The voltage-dependent anion channel (VDAC) of the outer mitochondrial membrane mediates metabolic flow, Ca\(^{2+}\), and cell death signaling between the endoplasmic reticulum (ER) and mitochondrial networks. We demonstrate that VDAC1 is physically linked to the endoplasmic reticulum Ca\(^{2+}\)-release channel inositol 1,4,5-trisphosphate receptor (IP\(_3\)R) through the molecular chaperone glucose-regulated protein 75 (grp75). Functional interaction between the channels was shown by the recombinant expression of the ligand-binding domain of the IP\(_3\)R on the ER or mitochondrial surface, which directly enhanced Ca\(^{2+}\) accumulation in mitochondria. Knockdown of grp75 abolished the stimulatory effect, highlighting chaperone-mediated conformational coupling between the IP\(_3\)R and the mitochondrial Ca\(^{2+}\) uptake machinery. Because organelle Ca\(^{2+}\) homeostasis influences fundamentally cellular functions and death signaling, the central location of grp75 may represent an important control point of cell fate and pathogenesis.

Introduction

Mitochondria and ER of eukaryotic cells form two intertwined endomembrane networks, and their dynamic interaction controls metabolic flow, protein transport, intracellular Ca\(^{2+}\) signaling, and cell death (Ferri and Kroemer, 2001; Berridge et al., 2003; Szabadkai and Rizzuto, 2004; Yi et al., 2004; Brough et al., 2005; Levine and Rabouille, 2005). Mitochondrial Ca\(^{2+}\) uptake, via a yet to be identified Ca\(^{2+}\) channel of the inner mitochondrial membrane (the mitochondrial Ca\(^{2+}\) uniporter), regulates processes as diverse as aerobic metabolism (Hajnoczky et al., 1995), release of caspase cofactors (Pinton et al., 2001), and feedback control of neighboring ER or plasma membrane Ca\(^{2+}\) channels (Hajnoczky et al., 1999; Gilabert and Parekh, 2000). A corollary of the efficient mitochondrial Ca\(^{2+}\) uptake during IP\(_3\)-induced Ca\(^{2+}\) release is the close apposition of ER and outer mitochondrial membranes (OMM; Mannella et al., 1998; Rizzuto et al., 1998b; Marsh et al., 2001; Frey et al., 2002). The molecular determinants of this crosstalk, however, are still largely unknown (Walter and Hajnoczky, 2005). Recently, PACS2, which is an ER-associated vesicular-sorting protein, was proposed to link the ER to mitochondria (Simmen et al., 2005). The knockdown of PACS2 led to stress-mediated uncoupling of the organelles, which was also reflected by the inhibition of Ca\(^{2+}\) signal transmission.

On the other side, the abundant OMM channel voltage-dependent anion channel 1 (VDAC1) was also suggested to participate in the interaction. It was shown to be present at ER–mitochondrial contacts and to mediate Ca\(^{2+}\) channeling to the intermembrane space from the high [Ca\(^{2+}\)] microdomain generated by the opening of the inositol 1,4,5-trisphosphate receptor (IP\(_3\)R; Gincel et al., 2001; Rapizzi et al., 2002). In addition, VDAC1 mediates metabolic flow through the OMM, forming an ATP microdomain close to the ER and sarcoplasmic reticulum Ca\(^{2+}\) ATPases (SERCAs; Ventura-Clapier et al., 2004; Vendelin et al., 2004), and both VDAC1 and VDAC2 take part in metabolic and apoptotic protein complexes (Cheng et al., 2003; Colombini, 2004; Lemasters and Holmuhamedov, 2006).

The transfer and assembly of components of cellular protein complexes were shown to be assisted by molecular chaperones,
adding a novel function to their role in nascent protein folding (Young et al., 2003; Soti et al., 2005). Accordingly, Ca\textsuperscript{2+} binding-, heat shock-, and glucoseregulated chaperone family members are abundantly present along the Ca\textsuperscript{2+} transfer axis, linking the ER and mitochondrial networks. Well known examples are the Ca\textsuperscript{2+}-binding chaperones of the ER lumen (Michalak et al., 2002), immunophilins interacting with ER Ca\textsuperscript{2+}-release channels and the mitochondrial permeability transition pore (Bultynck et al., 2001; Forte and Bernardi, 2005), and several heat shock family members localized at the mitochondrial membranes, which are proposed to interact with the components of the mitochondrial permeability transition pore, such as VDAC (He and Lemasters, 2003; Gupta and Knowlton, 2005; Wadhwa et al., 2005). Still, their exact role at the ER–mitochondria interface is not well known, although recently, weak links between chaperones were proposed to stabilize signaling and organellar cellular networks (Csermely, 2004; Soti et al., 2005).

Considering the central position of VDAC at the ER–mitochondrial interface outlined in the previous paragraphs, we used VDAC1 as a starting point for protein biochemical studies, to explore molecular interactions between the ER and mitochondrial networks. We found that through the OMM-associated fraction of the glucose-regulated protein 75 (grp75) chaperone (Zahedi et al., 2006), VDAC1 interacts with the ER Ca\textsuperscript{2+}-release channel IP\textsubscript{3}R. Organellar Ca\textsuperscript{2+} measurements, using targeted recombinant Ca\textsuperscript{2+} probes, confirmed functional interaction between the IP\textsubscript{3}R and the mitochondrial Ca\textsuperscript{2+} uptake machinery, which was abolished by grp75 knockdown.

