Received March 1, 2020

Background & objectives: Obesity is a rising pandemic in childhood. There is scarcity of evidence on the efficacy of yoga in achieving weight loss in overweight/obese children. The objective of this study was to assess the efficacy of family-based comprehensive yoga intervention in the reduction of body mass index (BMI) in overweight/obese children, in comparison to standard dietary and lifestyle counselling and control group.

Methods: This was an open-label randomized controlled study. Children aged 8-15 yr who were overweight or had obesity were randomized to one of the three arms for 18 wk; standard weight management (group 1), yoga with dietary modification (group 2) and control (no intervention; group 3). Reduction in BMI and improvement in physiological, biochemical and psychological parameters from baseline to 18 wk was compared between the three arms. Late follow up was also done at 6-12 months.

Results: A total of 165 children with mean±standard deviation (SD) age of 11.6±1.8 yr and mean BMI 26.3±4.2 kg/m² were enrolled. Outcome analysis at 18 wk was performed for 109 children. Improved diet quality and reduced intake were observed in both intervention arms. The median (IQR) reduction in BMI in standard and yoga arms was similar [−1.4 (−3.1, −0.5) kg/m² and −1.2 (−2.3, −0.6) kg/m², respectively], while it increased by +0.3 (−0.3, 0.1) in the control arm. In the yoga arm, mean systolic BP reduced from 118 (10) to 114 (8) mmHg, (P=0.019). In the standard arm, significant improvement in psychological scores was noted. In group 3, the mean fasting glucose increased from 93±10 to 102±12 mg/dl (P<0.001).

Interpretation & conclusions: The findings of the present study suggest that yoga in conjunction with dietary modification is equally effective as the standard weight management for BMI reduction in the paediatric age group.

Key words Body mass index - body shape - diet - hypertension - insulin resistance - lifestyle - obesity - weight loss

India has the second-highest number of obese children and adolescents in the world1. Children and adolescents with obesity have a high prevalence of complications such as insulin resistance, dyslipidaemia,
hypertension and psychological distress\(^2,3\). Obesity in adolescents tracks into adulthood and is associated with high risk of cardiovascular disease and type 2 diabetes\(^4\). Changes in dietary habits and lifestyle, if introduced in formative years are more likely to be sustained and effective, than if introduced later in life.

The current evidence-based management of paediatric obesity is primarily based on diet and lifestyle modifications\(^5\). However, their efficacy in achieving the reduction of body mass index (BMI) is not very high\(^5\). Parental involvement with the programme is also important in its success\(^6\). Many obesity management programmes fail to generate enough enthusiasm in the parents for them to actively encourage and help the child\(^7\).

Yoga is the ancient Indian science which emphasizes on the attainment of complete health and well-being through various physical postures (asanas), breathing techniques (pranayama) and meditation\(^8\). Yoga has both physiological and psychological benefits in healthy individuals as well as those with various chronic conditions\(^9-11\). It is also effective in reducing stress\(^12\), and improving exercise tolerance\(^10,13\).

The literature is, however, scarce from the paediatric age group\(^12,14,15\), and what is reported either has the limitations of small sample size or inadequate methodology. The present study was hence, undertaken with the objective of assessing the efficacy of a family-based comprehensive yoga intervention of 18 wk duration in achieving reduction in BMI, improvement in cardiometabolic risk profile, and psychological wellbeing in overweight/obese children and adolescents, in comparison to the standard dietary and lifestyle intervention, and a control group with no intervention.

**Material & Methods**

This was a three armed open-label randomized controlled study (RCT) conducted at the department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India, between May 2016 and February 2019, after approval by the Institute Ethics Committee. The study was registered with the Clinical Trials Registry of India (CTRI/2016/04/006876).

**Participant recruitment:** Children aged 8-15 yr who were overweight or obese according to Indian BMI charts\(^16\) were enrolled, predominantly from the Paediatric OPD but also from families of the hospital staff, and those referred by families of children enrolled in the study. Children with obesity of syndromic or endocrine aetiology, any chronic medical illness, or any complication of obesity for which medications are needed, such as type 2 diabetes and stage 2 hypertension, were excluded. Written informed consent was taken from parents, and assent from the study participants. For each subject, one of the parents was also requested to participate in the study and follow the intervention assigned to the child.

