FANO-MUKAI FOURFOLDS OF GENUS 10 AS COMPACTIFICATIONS OF $\mathbb{C}^4$

YURI PROKHOROV AND MIKHAIL ZAIDENBERG

Abstract. It is known that the moduli space of smooth Fano-Mukai fourfolds $V_{18}$ of genus 10 has dimension one. We show that any such fourfold is a completion of $\mathbb{C}^4$ in two different ways. Up to isomorphism, there is a unique fourfold $V_{18}^s$ acted upon by $\text{SL}_2(\mathbb{C})$. The group $\text{Aut}(V_{18}^s)$ is a semidirect product $\text{GL}_2(\mathbb{C}) \rtimes (\mathbb{Z}/2\mathbb{Z})$. Furthermore, $V_{18}^s$ is a $\text{GL}_2(\mathbb{C})$-equivariant completion of $\mathbb{C}^4$, and as well of $\text{GL}_2(\mathbb{C})$. The restriction of the $\text{GL}_2(\mathbb{C})$-action on $V_{18}^s$ to $\mathbb{C}^4 \hookrightarrow V_{18}^s$ yields a faithful representation with an open orbit. There is also a unique, up to isomorphism, fourfold $V_{18}^a$ such that the group $\text{Aut}(V_{18}^a)$ is a semidirect product $(\mathbb{G}_a \times \mathbb{G}_m) \rtimes (\mathbb{Z}/2\mathbb{Z})$. For a Fano-Mukai fourfold $V_{18}$ neither isomorphic to $V_{18}^s$, nor to $V_{18}^a$, the group $\text{Aut}(V_{18})$ is a semidirect product of $(\mathbb{G}_m)^2$ and a finite cyclic group whose order is a factor of 6. Besides, we establish that the affine cone over any polarized Fano-Mukai variety $V_{18}$ is flexible in codimension one, and flexible if $V_{18} = V_{18}^a$.

1. Introduction

Let $V$ be a compact complex manifold, and let $A$ be a closed analytic subset in $V$. The pair $(V, A)$ is called a compactification of $\mathbb{C}^n$ if $V \setminus A$ is biholomorphically equivalent to $\mathbb{C}^n$. A compactification $(V, A)$ of $\mathbb{C}^n$ is said to be projective if $V$ is a smooth projective variety. A celebrated Hirzebruch problem ([Hir54, Problem 27]) asks to describe all possible compactifications of $\mathbb{C}^n$ with $b_2(V) = 1$. For any projective compactification $(V, A)$ of $\mathbb{C}^n$ the Kodaira dimension of $V$ is negative (see [Kod72, Theorem 3]). It is unknown, however, whether the complement $V \setminus A$ must be automatically biregularly isomorphic to $\mathbb{C}^n$. There is a related open problem ([Zai93]) on existence of an affine algebraic variety $X$ non-isomorphic to $\mathbb{C}^n$ biregularly, but analytically isomorphic to $\mathbb{C}^n$.

In this paper we deal with projective compactifications $(V, A)$ of $\mathbb{C}^n$ with $b_2(V) = 1$ and with $V \setminus A$ biregularly isomorphic to $\mathbb{C}^n$. Then $V$ is a Fano manifold with Picard number one. In the first nontrivial case $n = 3$ the classification was completed in a series of papers [PS88], [Fur90], [Pro91], [Fur93], see also the references therein. Such a threefold $V$ is one of the following:

- $\mathbb{P}^3$;
- a smooth quadric $Q \subset \mathbb{P}^4$;
- a del Pezzo quintic threefold $V_5 \subset \mathbb{P}^6$;
- a Fano threefolds $V_{22} \subset \mathbb{P}^{13}$ varying in a proper subset of codimension 2 in the moduli space.

All the possibilities for the divisor $A$ are also described.

The four-dimensional case is much more complicated. Indeed, already the very classification of smooth Fano fourfolds is still lacking.

Recall that the Fano index $\iota(V)$ of a Fano manifold $V$ is the largest integer $\iota$ such that the canonical class $K_V$ is divisible by $\iota$ in the Picard group. It is well known that $1 \leq \iota(V) \leq \dim V + 1$. Furthermore, $\iota(V) = \dim V + 1$ if and only if $V \cong \mathbb{P}^n$ and $\iota(V) = \dim V$ if and only if $V$ is a quadric $Q^n \subset \mathbb{P}^{n+1}$. This implies immediately that $(\mathbb{P}^n, \mathbb{P}^{n-1})$ and $(Q^n, Q')$, where $Q'$ is a singular hyperplane section of the quadric $Q^n$, are the only projective compactifications of $\mathbb{C}^n$ with $b_2(V) = 1$ and $\iota(V) \geq n$.

A Fano manifold $V$ with $\text{rk} \text{Pic}(V) = 1$ is called a del Pezzo manifold if $\iota(V) = \dim V - 1$ and a Fano-Mukai manifold if $\iota(V) = \dim V - 2$. Compactifications $(V, A)$ of $\mathbb{C}^4$ with $b_2(V) = 1$ and $\iota(V) = 3$ were classified in [Pro94]. Such a del Pezzo fourfold $V = W_5 \subset \mathbb{P}^7$ is unique up to isomorphism, and there are exactly four possible choices for a divisor $A \subset V$ with $V \setminus A \cong \mathbb{C}^4$. All such divisors $A$ are singular. The singular locus of $A$ is either a plane, or a special line of one of two possible types, or finally a unique ordinary double point.

In [PZ15, § 6.3] we asked the following question:

Which Fano-Mukai fourfolds can serve as compactifications of $\mathbb{C}^4$?

We give the answer for the Fano-Mukai fourfolds $V_{18} \subset \mathbb{P}^{12}$ of genus 10 and Fano index 2. According to [Muk89] there is a homogeneous space $G_2/P \subset \mathbb{P}^{13}$ of the simple algebraic group of type $G_2$ such that any variety $V_{18}$ is isomorphic to a hyperplane section of $G_2/P$. Up to isomorphism, such varieties $V_{18}$ form a one-parameter family, see Remark 13.4. It occurs that all of them are compactifications of $\mathbb{C}^4$, see Theorem 1.1. There are two distinguished members of the family. One of them, denoted by $V_{18}^*$, is quasihomogeneous with respect to a $\text{GL}_2(\mathbb{C})$-action and yields a $\text{GL}_2(\mathbb{C})$-equivariant compactification of $\mathbb{C}^4$. [Muk89]
and of $\text{GL}_2(\mathbb{C})$. Another one, denoted by $V_{18}^s$, is acted upon by the product $\mathbb{G}_a \times \mathbb{G}_m$. This group is the identity component of $\text{Aut}(V_{18}^a)$ and has index two in the full automorphism group. Any other smooth member $V_{18}$ of the family is acted upon by the torus of rank two, see Theorem 1.3 below. More formally, our main results are the following three theorems.

1.1. **Theorem.** Any smooth Fano-Mukai fourfold $V = V_{18} \subset \mathbb{P}^{12}$ of genus 10 contains at least two distinct $\text{Aut}^0(V)$-invariant cones over rational twisted cubic curves. If $S \subset V$ is such a cone, then there is a unique $\text{Aut}^0(V)$-invariant hyperplane section $A = A_S$ of $V$ with $\text{Sing}(A) = S$ such that $(V, A)$ is an $\text{Aut}^0(V)$-equivariant compactification of $\mathbb{C}^4$.

1.2. **Theorem.** Given a Fano-Mukai fourfold $V = V_{18} \subset \mathbb{P}^{12}$ of genus 10 consider a Mukai realization of $V$ as a hyperplane section of $G_2/P \hookrightarrow \mathbb{P}^{13}$, see Section 7. Then the $\text{Aut}^0(V)$-action on $V$ extends to an $\text{Aut}^0(V)$-action on $G_2/P$ induced by the natural $G_2$-action.

1.3. **Theorem.** (i) There exists a smooth Fano-Mukai fourfold $V_{18}^a$ of genus 10 with

\begin{equation}
\text{Aut}(V_{18}^a) \cong \text{GL}_2(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z}),
\end{equation}

where the generator of $\mathbb{Z}/2\mathbb{Z}$ acts on $\text{GL}_2(\mathbb{C})$ via $M \mapsto (M^t)^{-1}$. Furthermore, $\text{Aut}^0(V_{18}^a) \cong \text{GL}_2(\mathbb{C})$ has a principal dense open orbit in $V_{18}^a$ and exactly two fixed points. Any Fano-Mukai fourfold $V_{18}$ of genus 10 whose automorphism group has non-abelian identity component is isomorphic to $V_{18}^a$.

(ii) There exists a smooth Fano-Mukai fourfold $V_{18}^s$ of genus 10 with

\begin{equation}
\text{Aut}(V_{18}^s) \cong (\mathbb{G}_a \times \mathbb{G}_m) \rtimes (\mathbb{Z}/2\mathbb{Z}),
\end{equation}

where the generator of $\mathbb{Z}/2\mathbb{Z}$ acts by the inversion $g \mapsto g^{-1}$ on $\mathbb{G}_a \times \mathbb{G}_m$. Such a fourfold is unique up to isomorphism.

