ABSTRACT. We find probability error bounds for approximations of functions $f$ in a separable reproducing kernel Hilbert space $\mathcal{H}$ with reproducing kernel $K$ on a base space $X$, firstly in terms of finite linear combinations of functions of type $K_{x_i}$ and then in terms of the projection $\pi_n^x$ on $\text{span}\{K_{x_i}\}_{i=1}^n$, for random sequences of points $x = (x_i)_{i \in \mathbb{N}}$ in the base space $X$. Previous results demonstrate that, for sequences of points $(x_i)_{i \in \mathbb{N}}$ constituting a so-called uniqueness set, the orthogonal projections $\pi_n^x$ to $\text{span}\{K_{x_i}\}_{i=1}^n$ converge in the strong operator topology to the identity operator. The main result shows that, for a given probability measure $P$, letting $P_K$ be the measure defined by $dP_K(x) = K(x, x)\, dP(x)$, $x \in X$, and $\mathcal{H}_P$ denote the reproducing kernel Hilbert space that is the operator range of the nonexpansive operator $L^2(X; P_K) \ni \lambda \mapsto L_{P,K}\lambda := \int_X \lambda(x)K_x\, dP(x) \in \mathcal{H}$, where the integral exists in the Bochner sense, under the assumption that $\mathcal{H}_P$ is dense in $\mathcal{H}$ any sequence of points sampled independently from $P$ yields a uniqueness set with probability 1. This result improves on previous error bounds in weaker norms, such as uniform or $L^p$ norms, which yield only convergence in probability and not almost certain convergence. Two examples that show the applicability of this result to a uniform distribution on a compact interval and to the Hardy space $H^2(D)$ are presented as well.

1. Introduction

Several machine learning algorithms that use positive semidefinite kernels, such as support vector machines (SVM), have been analyzed and justified rigorously using the theory of reproducing kernel Hilbert spaces (RKHS), yielding statements of optimality, convergence and $L^p$ approximation bounds, e.g. see F. Cucker and S. Smale [4]. Reproducing kernel Hilbert spaces are Hilbert spaces of functions associated to a suitable kernel such that convergence with respect to the Hilbert space norm implies pointwise convergence, and in the context of approximation possess various favourable properties resulting from the Hilbert space structure. For example, under certain conditions on the kernel, every function in the Hilbert space is sufficiently differentiable and differentiation is in fact a nonexpansive linear map with respect to the Hilbert space norm. Hence, the theory has the potential to justify the simultaneous approximation of derivatives of functions in various numerical applications, as long as convergence is demonstrated with respect to the Hilbert space norm.

Key words and phrases. Reproducing kernel Hilbert space, error approximation bounds, almost certain convergence, uniqueness set, Bochner integral, Markov-Bienaymé-Chebyshev inequality.
In order to substantiate the motivation for our investigation, we briefly review previously obtained bounds on the approximation of functions as linear combinations of kernels evaluated at finitely many points. The theory of V.N. Vapnik and A.Ya. Chervonenkis of statistical learning theory [18], [19], [20], relies on concentration inequalities such as Hoeffding’s inequality to bound the supremum distance between expected and empirical risk. The theory considers a data space \( X \subseteq \mathbb{R}^d \) on which an unknown probability distribution \( P \) is defined, a hypothesis set \( \mathcal{H} \) and a loss function \( V : \mathcal{H} \times X \to \mathbb{R}_+ \), such that one wishes to find a hypothesis \( h \in \mathcal{H} \) that minimizes the expected risk

\[
R[h] := \int V(h, x) \, dP(z).
\]

Since \( P \) is not known in general, instead of minimizing the expected risk one usually minimizes the empirical risk

\[
\hat{R}_S[h] = \frac{1}{n} \sum_{i=1}^{n} V(h, x_i)
\]

over a finite set \( S = \{x_i\}_{i=1}^{n} \subseteq X \) of samples. Vapnik-Chervonenkis theory measures the probability with which the maximum distance between \( R \) and \( \hat{R}_S \) falls below a given threshold. Recall that the Vapnik-Chervonenkis (VC) dimension of \( \mathcal{H} \) with respect to \( V \) is the maximum cardinality of finite subsets \( Y \subseteq X \) that can be shattered by \( \mathcal{H} \), i.e. for each \( Y' \subseteq Y \), there exist \( h \in \mathcal{H} \) and \( \alpha \in \mathbb{R} \) such that

\[
Y' = \{ x \in Y \mid V(h, x) \geq \alpha \};
\]

\[
Y \setminus Y' = \{ x \in Y \mid V(h, x) < \alpha \}.
\]

Thus, they prove that, assuming that \( A \leq V(h, x) \leq B \) for each \( h \in \mathcal{H}, x \in X \) and the VC dimension of \( \mathcal{H} \) is \( d < \infty \), then, for any \( \eta \in (0, 1) \),

\[
P\left( \sup_{h \in \mathcal{H}} \left| R[h] - \hat{R}_S[h] \right| \geq (B - A) \sqrt{\frac{d \log \frac{2en}{d} - \log \frac{\eta n}{4}}{n}} \right) \leq \eta.
\]

F. Girosi, see [7] and [10, Proposition 2], has used this general result to bound the uniform distance between integrals \( \int J(x, y) \lambda(y) \, dy \) and sums of the form \( \frac{1}{n} \sum_{i=1}^{n} J(x, x_i) \), by reinterpreting \( \mathcal{H} \) as \( \mathbb{R}^d \), \( V \) as \( J \) and \( dP(y) \) as \( \frac{|\lambda(y)|}{||\lambda||_{L^1}} \, dy \). M.A. Kon and L.A. Raphael [10] then applied this methodology to obtain uniform approximation bounds of functions in reproducing kernel Hilbert spaces. They consider two cases where the Hilbert space is dense in \( L^2(\mathbb{R}^d) \) with a stronger norm [10, Theorem 4], and where it is a closed subspace with the same norm [10, Theorem 5]. Also, M.A. Kon, L.A. Raphael, and D.A. Williams [11] extended Girosi’s approximation estimates for functions in Sobolev spaces. While these bounds guarantee uniform convergence in probability, the approximating functions are not orthogonal projections of \( f \) nor necessarily elements of a reproducing kernel Hilbert space, and hence may not capture \( f \) exactly at \( (x_i)_{i=1}^{n} \) nor converge monotonically. Furthermore, the fact that the norm is not a RKHS norm means that derivatives of \( f \) may not be approximated in general, since differentiation is not bounded with respect to the uniform norm, unlike the RKHS norm associated to a continuously differentiable kernel.
The purpose of this article is thus to establish sufficient conditions for convergence and approximation in the reproducing kernel Hilbert space norm. In Section 3, we find probability error bounds for approximations of functions $f$ in a separable reproducing kernel Hilbert space $\mathcal{H}$ with reproducing kernel $K$ on a base space $X$, firstly in terms of finite linear combinations of functions of type $K_x$ and then in terms of the projection $\pi^n_x$ onto $\text{span}\{K_{x_i}\}_{i=1}^n$, for random sequences of points $x = (x_i)_i$ in the base space $X$. Previous results demonstrate that, for sequences of points $(x_i)_{i=1}^\infty$ constituting a so-called uniqueness set, the orthogonal projections $\pi^n_x$ to $\text{span}\{K_{x_i}\}_{i=1}^n$ converge in the strong operator topology to the identity operator. Our main results show that, for a given probability measure $P$, letting $P_K$ be the measure defined by $dP_K(x) = K(x,x) dP(x)$, $x \in X$, and $\mathcal{H}_P$ denote the reproducing kernel Hilbert space that is the operator range of the nonexpansive operator
\[
L^2(X; P_K) \ni \lambda \mapsto L_{P,K}\lambda := \int_X \lambda(x) K_x dP(x) \in \mathcal{H},
\]
where the integral exists in the Bochner sense, under the assumption that $\mathcal{H}_P$ is dense in $\mathcal{H}$ any sequence of points sampled independently from $P$ yields a uniqueness set with probability 1. This improves on the results obtained by Kon and Raphael in several senses: the convergence of approximations is in the RKHS norm, which is stronger than the uniform norm whenever the kernel is bounded; the type of convergence with respect to the points $(x_i)_i$ is strengthened from convergence in probability to almost certain convergence; and the separability of $\mathcal{H}$ then allows the result to be extended from the approximation of a single function to the simultaneous approximation of all functions in the Hilbert space.

Our approach uses some ideas and facts from convergence of discrete samplings in RKHSs coming from H. Körzelioğlu [12] and S. Saitoh and Y. Sawano [15] and, for this reason, in Subsection 2.2 we briefly review some concepts and results related to projections on finite dimensional subspaces generated by sampling sequences, uniqueness sets, and realizations of RKHSs from discrete samplings. Then, in Subsection 2.3 we briefly review some basic concepts and results on the Bochner integral that plays a major role in our main results and, finally, in Subsection 2.4 we review the Markov-Bienaymé-Chebyshev Inequality that we use.

These results are confined to the special case of a separable RKHS $\mathcal{H}$ of functions on an arbitrary set $X$, due to several reasons, one of them being the fact that the Bochner integral is requiring this extra assumption, but we not see this as a loss of generality since most of the spaces of interest for applications are separable. In the last section we present two examples that point out the applicability, and the limitations of our results as well, the first to the uniform probability distribution on the compact interval $[-\pi, \pi]$, together with a class of bounded continuous kernels, and the second to the Hardy space $H^2(\mathbb{D})$ corresponding to the Szegő kernel which is unbounded. In each case we calculate precisely the space $\mathcal{H}_P$, its reproducing kernel $K_P$, and the operator $L_{P,K}$.

2. Notation and Preliminary Results

2.1. Reproducing Kernel Hilbert Spaces. In this subsection, we briefly review some concepts and facts on reproducing kernel Hilbert spaces, following classical texts.
such as N. Aronszajn [1], [2] and L. Schwartz [16], or more modern ones such as S. Saitoh and Y. Sawano [15], Chapter 2] and V.I. Paulsen and M. Raghupathi [13].

Throughout this article we denote by $\mathcal{F}$ one of the commutative fields $\mathbb{R}$ or $\mathbb{C}$. For a nonempty set $X$ let $\mathbb{F}^X$ denote the set of $\mathbb{F}$-valued functions on $X$, forming an $\mathbb{F}$-vector space under pointwise addition and scalar multiplication. For each product induced by a positive semidefinite $d$ on Hilbert spaces, if each evaluation map is continuous, this renders $\mathbb{F}^X$ into a complete Hausdorff locally convex space. With respect to this topology, if $X$ is a topological space, a map $\phi: X \rightarrow \mathbb{F}^X$ is continuous if and only if $\nu_{\phi} \circ \phi: X \rightarrow \mathbb{F}$ is continuous for all $p \in X$.

We are interested in Hilbert spaces $\mathcal{H} \subseteq \mathbb{F}^X$ with topologies at least as strong as the topology of pointwise convergence of $\mathbb{F}^X$, so that the convergence of a sequence of functions in $\mathcal{H}$ implies that the functions also converge pointwise. When $X$ is a finite set, $\mathbb{F}^X \cong \mathbb{F}^d$, where $d$ is the number of elements of $X$, can itself be made into a Hilbert space with a canonical inner product $(f, g) := \sum_{p \in X} f(p)g(p)$, or in general by an inner product induced by a positive semidefinite $d \times d$ matrix. This leads to the concept of reproducing kernel Hilbert spaces.

Recalling the F. Riesz’s Theorem of representations of bounded linear functionals on Hilbert spaces, if each $\nu_p : \mathcal{H} \rightarrow \mathbb{F}$ restricted to $\mathcal{H} \subseteq \mathbb{F}^X$ is continuous, for each $p \in X$, then there exists a unique vector $K_p \in \mathcal{H}$ such that $\nu_p = \langle \cdot, K_p \rangle$. But, since each vector in $\mathcal{H}$ is itself a function $X \rightarrow \mathbb{F}$, these vectors altogether define a map $K : X \times X \rightarrow \mathbb{F}$, $K(p, q) := K_q(p)$. Also, recall that a map $K: X \times X \rightarrow \mathbb{F}$ is usually called a kernel.