**Sample size:** The sample size needed for the study was calculated as 37 per group (total \(n=111\)), taking a difference in BMI reduction of 1 kg/m\(^2\) between the groups as clinically relevant, with common standard deviation (SD) of 0.5 kg/m\(^2\), \(\alpha\) as 0.05 and power as 90 per cent. Considering that high attrition has been reported in previous paediatric weight reduction trials\(^17\), we planned to enrol up to 50 per cent more subjects and in a 3:3:2 ratio, with a smaller number of subjects in the non-intervention arm.

**Baseline evaluation of the subjects:** Age, gender, socioeconomic and family history were recorded. Dietary assessment was done using a semi-quantitative food frequency questionnaire by the study dieticians\(^18\). The intake of various macro- and micro-nutrients was calculated by DietSoft nutrient calculator software (https://dietsoft.in/), based on the nutritive value of Indian foods\(^19\).

Height was measured using a stadiometer (Seca 213, Hamburg, Germany) and weight using an electronic scale (Seca 874dr, Hamburg, Germany) to an accuracy of 0.1 cm and 0.1 Kg, respectively, and BMI was calculated. Waist circumference (WC) was measured using a non-stretchable tape according to WHO guidelines\(^20\). Central adiposity was considered present if WC was \(>+2\) Z score based on Indian reference ranges\(^16\), or more than the adult cut-offs of 90 and 80 cm for Asian males and females\(^21\), respectively. Blood pressure (BP) was measured three times after a 10 min rest, using an automated instrument (Omron HEM-7203, Kyoto, Japan) with appropriate sized cuff, in the seated position, and the two readings closest to each other were averaged. Hypertension was diagnosed as BP \(\geq 95^{th}\) centile or \(\geq 130/80\) (whichever was lower) for children under 13 yr and \(\geq 130/80\) in adolescents \(>13\) yr of age\(^22\). Heart rate was measured at rest and after exercise using the 3 min Kasch Pulse Recovery test. During this, the participant climbed up and down a 12 inches step 24 times/min to...
the beat of a metronome set at 96 beats/min for three minutes. One minute after the test, the carotid pulse rate was counted for 30 sec in the seated position using a stopwatch.

Fasting venous sample was obtained after a 12 h overnight fast for estimation of glucose, insulin, triglycerides (TG), total cholesterol (TC) and high-density lipoprotein cholesterol (HDL) levels. Subjects were asked to collect saliva by passive drooling about half an hour after waking up in the morning (after rinsing the mouth, and not eating/drinking anything other than water) and bring it with them. Glucose, TG, TC and HDL were estimated by clinical chemistry analyzer (Roche Cobas 6000, Roche Diagnostics, GmbH, Germany) and serum insulin and salivary cortisol by electrochemiluminescence (Roche Cobas e411, Roche Diagnostics, GmbH, Germany). Homeostatic model assessment of insulin resistance (HOMA-IR) was calculated as fasting insulin (µU/ml) × fasting glucose (mg/dl)/405

Fasting glucose was considered impaired if ≥100 and <126 mg/dl and HOMA-IR was considered high if >2.5. Age appropriate cut-offs were used to define abnormal values for TG, total, LDL and HDL cholesterol27,28. Salivary cortisol >0.65 mcg/dl was considered as suggestive of stress.

Three validated psychological questionnaires were used, Kindl R for assessing health-related quality of life (QoL), Body Shape Questionnaire-16 (BSQ) for assessing concern over physical appearance, and Cohen’s Perceived Stress Scale (PSS) for assessing stress levels. These were administered under the guidance of a clinical psychologist (RS).

Kindl R has 24 items and score <45 indicate suboptimal QoL. BSQ has 16 items, with possible score from 16 to 96. Scores between 38-51, 52-66 and >66 indicate mild, moderate and marked concern for shape, respectively. PSS is a 10 item scale with possible score from 0 to 40. Scores < 13, 14-26 and >26 indicate low, moderate and high perceived stress, respectively.