(iii) For any smooth Fano-Mukai fourfold $V_{18}$ of genus 10 non-isomorphic to one of the $V_{18}^a$ and $V_{18}^s$ one has

\begin{equation}
(\mathbb{G}_m)^2 \subset \text{Aut}(V_{18}) \subset (\mathbb{G}_m)^2 \rtimes (\mathbb{Z}/6\mathbb{Z}).
\end{equation}

See also Theorems 1.2 and 1.3 for some additional information. In particular, it occurs that the fourfold $V_{18}^s$ contains two one-parameter families of cones over twisted cubics and a unique pair of $\text{Aut}^0(V)$-invariant such cubic cones. The number of cubic cones in $V_{18}^a$ equals 4, and equals 6 in $V_{18} \not\cong V_{18}^a$. Any such cone $S$ defines an $\text{Aut}^0(V)$-invariant compactification $(V_{18}, A_S)$ of $\mathbb{C}^4$ as in Theorem 1.1.

The proofs of Theorems 1.1–1.3 are done in Section 13. They use a construction of $V_{18}$ starting with $\mathbb{P}^4$ via a sequence of two Sarkisov links, see Sections 2–4 for details. The first Sarkisov link gives the quintic del Pezzo fourfold $W_5 \subset \mathbb{P}^7$. In Sections 5–6 we study the automorphism group of $W_5$ (cf. [PdV99]), its action on $W_5$, and the stabilizers of certain rational normal quintic scrolls in $W_5$. Such a scroll $F$ serves as the center of blowup for the second Sarkisov link. For a properly chosen $F$ the stabilizer of $F$ in $\text{Aut}^0(W_5)$ is isomorphic to the automorphism group $\text{Aut}^0(V_{18})$ of the resulting Fano-Mukai fourfold $V_{18}$. On the other hand, the construction of S. Mukai ([Muk88]) embeds any Fano-Mukai fourfold $V_{18}$ onto a hyperplane section of $G_2/P \subset \mathbb{P}^{13}$. Using results of M. Kapustka and K. Ranestad ([KR13]) we compute in Section 7 the stabilizers of these hyperplane sections as subgroups of $\text{Aut}^0(V_{18})$. It remains to show that such a stabilizer coincides actually with the whole group $\text{Aut}^0(V_{18})$, cf. Theorem 1.2. To this end, following again ([KR13])
we study in detail the Hilbert schemes of lines and of rational normal cubic scrolls on $V_{18}$ (see Sections \[8\, \[9\]), and the subschemes of rational cubic cones (see Section \[10\). The latter cones occur to be in one-to-one correspondence with the lines on certain singular del Pezzo sextic surfaces. This geometry allows us to describe the automorphism groups of the fourfolds $V_{18}$, see Sections \[11\, \[12\]. This leads finally in Section \[13\ to our main results. In Section \[14\ (see Theorem \[14.3\]) we deduce the flexibility in codimension one of the affine cones over the Fano-Mukai fourfolds $V_{18}$ and the flexibility if $V_{18} = V_{18}$, cf. \[AFK\,13\]. The concluding Section \[15\ contains some remarks and open problems.

2. LINKING the del Pezzo fourfold $W_5$ to $\mathbb{P}^4$

2.1. In this and the next sections $W = W_5 \subset \mathbb{P}^7$ stands for a del Pezzo quintic fourfold realized as a smooth section of the Grassmannian $Gr(2, 5)$ under its Plücker embedding in $\mathbb{P}^9$ by a general linear subspace of codimension 2 in $\mathbb{P}^9$. In fact, a del Pezzo quintic fourfold is unique up to isomorphism (\[Fuj81\). We use the following description of the planes in $W$ (see the classical paper \[Tod30\ for more details and \[PdV99, Prop. 6.3\] for a modern treatment).

2.1.1. We regard the Grassmannian $Gr(2, 5)$ as the variety of lines in $\mathbb{P}^4 = \mathbb{P}(\mathbb{C}^5)$. Recall that any plane in $Gr(2, 5) \subset \mathbb{P}^9$ is a Schubert variety of one of the following two types:

- $\sigma_{2,2}$, that is, the Schubert variety of lines in a fixed plane $\mathbb{P}^2 \subset \mathbb{P}^4$;
- $\sigma_{3,1}$, that is, the Schubert variety of lines passing through a fixed point and contained in a fixed 3-space $\mathbb{P}^3 \subset \mathbb{P}^4$.

2.1.2. Let $\mathcal{P}$ be a pencil of hyperplane sections which cut out a del Pezzo quintic fourfold $W$ in $Gr(2, 5) \subset \mathbb{P}^9$. It can be treated as a pencil of skew-symmetric bilinear forms $\lambda_1 q_1 + \lambda_2 q_2 \in (\wedge^2 \mathbb{C}^5)'$. Since $W$ is smooth, each form $\lambda_1 q_1 + \lambda_2 q_2 \in \mathcal{P}$ is of rank 4. Consider the map $\nu : \mathcal{P} \to \mathbb{P}(\mathbb{C}^5)$ that sends a form $\lambda_1 q_1 + \lambda_2 q_2$ to the projectivization of its kernel $\text{ker}(\lambda_1 q_1 + \lambda_2 q_2) \subset \mathbb{C}^5$. This map is given by the Pfaffians of the corresponding matrix. Hence the image $\nu(\mathcal{P})$ is a conic in $\mathbb{P}^4 = \mathbb{P}(\mathbb{C}^5)$ (\[PdV99, Prop. 6.3\]). The linear span $\Theta = \langle \nu(\mathcal{P}) \rangle$ is a plane in $\mathbb{P}(\mathbb{C}^5)$, which is a maximal common isotropic subspace for the forms $\lambda_1 q_1 + \lambda_2 q_2 \in \mathcal{P}$. Such a subspace is unique. This defines a unique $\sigma_{2,2}$-plane $\Xi \subset W$ parameterizing the lines in $\Theta \cong \mathbb{P}^2$. On the other hand, there is a one-parameter family of $\sigma_{3,1}$-planes $\Pi_\gamma$ parameterizing the lines passing through a point $\gamma \in \nu(\mathcal{P})$ and contained in the three-dimensional subspace in $\mathbb{P}^4$ orthogonal to $\nu(\mathcal{P})$ with respect to any form $\lambda_1 q_1 + \lambda_2 q_2 \in \mathcal{P}$. Let $\Upsilon \subset \Xi$ be the dual conic of $\nu(\mathcal{P}) \subset \Theta$. Each plane $\Pi_\gamma$ meets $\Xi$ along a tangent line $l_\gamma$ to $\Upsilon$ at a point $\gamma \in \Upsilon$. Any two distinct planes $\Pi_\gamma$ and $\Pi_{\gamma'}$ meet at a unique point $l_\gamma \cap l_{\gamma'}$ on $\Xi \setminus \Upsilon$.

The planes $\{\Pi_\gamma\}_{\gamma \in \Upsilon}$ and $\Xi$ are the only planes contained in $W$. The union $R = \bigcup_{\gamma \in \Upsilon} \Pi_\gamma$ is a hyperplane section of $W$. The threefold $R$ contains also $\Xi$ and is singular along $\Xi$ (see, e.g., \[Tod30\, \[PdV99 Prop. 6.3\] and the references therein). The triple $W \supset R \supset \Xi$ plays an important role in what follows.

Consider the following Sarkisov link (for the proofs, see \[Fuj81\, \[Pro94\, \[PZ16 Prop. 4.9\] and the references therein).

2.2. Proposition. In the notation as before, the following hold.
(i) There is a commutative diagram

\[
\begin{array}{ccc}
\Xi & \subset & R \\
\rho \downarrow & & \downarrow \phi \\
\hat{W} & \subset & \hat{R}
\end{array}
\]

(2.2.1)

where \( \rho \) is the blowup of the plane \( \Xi \) in \( W \) and \( \varphi \) is the blowup of a rational twisted cubic curve \( \Gamma \subset \mathbb{P}^4 \).

(ii) The \( \rho \)-exceptional divisor \( \hat{E} = \rho^{-1}(\Xi) \) is the proper transform in \( \hat{W} \) of the linear span \( \langle \Gamma \rangle \cong \mathbb{P}^3 \) of \( \Gamma \) in \( \mathbb{P}^4 \). The \( \varphi \)-exceptional divisor \( \hat{R} \) is the proper transform of \( R \) in \( \hat{W} \).

(iii) The morphism \( \varphi \) (\( \rho \), respectively) is defined by the linear system \( |H^* - \hat{E}| \) (\( |2L^* - \hat{R}| \), respectively) on \( \hat{W} \), where \( H \) (\( L \), respectively) is the class of hyperplane section on \( W \) (on \( \mathbb{P}^4 \), respectively), and \( H^* = \rho^*(H) \), \( L^* = \varphi^*(L) \). The birational map \( \phi : W \subset \mathbb{P}^7 \dashrightarrow \mathbb{P}^4 \) is the linear projection with center \( \Xi \).