**Definition 2.1.** Let $\mathcal{H} \subseteq \mathbb{F}^X$ be a Hilbert space, $K: X \times X \rightarrow \mathbb{F}$ a kernel. For each $p \in X$ define $K_p := K(\cdot, p) \in \mathbb{F}^X$. $K$ is said to be a reproducing kernel for $\mathcal{H}$, and $\mathcal{H}$ is then said to be a reproducing kernel Hilbert space (RKHS), if, for each $p \in X$, we have

(i) $K_p \in \mathcal{H}$;
(ii) $\nu_p = \langle \cdot, K_p \rangle$, that is, for every $f \in \mathcal{H}$ we have $f(p) = \langle f, K_p \rangle$.

The second property is referred to as the reproducing property of the kernel $K$.

We may then summarize the last few paragraphs with the following characterization.

**Theorem 2.2.** Let $\mathcal{H} \subseteq \mathbb{F}^X$ be a Hilbert space. The following assertions are equivalent:

(i) The canonical injection $i_\mathcal{H}: \mathcal{H} \rightarrow \mathbb{F}^X$ is continuous.
(ii) For each $p \in X$, the map $\nu_p: \mathcal{H} \rightarrow \mathbb{F}$ is continuous.
(iii) $\mathcal{H}$ admits a reproducing kernel.

In that case, the reproducing kernel admitted by the Hilbert space is unique, by the uniqueness of the Riesz representatives $K_p$ of the evaluation maps. We may further apply the reproducing property to each $K_q$ to obtain that $K(p, q) = \langle K_q, K_p \rangle$ for each $p, q \in X$, yielding the following properties:
(i) For each \( p \in X \), \( K(p, p) = \|K_p\|^2 \geq 0 \).

(ii) For each \( p, q \in X \), \( K(q, p) = \overline{K(p, q)} \) and

\[
(2.1) \quad |K(p, q)|^2 \leq K(p, p)K(q, q).
\]

(iii) For each \( n \in \mathbb{N} \), \( (c_i)_{i=1}^n \in \mathbb{F}^n \), \( (p_i)_{i=1}^n \in X^n \),

\[
\sum_{i=1}^n \sum_{j=1}^n c_i c_j K(p_i, p_j) = \| \sum_{i=1}^n c_i K_{p_i} \|^2 \geq 0.
\]

The property in (2.1) is the analogue of the Schwarz Inequality. As a consequence of it, if \( K(p, p) = 0 \) for some \( p \in X \) then \( K(p, q) = K(q, p) = 0 \) for all \( q \in X \).

For any \( K : X \times X \to \mathbb{F} \), each \( K_p \in \mathbb{F}^X \) so we may define the subspace

\[
\tilde{H}_K := \text{span} \{ K_p \mid p \in X \}
\]

of \( \mathbb{F}^X \). If \( K \) is the reproducing kernel of a Hilbert space \( \mathcal{H} \), \( \tilde{H}_K \) is also a subspace of \( \mathcal{H} \) and

\[
\tilde{H}_K^+ = \{ f \in \mathcal{H} \mid \forall p \in X, f(p) = \langle f, K_p \rangle = 0 \} = \{0\},
\]

therefore, \( \tilde{H}_K \) is a dense subspace of \( \mathcal{H} \), equivalently, \( \{ K_p \mid p \in X \} \) is a total set for \( \mathcal{H} \).

The property at item (iii) is known as the positive semidefiniteness property. A positive semidefinite kernel \( K \) is called definite if \( K(p, p) \neq 0 \) for all \( p \in X \). Positive semidefiniteness is in fact sufficient to characterize all reproducing kernels.

**Theorem 2.3** (Moore-Aronszajn). Let \( K : X \times X \to \mathbb{F} \) be a positive semidefinite kernel. Then there is a unique Hilbert space \( \mathcal{H}_K \subseteq \mathbb{F}^X \) with reproducing kernel \( K \).

Let us briefly recall the construction of the Hilbert space \( \mathcal{H}_K \) in the proof. We first render \( \tilde{H}_K \) into a pre-Hilbert space satisfying the reproducing property. Define on \( \tilde{H}_K \) the inner product

\[
\langle \sum_{i=1}^n a_i K_{p_i}, \sum_{j=1}^m b_j K_{q_j} \rangle_{\tilde{H}_K} := \sum_{i=1}^n \sum_{j=1}^m a_i \overline{b_j} K(q_j, p_i)
\]

for any \( \sum_{i=1}^n a_i K_{p_i}, \sum_{j=1}^m b_j K_{q_j} \in \tilde{H}_K \). It is proven that the definition is correct and provides indeed an inner product.

Let \( \hat{H}_K \) be the completion of \( \tilde{H}_K \), then \( \hat{H}_K \) is a Hilbert space with an isometric embedding \( \phi : \hat{H}_K \to \tilde{H}_K \) whose image is dense in \( \tilde{H}_K \). It is proven that this abstract completion can actually be realized in \( \mathbb{F}^X \) and that it is the RKHS with reproducing kernel \( K \) that we denote by \( \mathcal{H}_K \).

In applications, one of the most useful tool is the interplay between reproducing kernels and orthonormal bases of the underlying RKHSs. Although this fact holds in higher generality, we state it for separable Hilbert spaces since, most of the time, this is the case of interest.

**Theorem 2.4.** Let \( \mathcal{H} \subseteq \mathbb{F}^X \) be a separable RKHS, with reproducing kernel \( K \), and let \( \{ \phi_n \}_n \) be an orthonormal basis of \( \mathcal{H} \). Then

\[
K(p, q) = \sum_{n=1}^{\infty} \phi_n(p) \overline{\phi_n(q)}, \quad p, q \in X,
\]
where the series converges absolutely pointwise.

We now recall a list of useful results about the construction of new RKHSs and positive semidefinite kernels from existing ones. The main result shows that the concept of reproducing kernel Hilbert space is actually a special case of the concept of operator range.

**Theorem 2.5.** Let $\mathcal{H}$ be a Hilbert space, $\phi: \mathcal{H} \to \mathbb{F}^X$ a continuous linear map. Then $\phi(\mathcal{H}) \subseteq \mathbb{F}^X$ with the norm

$$\|f\|_{\phi(\mathcal{H})} := \min \{ \|u\|_{\mathcal{H}} \mid u \in \mathcal{H}, \ f = \phi(u) \}$$

is a RKHS, unitarily isomorphic to $(\ker \phi)^\perp$.

The kernel for $\phi(\mathcal{H})$ is then given by the map $(p,q) \mapsto \langle u_q, u_p \rangle = (ev_p \circ \phi)(u_q) = \phi(u_q)(p)$ where $u_q \in \mathcal{H}$ such that $ev_q \circ \phi = \langle \cdot, u_q \rangle$ on $\mathcal{H}$.

Applying this proposition to particular continuous linear maps, one obtains the following useful results.

**Corollary 2.6** (Pullback of Kernel). Let $\mathcal{H} \subseteq \mathbb{F}^X$ be a RKHS, $K$ its reproducing kernel. Let $F$ be another nonempty set and $f: F \to X$ a function. Then

$$f^* \mathcal{H} := \mathcal{H} \circ f = \{ g \circ f \mid g \in \mathcal{H} \} \subseteq \mathbb{F}^F$$

is a Hilbert space with reproducing kernel

$$F \times F \ni (p,q) \mapsto f^* K(p,q) := K(f(p), f(q)) \in \mathbb{F},$$

and norm

$$\|g\|_{f^* \mathcal{H}} = \min \{ \|g'\|_{\mathcal{H}} \mid g' \circ f = g \}.$$

**Corollary 2.7** (Restriction of Kernel). Let $\mathcal{H} \subseteq \mathbb{F}^X$ be a RKHS, $K$ its corresponding kernel. Let $F \subseteq X$. Then

$$\mathcal{H}|_F := \{ g|_F \mid g \in \mathcal{H} \}$$

is a Hilbert space with reproducing kernel $K|_{F \times F}$ and norm

$$\|g\|_{\mathcal{H}|_F} = \min \{ \|g'\|_{\mathcal{H}} \mid g'|_F = g \}.$$

**Proof.** In the preceding theorem, take $f = i_F: F \to X$ the inclusion map from $F$ to $X$. Then for each $g \in \mathcal{H}$, $g \circ i_F = g|_F$ since for all $p \in F$, $(g \circ i_F)(p) = g(i_F(p)) = g(p) = (g|_F)(p)$.

**Remark 2.8.** In view of the previous corollary and the Schwarz Inequality, letting $X_0 := \{ p \in X \mid K(p,p) = 0 \}$ it follows that $K(p,q) = 0$ for all $p, q \in X$ and hence, by the previous corollary, restricting to $X \setminus X_0$ we get a RKHS canonically isomorphic to $\mathcal{H}_K$. Consequently, modulo a restriction of the kernel to a smaller base set, assuming that the kernel is positive definite is not an essentially particular case.

**Corollary 2.9** (Sum of Kernels). Let $\mathcal{H}_1, \mathcal{H}_2 \subseteq \mathbb{F}^X$ be RKHSs with kernels $K_1$ and $K_2$. Then

$$\mathcal{H}_1 + \mathcal{H}_2 := \{ f_1 + f_2 \mid f_1 \in \mathcal{H}_1, \ f_2 \in \mathcal{H}_2 \}$$

is a Hilbert space with reproducing kernel $K_1 + K_2$ and norm

$$\|g\|^2_{\mathcal{H}_1 + \mathcal{H}_2} = \min \{ \|g_1\|^2_{\mathcal{H}_1} + \|g_2\|^2_{\mathcal{H}_2} \mid g_1 \in \mathcal{H}_1, \ g_2 \in \mathcal{H}_2, \ g_1 + g_2 = g \}.$$
Corollary 2.10 (Scaling of Kernel). Let $\mathcal{H} \subseteq F^X$ be a RKHS with kernel $K$, $f \in F^X$. Then

$$f \mathcal{H} := \{fg \mid g \in \mathcal{H}\},$$

is a RKHS with kernel $\bar{f}Kf$, $(\bar{f}Kf)(p, q) = \bar{f}(p)K(p, q)f(q)$ for each $p, q \in X$.

Corollary 2.11 (Normalization of Kernel). Let $\mathcal{H} \subseteq F^X$ be a RKHS with kernel $K$. Then the kernel $K'$ defined by

$$K'(p, q) := \begin{cases} \frac{K(p, q)}{\sqrt{K(p, p)K(q, q)}} & K(p, p) = K(q, q) = 0, \\ 0, & \text{either } K(p, p) = 0 \text{ or } K(q, q) = 0, \end{cases}$$

for each $p, q \in X$, is positive semidefinite with associated RKHS

$$\mathcal{H}' := \left\{ \frac{g}{\sqrt{K(\cdot, \cdot)}} \mid g \in \mathcal{H} \right\}$$

canonically isomorphic to $\mathcal{H}$. Here, see Remark 2.8, we let $g(p)/\sqrt{K(p, p)} := 0$ for all $p \in X$ such that $K(p, p) = 0$.

We now consider domains equipped with an additional topological or differential structure and recall the relations between the properties of the kernel with respect to this structure to properties of the functions in the corresponding reproducing kernel Hilbert space, e.g. see [15, Section 2.1.3]. Let $\mathcal{H} \subseteq F^X$ be a RKHS, $K$ its corresponding kernel. Define

(2.2) $\Phi_K: X \to \mathcal{H}; \ p \mapsto K_p$.