Randomization into groups: Subjects were randomized using stratified randomization using a computer-generated sequence according to age group (above or below 12 yr) and gender into one of the three groups for 18 wk. Randomization sequence was generated by a biostatistician (not a part of the study team). Group allocation was done by the study dietician (AS) at enrolment, based on the slip picked by the subject from the container according to his/her gender and age group.

Group 1 - Standard weight management group: Children and their parents were counselled by the study dietician and individualized diet charts were given, with total caloric intake lower than the recommended dietary allowance for age and gender by 15-25 per cent (depending on BMI and physical activity level). Emphasis was laid on regular and balanced meals, increased intake of water, fiber, fruits and vegetables, and avoidance of sugar-sweetened beverages and processed foods. They were advised to undertake at least an hour of moderate-to-vigorous physical activity daily, have adequate sleep and restrict sedentary pursuits, especially screen time. A colourful printed booklet in Hindi was given educating them about healthy food choices and physical activity.

Group 2 - Comprehensive yoga programme group: This group also received detailed dietary counselling, advice on adequate sleep and restriction of sedentary pursuits as in group 1. In addition, they were enrolled in an intensive yoga programme, designed by yoga experts and previously validated at Integral Health Clinic (IHC), AIIMS, New Delhi. The asanas and pranayama included in the protocol are summarized in Table I. There was an intensive phase during which subjects and participating parents had to attend a minimum of three but preferably five classes per week for two weeks at IHC. From wk 3 to 6, one class per wk, and from week seven to 18, one class every four weeks had to be attended. Classes of two hour duration were held daily by the yoga instructor employed for the study, and the time was adjusted according to the convenience of the families. From third week onwards, subjects were asked to practice yoga at home at least five times per week for an hour. Parents were asked to maintain a log. A compact disc with a video and a booklet (both prepared especially for the study) with detailed instructions for all asanas and pranayams included in the protocol were given for the study protocol were given to the subjects.

Group 3 - Control (waitlisted) group: No specific physical activity/lifestyle counselling was provided to subjects in this group. After outcome analysis at 18 wk, they were given dietary and lifestyle counselling and also offered yoga training.

Measures to ensure compliance and reduce drop-outs: The dieticians maintained weekly telephonic contact with groups 1 and 2 subjects and the yoga teacher with group 2 subjects till 18 wk to motivate them and
resolve queries. Follow up visits were scheduled at six and 12 wk to emphasize compliance. Group sessions were held separately for families in groups 1 and 2 to reinforce the advice using interactive games and quizzes. Families shared healthy recipes and the stories of their efforts. Small gifts (badminton rackets, skipping ropes, exercise mats, slogan tees, etc.) were given as incentives to children. Children in groups 1 and 3 were offered yoga training after study completion as an incentive to maintain participation.

**Assessment of compliance till 18 wk:** Compliance with dietary advice was assessed in both groups 1 and 2 by the dietician. Detailed assessment of the dietary intake was made at baseline and 18 wk. In group 2, compliance with yoga protocol was adjudged by: (i) percentage of classes attended out of maximum 17 (10 in intensive phase, 4 in weekly and 3 in monthly sessions); and (ii) regularity of yoga practice at home score of 0 was assigned if the practice was done for 0-2 days/wk, the score of 1 if practice done for 3-4 days/wk, and score of 2 if practice done for 5-7 days/wk. The scores for each week between the 3rd and 18th wks were added and expressed as percentage of the maximum possible score of 32. The final score was the average of these two percentage scores.

**Outcomes:** The primary outcome was the comparison of the change in BMI from baseline to 18 wk between the three groups. The secondary outcomes were comparisons of change in WC, BP, resting and post-exercise heart rate, biochemical parameters and the scores on psychological questionnaires from baseline to 18 wk. In addition, the persistence of the reduction in BMI was assessed at delayed follow up done between six and 12 months for the children in groups 1 and 2.

**Statistical analysis:** Data were analyzed by Stata 12.1 (Stata Corp 4905 College Station, Texas, USA). The categorical data are presented as frequency (percentage) and continuous data as mean±SD or median (interquartile range), as appropriate. Paired t test was done to assess the treatment effect within the groups from baseline to 18 wk. To assess the statistical significance of the difference in outcomes across the three study groups, the ANCOVA model was run with appropriate covariates and confounders. ANOVA model followed by Bonferroni adjustment was used to compare the change from baseline to 18 wk across the three intervention groups. Repeated measure ANOVA was also used to assess the sustainability of treatment effect at late follow up. Kruskal-Wallis or rank-sum tests were used for non-parametric data. Two-sided \( P<0.05 \) was considered significant.