2.2. Corollary \([\text{Pro94}]\). \((W, R)\) is a compactification of \( \mathbb{C}^4 \).

Proof. Indeed, due to (2.2.1) we have isomorphisms

\[
(2.2.3) \quad W \setminus R \cong \hat{W} \setminus (\hat{R} \cup \hat{E}) \cong \mathbb{P}^4 \setminus \langle \Gamma \rangle \cong \mathbb{C}^4.
\]

\( \square \)

2.2.4. Corollary. \( \text{[1]} \) There is an isomorphism \( \text{Aut}(W) \cong \text{Aut}(\mathbb{P}^4, \Gamma) \).

Proof. Indeed, the plane \( \Xi \subset W \) is \( \text{Aut}(W) \)-invariant. Due to diagram (2.2.1) one has \( \text{Aut}(W) = \text{Aut}(W, \Xi) \cong \text{Aut}(\mathbb{P}^4, \Gamma) \).

\( \square \)

2.3. Lemma. In the notation as before, the following hold.

(a) \( \varphi|_{\hat{R}} : \hat{R} \to \Gamma \) is a \( \mathbb{P}^2 \)-bundle.

(b) For any \( \gamma \in \Gamma \), the fiber \( \hat{\Pi}_\gamma := (\varphi|_{\hat{R}})^{-1}(\gamma) \subset \hat{R} \) is sent by \( \rho \) isomorphically onto a plane \( \Pi_\gamma \subset R \).

(c) \( \rho|_{\hat{R}} : \hat{R} \to R \) is the normalization morphism.

(d) Let \( \hat{\Xi} := \hat{E} \cap \hat{R} = (\rho|_{\hat{R}})^{-1}(\Xi) \). Then \( \hat{\Xi} \cong \mathbb{P}^1 \times \mathbb{P}^1 \) and \( \varphi|_{\hat{\Xi}} : \hat{\Xi} \to \Xi \) is a double cover branched along the conic \( \Upsilon \subset \Xi \) (see (2.1.2)).

Proof. \( \text{[a]} \) follows since \( \hat{R} = \mathbb{P}(\mathcal{N}_{\Upsilon/\mathbb{P}^4}) \) is the exceptional divisor of the blowup of \( \Gamma \) in \( \mathbb{P}^4 \).

\( \text{[b]} \) Let \( L \) be a hyperplane in \( \mathbb{P}^4 \). On \( \hat{W} \) one has (\( \text{[PZ16 Prop. 4.9]} \)):

\[
L^* \sim H^* - \hat{E} \quad \text{and} \quad \hat{R} \sim H^* - 2\hat{E}.
\]

Hence \( \varphi \) is defined by the linear system \( |H^* - \hat{E}| \) on \( \hat{W} \), and

\[
(2.3.1) \quad H^* \sim 2L^* - \hat{R} \quad \text{and} \quad \hat{E} \sim L^* - \hat{R}.
\]

So, \( \rho \) is the morphism given by the base point free linear system \( |2L^* - \hat{R}| \) on \( \hat{W} \), and the map \( \phi^{-1} \) in (2.2.1) is defined by the family of quadrics in \( \mathbb{P}^4 \) passing through \( \Gamma \).

We have: \( \mathcal{O}_{\hat{R}}(\hat{R}) = \mathcal{O}_{\mathbb{P}(\mathcal{N}_{\Upsilon/\mathbb{P}^4})}(-1) \). Since \( \mathcal{O}_{\hat{\Pi}_\gamma}(L^*) = \mathcal{O}_{\hat{\Pi}_\gamma} \), we obtain

\( \text{[Cf. Lemma 5.4]} \)
\[ \mathcal{O}_{\hat{\Pi}_\gamma}(H^*) = \mathcal{O}_{\hat{\Pi}_\gamma}(2L^* - \hat{R}) \cong \mathcal{O}_{\mathbb{P}^2}(1). \]

It follows that
\[ H^2 \cdot \Pi_\gamma = (H^*)^2 \cdot \hat{\Pi}_\gamma = 1. \]

Therefore, \( \{\Pi_\gamma\} \) is a family of planes in \( \mathbb{P}^7 \) that covers \( R \). However, there is just one such family, see [2.1.2] This proves (b)

(c) \( \hat{R} \) is smooth being an exceptional divisor of the blowup \( \varphi \) with a smooth center. Hence to establish (c) it suffices to show that \( \rho|_{\hat{R}} : \hat{R} \to R \) is a finite birational morphism.

Suppose that \( \varphi|_{\hat{R}} \) contracts a curve \( J \subset \hat{R} \). Clearly, \( J \) is not contained in a fiber \( \cong \mathbb{P}^2 \) of \( \rho|_{\hat{R}} \). Therefore, \( J \) meets any fiber of \( \rho|_{\hat{R}} \). But then the planes \( \Pi_\gamma \) should pass all through a common point \( \rho(J) \), which is not the case (see 2.1.2). Since \( \rho \) is a birational morphism of smooth varieties, \( \rho|_{\hat{R}} \) is birational.

(d) By construction, \( \hat{\Xi} = \hat{E} \cap \hat{R} \) is the exceptional divisor of the blowup \( \varphi|_{\hat{E}} : \hat{E} \to \langle \Gamma \rangle \cong \mathbb{P}^3 \) with center \( \Gamma \). Since \( \mathcal{N}_{\Gamma/\mathbb{P}^3} \cong \mathcal{O}_{\mathbb{P}^1}(5) \oplus \mathcal{O}_{\mathbb{P}^1}(5) \) (see e.g. [EvdV81]), we have \( \hat{E} \cap \hat{R} \cong \mathbb{P}(\mathcal{N}_{\Gamma/\mathbb{P}^3}^\vee) \cong \mathbb{P}^1 \times \mathbb{P}^1 \). On \( \hat{W} \) one has \( L^2 \cdot \hat{R}^2 = 0 = L^3 \cdot \hat{R}^1 \). By (2.3.1) and [PZ16, Lem. 2.3, Lem. 4.6] the degree of the morphism \( \rho|_{\hat{\Xi}} : \hat{\Xi} \to \Xi \) equals
\[ H^2 \cdot \hat{E} \cdot \hat{R} = (2L^* - \hat{R}) \cdot (L^* - \hat{R}) = 5\hat{R}^3 \cdot L^* - \hat{R}^4 = 2. \]

It follows that \( \rho|_{\hat{\Xi}} : \hat{\Xi} \to \Xi \) is equivalent to a covering \( \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^2 \) of degree 2 branched along a smooth conic. Furthermore, \( \varphi|_{\hat{E}} : \hat{E} \to \Gamma \) is equivalent to a canonical projection \( \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1 \), with fibers being the lines \( \hat{\Pi}_\gamma \cap \hat{\Xi} \). These lines are sent by \( \rho \) to the tangent lines \( \Pi_\gamma \cap \Xi \) of \( \Upsilon \). Hence \( \Upsilon \) is the branching divisor of \( \hat{\Xi} \to \Xi \) and the image of the ramification divisor of type (1, 1) on \( \hat{\Xi} \cong \mathbb{P}^1 \times \mathbb{P}^1 \). Now (d) follows. \( \square \)

2.4. Lemma. There exists a smooth rational curve \( \hat{\Gamma} \subset \hat{R} \) such that

- the restrictions \( \varphi|_{\hat{\Gamma}} : \hat{\Gamma} \to \Gamma \) and \( \rho|_{\hat{\Gamma}} : \hat{\Gamma} \to \rho(\hat{\Gamma}) \) are isomorphisms;
- \( \rho(\hat{\Gamma}) \subset R \) is a twisted cubic;
- \( \hat{E} \cap \hat{\Gamma} = \emptyset \) and \( \langle \rho(\hat{\Gamma}) \rangle \cap \Xi = \emptyset \).

Proof. Fix a point \( P \in \mathbb{P}^4 \setminus \langle \Gamma \rangle \). Let \( N \subset \mathbb{P}^4 \) be the cone over \( \Gamma \) with vertex \( P \), and let \( \hat{N} \) be the proper transform of \( N \) in \( \hat{W} \). Consider the curve \( \hat{\Gamma} = \hat{N} \cap \hat{R} \). We claim that \( \hat{\Gamma} \) satisfies the conditions of the lemma. Indeed, since \( \Gamma \subset N \) is a Cartier divisor, \( \varphi|_{\hat{N}} : \hat{N} \to N \) is an isomorphism, and \( \varphi(\hat{\Gamma}) = \Gamma \). Hence \( \varphi|_{\hat{\Gamma}} : \hat{\Gamma} \to \Gamma \) is an isomorphism as well.

Furthermore, one has \( \Gamma = N \cap \langle \Gamma \rangle \), and \( N \) meets \( \langle \Gamma \rangle \) transversely along \( \Gamma \). It follows that \( \hat{E} \) and \( \hat{\Gamma} \) are disjoint. Since \( \hat{E} \) is the exceptional divisor of \( \rho \) and \( \rho|_{\hat{E}} = \Xi \), we conclude that \( \rho|_{\hat{\Gamma}} : \hat{\Gamma} \to \rho(\hat{\Gamma}) \) is an isomorphism, and \( \rho(\hat{\Gamma}) \cap \Xi = \emptyset \). Moreover, since \( \rho(\hat{\Gamma}) \) does not meet the center \( \Xi \) of the birational projection \( \phi : \hat{W} \dashrightarrow \mathbb{P}^4 \), the restriction \( \phi|_{\rho(\hat{\Gamma})} : \rho(\hat{\Gamma}) \to \Gamma \) is an isomorphism preserving the degree. Therefore, \( \rho(\hat{\Gamma}) \) is a twisted cubic, since \( \Gamma \subset \mathbb{P}^4 \) is.