Theorem 2.12 (Boundedness of Kernel). Let $\mathcal{H} \subseteq F^X$ be a RKHS, $K$ its corresponding kernel. Then $K$ is bounded iff $\Phi_K$ is bounded. In that case every function in $\mathcal{H}$ is bounded, and convergence in $\mathcal{H}$ implies uniform convergence.

Theorem 2.13 (Continuity of Kernel). Suppose $X$ is a metric space, let $\mathcal{H} \subseteq F^X$ be a RKHS, $K$ its corresponding kernel. Then $K$ is (uniformly) continuous iff $\Phi_K$ is (uniformly) continuous. In that case every function in $\mathcal{H}$ is (uniformly) continuous, and convergence in $\mathcal{H}$ implies uniform convergence on compact sets.

Theorem 2.14 (Differentiability of Kernel). Suppose $X \subseteq \mathbb{R}^d$ is open, let $\mathcal{H} \subseteq F^X$ be a RKHS, $K$ its corresponding kernel. Then for $j = 1, \ldots, d$, $K$ is continuously differentiable in the $j$th component of both entries on $X$ if and only if $\Phi_K$ is continuously differentiable in the $j$th component, i.e. the limit

$$\partial_q K_q := \lim_{h \to 0} \frac{K_{q+he_j} - K_q}{h}$$

exists and is continuous with respect to $q \in X$, where $(e_j)_{j=1}^d$ is the canonical basis for $\mathbb{R}^d$. In that case, every function in $\mathcal{H}$ is once continuously differentiable in the $j$th component, and we have $(\partial_j f)(q) = \langle f, \partial_q K_q \rangle$ for each $f \in \mathcal{H}, q \in X$.

The $j$th partial derivatives of functions in $\mathcal{H}$ are contained in another reproducing kernel Hilbert space $\partial_j \mathcal{H}$, with kernel $\partial_{p_j} \partial_{q_j} K$, such that the map $\partial_j: \mathcal{H} \to \partial_j \mathcal{H}$ is not only continuous but non-expansive, and unitary if $\mathcal{H}$ does not contain any nonzero function constant in the $j$th component.
The previous theorem has natural generalizations for functions of class $C^k(X)$ for $k \geq 1$, and functions that are real or complex analytic on $X$.

2.2. Convergence of Discrete Sampling in RKHSs. Let $(\mathcal{H}, K)$ be a separable RKHS over a set $X$. Given $f \in \mathcal{H}$ and fixed $(x_i)_{i=1}^N \subset X$, the problem of finding the optimal $(\omega_i^N(f))_{i=1}^N \in \mathbb{F}^N$ to minimize $\|f - \sum_{i=1}^N \omega_i^N(f)K_{x_i}\|_H$ is straightforward: $\sum_{i=1}^N \omega_i^N(f)K_{x_i}$ is the orthogonal projection of $f$ to span$\{K_{x_i}\}_{i=1}^N$.

We may assume without loss of generality that $\{K_{x_i}\}_{i=1}^N$ are linearly independent, by removing points as necessary without affecting span$\{K_{x_i}\}_{i=1}^N$ (or losing any information about $f$, since $\sum_{i=1}^N c_iK_{x_i} = 0$ implies $\sum_{i=1}^N \overline{c_i}f(x_i) = 0$ by the reproducing property).

The following proposition can be tracked back to H. Körezlioğlu [12]. We provide a proof for the reader’s convenience.

**Proposition 2.15.** Let $(x_i)_{i=1}^N \subset X$ such that $\{K_{x_i}\}_{i=1}^N$ are linearly independent. Consider the finite-dimensional subspace $\mathcal{H}_x^N := \text{span}\{K_{x_i}\}_{i=1}^N$ of $\mathcal{H}$. Then the orthogonal projection $\pi_x^N$ of $\mathcal{H}$ onto $\mathcal{H}_x^N$ is given by

$$\pi_x^N(f) = \sum_{i=1}^N \omega_i^N(f)K_{x_i} := \sum_{i=1}^N \sum_{j=1}^N f(x_j)\Gamma_{ji}^N K_{x_i} = \sum_{i=1}^N \sum_{j=1}^N \langle f, K_{x_j} \rangle \Gamma_{ji}^N K_{x_i}$$

for any $f \in \mathcal{H}$, where $\Gamma^N \in \mathcal{M}_N(\mathbb{F})$ is the inverse of the Gram matrix $G^N := [K(x_i, x_j)]_{i,j=1}^N$, and $\langle (K_{x_i}, K_{x_j}) \rangle_{i,j=1}^N$ of $\{x_1, \ldots, x_N\}$.

More generally, if $\{K_{x_i}\}_{i=1}^N$ are not linearly independent, for any subset $s = (x_i)_{j=1}^K$ such that $\{K_{x_i}\}_{i=1}^N$ form a basis for $\mathcal{H}_x^N$, we have $\mathcal{H}_x^N = \mathcal{H}_s^K$ and

$$\rho_s^K = \sum_{j=1}^K \sum_{j=1}^K \langle \cdot, K_{x_{ik}} \rangle \Gamma_{ij}^K K_{x_{ij}}.$$"
a countable subset of \( \{ K_p \}_{p \in X} \) which is total in \( \mathcal{H} \); thus, there exists a countable set \( F \subset X \) such that \( \text{span}\{K_x\}_{x \in F} \) is dense in \( \mathcal{H} \). This motivates the following definition:

**Definition 2.16.** A countable subset \( \{ x_i \}_{i=1}^{\infty} \) of \( X \) is called a **uniqueness set** for \( \mathcal{H} \) if \( \{ K_{x_i} \}_{i=1}^{\infty} \) is a total set in \( \mathcal{H} \), that is, if \( f \in \mathcal{H} \) such that \( f(x_i) = 0 \) for all \( i \in \mathbb{N} \) implies \( f = 0 \).

**Theorem 2.17** (Ultimate realization of RKHSs, [15 Theorem 2.33]). Let \( (\mathcal{H}, K) \) be a RKHS on \( X \), \( \{ x_i \}_{i=1}^{\infty} \) a uniqueness set such that \( \{ K_{x_i} \}_{i=1}^{\infty} \) is linearly independent, \( G^N \) the Gram matrix for \( \{ x_i \}_{i=1}^{N} \), \( \Gamma^N = (G^N)^{-1} \). Then for each \( f \in \mathcal{H} \),

\[
\lim_{N \to \infty} \pi^N f = \lim_{N \to \infty} \sum_{i=1}^{N} \sum_{j=1}^{N} f(x_i) \Gamma^N_{ij} K_{x_j} = f
\]

under the topology of \( \mathcal{H} \), with distance decreasing monotonically. Consequently,

\[
\langle f, g \rangle = \lim_{N \to \infty} \sum_{i=1}^{N} \sum_{j=1}^{N} f(x_i) \Gamma^N_{ij} \bar{g}(x_j)
\]

for \( f, g \in \mathcal{H} \), and

\[
f(x) = \langle f, K_x \rangle = \lim_{N \to \infty} \sum_{i=1}^{N} \sum_{j=1}^{N} f(x_i) \Gamma^N_{ij} K(x, x_j)
\]

for \( f \in \mathcal{H}, x \in X \).

**Proof.** Since each \( \pi^N_x \), being a projection, is a continuous linear operator with operator norm 1, and \( \text{span}\{K_{x_i}\}_{i=1}^{\infty} \) is dense in \( \mathcal{H} \), showing \( \lim_{N \to \infty} \pi^N_x f = f \) for \( f \in \text{span}\{K_{x_i}\}_{i=1}^{\infty} \) is sufficient.

But for each \( f \in \text{span}\{K_{x_i}\}_{i=1}^{\infty} \), since \( f \) is a linear combination of finitely many \( K_{x_i}s \), there exists \( N_f \in \mathbb{N} \) such that \( f \in \text{span}\{K_{x_i}\}_{i=1}^{N_f} \). Then for each \( N \geq N_f \), \( \pi^N_x f = f \), so \( \lim_{N \to \infty} \pi^N_x f = f \). \( \square \)

The previous theorem has implications in interpolation theory, e.g. see [15 Corollary 2.6].

**Corollary 2.18.** Let \( \{ x_i \}_{i=1}^{\infty} \) be a uniqueness set for \( (\mathcal{H}, K) \), \( \{ y_i \}_{i=1}^{\infty} \) a sequence in \( \mathcal{F} \). Suppose \( \{ y_i \}_{i=1}^{\infty} \) satisfies

\[
\sup_{N \in \mathbb{N}} \sum_{i=1}^{N} \sum_{j=1}^{N} y_i \Gamma^N_{ij} y_j < \infty.
\]

Then there exists (unique) \( F \in \mathcal{H} \) such that \( F(x_i) = y_i \) for all \( i \in \mathbb{N} \).

### 2.3. Integration of RKHS-Valued Functions.

In the next sections we will consider integrals of Hilbert space-valued functions. We first provide fundamental definitions and properties concerning the **Bochner integral**, an extension of the Lebesgue integral for Banach space-valued functions, following D.L Cohn [3 Appendix E].

Let \( (\mathcal{E}; \| \cdot \|) \) be a (real or complex) Banach space and \( (X, \Sigma, \mu) \) a finite measure space. On \( \mathcal{E} \) we consider the Borel \( \sigma \)-algebra denoted by \( \mathcal{B}(\mathcal{E}) \). A map \( f : X \to \mathcal{E} \) is called **measurable** if \( f^{-1}(S) \in \Sigma \) for all \( S \in \mathcal{B}(\mathcal{E}) \) and it is called **strongly measurable** if it is measurable and its range \( f(X) \) is separable. If \( \mathcal{E} \) is a separable Banach space...
then the concepts coincide. Both sets of measurable functions, respectively strongly measurable functions, are vector spaces.

A map \( \phi : X \rightarrow E \) is \textit{simple} if it is measurable and its range \( \phi(X) \) is finite, equivalently, there exist \( b_1, \ldots, b_n \in E \) and \( E_1, \ldots, E_n \in \Sigma \) such that

\[
\phi = \sum_{k=1}^{n} b_k \chi_{E_k},
\]

where we denote, as usually, by \( \chi_A \) the characteristic (or indicator) function of \( A \).

It is proven that, a function \( f : X \rightarrow B \) is strongly measurable if and only if there exists a sequence of simple functions \( (\phi_n) \) such that \( \phi_n \rightarrow f \) pointwise on \( X \). In addition, in this case, the sequence \( (\phi_n) \) can be chosen such that \( \|\phi_n(x)\| \leq \|f(x)\| \) for all \( x \in X \).

A function \( f : X \rightarrow E \) is \textit{Bochner integrable} if it is strongly measurable and the scalar function \( X \ni x \mapsto \|f(x)\| \in \mathbb{R} \) is integrable. In this case, the Bochner integral of \( f \) is defined as follows. Firstly, for a Bochner integrable function \( \phi \) as in (2.3), it is proven that \( \mu(E_k) < \infty \) for all \( k = 1, \ldots, n \) and then, its Bochner integral is defined by

\[
\int_X \phi(x) \, d\mu(x) := \sum_{k=1}^{n} b_k \mu(E_k) \in E.
\]

In general, if \( f \) is Bochner integrable, then there exists a sequence of simple functions \( (\phi_n) \) that converges pointwise to \( f \) on \( X \) and \( \|\phi_n(x)\| \leq \|f(x)\| \) for all \( x \in X \) and all \( n \in \mathbb{N} \). In this case, it can be proven that the sequence \( (\int_X \phi_n(x) \, d\mu(x)) \) is Cauchy in \( E \), hence it has a limit and we define

\[
\int_X f(x) \, d\mu(x) := \lim_{n \rightarrow \infty} \int_X \phi_n(x) \, d\mu(x).
\]

It can be proven that this definition is correct, that is, it does not depend on the sequence \( (\phi_n) \).