**Results**

**VDAC1, grp75, and IP\textsubscript{3}Rs are present in a macromolecular complex at the ER-mitochondria interface**

We performed yeast two-hybrid screens of human liver and kidney LexA-AD–fused libraries, using rat VDAC1-LexA-DNA-BD fusion protein as bait. Among the putative interactors we found cytoskeletal elements, which were previously thought to participate in sorting of VDAC or in mitochondrial dynamics (Schwarzer et al., 2002; Varadi et al., 2004) and a group of chaperone proteins (Table I). To investigate whether the chaperones participate in mediating organelle interactions, we focused our attention on the human heat shock 70 kD protein 9B/grp75 (nt 1,456–2,089 from GenBank/EMBL/DDBJ under accession no. BC000478; aa 471–681). The yeast homologue of grp75 is usp75, IP\textsubscript{3}R, and VDAC were found to be cytoskeletal and signaling elements (shown in bold); another group (shown in normal) were probably reflecting the requirement of efficient folding of the VDAC1 protein in yeast. The results of sequencing of the remaining clones are shown in the table. One group of the putative interacting proteins were found to be cytoskeletal and signaling elements (shown in bold); another group (shown in normal) were found to be folding intermediates, presumably underlying the proper function of VDAC1.

Yeast two-hybrid screening was carried using the pLexA system according to the protocol of Gyuris et al. (1993). For details see Supplementary materials and methods. Approximately 90% of the clones contained a sub-sequence of the ER-resident chaperone heat shock 70-kD protein 5 (HSPA5, grp-78), most probably reflecting the requirement of efficient folding of the VDAC1 protein in yeast. The results of sequencing of the remaining clones are shown in the table. The lumen of the putative interacting proteins were found to be cytoskeletal and signaling elements (shown in bold); another group (shown in normal) were found to be folding intermediates, presumably underlying the proper function of VDAC1.

Based on these findings, we used further biochemical approaches to investigate the role of grp75 at the ER–mitochondria contact sites. We took advantage of a previously developed method to purify a mitochondria-associated ER subfraction (mitochondria-associated membrane (MAM) fraction [Vance, 1990]). The MAM was previously shown to be enriched in lipid synthases and transferases (Vance, 2003), and it likely represents the membrane microdomain engaged in ER–mitochondrial Ca\textsuperscript{2+} transfer (Filippin et al., 2003; Szabadkai and Rizzuto, 2004; Yi et al., 2004). Indeed, immunoblot screening of the MAM fraction, purified from rat liver and HeLa cells, revealed the presence of grp75, as well as Ca\textsuperscript{2+} channels from both the OMM (VDAC1) and the ER (IP\textsubscript{3}R; Fig. 1 A). In liver cells, given the higher yield, the microsomal fraction and the different mitochondrial extracts (the crude mitochondrial pellet [Mito C], the low-density MAM, and the high-density mitochondrial fraction containing the matrix proteins [Mito P]) were separately analyzed. As expected, VDAC and grp75 are not enriched in the MAM, given that the former is highly expressed throughout the OM (because of its role in ion and metabolite diffusion) and the latter is mostly in the matrix (but the two pools show different macromolecular assemblies; see following paragraph). Conversely, the IP\textsubscript{3}R, besides the microsomes, is present in the crude mitochondria and the MAM fractions and is absent in the purified mitochondria (Fig. 1 A).

We next investigated whether grp75 and the ER and mitochondrial Ca\textsuperscript{2+} channels are part of the macromolecular complex, and whether the grp75 pool involved is that present in the MAM fraction. For this purpose, we separately analyzed the MAM and the Mito P fractions by 2D Blue native (Fig. 1 B; first dimension, central part of the image) and SDS-PAGE protein separation. In the latter dimension, grp75, IP\textsubscript{3}R, and VDAC were revealed by immunoblotting. Although VDAC1 was present in different amounts in complexes of a wide molecular weight
range, we found a specific complex characterized by the presence of VDAC, the IP₃R, and grp75, suggesting their interaction in the native state. The specificity of the complex formation of VDAC, the IP₃R, and grp75 was corroborated by the finding that SERCA2b showed different localization in the 2D separation (Fig. S1, available at http://www.jcb.org/cgi/content/full/jcb.200608073/DC1). In Mito P, grp75 was found in lower molecular weight complexes (<400 kD), which is similar to previous data in yeast (Dekker et al., 1997), confirming that grp75 is involved in high molecular weight protein–protein interactions only in the MAM. To confirm the different location of the two grp75 pools, we verified that whereas the matrix-localized grp75 was resistant to proteinase K digestion (similar to the matrix enzyme MnSOD; Fig. 1 C), grp75 of the MAM fraction was degraded by the enzyme, documenting its association with the cytosolic surface of mitochondria.

To further investigate the arrangement of the grp75–VDAC–IP₃R complex, we used coimmunoprecipitation studies of the involved proteins. Immunoprecipitation of both IP₃Rs and VDAC led to the coprecipitation of grp75 (Fig. 1, D and E, respectively), but no IP₃R was found in the VDAC precipitate, and no VDAC was detectable in the IP₃R precipitate. However, immunoprecipitation of grp75 led to the copurification of both VDAC and the IP₃R (Fig. 1 F). These results strongly suggest that grp75 has a central role in setting up the protein complex with VDAC and the IP₃R. Moreover, the interactions were detected both in the presence and absence of Mg²⁺-ATP (unpublished data), further suggesting the scaffolding, rather than chaperoning, function of grp75 in the complex.

