\infty}{(c_1 q; q^2)_\infty(c_0 c_2 q^2; q^4)_\infty} + \frac{(c_0 q^2; q^2)_\infty(c_2 q^2; q^4)_\infty}{(-c_1 q; q^2)_\infty} \right). \]

Substituting the correct values of \(q, c_0, c_1, c_2\) in (4.2) and simplifying completes the proof. \(\square\)

4.3. The module \(L(2\Lambda_1)\). Finally, we conclude with the character formula for the module \(L(2\Lambda_1)\), whose ground state path \(\cdots \otimes b_2 \otimes b_0 \otimes b_2 \otimes b_0\) is of period 2. Apart from the fixed last parts of the multi-grounded partitions, everything works in the same way as in the previous section, so we provide less detail this time.

**Proof of (1.8) of Theorem L.** The relation \(\gg\) and the values of \(q, c_0, c_1, c_2\) and \(D\) are defined exactly as in the last section, but now we want to study the multi-grounded partitions in \(\mathbb{P}_{c_0 \otimes c_2}\). Thus, using Definition 2.3 or Proposition 2.4, the two fixed last parts of our partitions must be \((1_{c_0}, -1_{c_2})\).

Applying Theorem 2.5 with \(d = 2\) and \(D = 2\) gives

\[ \sum_{\pi \in \mathbb{Z} P_{c_0 \otimes c_2}} C(\pi) q^{||\pi||} = \frac{e^{-2\Lambda_1} \text{ch} L(2\Lambda_1)}{(q^2; q^2)_\infty}, \]

where \(q = e^{-\delta/2}, c_0 = e^{\alpha_1}, c_1 = 1, c_2 = e^{-\alpha_1}\).

The generating function for \(\mathbb{Z} P_{c_0 \otimes c_2}\) can be computed almost exactly as the one for \(\mathbb{Z} P_{c_0 \otimes c_0}\), except that now there can be an isolated \(-1_{c_2}\) before the fixed tail \((1_{c_0}, -1_{c_2})\), but no \(1_{c_0}\), otherwise our partition would end with \((1_{c_0}, -1_{c_2}, 1_{c_0}, -1_{c_2})\), which is forbidden. Thus instead of multiplying our generating function by \(c_0 c_2 (1 + c_0 q)\) like in the previous section, we now multiply it by \(c_0 c_2 (1 + c_2 q^{-1})\). Thus, omitting the condition on the parity of the number of parts, we obtain the generating function

\[ \frac{c_0 c_2 (-c_0 q^2; q^2)_\infty(-c_2 q^{-1}; q^2)_\infty}{(c_1 q; q^2)_\infty(c_0 c_2 q^2; q^4)_\infty}. \]
Now, to take back into account the fact that there must be an even number of parts, we use (1.5).
Thus the multi-grounded partitions in \( \frac{1}{2}p_{c_0}^{2c_0} \) are generated by:
\[
\sum_{\pi \in \frac{1}{2}p_{c_0}^{2c_0}} C(\pi) q^{|\pi|} = e_{c_0,c_1,c_2} \left( \frac{c_0c_2(-c_0q^2;q^2)_\infty(-c_2q^{-1};q^2)_\infty}{(c_1q^2;q^2)_\infty(c_0c_2q^4;q^4)_\infty} \right) = \frac{c_0c_2}{(c_0c_2q^4;q^4)_\infty} \left( \frac{(-c_0q^3;q^2)_\infty(-c_2q^{-1};q^2)_\infty}{(c_1q^2;q^2)_\infty} \right) + \frac{c_0c_2}{(c_0c_2q^4;q^4)_\infty} \left( \frac{c_0q^3;q^2)_\infty(c_2q^{-1};q^2)_\infty}{(-c_1q^2;q^2)_\infty} \right).
\]
Substituting the correct values of \(q, c_0, c_1, c_2\) in (1.4) and simplifying completes the proof. \(\Box\)