Bochner integrable functions share many properties with scalar-valued integrable functions, but not all. For example, the collection of all Bochner integrable functions make a vector space and, for any Bochner integrable function \( f \) we have

\[
\left\| \int_X f(x) \, d\mu(x) \right\| \leq \int_X \|f(x)\| \, d\mu(x).
\]

Also, letting \( L^1(X; \mu; E) \) denote the collection of all equivalence classes of Bochner integrable functions, identified \( \mu \)-almost everywhere, this is a Banach space with norm

\[
\|f\|_1 := \int_X \|f(x)\| \, d\mu(x), \quad f \in L^1(X; \mu; E).
\]

In addition, the Dominated Convergence Theorem holds for the Bochner integral as well, e.g. see [3, Theorem E.6].

In this article, we will use the following result, which is a special case of a theorem of E. Hille, e.g. see [5, Theorem III.2.6]. In Hille’s Theorem, the linear transformation is supposed to be only closed and, consequently, additional assumptions are needed, so we provide a proof for the special case of bounded linear operators for the reader’s convenience.
Theorem 2.19. Let $\mathcal{E}$ be a Banach space, $(X, \mu)$ a measure space, and $f: X \to \mathcal{E}$ a Bochner integrable function. If $L: \mathcal{E} \to \mathcal{F}$ is a continuous linear transformation between Banach spaces, then $L \circ f: X \to \mathcal{F}$ is Bochner integrable and
\[
\int_X (L \circ f)(x) \, d\mu(x) = L \int_X f(x) \, d\mu(x).
\]

Proof. Since $f$ is Bochner integrable, there exists a sequence $(\phi_n)_n$ of simple functions that converges pointwise to $f$ on $X$ and $\|\phi_n(x)\| \leq \|f(x)\|$ for all $x \in X$ and all $n \in \mathbb{N}$. Then,
\[
\|L\phi_n(x) - Lf(x)\| = \|L(\phi_n(x) - f(x))\| \leq \|L\|\|\phi_n(x) - f(x)\| \to 0, \quad x \in X,
\]
hence the sequence $(L \circ \phi_n)_n$ converges pointwise to $L \circ f$. Also, it is easy to see that $L \circ \phi_n$ is a simple function for all $n \in \mathbb{N}$. These show that $L \circ f$ is strongly measurable. Since $\|Lf(x)\| \leq \|L\|\|f(x)\|$ for all $x \in X$ and $f$ is Bochner integrable, it follows that
\[
\int_X \|Lf(x)\| \, d\mu(x) \leq \|L\| \int_X \|f(x)\| \, d\mu(x) < \infty,
\]
hence $L \circ f$ is Bochner integrable.

On the other hand,
\[
\|L\phi_n(x)\| \leq \|L\|\|\phi_n(x)\| \leq \|L\|\|f(x)\|, \quad x \in X, \ n \in \mathbb{N},
\]
hence, by the Dominated Convergence Theorem for the Bochner integral, it follows that
\[
\int_X Lf(x) \, d\mu(x) = \lim_{n \to \infty} \int_X L\phi_n(x) \, d\mu(x) = \lim_{n \to \infty} L \int_X \phi_n(x) \, d\mu(x) = L \int_X f(x) \, d\mu(x). \quad \Box
\]

A direct consequence of this fact is a sufficient condition for when a pointwise integral coincides with the Bochner integral, valid not only for RKHSs but also for Banach spaces of functions on which evaluation maps at any point are continuous, e.g. $C(Y)$ for some compact Hausdorff space $Y$.

Proposition 2.20. Let $(X, \Sigma, \mu)$ be a measure space, $\mathcal{B} \subseteq \mathbb{F}^X$ a Banach space of functions on $X$ such that all evaluation maps on $\mathcal{B}$ are continuous. Let $\lambda: X \times X \to \mathbb{F}$ be such that for each $q \in X$ we have $\lambda_q := \lambda(\cdot, q) \in \mathcal{B}$.

If, for each $q \in X$, the map $X \ni q \mapsto \lambda_q \in \mathcal{B}$ is Bochner integrable, then the scalar map $X \ni q \mapsto \lambda(p, q) \in \mathbb{F}$ is integrable, for each fixed $p \in X$.

Moreover, in that case, the pointwise integral map $X \ni p \mapsto \int_X \lambda(p, q) \, d\mu(q)$ lies in $\mathcal{B}$ and coincides with the Bochner integral $\int_X \lambda_q \, d\mu(q)$.

Proof. Since, for each $q \in X$, the map $X \ni q \mapsto \phi(q) := \lambda(\cdot, q) \in \mathcal{B}$ is Bochner integrable, and taking into account that, for all $p \in X$, the linear functional $\text{ev}_p$ is continuous, by Theorem 2.19 we have
\[
\text{ev}_p \int_X \phi(q) \, d\mu(q) = \int_X \text{ev}_p \circ \phi(q) \, d\mu(q).
\]
Since \( ev_p \circ \phi(q) = \lambda(p, q) \) for all \( p, q \in X \), this means that the scalar map \( X \ni q \mapsto \lambda(p, q) \in \mathbb{F} \) is integrable, for each fixed \( p \in X \), and

\[
ev_p \int_X \phi(q) \, d\mu(q) = \int_X \lambda(p, q) \, d\mu(q), \quad p \in X,
\]
hence, the pointwise integral map \( X \ni p \mapsto \int_X \lambda(p, q) \, d\mu(q) \) lies in \( \mathcal{B} \) and coincides with the Bochner integral \( \int_X \phi(q) \, d\mu(q) \).

\[ \square \]

### 2.4. The Markov-Bienaymé-Chebyshev Inequality

We use a generalization of the celebrated Markov-Bienaymé-Chebyshev Inequality on the concentration of probability measures to obtain regions of large measure with small approximation error, in terms of the Hilbert space norm and not simply the uniform norm.

**Theorem 2.21** (Markov-Bienaymé-Chebyshev’s Inequality). Let \( (X; \Sigma; P) \) be a probability space, \( (\mathcal{B}; \| \cdot \|) \) be a Banach space, \( h: \mathbb{R}_{>0} \rightarrow \mathbb{R}_{>0} \) a nondecreasing function, and let \( g: X \rightarrow \mathcal{B} \) be a Borel measurable function. Then, for any \( \delta > 0 \), we have

\[
P(\{x \in X \mid \|g(x)\| \geq \delta\}) \leq \frac{1}{h(\delta)} \int_X h(\|g(x)\|) \, dP(x).
\]

**Proof.** For any \( \delta > 0 \) let \( S_\delta := \{x \in X \mid \|g(x)\| \geq \delta\} \) and observe that, since \( g \) is Borel measurable it follows that \( S_\delta \in \Sigma \). Since \( h \) is nondecreasing it is measurable and we have \( h(\|g(x)\|) \geq h(\delta) \) for all \( x \in S_\delta \). Then, since \( P \) is nonnegative, we have

\[
\frac{1}{h(\delta)} \int_X h(\|g(x)\|) \, dP(x) \geq \frac{1}{h(\delta)} \int_{S_\delta} h(\|g(x)\|) \, dP(x) \\
\geq \frac{1}{h(\delta)} \int_{S_\delta} h(\delta) \, dP(x) = P(S_\delta).
\]

This inequality is mostly used when \( h(t) = t^p \) for some \( 0 < p < \infty \). In particular, for \( p = 2 \), we get the following

**Corollary 2.22.** Let \( (X; \Sigma; P) \) be a probability space, \( (\mathcal{B}; \| \cdot \|) \) a Banach space, and let \( f, g: X \rightarrow \mathcal{B} \) be two Borel measurable functions. Then, for any \( \delta > 0 \), we have

\[
P(\{x \in X \mid \|g(x)\| \geq \delta\}) \leq \frac{1}{\delta^2} \int_X \|g(x)\|^2 \, dP(x).
\]

The classical Bienaymé-Chebyshev Inequality

\[
P(\{x \in X \mid |f(x) - E(f)| \geq k\sigma\}) \leq \frac{1}{k^2},
\]

is obtained from Corollary 2.22, applied for \( \mathcal{B} = \mathbb{R} \), \( g(x) = f(x) - E(f) \), and \( \delta = k\sigma \), for \( k > 0 \), where \( E(f) = \int_X f(x) \, dx \) is the expected value of the random variable \( f \) and \( \sigma^2 = E((f - E(f))^2) = E(f^2) - E(f)^2 > 0 \) is the variance of \( f \).

### 3. Main Results

Throughout this section we consider a probability measure space \((X; \Sigma; P)\) and a RKHS \((\mathcal{H}; \langle \cdot, \cdot \rangle)\) in \( \mathbb{F}^X \), with norm denoted by \( \| \cdot \| \), such that its reproducing kernel \( K \) is measurable. In addition, throughout this section, the reproducing kernel Hilbert space \( \mathcal{H} \) is supposed to be separable.
Definition 3.1. On the measurable space $(X; \Sigma)$ we define the measure $P_K$ by
\[ dP_K(x) = K(x, x) \, dP(x), \quad x \in X; \]
more precisely, $P_K$ is the absolutely continuous measure with respect to $P$ such that the function $X \ni x \mapsto K(x, x)$ is the Radon-Nikodym derivative of $P_K$ with respect to $P$.

With respect to the measure space $(X; \Sigma; P_K)$ we consider the Hilbert space $L^2(X; P_K)$ and first obtain a natural bounded linear operator mapping $L^2(X; P_K)$ to $\mathcal{H}$.

Proposition 3.2. With notation and assumptions as before, let $\lambda: X \to \mathbb{F}$ be a measurable function such that the integral $\int_X |\lambda(x)|^2 \, dP_K(x)$ is finite. Then the Bochner integral
\[ \int_X \lambda(x) K_x \, dP(x) \]
exists in $\mathcal{H}$.

In addition, the mapping
\[ (3.1) \quad L^2(X; P_K) \ni \lambda \mapsto L_{P,K} \lambda := \int_X \lambda(x) K_x \, dP(x) \in \mathcal{H}, \]
is a nonexpansive, hence bounded, linear operator.

Proof. By assumptions, the map $X \ni x \mapsto \lambda(x) K_x \in \mathcal{H}$ is measurable and, since $\mathcal{H}$ is separable, it follows that this map is actually strongly measurable. Letting $\| \cdot \|$ denote the norm on $\mathcal{H}$ and using the assumption that $\int_X |\lambda(x)|^2 K(x, x) \, dP(x)$ is finite, we have
\[ \int_X \| \lambda(x) K_x \|^2 \, dP(x) = \int_X |\lambda(x)|^2 K(x, x) \, dP(x) < \infty, \]
hence, by the Schwarz Inequality and taking into account that $P$ is a probability measure, we have
\[ \int_X \| \lambda(x) K_x \| \, dP(x) \leq \sqrt{\int_X \| \lambda(x) K_x \|^2 \, dP(x)} < \infty. \]

By Theorem 2.19 this implies that the Bochner integral $\int_X \lambda(x) K_x \, dP(x)$ exists in $\mathcal{H}$. Consequently, the mapping $L_{P,K}$ as in (3.1) is correctly defined and it is clear that it is a linear transformation.

For arbitrary $\lambda \in L^2(X; P_K)$, by the triangle inequality for the Bochner integral (2.4) we then have
\[ \left\| \int_X \lambda(x) K_x \, dP(x) \right\|^2 \leq \left( \int_X \| \lambda(x) K_x \| \, dP(x) \right)^2 \]
\[ = \left( \int_X |\lambda(x)| K(x, x)^{1/2} \, dP(x) \right)^2 \]
and applying the Schwarz Inequality for the integral and taking into account that $P$ is a probability measure
\[ \leq \int_X |\lambda(x)|^2 K(x, x) \, dP(x) = \| \lambda \|^2_{L^2(X; P_K)}, \]
hence $L_{P,K} : L^2(X; P_K) \to \mathcal{H}$ is a nonexpansive linear operator. \hfill \Box

Using the bounded linear operator $L_{P,K}$ defined as in (3.1), let us denote its range by

\begin{equation}
\mathcal{H}_P := L_{P,K}(L^2(X; P_K)),
\end{equation}

which is a subspace of the RKHS $\mathcal{H}$.