Direct regulation of mitochondrial Ca²⁺ uptake by the IP₃R ligand-binding domain

If the IP₃R is in a macromolecular assembly with VDAC, we assumed that the mitochondrial Ca²⁺ uptake machinery might be regulated by the large cytoplasmic domain of the IP₃R. This scheme was also supported by previous studies showing that the ligand-binding domain of the IP₃R (aa 224–605; denoted as IP₃R-LBD224-605), located on the surface of the cytoplasmic domain, participates in intramolecular interactions with other IP₃R domains (Boehning and Joseph, 2000), as well as in linking the receptor with other protein partners (Bosanac et al., 2004). To assess a direct role of the IP₃R in mitochondrial Ca²⁺ uptake, we coexpressed in HeLa cells mRFP1-tagged IP₃R-LBD224-605 with cytosolic (cytAEQ) or mitochondrially targeted (mtAEQmut)
aequorin-based Ca\textsuperscript{2+} probes, and evaluated global and organellar Ca\textsuperscript{2+} responses to agonist stimulation. After reconstitution with the aequorin cofactor coelenterazine, cells were challenged with histamine (in incremental doses from 1 to 100 \textmu\text{M}), and luminescence was measured and converted to [Ca\textsuperscript{2+}].

Recombinant expression of the IP\textsubscript{3}R-LBD\textsubscript{224-605} caused a marked increase in mitochondrial Ca\textsuperscript{2+} uptake at each agonist concentration applied, in spite of reduced cytoplasmic Ca\textsuperscript{2+} response ([Ca\textsuperscript{2+}]), because of IP\textsubscript{3} buffering and consequent reduction of IP\textsubscript{3}-induced Ca\textsuperscript{2+} release from the ER (see Fig. 2 [A and B] and

Figure 2. Effect of the IP\textsubscript{3}R ligand-binding domain on mitochondrial Ca\textsuperscript{2+} uptake. [A and C] HeLa cells were transfected with mitochondrially targeted (mtAEQmut; top) and cytosolic aequorin (bottom). Control traces are shown in black; traces from cells cotransfected with the IP\textsubscript{3}R-LBD\textsubscript{224-605} (A) and the IP\textsubscript{3}R-LBD\textsubscript{224-605} K508 mutant (C) are shown in gray. Traces are representative of >15 experiments from >5 preparations. (B) Effect of the cytosolic-, OMM-, and ER-targeted IP\textsubscript{3}R-LBD\textsubscript{224-605} on peak mitochondrial and cytosolic Ca\textsuperscript{2+} responses (top and bottom, respectively). (D) Effect of the OMM-IP\textsubscript{3}R-LBD\textsubscript{224-605} (K508A), the IP\textsubscript{3}-binding PH domain of the p130 PLC-like protein (OMM-p130-PH), and the OMM-targeted N-terminal (1-604 aa) part of the IP\textsubscript{3}R (OMM-IP\textsubscript{3}R-LBD\textsubscript{1-604}) on mitochondrial (top) and cytoplasmic Ca\textsuperscript{2+} responses (bottom) after 100 \textmu\text{M} histamine stimulation. Data in B and D were normalized to mean of the control group. Mean \pm SEM of variation is shown as percentage. Cells were transfected, and [Ca\textsuperscript{2+}] was measured as described in Materials and methods. Values are shown. *, P < 0.05; **, P < 0.01. For absolute values see Table S1, available at http://www.jcb.org/cgi/content/full/jcb.200608073/DC1.
which is unable to bind IP$_3$. The K508 mutant increased the mitochondrial Ca$^{2+}$ stimulatory effect of ER-IP$_3$R-LBD$_{224-605}$ on [Ca$^{2+}$]$_{m}$. Morphological imaging and mitochondrial loading with the potential-sensitive dye teramethylrhodamine methyl ester showed that the effect was not caused by changes in mitochondrial morphology (Fig. 3 A) or to the modification of mitochondrial membrane potential (not depicted).

To confirm that activation of mitochondrial Ca$^{2+}$ uptake can be exerted from the original site of the IP$_3$R (i.e., from the ER membrane), we expressed IP$_3$R-LBD$_{224-605}$ fused to a C-terminal ER-targeting sequence derived from the yeast UBC6 protein (denoted as ER-IP$_3$R-LBD$_{224-605}$; Varnai et al., 2005). Expression of this construct reduced the steady-state ER [Ca$^{2+}$]$_{i}$ (Fig. S2 and Fig. 2 B, respectively), which were probably caused by direct activation of the IP$_3$R, as previously reported for COS-7 cells (Varnai et al., 2005), although store depletion was incomplete in HeLa cells at the expression levels of this study. Still, most importantly, expression of the ER-targeted IP$_3$R-LBD$_{224-605}$ augmented mitochondrial Ca$^{2+}$ accumulation after cellular stimulation by histamine, similar to what was observed upon expression of the OMM-targeted IP$_3$R-LBD$_{224-605}$ domain (Fig. 3 B shows the intracellular localization of ER-IP$_3$R-LBD$_{224-605}$; Fig. 2 B shows the stimulatory effect of ER-IP$_3$R-LBD$_{224-605}$ on [Ca$^{2+}$]$_{m}$). These results strongly suggested that the IP$_3$R, acting from the ER surface, regulates mitochondrial Ca$^{2+}$ uptake at an OMM site, independent of its Ca$^{2+}$-channeling function.