Finally, if \( \Xi \) meets \( \langle \rho(\hat{\Gamma}) \rangle \cong \mathbb{P}^3 \), then \( \rho(\hat{\Gamma}) \) has a 2-secant line meeting \( \Xi \). However, in the latter case \( \phi|_{\rho(\hat{\Gamma})} : \rho(\hat{\Gamma}) \to \Gamma \) cannot be an isomorphism, a contradiction. \( \square \)
3. Linking the Fano-Mukai fourfolds $V_{18}$ to $W_5$

Any smooth Fano-Mukai fourfold $V_{18}$ of genus 10 can be obtained starting with $W_5$ via a Sarkisov link. This link can be described as follows.

3.1. **Proposition.** Let $V = V_{18} \subset \mathbb{P}^{12}$ be a smooth Fano-Mukai fourfold, and let $S \subset V$ be either a smooth two-dimensional cubic scroll, or a cone over a rational twisted cubic curve\footnote{Such cones are the only cubic cones in $V$, see 4.5. Hence in the sequel we call them simply cubic cones. We will show that any smooth variety $V_{18}$ contains a cubis scroll or a cubic cone.}. Then $V \cap \langle S \rangle = S$ as a scheme, and there is a Sarkisov link

$$
\begin{array}{cccc}
S' & \subset & \langle S \rangle \cap V \subset A & \xleftarrow{\theta} V \\
\xi & \Rightarrow & W & \supset B = W \cap \langle F \rangle \\
\eta & \Rightarrow & \tilde{A} & \supset \tilde{F}
\end{array}
$$

where

- $\xi$ is the blowup of $S$ in $V$ with exceptional divisor $\tilde{B}$;
- $\eta$ is the blowup of a smooth rational quintic scroll $F \subset W$ with exceptional divisor $\tilde{A}$;
- $\xi$ sends $\tilde{A}$ to a hyperplane section $A$ of $V$ with $\text{Sing}(A) = S$, and $\eta$ sends $\tilde{B}$ to the hyperplane section $B = W \cap \langle F \rangle$;
- the map $\theta : V \dashrightarrow W = W_5$ comes from the linear projection $\mathbb{P}^{12} \dashrightarrow \mathbb{P}^7$ with center $\langle S \rangle \cong \mathbb{P}^4$.

**Proof.** The proof proceeds in several steps.

3.1.2. **Claim.** We have $V \cap \langle S \rangle = S$ as a scheme.

**Proof.** It is well known that any linearly non-degenerate surface of degree 3 in $\mathbb{P}^4$ is an intersection of three quadrics. On the other hand, $V = V_{18} \subset \mathbb{P}^{12}$ is an intersection of quadrics too (see [Isk77, Lem. 2.10]). Let $Q \subset H^0(\mathbb{P}^{12}, \mathcal{O}_{\mathbb{P}^{12}}(2))$ be the linear system of quadrics passing through $V$, and let $Q'$ be the restriction of $Q$ to $\langle S \rangle$. Then $Q'$ cuts out on $\langle S \rangle$ a scheme $V \cap \langle S \rangle$ of dimension 2 containing $S$. Hence $2 \leq \dim Q' \leq 3$. Suppose that dim $Q' = 2$, that is, $Q'$ is generated by two linearly independent quadrics $Q_1, Q_2 \in Q'$. Then $Q_1 \cap Q_2 = S \cup \Pi$, where $\Pi \subset V$ is the residual plane. However, a Fano-Mukai fourfold of genus 10 does not contain any plane ([KR13, Lem. 3]). Hence dim $Q' = 3$. So, any quadric in $\langle S \rangle$ containing $S$ is a member of $Q'$. Since these quadrics cut out in $\mathbb{P}^4$ the surface $S$, it follows that $S = V \cap \langle S \rangle$ (as a scheme). $\square$

3.1.3. **Claim.** There exists a line $l$ on $V$ meeting $S$.

**Proof.** Let $L = V \cap \mathbb{P}^{11}$ be a general hyperplane section of $V$. Then $L$ meets $S$ along a twisted cubic curve, say, $\Gamma'$. By the adjunction formula and the Lefschetz hyperplane section theorem, $L \subset \mathbb{P}^{11}$ is an anticanonically embedded Fano threefold with $\text{Pic} L = \mathbb{Z} \cdot K_L$. It is known ([IP99, Prop. 4.2.2]) that $L \subset \mathbb{P}^{11}$ carries a one-parameter family of lines. Since $\text{Pic} L \cong \mathbb{Z}$, the surface $T \subset L$ swept up by these lines meets $\Gamma'$. Now the claim follows. $\square$

The next claim concludes the proof of Proposition 3.1.
3.1.4. Claim. Consider the linear projection \( \theta : \mathbb{P}^{12} \supset V \longrightarrow W := \theta(V) \subset \mathbb{P}^{7} \) with center \( \langle S \rangle \cong \mathbb{P}^{4} \). Consider also the blowup \( \xi : \tilde{W} \rightarrow V \) with center \( S \). Then \( W \subset \mathbb{P}^{7} \) is a smooth del Pezzo quintic fourfold, and there is a morphism \( \eta : \tilde{W} \rightarrow W \) such that these objects and morphisms fit in diagram (3.1.1).

Proof. Let \( \tilde{B} \) be the exceptional divisor of the blowup \( \xi : \tilde{W} \rightarrow V \) with center \( S \). One can check that \( \tilde{W} \) is smooth. Let \( L \) be a hyperplane section of \( V \). Consider the proper transform \( |L^* - \tilde{B}| \) on \( \tilde{W} \) of the linear system of hyperplanes in \( \mathbb{P}^{12} \) passing through \( S \). It is nef and base point free. The morphism \( \eta = \Phi_{|L^* - \tilde{B}|} : \tilde{W} \rightarrow W \subset \mathbb{P}^{7} \) resolves indeterminacies of \( \theta \). Using [PZ16, Lem. 2.3] one computes \( (L^* - \tilde{B})^4 = 5 \) (cf. (3.1.9) and the subsequent paragraph). Thus, \( \deg \tilde{W} = 5 \), and so, \( \eta \) is birational. The divisor \( -K_{\tilde{W}} = (L^* - \tilde{B}) + L^* \) is ample being the sum of two non-proportional nef divisors. Let \( \eta : \tilde{W} \rightarrow W' \longrightarrow \tilde{W} \) be the Stein factorization. Then \( \eta' \) is either an isomorphism, or an extremal Mori contraction. Let, as before, \( H \) be a hyperplane section of \( W \subset \mathbb{P}^{7} \), and let \( H^* = \eta^*H \). Thus, \( H^* \sim L^* - \tilde{B} \) on \( \tilde{W} \).

Let \( \tilde{l} \subset \tilde{W} \) be the proper transform of a line \( l \subset V \) which meets \( S \) properly, see 3.1.3. Then \( \tilde{B} \cdot \tilde{l} \geq 1 \) and \( L^* \cdot \tilde{l} = 1 \). Hence

\[
H^* \cdot \tilde{l} = (L^* - \tilde{B}) \cdot \tilde{l} \leq 0.
\]

Since the linear system \( |H^*| \) is base point free, we have

\[
(3.1.5) \quad H^* \cdot \tilde{l} = 0, \quad \tilde{B} \cdot \tilde{l} = 1, \quad -K_{\tilde{W}} \cdot \tilde{l} = 1.
\]

It follows that a non-ample, nef divisor \( H^* \) supports an extremal ray \( \tilde{l} \) contracted by \( \eta \). In particular, \( \eta' \) is not an isomorphism.

Suppose that \( \eta' \) has a two-dimensional fiber, say, \( \tilde{M} \). By the main theorem in [AW98], \( \tilde{M} \) is isomorphic either to \( \mathbb{P}^{2} \), or to a quadric \( Q \subset \mathbb{P}^{3} \). Moreover, \( \mathcal{O}_{\tilde{M}}(-K_{\tilde{W}}) \cong \mathcal{O}_{\tilde{M}}(1) \), or, respectively, \( \mathcal{O}_{\tilde{M}}(-K_{\tilde{W}}) \cong \mathcal{O}_{\tilde{M}}(L^*) \) (cf. (4.4.3)). Therefore, \( \xi(\tilde{M}) \) is either a plane, or a quadric surface in \( V \). However, \( V \) contains neither a plane, nor a quadric surface, see [KR13, Lem. 3 and Cor. 3]. Thus, \( \eta' \) has no two-dimensional fiber, and so, it is not flipping (see e.g. [AW98, Main Theorem]). Thus, \( \eta' \) contracts a divisor, say \( \tilde{A} \subset \tilde{W} \), to a surface, say, \( F' = \eta'(\tilde{A}) \subset W' \). Again by the main theorem in [AW98], \( W' \) and \( \tilde{A} \) are smooth, and \( \eta' : \tilde{W} \rightarrow W' \) is the blowup of a smooth surface \( F' \subset W' \).