**Proposition 3.3.** $\mathcal{H}_P$ is a RKHS contained in $\mathcal{H}$, hence in $\mathbb{F}^X$, and its reproducing kernel $K_P$ is

\[ K_P(x, y) = \int_X K(x, z)K(z, y) \frac{dP(z)}{K(z, z)}, \quad x, y \in X, \]

where, whenever $K(z, z) = 0$, by convention we define $K(x, z)K(z, y)/K(z, z) = 0$ for all $x, y \in X$.

**Proof.** Since $L^2(X; P_K)$ is a Hilbert space and $L_{P,K}$ is a bounded linear map, by Theorem 2.5 it follows that $\mathcal{H}_P$ is a RKHS in $\mathbb{F}_X$, isometrically isomorphic to the orthogonal complement of $\ker L_{P,K} \subseteq L^2(X; P_K)$, and its norm is given by

\[ \|g\|_{\mathcal{H}_P} := \min \{ \|\lambda\|_{L^2(X; P_K)} \mid L_{P,K}\lambda = g \}, \quad g \in \mathcal{H}_P. \]

Let

\[ X_0 := \{ x \in X \mid K(x, x) = 0 \}, \]

and let us define $u_x : X \to \mathbb{F}$ by

\[ u_x(y) := \begin{cases} \frac{K(y, x)}{K(y, y)}, & y \in X \setminus X_0, \\ 0, & y \in X_0. \end{cases} \]

From the Schwarz Inequality for the kernel $K$, it follows that if $x \in X_0$ then $K(x, y) = 0$ for all $y \in X$. This shows that $u_x = 0$ for all $x \in X_0$.

For each $x \in X$, by the Schwarz inequality and the fact that $P$ is a probability measure we have

\[ \int_X |u_x(y)|^2 K(y, y) \, dP(y) = \int_{X \setminus X_0} \frac{|K(y, x)|^2}{K(y, y)} \, dP(y) \leq \int_{X \setminus X_0} \frac{K(y, y)K(x, x)}{K(y, y)} \, dP(y) = K(x, x)P(X \setminus X_0) < \infty, \]

hence, $u_x \in L^2(X, P_K)$. Then, taking into account that $K(x, y) = 0$ for all $y \in X_0$ and all $x \in X$, it follows that, for each $\lambda \in L^2(X, P_K)$ and $x \in X$, we have

\[
(L_{P,K}\lambda)(x) = \int_X \lambda(y)K(x, y) \, dP(y) = \int_{X \setminus X_0} \lambda(y)K(x, y) \, dP(y) = \int_{X \setminus X_0} \lambda(y) \frac{K(y, x)}{K(y, y)} K(y, y) \, dP(y) = \int_X \lambda(y) u_x(y) K(y, y) \, dP(y) = \langle \lambda, u_x \rangle_{L^2(X, P_K)}. 
\]
In conclusion, \( u_x \) is exactly the representative for the functional \( \text{ev}_x \mathcal{H}_P \) so, by Theorem 2.3, the kernel of \( \mathcal{H}_P \) is

\[
K_P(x, y) = \langle u_y, u_x \rangle_{L^2(X, P)} = \int_X u_y(z) u_x(z) K(z, z) \, dP(z) = \int_{X \setminus X_0} u_y(z) u_x(z) K(z, z) \, dP(z)
\]

and, using the convention that \( K(x, z) K(z, y) / K(z, z) = 0 \) whenever \( K(z, z) = 0 \) and for arbitrary \( x, y \in X \),

\[
= \int_X \frac{K(x, z) K(z, y)}{K(z, z)} \, dP(z).
\]

The first step in our enterprise is to find error bounds for approximations of functions in the reproducing kernel Hilbert space \( \mathcal{H} \) in terms of distributional finite linear combinations of functions of type \( K_x \).

**Theorem 3.4.** With notation and assumptions as before, let \( \lambda \in L^2(X; P_K) \) and \( f \in \mathcal{H} \). For each \( n \in \mathbb{N} \) and \( \delta > 0 \), consider the set

\[
A_{n, \delta} := \{ (x_1, \ldots, x_n) \in X^n \mid \| f - \frac{1}{n} \sum_{i=1}^{n} \lambda(x_i) K_{x_i} \|_{\mathcal{H}} \geq \delta \}. \tag{3.3}
\]

Then, letting \( P^n \) denote the product probability measure on \( X^n \) and defining the bounded linear operator \( L_{P,K} \) as in (3.1), we have

\[
P^n(A_{n, \delta}) \leq \frac{1}{\delta^2} \| f - L_{P,K} \lambda \|^2_{\mathcal{H}} + \frac{1}{n \delta^2} \left( \| \lambda \|^2_{L^2(X; P_K)} - \| L_{P,K} \lambda \|^2_{\mathcal{H}} \right).
\]

**Proof.** By Proposition 3.2, the Bochner integral \( \int_X \lambda(x) K_x \, dP(x) \) exists in \( \mathcal{H} \) and the linear operator \( L_{P,K} \) is well-defined and bounded. In order to simplify the notation, considering \( g: X^n \to \mathcal{H} \) the function defined by

\[
g(x_1, \ldots, x_n) = f - \frac{1}{n} \sum_{i=1}^{n} \lambda(x_i) K_{x_i}, \quad (x_1, \ldots, x_n) \in X^n,
\]

observe that \( g \) is measurable and for each \( \delta > 0 \) we have

\[
A_{n, \delta} = \{ (x_1, \ldots, x_n) \in X^n \mid \| g(x_1, \ldots, x_n) \| \geq \delta \}. \tag{3.4}
\]

Then we have

\[
\| g(x_1, \ldots, x_n) \|^2 = \| f - \frac{1}{n} \sum_{i=1}^{n} \lambda(x_i) K_{x_i} \|^2
\]

\[
= \| f \|^2 - \frac{2}{n} \sum_{i=1}^{n} \text{Re} \langle f, \lambda(x_i) K_{x_i} \rangle + \frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} \langle \lambda(x_i) K_{x_i}, \lambda(x_j) K_{x_j} \rangle. \tag{3.5}
\]

Since \( P^n \) is a probability measure we have

\[
\int_{X^n} \| f \|^2 \, dP^n(x_1, \ldots, x_n) = \| f \|^2.
\]
On the other hand, by Fubini’s theorem and the fact that the Bochner integral commutes with continuous linear operations, see Theorem 2.19, we have
\[
\int_{X^n} \text{Re} \langle f, \lambda(x_i)K_{x_i} \rangle \, dP^n(x_1, \ldots, x_n) = \text{Re} \langle f, \int_{X^n} \lambda(x_i)K_{x_i} \, dP^n(x_1, \ldots, x_n) \rangle \\
= \text{Re} \langle f, \int_X \lambda(x)K_x \, dP(x) \rangle = \text{Re} \langle f, \phi \rangle.
\]

Also, for each \( i = 1, \ldots, n \),
\[
\int_{X^n} \langle \lambda(x_i)K_{x_i}, \lambda(x_i)K_{x_i} \rangle \, dP^n(x_1, \ldots, x_n) = \int_{X^n} |\lambda(x_i)|^2 K(x_i, x_i) \, dP^n(x_1, \ldots, x_n) \\
= \int_X |\lambda(x)|^2 K(x, x) \, dP(x),
\]
and, for each \( i, j = 1, \ldots, n \), \( i \neq j \),
\[
\int_{X^n} \langle \lambda(x_i)K_{x_i}, \lambda(x_j)K_{x_j} \rangle \, dP^n(x_1, \ldots, x_n) = \int_X \langle \lambda(x_i)K_{x_i}, \int_X \lambda(x_j)K_{x_j} \, dP(x_j) \rangle \, dP(x_i) \\
= \langle \int_X \lambda(x)K_x \, dP(x), \int_X \lambda(x)K_x \, dP(x) \rangle \\
= \| \int_X \lambda(x)K_x \, dP(x) \|^2.
\]

Integrating both sides of (3.35) and using all the previous equalities, we therefore have
\[
\int_{X^n} \|g(x_1, \ldots, x_n)\|^2 \, dP^n(x_1, \ldots, x_n) = \|f\|^2 - \frac{2}{n} \sum_{i=1}^n \text{Re} \langle f, \int_X \lambda(x)K_x \, dP(x) \rangle \\
+ \frac{1}{n^2} \sum_{i=1}^n \sum_{i \neq j=1}^n \| \int_X \lambda(x)K_x \, dP(x) \|^2 + \frac{1}{n} \sum_{i=1}^n \int_X |\lambda(x)|^2 K(x, x) \, dP(x) \\
= \|f\|^2 - 2\text{Re} \langle f, \int_X \lambda(x)K_x \, dP(x) \rangle + \frac{n-1}{n} \| \int_X \lambda(x)K_x \, dP(x) \|^2 \\
+ \frac{1}{n} \int_X |\lambda(x)|^2 K(x, x) \, dP(x) \\
= \left\| f - \int_X \lambda(x)K_x \, dP(x) \right\|^2 + \frac{1}{n} \left( \int_X |\lambda(x)|^2 K(x, x) \, dP(x) - \| \int_X \lambda(x)K_x \, dP(x) \|^2 \right) \\
= \|f - L_{P,K}\lambda\|^2 + \frac{1}{n} \left( \|L_{P,K}\lambda\|^2 \right).
\]

Finally, in view of the Markov-Bienaymé-Chebyshev Inequality as in (2.5), when \( X \) is replaced by \( X^n \) and \( P \) by \( P^n \), and taking into account the previous equality and (3.4), we get
\[
P^n(A_{n,\delta}) \leq \frac{1}{\delta^2} \int_{X^n} \|g(x_1, \ldots, x_n)\|^2 \, dP^n(x_1, \ldots, x_n) \\
= \frac{1}{\delta^2} \|f - L_{P,K}\lambda\|^2 + \frac{1}{n\delta^2} \left( \|\lambda\|^2_{L^2(X,P_K)} - \|L_{P,K}\lambda\|^2 \right),
\]
which is the required inequality.

As with the special case of kernel embeddings, for which \( \lambda = 1 \), see Smola et al. [17], we may use the bound in Theorem 3.4 to obtain a statement of convergence in probability.

**Theorem 3.5 (Convergence in Probability of Projections).** Let \( X, P, K, \) and \( \mathcal{H} \) be as in Theorem 3.4. For each sequence \( x = (x_i) \in \mathcal{X}^\mathbb{N} \) and each \( n \in \mathbb{N} \), let \( \pi^n_x \) denote the orthogonal projection of \( \mathcal{H} \) onto \( \text{span}\{K_{x_i}\}_{i=1}^n \). Let \( f \in \mathcal{H} \) and, for each \( \delta > 0 \) and \( n \in \mathbb{N} \), define

\[
B_{n,\delta} := \{(x_1, \ldots, x_n) \in \mathcal{X}^n \mid \|f - \pi^n_x f\| \geq \delta\}.
\]

Then, for each \( \delta > 0 \)

\[
\limsup_{n \to \infty} P^n(B_{n,\delta}) \leq \frac{1}{\delta^2} d_\mathcal{H}(f, \mathcal{H}_P)^2,
\]

where \( d_\mathcal{H}(f, \mathcal{H}_P) = \inf_{g \in \mathcal{H}_P} \|f - g\| \).