**Stimulation of mitochondrial Ca$^{2+}$ uptake by the IP$_3$R-LBD is the result of specific protein interactions at the ER-OMM interface**

Based on our conclusions, we further investigated whether the effect of the N-terminal cytosolic domain of the IP$_3$R reflects specific protein–protein interactions at the ER–mitochondrial contacts. We first verified that the effect of IP$_3$R-LBD$_{224-605}$ on mitochondrial Ca$^{2+}$ uptake is independent of IP$_3$ buffering. For this purpose, we used a point-mutated (K508A) IP$_3$R-LBD$_{224-605}$, which is unable to bind IP$_3$. The K508 mutant increased the [Ca$^{2+}$]$_{m}$ rise in a manner similar to the wild-type (although slightly less efficient), but, as expected, did not modify the [Ca$^{2+}$]$_{i}$ response (Fig. 2, C and D). The capacity of an IP$_3$-insensitive IP$_3$R-LBD$_{224-605}$ to enhance mitochondrial Ca$^{2+}$ uptake was also confirmed in digitonin-permeabilized HeLa cells. In this case, mitochondrial Ca$^{2+}$ uptake is exclusively dictated by the perfused [Ca$^{2+}$], and it is totally independent of IP$_3$R activity. In permeabilized cells, Ca$^{2+}$ uptake was triggered by the perfusion of an intracellular buffer containing Ca$^{2+}$ buffered at 1 μM. Under those conditions, in which protein interactions might have been affected by the application of digitonin, both the wild-type and the K508A OMM-IP$_3$R-LBD$_{224-605}$ increased the rate of mitochondrial Ca$^{2+}$ uptake, although also in this case the wild-type was more efficient (14.71 ± 4.66% increase, n = 25, P < 0.01 vs. 6.58 ± 4.23% increase, n = 25, P > 0.05).

The notion that IP$_3$ binding cannot account for the mitochondrial effect was further confirmed by the demonstration that a structurally unrelated IP$_3$-binding protein domain, the PH domain of the PLC-like protein p130 (p130PH; Lin et al., 2005), targeted to the OMM, reduced both the [Ca$^{2+}$]$_{m}$ and [Ca$^{2+}$]$_{i}$ responses (Fig. 2 D). Interestingly, the reduction of the [Ca$^{2+}$]$_{m}$ response was more pronounced for the OMM-targeted PH domain than for the untargeted cytosolic version of the IP$_3$ buffer, although the two proteins were equally effective on [Ca$^{2+}$]. These data (Fig. S3, available at http://www.jcb.org/cgi/content/full/jcb.200608073/DC1) further stress the strict dependence of mitochondrial Ca$^{2+}$ homeostasis on the ER–mitochondrial contacts, and thus on the Ca$^{2+}$ release occurring in these microdomains.

The IP$_3$R-LBD$_{224-605}$ was also shown to play an important role in the regulation of IP$_3$R channel activity by interacting with the N-terminal repressor domain (aa 1–223; Boehning and Joseph, 2000; Varnai et al., 2005). Still, expressing the entire N-terminal surface domain of the IP$_3$R, targeted to the exterior of the OMM (OMM-IP$_3$R$_{1-604}$), augmented mitochondrial Ca$^{2+}$ uptake (Fig. 2 D). These results exclude that the stimulatory effect of the IP$_3$R-LBD$_{224-605}$ was exerted through unmasking this intramolecular interaction in the endogenous IP$_3$R; instead, they...
support a model in which the entire N-terminal IP₃R exerts direct activation on the mitochondrial Ca²⁺ uptake machinery.

Finally, we investigated the regulatory activity on mitochondria of the IP₃R-LBD₂₂₄₋₆₀₅ when the [Ca²⁺]ₘ rise is elicited in the cell by the opening of plasma membrane channels. Under those conditions, not only the [Ca²⁺]ₘ rise is IP₃R-independent, but the [Ca²⁺]ₘ and ensuing [Ca²⁺]ₘ increases are markedly slower and smaller than upon ER Ca²⁺ release. We thus measured [Ca²⁺]ₘ after emptying the ER Ca²⁺ pool with the SERCA blocker tert-butyl-benzohydroquinone (tBHQ) in Ca²⁺-free medium and re-adding CaCl₂. This protocol induces capacitative Ca²⁺ entry, causing a [Ca²⁺]ₘ rise and subsequent mitochondrial Ca²⁺ uptake. As presented in Fig. 4, IP₃R-LBD₂₂₄₋₆₀₅-expressing cells showed an ~60% increase in the influx-dependent [Ca²⁺]ₘ rise response (top), even if the [Ca²⁺]ₘ rise remained unaltered (bottom). This increase in [Ca²⁺]ₘ was almost doubled, as compared with the effect after histamine/IP₃-induced Ca²⁺ release from the ER (Fig. 2 B). Thus, we concluded that local IP₃-buffering masks the stimulatory effect of the IP₃R-LBD₂₂₄₋₆₀₅ upon ER Ca²⁺ release, and, indeed, the effect of the IP₃R-LBD is established at the ER–mitochondrial contacts.