We have \( -K_{\tilde{W}} = 2H^* + \tilde{B} \). Set \( H' = \eta^*H^* \) and \( B' = \eta^*\tilde{B} \). Then \( -K_{W'} = 2H' + B' \). Since \( \text{rk} \text{Pic} W' = 1 \), the Fano index of \( W' \) is at least 3. Since \( H'^{4} = H^{4} = 5 \), \( H' \) is not divisible. It follows from the classification that \( W' \) is a del Pezzo fourfold of degree 5 and \( H' \sim B' \) (Fuj81]). Moreover, \( H' = -\frac{1}{3}K_{W'} \) is very ample. Hence \( W' \rightarrow W \) is an isomorphism. Thus we have \( -K_{W} \sim 3H' \) and

\[
(3.1.6) \quad -K_{\tilde{W}} \sim 3H^* - \tilde{A} \sim 2H^* + \tilde{B}, \quad \tilde{B} \sim H^* - \tilde{A}.
\]

It remains to show that the smooth surface \( F \subset W \) is a rational quintic scroll. On \( \tilde{W} \) we have \( \tilde{B} \sim H^* - \tilde{A} \) due to (3.1.6). Since \( V \) is smooth and \( S \subset V \) has at worst isolated singularities, the intersection numbers \( (L^*)^{i} \cdot \tilde{B}^{4-i} \) for \( i > 0 \) can be computed in a usual
way (see, e.g., [PZ16, Lem. 2.3]). This gives:

\[(L^*)^4 = 18, \quad (L^*)^3 \cdot B = 0, \quad (L^*)^2 \cdot \tilde{B}^2 = -3, \quad L^* \cdot \tilde{B}^3 = -1.\]

Since \(H^* \sim L^* - \tilde{B}\) and, by (3.1.6),

\[(3.1.8) \quad \tilde{A} \sim L^* - 2\tilde{B},\]

then the equality \((H^*)^3 \cdot \tilde{A} = 0\) reads

\[(3.1.9) \quad (L^* - \tilde{B})^3 \cdot (L^* - 2\tilde{B}) = 0.\]

Expressing \(\tilde{B}^4\) via the intersection numbers \((L^*)^i \cdot \tilde{B}^{4-i}, i = 1, \ldots, 4,\) from (3.1.7) and (3.1.9) one gets \(\tilde{B}^4 = 1\). Furthermore,

\[\deg F = -(H^*)^2 \cdot \tilde{A}^2 = -(L^* - \tilde{B})^2 \cdot (L^* - 2\tilde{B})^2 = 5.\]

Since \(\tilde{B} \sim H^* - \tilde{A}\), the divisor \(B := \eta(\tilde{B})\) is a hyperplane section of \(W\) passing through \(F\). For any such hyperplane section, say, \(D\), the proper transform \(\tilde{D}\) of \(D\) in \(W\) belongs to the linear system \(|B|\). However, this linear system contains just a single member \(\tilde{B}\). Indeed, the \(\xi\)-exceptional divisor \(\tilde{B}\) is covered by lines with negative intersection with \(\tilde{B}\), and so, is not movable. Therefore, there is just one hyperplane section \(B\) in \(W\) through \(F\), that is, \(\langle F \rangle \cap W = B\). Finally, \(F \subset \langle F \rangle \cong \mathbb{P}^6\) is a linearly nondegenerate surface of minimal degree, hence a rational quintic scroll, see [EH87, Thm. 1].

This ends the proof of Proposition 3.1.

\[\Box\]

4. Linking \(W_5\) to \(V_{18}\)

4.1. Notation. Consider again a smooth del Pezzo quintic fourfold \(W = W_5 \subset \mathbb{P}^7\) with a distinguished hyperplane section \(R\) of \(W\) swept up by the planes contained in \(W\), with a distinguished plane \(\Xi = \text{Sing} R \cong \mathbb{P}^2\) and a distinguished smooth conic \(\Upsilon \subset \Xi\). Let \(F\) be a smooth rational quintic scroll in \(W\), not necessarily contained in \(R\). Let \(\eta : \tilde{W} \to W\) be the blowup with center \(F\) and exceptional divisor \(\tilde{A}\). Consider the hyperplane section \(B = W \cap \langle F \rangle\) of \(W\), and let \(\tilde{B}\) be the proper transform of \(B\) in \(\tilde{W}\). Clearly, \(B\) is smooth in codimension 1, and so, \(\tilde{B} \sim H^* - \tilde{A}\) on \(\tilde{W}\), where \(H\) is the class of a hyperplane section of \(W\).

4.1.1. Remark. Recall that a rational normal quintic scroll \(F\) spans \(\mathbb{P}^6\). There exist such scrolls of two different kinds, namely,

\[\begin{align*}
(i) \quad & F \cong \mathbb{F}_1, \text{ where the embedding } \mathbb{F}_1 \hookrightarrow \mathbb{P}^6 \text{ is given by the linear system } |s_0 + 3f|; \\
(ii) \quad & F \cong \mathbb{F}_3, \text{ where the embedding } \mathbb{F}_3 \hookrightarrow \mathbb{P}^6 \text{ is given by the linear system } |s_0 + 4f|, \\
& \text{with the exceptional section } s_0 \text{ and a fiber } f.
\end{align*}\]

The following proposition is an analog of Theorem 2.1.a in [PZ15]. The latter theorem is proven in [PZ15] under an additional assumption that the given rational quintic scroll \(F \subset W\) does not meet any plane in \(W\) along a conic. We do not keep any longer this assumption. Nonetheless, a part of the proof of Theorem 2.1.a in [PZ15] goes through in our setup as well.

4.2. Proposition. For any smooth rational quintic scroll \(F \subset \mathbb{P}^7\) contained in \(W\), the data \((W, F, \tilde{W}, \tilde{A}, \tilde{B})\) as in 4.1 fits in a Sarkisov link (3.1.1), where
(a) $V = V_{18} \subset \mathbb{P}^{12}$ is a Fano-Mukai fourfold of genus 10 with at worst ordinary double points as singularities;

(b) $\xi$ is a birational Mori contraction that contracts the divisor $\tilde{B}$ to a surface $S = V \cap \langle S \rangle$, and sends $\tilde{A}$ to a hyperplane section $A$ of $V$ with $\text{Sing}(A) = S$;

(c) $S$ is either a smooth rational cubic scroll, or a cone over a rational normal twisted cubic curve;

(d) $\xi$ has at most a finite number of two-dimensional fibers. If $\tilde{Y}_1, \ldots, \tilde{Y}_k$ are the two-dimensional fibers of $\xi$, then both $V$ and $S$ are smooth outside the finite set $\xi(\bigcup \tilde{Y}_i)$, and $\xi|_{\tilde{W}\setminus \bigcup \tilde{Y}_i} : \tilde{W}\setminus \bigcup \tilde{Y}_i \to V\setminus \{\xi(\bigcup \tilde{Y}_i)\}$ is the blowup of $S\setminus \{\xi(\bigcup \tilde{Y}_i)\}$. In particular, if $\xi$ has no two-dimensional fiber, then both $V$ and $S$ are smooth, and $\tilde{W} \to V$ is the blowup of $S$.

**Proof of Proposition 4.2.** The following two facts are borrowed in [PZ15].

### 4.2.1. Claim ([PZ15] Lem. 5.5]).

On $\tilde{W}$ the following equalities hold:

\[(4.2.2) \quad (H^*)^4 = 5, \quad (H^*)^3 \cdot \tilde{A} = 0, \quad (H^*)^2 \cdot \tilde{A}^2 = -5, \quad H^* \cdot \tilde{A}^3 = -8, \quad \tilde{A}^4 = -6.\]

### 4.2.3. Claim ([PZ15] Lem. 5.2]).

The linear system $|2H^* - \tilde{A}|$ is base point free and defines a morphism $\Phi_{|2H^* - \tilde{A}|} : \tilde{W} \to \mathbb{P}^{12}$.

Letting $V = \Phi_{|2H^* - \tilde{A}|}(\tilde{W}) \subset \mathbb{P}^{12}$, consider the Stein factorization

\[(4.2.4) \quad \Phi_{|2H^* - \tilde{A}|} : \tilde{W} \xrightarrow{\xi} U \xrightarrow{\psi} V \subset \mathbb{P}^{12}.\]

An easy computation using (4.2.2) gives

\[(2H^* - \tilde{A})^4 = 18 \quad \text{and} \quad (2H^* - \tilde{A})^3 \cdot \tilde{B} = (2H^* - \tilde{A})^3 \cdot (H^* - \tilde{A}) = 0.\]

Therefore, $\xi$ in (4.2.4) is birational and contracts $\tilde{B}$. Furthermore,

\[(4.2.5) \quad \deg V \cdot \deg \psi = 18.\]

We have $\text{rk Pic}(\tilde{W}) = 2$. Hence the Mori cone of $\tilde{W}$ is generated by two extremal rays. These rays are generated by the nef divisors $2H^* - \tilde{A}$ and $H^*$. Their sum is an ample anticanonical divisor $-K_{\tilde{W}}$. So, the morphism $\xi$ in (4.2.4) is a Mori contraction, and $\text{Pic}(U) \cong \mathbb{Z} \cdot L$, where $\xi^*L = 2H^* - \tilde{A}$. One has

\[(4.2.6) \quad L^2 \cdot S = -(2H^* - \tilde{A})^2 \cdot \tilde{B}^2 = -(2H^* - \tilde{A})^2 \cdot (H^* - \tilde{A})^2 = 3.\]

Thus, $S = \xi(\tilde{A})$ is a surface in $\mathbb{P}^{12}$ of degree 3. By the main theorem of [AW98], $U$ has at worst ordinary double points as singularities. Since $-K_{\tilde{W}} = 2(2H^* - \tilde{A}) - \tilde{B}$, we have $-K_U = 2L$, that is, $U$ is a Fano-Mukai fourfold (possibly with ordinary double points). Moreover, outside an at most finite union of two-dimensional fibers of $\xi$, the morphism $\xi$ is a blowup of a smooth surface in a smooth fourfold. Consequently, the surface $S$ has at worst isolated singularities.