In particular, if \( f \) belongs to \( \overline{\mathcal{H}_P}^\mathcal{H} \), the closure of \( \mathcal{H}_P \) with respect to the topology of \( \mathcal{H} \), then

\[
\lim_{n \to \infty} P^n(B_{n,\delta}) = 0.
\]

**Proof.** Let \( \lambda \in L^2(X, P_K) \) and fix \( \delta > 0 \), arbitrary. Then

\[
\|f - \pi^n_x f\| \leq \left\|f - \frac{1}{n} \sum_{i=1}^n \lambda(x_i)K_{x_i}\right\|
\]

hence, with notation as in (3.3), we have \( B_{n,\delta} \subseteq A_{n,\delta} \). By Theorem 3.4, this implies

\[
P^n(B_{n,\delta}) \leq \frac{1}{\delta^2} \|f - L_{P,K}\lambda\|^2 + \frac{1}{n\delta^2} \left[\|\lambda\|^2_{L^2(X, P_K)} - \|L_{P,K}\lambda\|^2_{\mathcal{H}}\right].
\]

Therefore,

\[
\limsup_{n \to \infty} P^n(B_{n,\delta}) \leq \limsup_{n \to \infty} \left[\frac{1}{\delta^2} \|f - L_{P,K}\lambda\|^2_{\mathcal{H}} + \frac{1}{n\delta^2} \left(\|\lambda\|^2_{L^2(X, P_K)} - \|L_{P,K}\lambda\|^2_{\mathcal{H}}\right)\right]
\]

\[
= \frac{1}{\delta^2} \|f - L_{P,K}\lambda\|^2_{\mathcal{H}}.
\]

Thus, since the left-hand side is independent of \( \lambda \),

\[
\limsup_{n \to \infty} P^n(B_{n,\delta}) \leq \inf_{\lambda \in L^2(X, P_K)} \frac{1}{\delta^2} \|f - L_{P,K}\lambda\|^2_{\mathcal{H}} = \frac{1}{\delta^2} d_\mathcal{H}(f, \mathcal{H}_P)^2.
\]

In particular, if \( f \) belongs to \( \overline{\mathcal{H}_P}^\mathcal{H} \), then \( d_\mathcal{H}(f, \mathcal{H}_P) = 0 \).

In fact, by noting that \( \|f - \pi^n_x f\| \), unlike \( \|f - \frac{1}{n} \sum_{i=1}^n \lambda(x_i)K_{x_i}\| \), is monotonically nonincreasing with respect to \( n \) by Theorem 2.17, we can strengthen the preceding statement to almost certain convergence after passing to a single measure space.

Firstly, recall that, e.g. see [3, Proposition 10.6.1], the countably infinite product space \( X^\mathbb{N} \) equipped with the smallest \( \sigma \)-algebra rendering each projection map \( X_i: X^\mathbb{N} \to X \) measurable admits a unique probability measure \( P^\mathbb{N} \) such that the projection maps are independent random variables with distribution \( P \).
Lemma 3.6. Let $X$, $P$, $K$, and $\mathcal{H}$ be as in Theorem 3.4 and $f \in \mathcal{H}$. For each $\delta > 0$ define
\[ S_{n,\delta} := \left\{ x = (x_k)_{k=1}^{\infty} \in X^\mathbb{N} \mid \| f - \pi_x^n f \| \geq \delta \right\}, \quad n \in \mathbb{N}, \]
and
\[ S_\delta := \left\{ x = (x_k)_{k=1}^{\infty} \in X^\mathbb{N} \mid \forall N \in \mathbb{N}, \exists n \geq N, \| f - \pi_x^n f \| \geq \delta \right\} = \bigcap_{N \in \mathbb{N}} \bigcup_{n \geq N} S_{n,\delta}. \tag{3.7} \]
Then,
\[ P_N(S_\delta) \leq \frac{1}{\delta^2} d_{\mathcal{H}}(f, \mathcal{H}_P)^2, \]
and, consequently, if $f \in \overline{\mathcal{H}_P}$, then
\[ P_N(S_\delta) = 0. \]

Proof. Observe that for each $n, m \in \mathbb{N}$ such that $n > m$, $\| f - \pi_x^n f \| \leq \| f - \pi_x^m f \|$, for each $x \in X^\mathbb{N}$, and hence $S_{n,\delta} \subseteq S_{m,\delta}$ for each $\delta > 0$. Then,
\[ S_\delta = \bigcap_{N \in \mathbb{N}} \bigcup_{n \geq N} S_{n,\delta}, \]
hence, for any $\lambda \in L^2(X, P_K)$,
\[ P_N(S_\delta) \leq \inf_{N \in \mathbb{N}} P_N(S_{N,\delta}) \leq \frac{1}{\delta^2} \| f - L_{P,K} \lambda \|_{\mathcal{H}}^2, \]
since $P_N$ is monotone and $S_\delta \subseteq S_{N,\delta}$ for all $N \in \mathbb{N}$. \hfill \square

Theorem 3.7 (Almost Certain Convergence of Projections). Let $X, P, K, \mathcal{H}$ be as in Theorem 3.4 and suppose $\mathcal{H}_P$ is dense in $\mathcal{H}$. Then, for each $f \in \mathcal{H}$,
\[ P_N \left( \left\{ x \in X^\mathbb{N} \mid \pi_x^n f \nrightarrow f \right\} \right) = 1, \]
hence,
\[ P_N \left( \left\{ x \in X^\mathbb{N} \mid \forall f \in \mathcal{H}, \pi_x^n f \nrightarrow f \right\} \right) = 1. \]

Proof. Let $f \in \mathcal{H}$. With the same sets $S_\delta$ defined in (3.7),
\[ \left\{ x \in X^\mathbb{N} \mid \pi_x^n f \nrightarrow f \right\} = \left\{ x \in X^\mathbb{N} \mid \exists \delta > 0, \forall N \in \mathbb{N}, \exists n \geq N, \| f - \pi_x^n f \| \geq \delta \right\} = \bigcup_{\delta > 0} S_\delta. \]
Observe further that $S_\delta \subseteq S_{\delta'}$ whenever $\delta > \delta'$, and for each $\delta > 0$ there exists $m \in \mathbb{N}$ such that $\delta > 1/m$, so that
\[ \left\{ x \in X^\mathbb{N} \mid \pi_x^n f \nrightarrow f \right\} = \bigcup_{0 < \delta \leq 1} S_\delta = \bigcup_{m \in \mathbb{N}} S_{1/m}, \]
thus
\[ P_N \left( \left\{ x \in X^\mathbb{N} \mid \pi_x^n f \nrightarrow f \right\} \right) \leq \sum_{m \in \mathbb{N}} P_N(S_{1/m}) = \sum_{m \in \mathbb{N}} 0 = 0. \]
Since $\mathcal{H}$ is separable let $\mathcal{D}$ be a countable dense subset of $\mathcal{H}$. Since each $\pi^n_x$ is a continuous linear operator with operator norm 1, $\pi^n_x f \to f$ for all $f \in \mathcal{H}$ iff $\pi^n_x f \to f$ for all $f \in \mathcal{D}$. Thus by the countable subadditivity of $P_N$,

$$P_N \left( \left\{ x \in X^N \mid \exists f \in \mathcal{H}, \pi^n_x f \not\to f \right\} \right) = P_N \left( \bigcup_{f \in \mathcal{D}} \left\{ x \in X^N \mid \pi^n_x f \not\to f \right\} \right) \leq \sum_{f \in \mathcal{D}} P_N \left( \left\{ x \in X^N \mid \pi^n_x f \not\to f \right\} \right) = 0. \quad \square$$

In summary, for a given probability measure $P$ under the assumption that it renders the space $\mathcal{H}_P$, the image of $L_{P,K}$, dense in $\mathcal{H}$, a sequence of points sampled independently from $P$ yields a uniqueness set with probability 1. As a final result, in the next proposition we show a sufficient condition, valid for many applications, when this assumption holds.

**Proposition 3.8.** Let $X$ be a topological space, $P$ a Borel probability measure on $X$, $\mathcal{H} \subseteq L^\infty(X; P_K)$ a RKHS with kernel $K$, and let $P_K$, $L_{P,K}$ and $\mathcal{H}_P$ defined as in Definition 3.1, (3.1), and (3.2), respectively.

Suppose that $K$ is continuous on $X$, that $\mathcal{H} \subseteq L^2(X; P_K)$, and that $P$ is strictly positive on any nonempty open subset of $X$. Then $\mathcal{H}_P$ is dense in $\mathcal{H}$.

**Proof.** The assertion is clearly equivalent with showing that the orthogonal complement of $\mathcal{H}_P$ in $\mathcal{H}$ is the null space. To this end, let $f \in \mathcal{H}$, $f \perp \mathcal{H}_P$. That is, for each $\lambda \in L^2(X; P_K)$,

$$\langle f, L_{P,K} \lambda \rangle_{\mathcal{H}} = \langle f, \int_X \lambda(x) K_x \, dP(x) \rangle = 0.$$

Then noting the fact that $\int_X \lambda(x) K_x \, dP(x)$ is a Bochner integral and hence, by Theorem 2.19 it commutes with inner products,

$$0 = \langle f, \int_X \lambda(x) K_x \, dP(x) \rangle = \int_X \overline{\lambda(y)} \langle f, K_x \rangle \, dP(x) = \int_X \overline{\lambda(x)} f(x) \, dP(x).$$

By assumption, $f \in \mathcal{H} \subseteq L^2(X; P_K)$, so we can take $\lambda = f$ to obtain

$$\int_X |f(x)|^2 \, dP(x) = \int_X \overline{f(x)} f(x) \, dP(x) = 0.$$

This implies that $f = 0$ $P$-almost everywhere, i.e. the set $f^{-1}(\mathbb{F} \setminus \{0\})$ has zero $P$ measure.

Since $K$ is continuous by assumption, by Theorem 2.13 each $f \in \mathcal{H}$ is continuous hence $f^{-1}(\mathbb{F} \setminus \{0\})$ is an open subset of $X$. But, since $P$ is assumed strictly positive on any nonempty open set, it follows that $f^{-1}(\mathbb{F} \setminus \{0\})$ must be empty, hence $f = 0$ identically. \quad \square

4. **Examples**

In this final section we provide detailed examples of applicability of the results on approximation error bounds obtained in the previous section.
4.1. **Uniform distribution on a compact interval.** Let \((\mu_j)_{j \in \mathbb{Z}} \in l_1(\mathbb{Z})\) be such that \(\mu_j > 0\) for all \(j \in \mathbb{Z}\) and denote \(\mu := \sum_{j \in \mathbb{Z}} \mu_j\). For each \(j \in \mathbb{Z}\) define
\[
\phi_j : [-\pi, \pi] \to \mathbb{C}, \quad \phi_j(t) := e^{ijt}, \quad t \in [-\pi, \pi],
\]
and consider the Hilbert space
\[
\mathcal{H} = \left\{ \sum_{j \in \mathbb{Z}} c_j \phi_j \mid \sum_{j \in \mathbb{Z}} \frac{|c_j|^2}{\mu_j} < \infty \right\},
\]
with the inner product
\[
\langle \sum_{j \in \mathbb{Z}} c_j \phi_j, \sum_{j \in \mathbb{Z}} d_j \phi_j \rangle = \sum_{j \in \mathbb{Z}} \frac{c_j \overline{d}_j}{\mu_j}.
\]
Then \(\{\sqrt{\mu_j} \phi_n\}_{j \in \mathbb{Z}}\) is an orthonormal basis of \(\mathcal{H}\) and, for an arbitrary function \(f \in \mathcal{H}\), we have the Fourier representation
\[
(4.1) \quad f(t) = \sum_{j \in \mathbb{Z}} c_j \phi_j(t), \quad t \in [-\pi, \pi],
\]
with coefficients \(\{c_j\}_{j \in \mathbb{Z}}\) subject to the condition
\[
(4.2) \quad \|f\|^2_{\mathcal{H}} := \sum_{j \in \mathbb{Z}} \frac{|c_j|^2}{\mu_j} < \infty,
\]
where the convergence of the series from (4.1) is at least guaranteed with respect to the norm \(\| \cdot \|_{\mathcal{H}}\). However, for any \(m \in \mathbb{N}_0\) and \(t \in [-\pi, \pi]\), by the Cauchy inequality we have
\[
\sum_{|j| \geq m} |c_j \phi_j(t)| \leq \left( \sum_{|j| \geq m} |c_j|^2 \right)^{1/2} \left( \sum_{|j| \geq m} \mu_j \right)^{1/2} \to 0 \quad \text{as} \quad m \to \infty,
\]
hence the convergence in (4.1) is absolutely and uniformly on \([-\pi, \pi]\), in particular \(f\) is continuous.