Down-regulation of grp75 abolishes the functional coupling between the IP₃R and mitochondria

Because our proteomic studies suggested that the interaction of the VDAC and IP₃R channels is mediated by grp75, we investigated whether the stimulatory effect of the OMM-targeted IP₃R-LBD₂₂₄₋₆₀₅ on mitochondrial Ca²⁺ uptake requires the presence of grp75. A first series of experiments showed that strong inhibition of grp75 expression (48 h after transfection) in itself strongly reduced mitochondrial Ca²⁺ uptake, most probably because of alterations of mitochondrial function through inhibition of protein import and ΔΨm loss (unpublished data). Thus, we opted for a lower silencing efficiency by conducting experiments 24 h after transfection (Fig. 5, inset). We expressed control and grp75 siRNAs in HeLa cells, cotransferring them with the IP₃R-LBD₂₂₄₋₆₀₅ construct and mtAEQmut. Under those conditions, grp75 siRNA had no effect on the [Ca²⁺]ₘ response to histamine stimulation (Fig. 5, A and B). However, the down-regulation of grp75 prevented the stimulatory effect on mitochondrial Ca²⁺ uptake of the IP₃R-LBD₂₂₄₋₆₀₅, which was expressed both on the OMM and the ER surface (Fig. 5 B). Thus, we concluded that grp75 is not only physically associated with the IP₃R–VDAC1 complex, but is also necessary for functional coupling between these proteins. These results also show that although moderate knockdown of grp75 does not interfere with its function in the mitochondrial matrix, in accordance with previous results on mitochondrial protein import (Sanjuan Szklarz et al., 2005), the low amount of grp75 at the ER–mitochondrial contacts is a limiting factor for the stimulatory effect of the IP₃R-LBD.

In the final set of experiments, we further investigated the role of grp75 in mitochondrial Ca²⁺ uptake regulation by overexpressing the protein. Most likely caused by its differentially localized pools, grp75 appeared to modify mitochondrial Ca²⁺ uptake after IP₃-induced Ca²⁺ release through diverse mechanisms. Indeed, as shown in Fig. 6 (A and B), overexpression of the wild-type protein led to reduced histamine-induced [Ca²⁺]ₘ response. However, at the same time, it also significantly decreased the steady-state [Ca²⁺]ₘ level (Fig. 6 B, right), thus, reducing the driving force for IP₃-induced Ca²⁺ release, which in turn might be responsible for the dampened mitochondrial Ca²⁺ accumulation. This parallel reduction of [Ca²⁺]ₘ and [Ca²⁺]ₘ may reflect two different effects of grp75: (1) OMM-localized grp75, presumably through the interaction with the IP₃R or other members of the ER Ca²⁺-handling machinery, may increase the Ca²⁺ leak from the ER through the IP₃R, as previously shown for Bcl-2 (Pinton et al., 2000; Bassik et al., 2004); (2) matrix-localized grp75 may modify mitochondrial parameters (e.g., pH) or import of Ca²⁺-handling proteins, leading to altered mitochondrial Ca²⁺ uptake, as well as the ATP supply.
for ER Ca$^{2+}$ accumulation through the SERCA pumps. To dissect these effects, we again used the approach of measuring IP$_3$-independent mitochondrial Ca$^{2+}$ uptake after capacitative Ca$^{2+}$ influx. In addition, to distinguish OMM-based effects from those in the mitochondrial matrix, we expressed a truncated grp75 lacking the N-terminal 51-aa mitochondrial-targeting sequence, and thus unable to enter the mitochondrial matrix. Ca$^{2+}$ influx was induced by depleting the ER Ca$^{2+}$ store with tBHQ in the absence of extracellular Ca$^{2+}$, as described in the previous section (Fig. 4). This “cytosolic” form of grp75 (grp75cyt) did not change the bulk cytosolic [Ca$^{2+}$]$_{i}$ response to readdition of Ca$^{2+}$ in the extracellular medium, but significantly increased mitochondrial Ca$^{2+}$ accumulation (Fig. 6, C and D). Moreover, grp75cyt further potentiated the stimulatory effect of IP$_3$R-LBD224-605 targeted both to the OMM and ER surface. The percent increase of [Ca$^{2+}$]$_{m}$ peaks normalized to the mean of controls shown in cells cotransfected with mtAEQmut and control siRNA (siRNA-grp75) and OMM-IP3R-LBD224-605 or ER-IP3R-LBD224-605 after stimulation with 100 μM histamine. The stimulatory effect of both the OMM- and ER-targeted IP3R-LBD224-605 was inhibited after the cotransfection with siRNA-grp75 (+), whereas the control Ca$^{2+}$ peaks remained unaffected. Data normalized to the mean ± the SEM of the control group are shown in percentages for absolute values see Table S1. *, P < 0.05; **, P < 0.01.