### 4.2.7. Claim. The morphism $\psi$ in (4.2.4) is birational.

**Proof.** Suppose that $\deg \psi > 1$. Then by [EH87, Thm. 1]) we have $\deg V \geq \text{codim}_{\mathbb{P}^{12}} V + 1 = 9$. Thus, $\deg V = 9$, $\deg \psi = 2$, and $V$ is either a smooth scroll, or a cone over a smooth scroll, or finally a cone with vertex a line over a rational normal curve of degree
9 in \( \mathbb{P}^3 \), see loc. cit. In the first two cases, \( \text{rk} \operatorname{Cl}(V) = 2 \). On the other hand, there is a natural injection \( \psi^* : \operatorname{Cl}(V) \hookrightarrow \operatorname{Cl}(U) \cong \mathbb{Z} \cdot L \). This leads to a contradiction. In the latter case \( \operatorname{Cl}(U) = \mathbb{Z} \cdot P \), where \( P \) is the class of a plane. As before, this gives a contradiction. \( \Box \)

The following assertion is well known, even in a more general form. However, due to the lack of a reference, we provide an argument.

4.2.8. **Claim.** The morphism \( \psi \) is an isomorphism.

**Proof.** It suffices to show that the graded algebra

\[
R(U, L) = \bigoplus_{n \geq 0} H^0(U, \mathcal{O}_U(nL))
\]

is generated by its component of degree 1. By our construction, the linear system \( |L| \) is base point free. By Bertini’s theorem, a general member \( X \in |L| \) is smooth. Then \( X \) is a smooth Fano threefold, and the anticanonical linear system \( |-K_X| = |\mathcal{O}_X(L)| \) is base point free.

By the Kawamata-Viehweg vanishing theorem, we have \( H^1(U, \mathcal{O}_U) = 0 \). Applying Lemma 2.9 in [Isk77], it is enough to show that the graded algebra

\[
R(X, L) = \bigoplus_{n \geq 0} H^0(X, \mathcal{O}_X(nL))
\]

is generated by its component of degree 1. Continuing in the same manner, one arrives at a smooth K3 surface \( Z \in |-K_X| \) and a smooth curve \( C \in |L|_Z \), where \( K_C = L|_C \). Since the map given by \( |K_C| = |L|_C \) is birational, \( C \) is not hyperelliptic. By a theorem of Max Noether ([GH94, Ch. 2, §3]), the algebra

\[
R(C, K_C) = \bigoplus_{n \geq 0} H^0(C, \mathcal{O}_C(nK_C))
\]

is generated by its component \( H^0(C, \mathcal{O}_C(K_C)) \). Now the claim follows. \( \Box \)

Thus, we may suppose in the sequel that \( V = U \) is a Fano-Mukai fourfold of degree 18 (so, of genus 10) with at worst ordinary double points as singularities, as claimed in (a), and \( \xi = \Phi_{|2H*-\tilde{A}|} \).

Since \( L^* \sim 2H^* - \tilde{A} \) and \( \tilde{B} \sim H^* - \tilde{A} \), one has \( \tilde{A} \sim L^* - 2\tilde{B} \) on \( \tilde{W} \). Note that \( \tilde{A} \subset \tilde{W} \) in (3.1.1) is smooth being a \( \mathbb{P}^1 \)-bundle over a smooth surface \( F \). Letting \( A = \xi(\tilde{A}) \subset V \), one deduces that \( A \) is a hyperplane section of \( V \) with desingularization \( \tilde{A} \), and \( S = \text{Sing}(\tilde{A}) \). This concludes the proof of (b).

To show (c) note that \( \deg S = 3 \) by (1.2.6), and \( S \) has at worst isolated singularities. We claim that \( \dim \langle S \rangle > 3 \). Indeed, using (4.2.2) one can compute

\[
L^* \cdot \tilde{B}^3 = (2H^* - \tilde{A}) \cdot (H^* - \tilde{A})^3 = -1.
\]

On the other hand, using [PZ16, Lem. 2.3(ii)] we obtain

\[
L^* \cdot \tilde{B}^3 = -L|_S \cdot K_S + K_V \cdot L \cdot S
\]
(the corresponding formula in loc. cit. works since $S$ has at worst isolated singularities, and $L$ is movable). So,

$$L|_S \cdot K_S = -L^* \cdot \tilde{B}^3 - 2L^2 \cdot S = 1 - 6 = -5.$$  

If $\dim(S) < 4$, then $S$ is a cubic surface in $\mathbb{P}^3$. In this case $L|_S \cdot K_S = -K^2_S = -3$, a contradiction. Therefore, $\dim(S) = 4$, and so, $S \subset \mathbb{P}^4$ is a linearly nondegenerate cubic surface, that is, a surface of minimal degree in $\mathbb{P}^4$. Now the assertion follows by the del Pezzo theorem ([EH87, Thm. 1]). This proves (c). Finally, (d) follows from [AW98, Main Theorem]. This ends the proof of Proposition 4.2. \(\square\)

Next we examine the alternative case, where $\xi$ in (3.1.1) has a two-dimensional fiber (cf. 4.2(d)). We need such a simple observation.

4.3. Remark (cf. [KPS16, Rem. 5.2.14]). A smooth conic $J \subset \Xi$ touches $\Upsilon$ with even multiplicities if and only if one of the following holds (see Figure 4.3.1):

(i) $J = \Upsilon$;
(ii) $J$ is tangent to $\Upsilon$ in a single point with multiplicity 4;
(iii) $J$ is tangent to $\Upsilon$ in two points.

![Figure 4.3.1.](image)

4.4. Proposition. With the assumptions and notation of 4.1 and 4.2, suppose that $\xi$ has a two-dimensional fiber $\tilde{\Upsilon}$. Then the following hold.

(a) $Y := \eta(\tilde{\Upsilon}) \subset W$ is a plane, and $Y \cap F$ is a reduced (but possibly reducible) conic. Conversely, the proper transform $\tilde{Y} \subset \tilde{W}$ of any plane $Y \subset W$ such that $Y \cap F$ is a conic, is a two-dimensional fiber of $\xi$.

(b) If $F \cong \mathbb{F}_1$, then $\tilde{\Upsilon}$ is a unique two-dimensional fiber of $\xi$, and $Y \cap F$ is a smooth conic, the exceptional section of $F \cong \mathbb{F}_1$.

(c) One of the following holds.

(i) $B$ is singular at a general point of $Y := \eta(\tilde{\Upsilon})$, $\xi(\tilde{\Upsilon})$ is a smooth point of $V$ and a (unique) singular point of the surface $S$. This point $\xi(\tilde{\Upsilon})$ is of type $\frac{1}{3}(1,1)$ in $S$. Furthermore, $B = R$ and $Y = \Xi$.

(ii) $B$ is smooth at a general point of $Y$, $\xi(\tilde{\Upsilon}) \in V$ is an ordinary double point, and the surface $S$ is smooth at $\xi(\tilde{\Upsilon})$. Furthermore, $Y$ is a plane of type $\sigma_{3,1}$ (that is, a $\Pi$-plane).

(d) If $V$ is smooth, then $F \cong \mathbb{F}_1$, $\tilde{\Upsilon}$ is the only two-dimensional fiber of $\xi$, $B = R$, $Y = \Xi$, $S$ is a cone over a twisted cubic curve, and the exceptional section of the ruling $F \to \mathbb{P}^1$ is a smooth conic $J := \Xi \cap F$ of one of types $\{1\}$ $\{\text{iii}\}$ in Remark 4.3, see Figure 4.3.1.
Proof. By Proposition 4.2(c), $S$ is normal and possesses at most one singular point. It follows from the main theorem and Proposition 4.11 in [AW98] that $Y \cong \mathbb{P}^2$ and

$$\phi_Y(3H^* - \tilde{A}) \cong \phi_Y(-K_Y) \cong \phi_{\mathbb{P}^2}(1).$$

Since $\tilde{Y}$ is contracted to a point under $\xi = \Phi_{[2H^*-\tilde{A}]}$, one has

$$\phi_Y(2H^* - \tilde{A}) = \phi_{\tilde{Y}}.$$ 

Then (4.4.1) and (4.4.2) imply

$$\phi_Y(H^*) \cong \phi_{\mathbb{P}^2}(1) \quad \text{and} \quad \phi_Y(\tilde{A}) \cong \phi_{\mathbb{P}^2}(2).$$

Thus, $Y \subset W$ is a plane, and $Y \cap F$ is a conic. The converse statement is left to the reader.