**Results**

A total of 165 overweight/obese children (112 boys), with mean±SD age of 11.6±1.8 yr and mean BMI and BMI Z score of 26.3±4.2 and 1.8±0.7 kg/m², respectively, were enrolled. At baseline, the mean systolic and diastolic BP of the enrolled subjects were 117±10 and 71±8 mmHg, respectively; mean fasting blood sugar was 92.3±12.7 mg/dl, and mean serum insulin and HOMA-IR were 15.1±10.6 mIU/l and 3.4±2.6, respectively. The mean serum triglyceride level was 127.7±55.7 mg/dl; and mean total, LDL and HDL cholesterol were 155.3±41.0, 88.4±34.3 and 41.0±11.7 mg/dl, respectively. Central obesity was present in 50 per cent, stage 1 hypertension in 26 per cent, impaired fasting glucose in 24 per cent, fasting hyperinsulinaemia in 37 per cent, elevated HOMA-IR in 45 per cent, elevated serum triglyceride, total and LDL cholesterol were present in 28, 13 and eight per cent, respectively, while low HDL was the most common dyslipidaemia, present in 50 per cent of the participants. The median (IQR) salivary cortisol was 0.07 (0.04, 0.17), with elevated level in five per cent. The mean score on Kindl QoL, PSS and BSQ were 84.8±11.5, 47.6±16.1 and 20.4±6.5, respectively. PSS

**Table 1. The set of asanas and pranayama included in the course**

| 1. Humming in meditative posture: Vajrasana, padmasana or Sukhasana (5-10 min) |
| 2. Loosening exercises from head to toes: 3-5 repetitions on each side (5-10 min) |
| 3. Surya Namaskar |
| Sitting: Konasana, Naukasana, Paschimotanasana |
| Lying prone: Dhanurasana, Makarasana, Bhujangasana |
| Lying supine: Uttitapadasana, Sarvangasana, Halasana |
| Starting with 2-3 repetitions, holding each pose up to 60 sec, gradually increasing to 10-15 repetitions (40-50 min) |
| 4. Pranayama (breathing exercises): 15-20 times each |
| 5. Relaxation in shavasana (5 min) |
score > 26 indicating high perceived stress, and BSQ score > 66 indicating marked concern with body shape were present in 17.6 and 17.4 per cent, respectively, while none of the subjects had low scores on QoL.

Fifty nine, 63 and 43 subjects were randomized to groups 1, 2 and 3, respectively. Table II presents the baseline clinical and anthropometric parameters of the subjects in the three groups. Primary outcome analysis at 18 wk could be done for 40, 41 and 28 subjects (total 109), with the total attrition being 34 per cent. Drop-out rate was similar in all the three groups. Delayed follow up (planned only for group 1 and 2) was done for 80 subjects out of the 81 for whom primary outcome analysis was done, at the median time of 8.3 (6.5, 13.5) months. The study flow chart is presented in the Figure, showing the reasons for attrition and the numbers for whom the results of various outcome parameters were available.

Table III presents the group-wise comparison of calorie and nutrient intake at baseline and 18 wk for all the subjects for whom detailed dietary assessment had been done at both these time points. Significant reduction in caloric intake and improvement in diet quality with increased fibre content, and reduced saturated fat, and free sugar intake was noted for subjects in both the intervention groups, indicating a good uptake of the dietary advice; while in group 3, there was no significant decrease in caloric intake.