**Discussion**

Based on previous observations (Gincel et al., 2001; Csordas et al., 2002; Rapizzi et al., 2002; Israelson et al., 2005), we used VDAC1 as the start point for proteomic search of interacting proteins and for unraveling the molecular basis of mitochondrial Ca$^{2+}$ homeostasis. An unexpected, but intriguing, finding of our biochemical studies was the central location of the chaperone grp75 in the interaction between ER and mitochondrial Ca$^{2+}$ channels. grp75, a conserved chaperone, has a well studied role in protein import through the IMM. Still, in yeast mitochondria, mtHsp70/Ssc1 was shown to be significantly more abundant than the translocase (TIM23 complex). Thus, only a small fraction of the protein appears to be involved directly in preprotein translocation (Dekker et al., 1997; Sanjuan Szklarz et al., 2005), suggesting the existence of different pools of the protein. Previous work also reported extramitochondrial localization of grp75 (Ran et al., 2000), and its interaction with extramitochondrial proteins such as the cytosolic p53 or the ER luminal grp94 (Takano et al., 2001; Wadhwa et al., 2002b), although the mechanisms that control the differential sorting of luminal grp94 (Takano et al., 2001; Wadhwa et al., 2002b), although the mechanisms that control the differential sorting of the protein are still completely unknown. According to our immunofluorescence and GFP-tagging studies in HeLa cells grp75 shows complete mitochondrial localization, but obviously cannot be discriminated from an OMM-associated pool. Biochemical studies, however, demonstrate that a matrix-localized pool participates in forming complexes in the 200–400-kD range and represents the major fraction of the total mitochondrial grp75 content, whereas a minor grp75 pool resides in the low-density (MAM) mitochondrial fraction, participating in complexes in
the megaDalton range and comprising OMM and ER membrane proteins. To further support an independent function of the non-matrix pool, we constructed a grp75 mutant lacking the mitochondrial presequence, and thus incompetent for import in the matrix. This protein retained the capacity to enhance mitochondrial Ca\(^{2+}\) accumulation, strongly arguing for the notion that this role of grp75 is not only independent from its chaperone activity in the matrix but also depends on a physically separated protein pool.

How is the newly identified regulatory activity on mitochondrial Ca\(^{2+}\) uptake exerted? In principle, two different mechanisms can be envisioned. In the first, grp75 could be involved in scaffolding the ER–mitochondria contacts, and thus determines the number of sites in which mitochondria are exposed to the high [Ca\(^{2+}\)] microdomains generated at the mouth of IP3Rs. Fluorescent labeling studies of the ER and mitochondria revealed a partial (5–20%) colocalization, reflecting these interactions. However, no increase in colocalization has been

---

**Figure 6. Effect of grp75 overexpression on mitochondrial Ca\(^{2+}\) responses and steady-state [Ca\(^{2+}\)]**

(A and B) HeLa cells were cotransfected with mtAEQ-mut or erAEQmut probes (controls) and mouse grp75. [Ca\(^{2+}\)]\(_{m}\) was measured as described in Fig. 2, after stimulation with 100 μM histamine, as indicated in A. The percent variation (± SEM) of [Ca\(^{2+}\)]\(_{m}\) peaks normalized to the mean of controls are shown in B (left); the effect of grp75 on steady-state [Ca\(^{2+}\)]\(_{m}\) is shown on the right. Steady-state [Ca\(^{2+}\)]\(_{m}\) was measured after refilling of the ER in the presence of 1 mM CaCl\(_2\) in the extracellular medium (n = 10, from four separate experiments). Before measurements, erAEQmut-transfected cells were reconstituted with coelenterazine n, after ER Ca\(^{2+}\) depletion in a solution containing 0 [Ca\(^{2+}\)], 600 μM EGTA, and 1 μM ionomycin, as previously described (Chiesa et al., 2001). For [Ca\(^{2+}\)]\(_{c}\) values see Table S1. [Ca\(^{2+}\)]\(_{c}\) in controls, 416 ± 19.3 μM; in grp75-overexpressing cells: 334 ± 13.6 μM; *P < 0.05. **P < 0.01. (C and D) [Ca\(^{2+}\)]\(_{c}\) (top) and [Ca\(^{2+}\)]\(_{m}\) (bottom) were measured in control and grp75 cyt-expressing cells, after induction of capacitative Ca\(^{2+}\) influx, after ER depletion with tBHQ in Ca\(^{2+}\)-free medium (100 μM KRB-EGTA; 4 min) and readdition of 2 mM CaCl\(_2\). Representative traces of controls, cells cotransfected with OMM-IP3R-LBD\(_{224-605}\), grp75cyt, or both are shown. The percent increase (± SEM) of [Ca\(^{2+}\)]\(_{m}\) peaks normalized to the mean of controls are shown in D. [Ca\(^{2+}\)]\(_{m}\) peak in controls, 9.7 ± 1.2 μM; in OMM-IP3R-LBD\(_{224-605}\)-expressing cells, 13.0 ± 1.8 μM; grp75cyt-expressing cells, 13.2 ± 1.6 μM; OMM-IP3R-LBD\(_{224-605}\)/grp75cyt-expressing cells, 18.8 ± 2.48. *P < 0.05; **P < 0.01.
observed by overexpression of grp75 (or of the IP₃R-LBD224-605; unpublished data), suggesting that they do not directly function as structural determinants of the contacts. In a second scenario, grp75 could control the interaction of ER and mitochondrial proteins at the existing organelle contacts, and thus allow cross-talk between signaling partners, e.g., the ion channels of the two membranes. Indeed, grp75, as shown by its knockdown and overexpression models, was necessary and sufficient for the stimulatory effect of the IP₃R-LBD224-605 on mitochondrial Ca²⁺ uptake. Moreover, the proteomic data also highlight the central role of grp75 in this interaction. VDAC and IP₃Rs coprecipitate with grp75, and the chaperone is coimmunoprecipitated by both anti-IP₃R and -VDAC antibodies, indicating that it is the key assembling molecule in the loose interaction between the two ion channels.