Assume that $Y \cap F = 2\Lambda$ is a double line. If $F \cong \mathbb{F}_3$, then there exists another line $\Lambda' \subset F$ meeting $\Lambda$. The plane $Y$ coincides with the tangent plane to $F$ at the point $\Lambda \cap \Lambda'$. Hence, $Y \cap F = 2\Lambda + \Lambda' \neq 2\Lambda$.

Thus, we may assume that $F \cong \mathbb{F}_1$ and $\Lambda$ is a ruling of $F$. Let $J$ be the negative section of $F = \mathbb{F}_1 \to \mathbb{P}^1$, and let $J'$ be a section disjoint with $J$. Then $J$ is a conic, $J'$ is a twisted cubic in $F$, and the linear spans $\langle J \rangle$ and $\langle J' \rangle$ are disjoint. The ruling $\Lambda$ meets $J$ in a point, say, $P_0$, and $J'$ in $P_1$. By our assumption, the plane $Y$ is tangent to $F$ along $\Lambda$. Hence $Y$ contains the tangent lines $T_{P_0}J$ and $T_{P_1}J'$. It follows that these lines intersect, and then also the linear spans $\langle J \rangle$ and $\langle J' \rangle$ do, a contradiction. This proves (a).

(b) In this case the only conic on $F$ is the negative section of $F \cong \mathbb{F}_1$.

To show (c) we note that $\eta$ provides a local analytic isomorphism of pairs $(\tilde{B}, \tilde{Y})$ and $(B, Y)$ at the corresponding generic points of $\tilde{Y}$ and $Y$, respectively. The statements of (c) follow now directly from the main theorem in [AW98] and the proof of Proposition 6.3 in loc. cit., except for the equalities $B = R$ and $Y = \Xi$ in (c)(ii). Let us show the latter equalities. Since the variety $B$ in (c)(ii) is a hyperplane section of $W$ singular along a plane $Y$ (see Definition 4.1), $B$ contains any line in $W$ meeting $\text{Sing}(B) \supset Y$. Any two planes in $W$ intersect. In particular, any plane in $W$ meets $Y$. Hence $B$ contains any plane in $W$. Consequently, $B$ coincides with the union $R = \bigcup_{\gamma \in \Upsilon} \Pi_\gamma$, see 2.1.2. It follows finally that $Y = \text{Sing}(R) = \Xi$ and $R = B \supset \mathcal{F}$.

(d) Since $V$ is smooth, (c)(ii) holds, and so, $B = R$, $Y = \Xi$, and $S$ is the cone over a twisted cubic curve. Since $Y = \Xi$, then according to (a) $F \cap \Xi$ is a conic. This conic contains the exceptional section, say, $J$ of $F \cong \mathbb{F}_n$, $n \in \{1, 3\}$. Thus, $J \subset \Xi$. For $P \in J$, let $\Lambda_P \subset F$ be the ruling through $P$.

Assume first that $F \cong \mathbb{F}_3$. Then $F \cap \Xi = J + \Lambda_0$, where $\Lambda_0$ is the ruling through the point $P_0 = J \cap \Lambda_0$. For a point $P \in J \setminus \{P_0\}$ one has $\Lambda_P \neq \Lambda_0$, and so, $\Lambda_P \not\subset \Xi$. Hence $\Lambda_P$ is contained in a (unique) plane $\Pi_\gamma$. This defines a (regular) map

$$\psi : J \setminus \{P_0\} \longrightarrow \Upsilon, \quad P \longmapsto \gamma.$$ 

Since each plane $\Pi_\gamma$ contains a unique ruling $\Lambda_P$, this map extends to a bijection $J \to \Upsilon$. The intersection $l_\gamma := \Pi_\gamma \cap \Xi$ is the tangent line to $\Upsilon$ at $\gamma$. Then $\psi^{-1}$ is defined as follows

$$\psi^{-1} : \Upsilon \longrightarrow J, \quad \gamma \longmapsto P = J \cap l_\gamma.$$ 

This map is bijective if and only if $J$ is a tangent line to $\Upsilon$. Thus $J = l_{\gamma_0}$ for some $\gamma_0 \in \Upsilon$. If $\Lambda_{\gamma_0} \not\subset \Xi$, then $\Pi_{\gamma_0} \cap F = J + \Lambda_{\gamma_0}$. By (c)(ii), $V$ is singular, a contradiction. Hence $\Lambda_{\gamma_0} \subset \Xi$ and $F \cap \Xi = J + \Lambda_{\gamma_0}$. In this case, $\Lambda_{\gamma_0} \not\subset J = l_{\gamma_0}$, and so, $\Lambda_{\gamma_0} \cap \Upsilon = \{\gamma_0, \gamma_1\}$.
where $\gamma_1 \neq \gamma_0$. On the other hand, $\Lambda_{\gamma_0}$ is contained in some plane $\Pi_\gamma$, because this is true for a general $\Lambda_\gamma$. Hence $\Lambda_{\gamma_0} = \Xi \cap \Pi_\gamma$ is tangent to $\Upsilon$, a contradiction. Thus, $F \cong \mathbb{F}_1$, as stated.

Assume now that $J \neq \Upsilon$. Define a correspondence between $\Upsilon$ and $J$ via

$$Z = \{(P, \gamma) \in J \times \Upsilon \mid P \in l_\gamma\},$$

where $l_\gamma$ is the line on $\Xi$ tangent to $\Upsilon$ at $\gamma$. Clearly, $Z$ is a curve of bidegree $(2, 2)$ on $J \times \Upsilon \cong \mathbb{P}^1 \times \mathbb{P}^1$.

The curve $Z$ admits a natural interpretation as a subvariety of the variety $\text{Fl}(\mathbb{P}^2) \subset \mathbb{P}^2 \times \mathbb{P}^{2\vee}$ of full flags on $\mathbb{P}^2$. Under this interpretation one has $p_1(Z) = J$ and $p_2(Z) = \Upsilon$, where $\Upsilon \subset \mathbb{P}^{2\vee}$ is the dual conic and $p_1, p_2$ are the canonical projections of the product $\mathbb{P}^2 \times \mathbb{P}^{2\vee}$ to the factors. Moreover, $Z = p_1^{-1}(J) \cap p_2^{-1}(\Upsilon)$. Note that $p_2^{-1}(\Upsilon) \cong \mathbb{P}^1 \times \mathbb{P}^1$. The restriction $\pi := p_1|_{p_2^{-1}(\Upsilon)} : p_2^{-1}(\Upsilon) \to \mathbb{P}^2$ is a double cover branched along $\Upsilon$.

Consider a generically one-to-one map $\delta : J \to \Upsilon$,

$$P \in J \mapsto \Lambda_P \mapsto \Pi_P \mapsto l_P = \Xi \cap \Pi_P \mapsto \gamma = l_P \cap \Upsilon \in \Upsilon,$$

where $\Pi_P \subset R$ is the plane containing the ruling $\Lambda_P \subset F$. The graph of $\delta$ in $J \times \Upsilon$ is a component of $Z$. Therefore, $Z$ splits into two components $Z_1$ and $Z_2$, which are curves of bidegree $(1, 1)$ on $\mathbb{P}^1 \times \mathbb{P}^1$. Also the preimage $\pi^{-1}(J) = p_1^{-1}(J) \cap p_2^{-1}(\Upsilon)$ splits into two irreducible components $Z_1$ and $Z_2$. This is possible only if $J$ touches the branch locus $\Upsilon$ with even multiplicities, hence only in the cases (ii) and (iii) in 4.3. \hfill \Box

4.5. Following [KR13] we call 'cubic scrolls' both smooth cubic scrolls and cones over rational twisted cubic curves. The latter cones in $V_{18}$ will be called 'cubic cones' for short. This does not lead to a confusion. Indeed, since $V$ is an intersection of quadrics ([Isk77, Lem. 2.10]), $V$ does not contain any cubic surface $F$ with $\langle F \rangle \cong \mathbb{P}^3$.

From Propositions 3.1, 4.2, and 4.4 we deduce the following corollaries.

4.5.1. **Corollary.** The cubic scroll $S \subset V$ in diagram (3.1.1) is a cubic cone if and only if $V$ is smooth, $F \subset R$, $F \cong \mathbb{F}_1$, and the exceptional section $J = F \cap \Xi$ of $F \to \mathbb{P}^1$ is a smooth conic touching $\Upsilon$ with even multiplicities. There are three types 4.3 (i), 4.3 (ii) and 4.3 (iii) of such pairs $(F, J)$.

The next corollary will be used in the proof of Theorem 1.1 cf. also Lemma 9.2.

4.5.2. **Corollary.** For any cubic cone $S \subset V$ there is a unique hyperplane section $A$ of $V$ with $\text{Sing}(A) = S$ such that $V \setminus A \cong \mathbb{C}^4$.