The mean±SD number of yoga classes attended was 14±3, number of days/wk on which yoga practice at home was done was 3±1 and the yoga compliance score was 67±17 per cent. The reasons for missing classes and home practise included not enjoying yoga, practical difficulty and dependence on parents for coming to IHC for classes, and sub-optimal involvement of the parents. Subjects’ age, gender and BMI were not found to have any effect on compliance score. However, the compliance score was found to have a significant effect on the reduction of BMI between 18 wk and baseline by regression analysis (β 0.05, P<0.001). The mean

aWC >2 SD for age and gender, or >90 cm in boys or >80 cm in girls; Data are presented as mean±SD unless specified. BMI, body mass index; HR, heart rate; BP, blood pressure; SD, standard deviation; WC, waist circumference
reduction in BMI of subjects in the highest, intermediate and lowest tertiles of compliance score were 2.5±1.1, 1.2±0.8 and 0.6±0.5 kg/m\(^2\) (P<0.001), respectively.

Table IV presents the comparison of the change in BMI, BMI Z score, weight, and WC from baseline to 18 wk for all the three groups, and from baseline to late follow up in groups 1 and 2. Subjects in both the intervention groups had a similar reduction in median BMI, weight and WC between baseline and 18 wk, while these parameters increased in the control group during the same period. The mean BMI and BMI Z score at late follow up were 24.2±3.8 kg/m\(^2\) and 1.4±0.6 for group 1, and 25.2±4.8 kg/m\(^2\) and 1.5±0.7 for group 2 subjects. Repeated measures ANOVA showed that the reduction in BMI and BMI Z score was significant (P<0.001) for subjects in both the intervention groups over the three time periods. BMI reduction of ≥1 kg/m\(^2\) from baseline to 18 wk was seen in 25 (62.5%) subjects in group 1, 24 (60%) subjects in group 2, and in none of the subjects in group 3.
At late follow up, BMI reduction of ≥1 kg/m² from baseline was present in 26 (65%) and 23 (57%) of the subjects in groups 1 and 2, respectively.

The results for some of the secondary objectives are presented in Table V. There was a significant reduction in systolic BP from baseline to 18 wk in group 2 subjects. The psychological scores showed a significant improvement only in group 1 subjects. None of the three groups showed a significant change in the salivary cortisol between baseline and 18 wk. No significant improvement was noted in the mean levels of any of the biochemical parameters in either group 1 or 2 (data not shown). In group 2, a significant decline in the percentage of children with elevated HOMA-IR was seen (66.7 to 40.7%, \( P=0.050 \)). In group 3, the mean fasting glucose increased from 93.0±10.5 to 102.0±12.4 mg/dl \( (P<0.001) \), and the proportion with impaired fasting glucose from 20 to 65 per cent \( (P=0.004) \) from baseline to 18 wk.

**Discussion**

We believe that the present study was the first RCT on the efficacy of a programme based on yoga and dietary modification in achieving reduction of BMI and improvement of various physiological, biochemical and psychological parameters in overweight/obese children from India. It was found to be as effective as the standard weight management strategies in achieving reduction in BMI Z score sustained over a median follow up duration of eight months. The attrition rate in our study was comparable to that reported previously in other paediatric weight loss RCTs. The compliance with dietary counselling was good as seen by the significant reduction in caloric intake and improvement in diet quality seen in both the intervention groups. The compliance with yoga protocol, including attendance for classes as well as regularity of home practise was variable, and this had a bearing on the benefit derived from it. The subjects in the highest tertile of compliance had a mean reduction in BMI of 2.5 kg/m², which was higher than that reported by previous paediatric dietary and lifestyle modification programmes, thus illustrating the efficacy of the study protocol. The median decline in BMI in groups 1 and 2 was 1.4 kg/m² and 1.2 kg/m², respectively, and median reduction in WC was about 4 cm. In comparison, the children in control arm had a median weight gain of 2.5 kg and increase in WC by 2.6 cm, representing the natural course of obesity. In addition, a significant decline in systolic BP and prevalence of elevated HOMA-IR was observed in the children in the yoga arm, and significant improvement in psychological parameters in group 1; while the mean fasting glucose increased significantly in group 3.