Within the IP₃R–grp75–VDAC complex, potentiation of mitochondrial Ca²⁺ accumulation by the IP₃R-LBD224-605 does not require IP₃ binding, as demonstrated by the fact that it is retained by the K508A mutant, which is unable to bind IP₃ (Varnai et al., 2005). Although the mutant shows the same stimulatory effect (Fig. 2), one should remember that wild-type IP₃R-LBD224-605, because of IP₃ buffering, reduces ER Ca²⁺ release, and thus conclude that the wild type is somewhat more effective than the mutant. To further confirm independence from IP₃ buffering, we measured mitochondrial Ca²⁺ uptake after capacitative influx through the plasma membrane (Figs. 4 and 6). Also, under those experimental conditions, the IP₃R-LBD224-605 potently stimulated mitochondrial Ca²⁺ uptake.

As for the molecular mechanism of the effect on the mitochondrial Ca²⁺ machinery, different scenarios could be envisioned. In the first, the recombinantly expressed IP₃R-LBD, both from the OMM and ER side, could interact with the endogenous IP₃R itself, and modify the probability of its interaction with grp75/VDAC. Indeed, it was previously shown that intramolecular interactions between different domains of the IP₃R, such as the 224–605 minimal IP₃-binding domain and the 1–223 N-terminal repression domain, regulate IP₃ channel opening upon IP₃ binding. Thus, one could hypothesize that the high expression levels of IP₃R-LBD224-605 represses an interaction between the extreme N-terminal of the endogenous receptor and grp75/VDAC. To clarify this issue, we expressed the whole (aa 1–604) IP₃R-LBD, which is targeted to the OMM. The IP₃R-LBD1-604 had the same effect as IP₃R-LBD224-605, thus, excluding competition of these two cytoplasmic, N-terminal domains of the IP₃R. In the second, simpler scenario, the IP₃R-LBD224-605 mimics the effect of the endogenous IP₃R. Thus, it directly enhances mitochondrial Ca²⁺ uptake by maximizing, within the macromolecular complex, the interaction with the mitochondrial VDAC channel. Indeed, the density of the exogenous IP₃R-LBD224-605, based on fluorescence labeling (Varnai et al., 2005) and Scatchard plot analysis of IP₃ binding (Wibo and Godfraind, 1994), can be assumed to be at least one order of magnitude higher than the endogenous receptor, and indeed, high expression levels were necessary for the effect of IP₃R on mitochondrial Ca²⁺ uptake.

The central role of grp75 in the IP₃R-LBD–induced augmentation of Ca²⁺ uptake was clearly shown by the siRNA-driven silencing of the protein, leading to the abolition of the effect. Conversely, high-level expression of grp75 induced a compound effect involving at least three different locations, as follows: (1) the ER, decreasing the steady [Ca²⁺]ER level; (2) the OMM, interacting with VDAC, whose permeability/ion selectivity was shown to be modified by grp75 binding (Schwarzer et al., 2002); and (3) the mitochondrial matrix, modifying mitochondrial parameters, such as pH or Ca²⁺ buffering capacity. Expression of the cytosolic grp75 and measurement of Ca²⁺ influx–induced mitochondrial Ca²⁺ uptake allowed us to eliminate the intramitochondrial effect and changes of ER Ca²⁺ handling. Importantly, mitochondrial Ca²⁺ uptake in this approach was markedly increased, and grp75si potentiated the effect of OMM-IP₃R-LBD, clarifying the effect of the OMM-associated pool of grp75.

In conclusion, we demonstrated that the IP₃R is part of a signaling complex that directly controls Ca²⁺ uptake into mitochondria. Much remains to be understood, but by these results, the concept of macromolecular assembly of signaling elements, previously put forward for several plasma membrane channels, can be extended to defined microdomains at the ER–mitochondrial interface. Such an arrangement highlights novel routes for pharmacological intervention that may be used for the modulation of downstream events such as metabolism and apoptosis.

Materials and methods

Yeast two-hybrid screening

Yeast two-hybrid screening was carried out using the plexA system according to the protocol of Gyuris et al. (1993). For details see Supplemental materials and methods (available at http://www.jcb.org/cgi/content/full/jcb.200608073/DC1).

Subcellular fractionation and proteomic analysis

HeLa cells and rat liver were homogenized, and crude mitochondrial fraction (8,000-g pellet) was subjected to separation on a 30% self-generated Percoll gradient, as previously described (Vance, 1990). A low-density band (denoted as the MAM fraction) and a high-density band (denoted as Mitop) were collected and analyzed by immunoblotting and Blue native/SDS-PAGE 2D separation, which are described in detail in the Supplemental materials and methods. Proteinase K (Sigma-Aldrich) digestion was performed with 50 μg enzyme in the presence of 50 μg protein (10 min; on ice) in solution A used to resuspend subcellular fractions (250 mM mannitol, 5 mM Hepes, and 0.5 mM EGTA, pH 7.4). Hypotonic shock (50 mM mannitol, 5 mM Hepes, and 0.1 mM EGTA, pH 7.4, for 30 min at room temperature) was applied to induce mitochondrial swelling.