By Theorem 2.4 \(\mathcal{H}\) has the reproducing kernel
\[
(4.3) \quad K(s, t) = \sum_{j \in \mathbb{Z}} \mu_j e^{ij(s-t)} = \sum_{j \in \mathbb{Z}} \mu_j \phi_j(s) \overline{\phi_j(t)}
\]
and the convergence of the series is guaranteed at least pointwise. In addition, for any \(t \in [-\pi, \pi]\) we have
\[
K(t, t) = \sum_{j \in \mathbb{Z}} \mu_j |\phi_j(t)|^2 = \sum_{j \in \mathbb{Z}} \mu_j = \mu,
\]
and hence the kernel \(K\) is bounded. In particular, this implies that, actually, the series in (4.3) converges absolutely and uniformly on \([-\pi, \pi]\), hence the kernel \(K\) is continuous on \([-\pi, \pi] \times [-\pi, \pi]\). That is, \(K(s, t)\) is given by \(\kappa(s-t)\) where \(\kappa : \mathbb{R} \to \mathbb{C}\) is a continuous function with period \(2\pi\) whose Fourier coefficients \((\mu_j)_{j \in \mathbb{Z}}\) are all positive and absolutely summable.

Let \(P\) be the normalized Lebesgue measure on \([-\pi, \pi]\), equivalently, the uniform probability distribution on \([-\pi, \pi]\), and observe that \(\{\phi_j\}_{j \in \mathbb{Z}}\) is an orthonormal basis of the Hilbert space \(L_P[-\pi, \pi]\). With notation as in Definition 3.1 we have
Proposition 3.3, is a RKHS, with kernel, \( H \) theorem for the Lebesgue integral, or by using the uniform convergence of the series and where, the series commutes with the integral either by the Bounded Convergence Theorem by multiplication with \( L \) of the Hilbert space \( d \).

Thus, letting \( f \) also, for arbitrary \( f \in \mathcal{H} \), we have

\[
(L_{P,K}\phi_j)(t) = \int_{-\pi}^{\pi} \phi_j(s) K(t, s) \, dP(s) = \int_{-\pi}^{\pi} \phi_j(s) \left( \sum_{k \in \mathbb{Z}} \mu_k \phi_k(t) \overline{\phi_k(s)} \right) \, dP(s)
\]

\[
= \sum_{k \in \mathbb{Z}} \mu_k \phi_k(t) \int_{-\pi}^{\pi} \phi_j(s) \overline{\phi_k(s)} \, dP(s) = \sum_{k \in \mathbb{Z}} \mu_k \phi_k(t) \delta_{jk} = \mu_j \phi_j(t),
\]

where, the series commutes with the integral either by the Bounded Convergence Theorem for the Lebesgue integral, or by using the uniform convergence of the series and the Riemann integral. Similarly, the Hilbert space \( \mathcal{H}_P := L_{P,K}(L^2_{P[K]}[-\pi, \pi]) \), as in Proposition 3.3, is a RKHS, with kernel,

\[
K_P(s,t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left( \sum_{j \in \mathbb{Z}} \mu_j \phi_j(s) \overline{\phi_j(z)} \right) \left( \sum_{l \in \mathbb{Z}} \mu_l \phi_l(z) \overline{\phi_l(t)} \right) \, dz
\]

\[
= \frac{1}{\mu} \sum_{j \in \mathbb{Z}} \sum_{l \in \mathbb{Z}} \mu_j \phi_j(s) \overline{\phi_l(t)} \frac{1}{2\pi} \int_{-\pi}^{\pi} \phi_j(z) \phi_l(z) \, dz
\]

\[
= \frac{1}{\mu} \sum_{j \in \mathbb{Z}} \sum_{l \in \mathbb{Z}} \mu_j \phi_j(s) \overline{\phi_l(t)} \delta_{jl} = \sum_{j \in \mathbb{Z}} \frac{\mu_j^2}{\mu} \phi_j(s) \phi_j(t).
\]

Thus, letting \( \mu_j' := \frac{\mu_j^2}{\mu} \leq \mu_j, j \in \mathbb{Z} \) and noting that \( \sum_{j \in \mathbb{Z}} \mu_j' \leq \sum_{j \in \mathbb{Z}} \mu_j < \infty \), we have

\[
\mathcal{H}_P = \left\{ \sum_{j \in \mathbb{Z}} c_j \phi_j \mid \sum_{j \in \mathbb{Z}} |c_j|^2 \mu_j' < \infty \right\} = \left\{ \sum_{j \in \mathbb{Z}} c_j \phi_j \mid \sum_{j \in \mathbb{Z}} \frac{|c_j|^2}{\mu_j' < \infty} \right\}.
\]

In particular, \( \mathcal{H}_P \) is dense in \( \mathcal{H} \) since both contain \( \text{span}\{\phi_j\}_{j \in \mathbb{Z}} \) as dense subsets, but this follows from the more general statement in Proposition 3.3 as well.

Let now \( \lambda \in L^2_{P[K]}[-\pi, \pi] = L^2_P[-\pi, \pi] \) be arbitrary, hence

\[
\lambda = \sum_{j \in \mathbb{Z}} \lambda_j \phi_j, \quad \sum_{j \in \mathbb{Z}} |\lambda_j|^2 < \infty, \quad ||\lambda||^2_{L^2_{P[K]}[-\pi, \pi]} = \frac{1}{\mu} \sum_{j \in \mathbb{Z}} |\lambda_j|^2.
\]

Then,

\[
(L_{P,K}\lambda)(t) = \left( L_{P,K} \sum_{j \in \mathbb{Z}} \lambda_j \phi_j \right)(t) = \sum_{j \in \mathbb{Z}} \lambda_j \mu_j \phi_j(t), \quad t \in [-\pi, \pi],
\]

and, consequently,

\[
||L_{P,K}\lambda||^2_{\mathcal{H}} = \sum_{j \in \mathbb{Z}} \frac{|\lambda_j|^2 \mu_j^2}{\mu_j} = \sum_{j \in \mathbb{Z}} \mu_j |\lambda_j|^2.
\]

Also, for arbitrary \( f \in \mathcal{H} \) as in (4.1) and (4.2), we have

\[
||f - L_{P,K}\lambda||^2_{\mathcal{H}} = ||\sum_{j \in \mathbb{Z}} (c_j - \lambda_j \mu_j) \phi_j||^2_{\mathcal{H}} = \sum_{j \in \mathbb{Z}} \frac{|c_j - \lambda_j \mu_j|^2}{\mu_j}.
\]
Let \((x_n)_{n \in \mathbb{N}}\) be a sequence of points in \([-\pi, \pi]\). By Theorem \ref{thm:approximation} and taking into account of the inequality \(\ref{eq:inequality2}\), for any \(N \in \mathbb{N}\) and \(\delta > 0\) we have

\[
P^N(\|f - \pi_x^N f\|_H \geq \delta) \leq P^N(\|f - \frac{1}{N} \sum_{n=1}^{N} \lambda(x_n)K_{x_n}\|_H \geq \delta) \leq \frac{1}{\delta^2} \sum_{j \in \mathbb{Z}} |c_j - \lambda_j\mu_j|^2 + \frac{1}{N\delta^2} \left(\sum_{j \in \mathbb{Z}} (\mu - \mu_j)|\lambda_j|^2\right).
\]

On the other hand, we observe that in the inequality \(\ref{eq:inequality4}\) the left hand side does not depend on \(\lambda\) and hence, for any \(\epsilon > 0\) there exists \(\lambda \in L^2_{P,K}[-\pi, \pi]\) such that

\[
P^N(\|f - \pi_x^N f\|_H \geq \delta) < \frac{\epsilon}{2} + \frac{1}{N\delta^2} \left(\sum_{j \in \mathbb{Z}} (\mu - \mu_j)|\lambda_j|^2\right),
\]

and then, for sufficiently large \(N\) we get

\[
P^N(\|f - \pi_x^N f\|_H \geq \delta) < \epsilon.
\]

In particular, if \(f \in \mathcal{H}_P\), that is, the inequality \(\ref{eq:inequality4}\) is replaced by the stronger one

\[
\sum_{j \in \mathbb{Z}} \frac{|c_j|^2}{\mu_j^2} < \infty,
\]

we can choose \(\lambda_j = c_j/\mu_j, j \in \mathbb{Z}\), and we have \(\lambda \in L^2_{P,K}[-\pi, \pi]\), hence

\[
P^N(\|f - \pi_x^N f\|_H \geq \delta) \leq \frac{1}{N\delta^2} \left(\sum_{j \in \mathbb{Z}} (\mu - \mu_j)|c_j|^2\right).
\]

For example, this is the case for \(f = \phi_k\) for some \(k \in \mathbb{Z}\), hence \(c_j = \delta_{j,k}, j \in \mathbb{Z}\), and letting \(\lambda = \phi_k/\mu_k\), hence \(\lambda_j = \delta_{j,k}/\mu_j, j \in \mathbb{Z}\), we have \(f = L_{P,K}\lambda\) and hence,

\[
P^N(\|\phi_k - \pi_x^N \phi_k\| \geq \delta) \leq \frac{1}{N\delta^2\mu_k^2} \sum_{z \in \mathbb{Z} \setminus \{k\}} \mu_j.
\]

This shows that, the larger \(\mu_k\) is, the faster \(\phi_k\) will be approximated but, since \(\mu_j \to 0\), \(\phi_j\)s cannot be approximated uniformly, in the sense that there does not exist a single \(N\) to make each \(\|\phi_j - \pi_x^N \phi_j\|_H\), bounded by the same \(\delta\) with the same probability \(\eta\).

This analysis can be applied more generally to kernels that admit an expansion analogous to \(\ref{eq:inequality4}\) under basis functions \((\phi_j)_j\) which constitute a total orthonormal set in \(L^2(X; P_K)\), e.g. as guaranteed by Mercer’s Theorem \cite[Theorem 2.30]{Mercer}.

### 4.2. The Hardy space \(H^2(\mathbb{D})\)

We consider the open unit disc in the complex plane \(\mathbb{D} = \{z \in \mathbb{C} \mid |z| < 1\}\) and the Szegö kernel

\[
K(z, \zeta) = \frac{1}{1 - z\overline{\zeta}} = \sum_{n=0}^{\infty} z^n\zeta^n, \quad z, \zeta \in \mathbb{D},
\]

where the series converges absolutely and uniformly on any compact subset of \(\mathbb{D}\). The RKHS associated to \(K\) is the Hardy space \(H^2(\mathbb{D})\) of all functions \(f: \mathbb{D} \to \mathbb{C}\) that are
holomorphic in $\mathbb{D}$ with power series expansion

$$f(z) = \sum_{n=0}^{\infty} f_n z^n,$$

such that the coefficients sequence $(f_n)_n$ is in $l^2(N_0)$. The inner product in $H^2(D)$ is

$$\langle \sum_{n=0}^{\infty} f_n z^n, \sum_{n=0}^{\infty} g_n z^n \rangle = \sum_{n=0}^{\infty} f_n \overline{g_n},$$

with norm

$$\| \sum_{n=0}^{\infty} f_n z^n \|^2 = \sum_{n=0}^{\infty} |f_n|^2.$$ 

For each $\zeta \in D$ we have

$$\| K_\zeta \| = (\sum_{n=0}^{\infty} |\zeta|^{2n})^{1/2} = \frac{1}{\sqrt{1 - |\zeta|^2}},$$

hence the kernel $K$ is unbounded.