So far, to the best of our knowledge, there is no RCT from India evaluating strategies for BMI reduction in children. A non-randomized study from Pune, found that school based interventions had no effect on BMI but led to improvement in lifestyle and fitness levels.
### Table IV. Comparison of the change in anthropometric parameters from baseline to 18 wk in the three groups and to late follow up in groups 1 and 2 for subjects who completed the study

### Table V. Comparison of change (within group) in the physiological parameters and psychological questionnaire scores from baseline to 18 wk for subjects who completed the study

| Physiological parameters | Study groups | Resting HR (per min) | Post-exercise HR (per min) | Systolic BP (mm Hg) | Diastolic BP (mm Hg) |
|--------------------------|-------------|----------------------|---------------------------|---------------------|--------------------|
|                          | Group 1 (n=35) | 85±9 | 79±9 | 118±14 | 117±10 | 114±9 | 116±10 | 70±8 | 70±6 |
|                          | Group 2 (n=40) | 84±9 | 81±8 | 119±15 | 116±9 | 118±10 | 114±8 | 73±10 | 71±7 |
|                          | Group 3 (n=27) | 86±12 | 79±9 | 122±16 | 116±10 | 118±9 | 116±8 | 73±8 | 75±9 |

| Psychological parameters | Study groups | Stress score | BSQ score | Kindl QoL |
|--------------------------|-------------|-------------|-----------|-----------|
|                          | Group 1 (n=29) | 20.1±6.4 | 42.8±16.0 | 85.2±10.5 | 90.6±10.4 |
|                          | Group 2 (n=30) | 19.2±5.0 | 46.0±17.0 | 84.8±12.3 | 86.0±13.2 |
|                          | Group 3 (n=22) | 20.5±7.6 | 54.5±15.5 | 85.7±14.2 | 86.1±14.7 |

The values with significant difference between baseline and 18 wk (by paired t test) are marked by asterisks; \( P ^* <0.05 \), \( P ^{**} <0.01 \). BSQ, body shape questionnaire; Kindl QoL, Kindl R questionnaire for assessing health-related quality of life.
among children in the intervention arm. In an RCT conducted in the UK, the median change in BMI Z score of only −0.005 and −0.114, respectively, were noted in overweight/obese children randomised to either a family-based intervention or usual care, with 28 per cent attrition. In a Malaysian paediatric study focussing on diet and exercise, there was no reduction in weight; however, the weight gain was lower in intervention group compared to control. In an Australian RCT, comparing parenting skills plus healthy lifestyle, or healthy lifestyle alone, median reduction in BMI Z score was 0.26 (similar in both arms), with 37 per cent attrition. In Iranian adolescent girls with obesity, BMI change of −1.07 kg/m² was observed in the diet and lifestyle arm, vs. +0.24 kg/m² in the control arm. Overall, the findings of these studies are in alignment with our study in terms of the percentage of children who completed the study, the magnitude of reduction in BMI, and the non-significant differences between the different interventions as long as dietary modification was done as part of the intervention. There are only a few studies on the efficacy for yoga for weight loss in children. In one study from Texas, USA, in which 20 children and adolescents participated in a 12 wk Ashtanga yoga programme, of these, 14 children aged 8-15 yr, completed the programme, and had an average weight loss of 2 kg.

The present study assessed not only weight loss but also changes in several psychological, physiological and metabolic parameters. However, the limitations were that there was attrition, many children did not attend all the yoga sessions, and did not adhere to the guidelines for home-based yoga practice, with parents’ involvement also being sub-optimal. The other limitation was that few biochemical, physiological and psychological outcome variables were not available for all the participants, and those with missing values had to be excluded from the analysis.

Overall, the present study demonstrated that yoga in conjunction with dietary modification is effective in reduction of BMI, systolic BP and prevalence of insulin resistance in overweight/obese children. However, its efficacy in reduction of BMI was not superior to that of an efficiently delivered dietary and lifestyle intervention. Further studies with focus on enhancing the compliance to yoga by making the classes more enjoyable and accessible, will be helpful in bringing out the true potential of yoga in improving the health and well being in overweight/obese children.

**Acknowledgment:** The authors acknowledge Ms Babita Upadhayaya and Kajal Chauhan, project dieticians, department of Pediatrics, AIIMS, New Delhi, for help with subject enrolment and dietary assessment, and Aman Agarwal, biostatistician, CIMR, AIIMS, Delhi, for help with statistical analysis.

**Financial support & sponsorship:** This study was supported by a grant from Ministry of AYUSH, Government of India (Grant No. Z28015/257/2015/HPC (EMR)-A AYUSH-B).