IP₃R and grp75 expression constructs

Mouse grp75, cloned into the expression vector pTOPO (Invitrogen), was provided by R. Wadwha (University of Tokyo, Tokyo, Japan; Wadwha et al., 1993). Full-length mouse IP₃R-1 was obtained from K. Mikoshiba (RIKEN Brain Science Institute, Wako City, Saitama, Japan). The constructs encoding the fusion proteins of the PH domain of the p130 protein (from GenBank/EMBL/DBJ under accession no.D45992; residues 95–233) and the mitochondrial LBD (residues 34–63) was fused to the N terminus of the IP₃R-LBD and p130PH constructs through a short linker (DPTSR). The OMM-IP₃R-LBD604mRFP1 construct was obtained by amplification of the 1–604 fragment of IP₃R-1 cDNA and insertion into the AKAP1/mRFP1 vector. The GRP75cyt cDNA was amplified from a human liver cDNA library (Origene) using the primers 5′-CCCAAGCTTGGACGCGAGAAGTTGTTGCTATGCT-3′ and 5′-CCGCCTACCTGTTGTTTCTTCATTGTAC-3′. After digestion with HindIII and BamHI, the product was
ligated into the pcDNA3 plasmid (Invitrogen) digested with the same restriction enzymes. The construct was verified with bidirectional sequencing.

Transient transfection was done by the Ca\(^{2+}\)-phosphate precipitation technique. Experiments were performed 24–36 h after transfection.

**Dynamic in vivo [Ca\(^{2+}\)] measurements with targeted aequorin probes**

cyaAEQ, mAEQmut, or eAEQmut-expressing cells were reconstituted with coelenterazine and transferred to the perfusion chamber, and light signal was collected in a purpose-built luminometer and calibrated into \([\text{Ca}^{2+}]_\text{c}\) values, as previously described (Chiesa et al., 2001). All aequorin measurements were performed in Krebs-Ringer bicarbonate (KRB) containing 1 mM CaCl\(_2\) (KRB/Ca\(^{2+}\)); Krebs-Ringer modified buffer: 135 mM NaCl, 5 mM KCl, 0.4 mM KH\(_2\)PO\(_4\), 1 mM CaCl\(_2\), 5.5 mM glucose, and 20 mM Hepes, pH 7.4. \([\text{Ca}^{2+}]_\text{c}\) after capacitative Ca\(^{2+}\) influx was measured by preincubating HeLa cells with the SERCA blocker BHQ (100 \(\mu\)M) in a KRB solution containing no Ca\(^{2+}\) and 100 \(\mu\)M EGTA. Cytoplasmic \([\text{Ca}^{2+}]_\text{c}\) signal and mitochondrial Ca\(^{2+}\) uptake were evoked by adding 2 mM CaCl\(_2\) to the medium. For \([\text{Ca}^{2+}]_\text{m}\) measurements, erAEQmut-expressing cells were reconstituted with coelenterazine \(n\), after ER Ca\(^{2+}\) depletion in a solution containing 0 \([\text{Ca}^{2+}]_\text{c}\), 600 \(\mu\)M EGTA, and 1 \(\mu\)M ionomycin, as previously described (Szabadkai et al., 2004). Experiments in permeabilized HeLa cells were performed as previously described (Rapizzi et al., 2002), except that 25 \(\mu\)M digitonin was used to preserve ER–mitochondrial contacts.

**Imaging techniques**

For 3D morphological image acquisition, the cells were transfected with mRFP1-fused IP, RlBD24A405 constructs and loaded with 50 nM MitoTracker Green (Invitrogen) for 20 min at 37°C. For morphological studies, cells were placed in a thermostatted chamber at 37°C in KRB/Ca\(^{2+}\) solution and imaged using an inverted microscope (Axiovert 200M; Carl Zeiss MicroImaging, Inc.) using a 63×/1.4 Plan-Apochromat objective, a CoolSNAP HQ interline charge-coupled device camera (Roper Scientific) and a fluorescein green (Invitrogen) for 20 min at 37°C. Images were deconvolved using the PSF-based Exhaustive Photon Reassignment software (Lifshitz, 1998; Rapizzi et al., 2002). To approximate real signal, only the voxels with \(<5\%\) difference in their normalized intensity were taken into account.

**Online supplemental material**

Table S1 shows \([\text{Ca}^{2+}]_\text{c}\) and \([\text{Ca}^{2+}]_\text{m}\) responses of HeLa cells expressing the constructs in this study. Fig. S1 shows the proteomic analysis of molecular components of the MAM fraction. Fig. S2 shows the effects of IP, RlBD24A405 on cytoplasmic Ca\(^{2+}\) responses and ER Ca\(^{2+}\) homeostasis. Fig. S3 shows the effect of cytosolic and OMM-targeted pl30/PH domain on mitochondrial Ca\(^{2+}\) uptake. Online supplemental material is available at http://www.jcb.org/cgi/content/full/jcb.200608073/DC1.