We consider $P$ the normalized Lebesgue measure on $D$, that is, for $z = x + iy = re^{i\theta}$ we have

$$dP(z) = \frac{1}{\pi} dA(x, y) = \frac{r}{\pi} d\theta dr,$$

hence,

$$dP_K(z) = \frac{r}{\pi(1 - r^2)} d\theta dr.$$

Then, $L^2(\mathbb{D}; P_K)$ is contractively embedded in $L^2(\mathbb{D}; P)$.

Further on, in view of Proposition 3.3 and 153, for any $z, \zeta \in D$ we have

$$K_P(z, \zeta) = \frac{1}{\pi} \int_{0}^{1} \int_{0}^{2\pi} \frac{r(1 - r^2)}{(1 - zre^{-i\theta})(1 - \zeta re^{i\theta})} d\theta dr$$

$$= \frac{1}{\pi} \int_{0}^{1} \int_{0}^{2\pi} \sum_{n=0}^{\infty} \sum_{k=0}^{\infty} (1 - r^2)r^{n+k+1}e^{i(n-k)\theta} z^n \zeta^k d\theta dr$$

which, by using twice the Bounded Convergence Theorem for the Lebesgue measure, equals

$$= \sum_{n=0}^{\infty} \sum_{k=0}^{\infty} \frac{1}{\pi} \int_{0}^{1} \int_{0}^{2\pi} (1 - r^2)r^{n+k+1}e^{i(n-k)\theta} d\theta dr z^n \zeta^k$$

$$= \sum_{n=0}^{\infty} 4 \int_{0}^{1} (1 - r^2)r^{2n+1} dr z^n \zeta^n$$

$$= \sum_{n=0}^{\infty} \frac{z^n \zeta^n}{(n + 1)(n + 2)}.$$
This shows that the RKHS $H^2_\lambda(D)$ induced by $K_\lambda$ consists of all functions $h$ that are holomorphic in $D$ with power series representation $h(z) = \sum_{n=0}^{\infty} h_n z^n$ and such that
\[
\sum_{n=0}^{\infty} (n+1)(n+2) |h_n|^2 < \infty.
\]
In particular, an orthonormal basis of $H^2_\lambda(D)$ is $\{z^n/\sqrt{(n+1)(n+2)}\}_{n \geq 0}$ and hence $H^2_\lambda(D)$ is dense in the Hardy space $H^2(D)$.

In order to calculate the operator $L_{P,K} : L^2(D; P_K) \to H^2(D)$, let $\lambda \in L^2(D; P_K)$ be arbitrary, that is, $\lambda$ is a complex valued measurable function on $D$ such that
\[
\|\lambda\|^2_{L^2(D; P_K)} = \frac{1}{\pi} \int_0^1 \int_0^{2\pi} \frac{|\lambda(re^{i\theta})|^2}{1-r^2} d\theta dr < \infty.
\]
Then, in view of Proposition 2.20, we have
\[
(L_{P,K}\lambda)(z) = \frac{1}{\pi} \int_0^1 \int_0^{2\pi} \lambda(re^{i\theta}) K(z, re^{i\theta}) r d\theta dr
\]
which, by the Bounded Convergence Theorem, equals
\[
= \sum_{n=0}^{\infty} \frac{1}{\pi} \int_0^1 \int_0^{2\pi} \lambda(re^{i\theta}) r^n e^{-in\theta} d\theta dr z^n = \sum_{n=0}^{\infty} \lambda_n z^n,
\]
where, for each integer $n \geq 0$ we denote
\[
\lambda_n = \frac{1}{\pi} \int_0^1 \int_0^{2\pi} \lambda(re^{i\theta}) r^n e^{-in\theta} d\theta dr.
\]
Observing that, letting $\phi_n(z) := \sqrt{n+1} z^n$, for all integer $n \geq 0$ and $z \in D$, the set $\{\phi_n\}_{n \geq 0}$ is orthonormal in $L^2(D; P)$, it follows that $\lambda_n = \langle \lambda, \phi_n \rangle_{L^2(D; P)}$ for all integer $n \geq 0$ and, hence, $(\lambda_n)_{n \geq 0}$ is the weighted sequence of Fourier coefficients of $\lambda$ with respect to the system of orthonormal functions $\{\phi_n\}_{n \geq 0}$ in $L^2(D; P)$. On the other hand, since $L^2(D; P_K)$ is contractively embedded in $L^2(D; P)$, this shows that $L_{P,K}$ is the restriction to $L^2(D; P_K)$ of a Bergman type weighted projection of $L^2(D; P)$ onto a subspace of the Hardy space $H^2(D)$, that happens to be exactly $H^2_\lambda(D)$.

Finally, let $f \in H^2(D)$ with power series representation as in (4.6) and let $\lambda \in L^2(D; P_K)$ with norm given as in (1.8). Then, by Theorem 3.4 and taking into account of the inequality (3.6), for any $N \in \mathbb{N}$ and $\delta > 0$ we have
\[
P^N(\|f - \pi_z^N f\|_{H^2(D)} \geq \delta) \leq P^N(\|f - \frac{1}{N} \sum_{i=1}^{N} \lambda(z_i) K_{z_i}\|_{H^2(D)} \geq \delta)
\]
\[
\leq \frac{1}{\delta^2} \sum_{n=0}^{\infty} |f_n - \lambda_n|^2 + \frac{1}{N\delta^2} (\|\lambda\|^2_{L^2(D; P_K)} - \sum_{n=0}^{\infty} |\lambda_n|^2),
\]
where $z = (z_i)_{i \in \mathbb{N}}$ denotes an arbitrary sequence of points in $D$ and $\pi_z^N$ denotes the projection of $H^2(D)$ onto $\operatorname{span}\{K_{z_i} : i = 1, \ldots, N\}$. By exploiting the fact that the left
hand side in (4.11) does not depend on $\lambda$ and the density of $H^2_P(\mathbb{D})$ in $H^2(\mathbb{D})$, for any $\varepsilon > 0$ there exists $\lambda \in L^2(\mathbb{D}; P_K)$ such that

$$P^N \left( \| f - \pi_z^N f \|_{H^2(\mathbb{D})} \geq \delta \right) \leq \frac{\varepsilon}{2} + \frac{1}{N\delta^2} \left( \| \lambda \|_{L^2(\mathbb{D}; P_K)}^2 - \sum_{n=0}^{\infty} |\lambda_n|^2 \right),$$

and hence, for $N$ sufficiently large, we have

$$P^N \left( \| f - \pi_z^N f \|_{H^2(\mathbb{D})} \geq \delta \right) \leq \varepsilon.$$

Let us consider now the special case when the function $f \in H^2_P(\mathbb{D})$, that is, with respect to the representation as in (4.6), we have the stronger condition

$$\sum_{n=0}^{\infty} (n+1)(n+2)|f_n|^2 < \infty.$$

In this case, letting

$$\lambda(z) := \sum_{n=0}^{\infty} (n+1)(n+2)(1 - |z|^2)f_n z^n, \quad z \in \mathbb{D},$$

calculations similar to (4.7) and (4.9) show that

$$\frac{1}{\pi} \int_0^1 \int_0^{2\pi} \frac{|\lambda(re^{i\theta})|^2r}{1-r^2} \, d\theta \, dr = \sum_{n=0}^{\infty} (n+1)(n+2)|f_n|^2 < \infty,$$

hence $\lambda \in L^2(\mathbb{D}; P_K)$, and

$$(L_{P,K}\lambda)(z) = \frac{1}{\pi} \int_0^{2\pi} \lambda(re^{i\theta})K(z, re^{i\theta})r \, d\theta \, dr = \sum_{n=0}^{\infty} f_n z^n = f(z), \quad z \in \mathbb{D},$$

hence, the first term in the right hand side of (4.11) vanishes and we get

$$P^N \left( \| f - \pi_z^N f \|_{H^2(\mathbb{D})} \geq \delta \right) \leq \frac{1}{N\delta^2} \sum_{n=0}^{\infty} (n^2 + 3n + 1)|f_n|^2.$$

For example, if $f(z) = z^n$ for some integer $n \geq 0$, then

$$P^N \left( \| f - \pi_z^N f \|_{H^2(\mathbb{D})} \geq \delta \right) \leq \frac{n^2 + 3n + 1}{N\delta^2},$$

showing that better approximations are obtained for smaller $n$ than for bigger $n$.

5. Some Conclusions and Further Directions of Investigation

Certain key properties of Hilbert spaces drive the analysis that has been obtained in this article, as well as the properties of reproducing kernel Hilbert spaces that render them attractive for function approximation. The Hilbert space structure provides orthogonal projections as the unique best approximation, which can be computed using the reproducing property as an exact interpolation, and are shown to converge monotonically to the function for uniqueness sets. The monotonicity of convergence is then used to derive almost certain convergence directly from convergence in probability, and thus establish sufficient conditions for almost every sequence of samples from a probability distribution to be a uniqueness set. For the approximation bound itself, stated in
Theorem 3.4, the mean squared distance in Chebyshev’s inequality can be calculated explicitly thanks to the norm being induced by an inner product and the existence of the Bochner integral.

We did not include in this article an example with the Gaussian kernel, one of the most useful kernels in applications, although calculations similar to those obtained in Section 4 are available. One of the reasons for this omission is that the Gaussian kernels have additional invariance and differentiability/analyticity properties that can be used in order to provide stronger results.

On the other hand, there is another domain of high interest that may benefit from the approximation in RKHSs, namely that of particle methods, e.g. see [6], [14], and the bibliography cited there. In these methods, an unknown differentiable function $f: \mathbb{R}^d \to \mathbb{R}$ is approximated in the form

$$f(x) \approx \sum_{i=1}^{N} \omega_i \kappa(x - x_i), \quad x_1, \ldots, x_N \in \mathbb{R}^d, \quad \omega_1, \ldots, \omega_N \in \mathbb{R},$$

where $\kappa$ is a smooth function concentrated around the origin that, in most cases, induces a positive definite kernel $K(x, y) := \kappa(x - y)$. The physical interpretation, from which the method derives its name, is that $f$ is a scalar field induced by finitely many particles, such that $x_i$ is the position of the $i$th particle and $\omega_i$ is a physical quantity the $i$th particle possesses. For example, if $f$ represents the mass density of a fluid, $\omega_i$ can be interpreted as the mass of the $i$th particle. This method of approximation dates back to J.H. Irving and J.G. Kirkwood, who have derived the Navier-Stokes equations of hydrodynamics as a macroscopic limit of the motion of microscopic particles [9].

This approximation is then used to approximate partial derivatives of $f$ using the corresponding partial derivatives of $\kappa$, which can be computed beforehand, so that desired solutions to boundary value problems in $f$ can be solved numerically by solving for $\omega_i$s and $x_i$s. However, for this approximation to be valid, it is not sufficient to demonstrate that approximations in the form of (5.1) converge pointwise or with respect to the uniform norm or an $L^p$ norm, because differentiation is not a continuous operator under these topologies.

In this context, it becomes helpful to consider (5.1) as an interpolation problem on the reproducing kernel Hilbert space induced by $k$, since results such as Theorem 2.14 guarantee that differentiation is in fact bounded and contractive with respect to the RKHS norm. In that case, the convergence of an approximation of the form (5.1) in the RKHS, as proven in Section 3, would entail the simultaneous convergence of all derivatives and thus justify the usage of such approximations for differential operators.

We plan to continue our investigations in this and other related directions.