**Proof.** By Proposition 3.1 $V$ and $S$ can be included in diagram (3.1.1), where $A$ is a hyperplane section of $V$ with $\text{Sing}(A) = S$. Such a divisor $A$ is unique being the image of the $\eta$-exceptional divisor $\tilde{A} \sim L^* - 2\tilde{B}$, see (3.1.8). Since $V$ is smooth and $S$ is singular, the cases (d) and (c)(ii) in Propositions 4.2 and 4.4, respectively, are excluded. So, there is a unique two-dimensional fiber $\tilde{Y}$ of $\xi$ with $\text{Sing} S = \xi(\tilde{Y})$, and we are in case (c)(i) of Proposition 4.4. Due to this proposition, we have

$$\eta(\tilde{Y}) = \Xi, \quad B = R, \quad \text{and so,} \quad F \subset R.$$

As follows from diagram (3.1.1), there are isomorphisms

$$V \setminus A \cong \tilde{W} \setminus (\tilde{A} \cup \tilde{R}) \cong W \setminus R \cong \mathbb{C}^4,$$
see Corollary 2.2.2. Thus, the pair \((V, A)\) yields a compactification of \(\mathbb{C}^4\) into a smooth Fano-Mukai fourfold \(V\) of genus 10.

Finally, we introduce the following notion.

4.6. Definition. We say that the pairs \((W, F)\) and \((V, S)\) are linked if they fit in diagram (3.1.1) and verify the conditions of one of Propositions 4.2 and 4.4.

In the sequel we deal only with linked pairs that verify the conditions of Corollary 4.5.1.

5. Automorphisms of \(W_5\)

Let us introduce the following notation.

5.1. Notation. Consider the linear space \(M_3 = S^3 \mathbb{C}^2\) of binary cubic forms \(f_3(x, y)\) and the projectivization \(\mathbb{P}(M_3 \oplus \mathbb{C}) \cong \mathbb{P}^4\). A point of \(\mathbb{P}^4\) can be viewed as a class \([(f_3, c)]\), where \(f_3 \in M_3\), \(c \in \mathbb{C}\), and \((f_3, c) \neq (0, 0)\). Up to automorphisms of \(\mathbb{P}^4\), a twisted cubic curve \(\Gamma \subset \mathbb{P}^4\) can be represented as the projectivization

\[
\Gamma = \mathbb{P}\left(\{(f_3, 0) \in M_3 \oplus \mathbb{C} \mid (0, 0) \in \mathbb{P}(M_3 \oplus \mathbb{C})\}\right) \subset \mathbb{P}(M_3 \oplus \{0\}) \subset \mathbb{P}(M_3 \oplus \mathbb{C}).
\]

So, the linear span \(\langle \Gamma \rangle\) is identified with the linear subspace \(\{c = 0\}\) in \(\mathbb{P}^4\), and the point

\[
P = \mathbb{P}(\{0\} \oplus \mathbb{C}) \in \mathbb{P}^4 \setminus \langle \Gamma \rangle\]

with the class \([(0, 1)]\).

The standard representation of \(GL_2(\mathbb{C})\) on \(\mathbb{C}^2\) induces an irreducible representation of \(GL_2(\mathbb{C})\) on \(M_3\), \((g, f_3) \mapsto f_3 \circ g^{-1}\). Adding the trivial one-dimensional representation yields a representation of \(GL_2(\mathbb{C})\) on \(M_3 \oplus \mathbb{C}\) and, in turn, a \(GL_2(\mathbb{C})\)-action on \(\mathbb{P}^4\), which fixes the point \(P\) and stabilizes the twisted cubic \(\Gamma\).

Let further \(\Delta \subset \mathbb{P}(M_3 \oplus \mathbb{C})\) be the closure of the locus of points \([(f_3, c)] \in \mathbb{P}(M_3 \oplus \mathbb{C})\), whose binary cubic form \(f_3\) has a multiple factor.

5.2. Remarks. 1. Clearly, \(\Delta\) is the cone over \(\Delta_0 := \Delta \cap \mathbb{P}(M_3)\) with vertex \(P\). The surface \(\Delta_0\) in \(\mathbb{P}^3 = \mathbb{P}(M_3)\) is the zero divisor of the discriminant \(\text{discr}(f_3)\). This quartic surface has cuspidal singularities along \(\Gamma\) and is smooth outside \(\Gamma\). In fact, \(\Delta_0\) is the tangent developable surface of \(\Gamma\), that is, the closure of the union of the tangent lines to \(\Gamma\). The cone \(N\) over \(\Gamma\) with vertex \(P\) is the singular locus of \(\Delta\).
2. The \(GL_2(\mathbb{C})\)-action on \(\mathbb{P}(M_3 \oplus \mathbb{C}) = \mathbb{P}^4\) has exactly 7 orbits, namely,

\[
\{P\}, \quad \Gamma, \quad \Delta_0 \setminus \Gamma, \quad \mathbb{P}(M_3) \setminus \Delta_0, \quad N \setminus (\Gamma \cup \{P\}), \quad \Delta \setminus (N \cup \Delta_0), \quad \mathbb{P}(M_3 \oplus \mathbb{C}) \setminus (\mathbb{P}(M_3) \cup \Delta).
\]

Thus, \(P\) is the unique fixed point of the \(GL_2(\mathbb{C})\)-action on \(\mathbb{P}^4\), while the last orbit in this list is the open orbit.
3. The center \(\Gamma\) of the blowup \(\varphi\) in (2.2.1) is invariant under the \(GL_2(\mathbb{C})\)-action on \(\mathbb{P}^4\) defined in 5.1. Hence this action lifts to \(\hat{W}\) stabilizing the exceptional divisors \(\hat{R}\) and \(\hat{E}\) of \(\varphi\) and \(\rho\), respectively, see Proposition 2.2. The \(GL_2(\mathbb{C})\)-action on \(\hat{W}\) induces an effective \(GL_2(\mathbb{C})\)-action on \(W\) via the contraction \(\rho : \hat{W} \to W\) of the \(GL_2(\mathbb{C})\)-invariant divisor \(\hat{E}\). Then the birational linear projection \(\phi : W \dashrightarrow \mathbb{P}^4\) with center \(\Xi\) along with diagram (2.2.1) are \(GL_2(\mathbb{C})\)-equivariant. The \(GL_2(\mathbb{C})\)-action on \(W\) extends to a linear \(GL_2(\mathbb{C})\)-action on \(\mathbb{P}^7 \supset W\). The latter action has \(W\) as an orbit closure, stabilizes \(R, \Xi, \) and \(\Upsilon\), and induces a linear \(GL_2(\mathbb{C})\)-action on \(\mathbb{C}^4 = \mathbb{P}^4 \setminus \mathbb{P}^3 \cong W \setminus R\), see (2.2.3), and a standard \(\text{PGL}_2(\mathbb{C})\)-action on \(\Xi\) with a unique closed orbit \(\Upsilon\).

Using 5.1 – 5.2 we describe in 5.3 – 5.6 the automorphism group \(\text{Aut}(W)\) and its action on \(W\).
5.3. **Lemma.** Let $\Gamma \subset \mathbb{P}^4$ be a rational twisted cubic curve, and $P \in \mathbb{P}^4 \setminus \langle \Gamma \rangle$ be a point. Then there are isomorphisms

\[(5.3.1) \quad \text{Aut}(\mathbb{P}^4, \Gamma, P) \cong \text{GL}_2(\mathbb{C})/\mu_3 \cong \text{GL}_2(\mathbb{C}),\]

where the cyclic group $\mu_3$ of order 3 is realized as the subgroup of scalar matrices $\{\zeta \cdot \text{id}_{\mathbb{C}^2}\}$ with $\zeta^3 = 1$. The stabilizer in $\text{Aut}(\mathbb{P}^4, \Gamma, P)$ of a general point $Q \in \mathbb{P}^4$ is trivial.

**Proof.** We leave to the reader to check the fact that the endomorphism $\text{GL}_2(\mathbb{C}) \to \text{GL}_2(\mathbb{C})$, $A \mapsto (\det A) \cdot A$, yields the second isomorphism in (5.3.1). Up to an automorphism of $\mathbb{P}^4$ one may suppose that the triple $(\mathbb{P}^4, \Gamma, P)$ is chosen as in 5.1. The $\text{GL}_2(\mathbb{C})$-action on $\mathbb{P}^4$ introduced in 5.1 fixes $P$ and stabilizes $\Gamma$. The scalar matrices $\zeta \cdot \text{id} \in \text{GL}_2(\mathbb{C})$ with $\zeta^3 = 1$, and only these, act identically on $\mathbb{P}^4$. This gives an embedding $\text{GL}_2(\mathbb{C})/\mu_3 \hookrightarrow \text{Aut}(\mathbb{P}^4, \Gamma, P)$. In fact, this embedding is an isomorphism. The latter follows by comparing the exact sequences

\[
1 \to \mathbb{G}_m \to \text{Aut}(\mathbb{P}^4, \Gamma, P) \to \text{Aut}(\Gamma) = \text{PGL}_2(\mathbb{C}) \to 1
\]

and

\[
1 \to \mathbb{G}_m = z(\text{GL}_2(\mathbb{C})/\mu_3) \to \text{Aut}(\mathbb{P}^4, \Gamma, P) \to \text{Aut}(\Gamma) = \text{PGL}_2(\mathbb{C}) \to 1,
\]

where $z(G)$ stands for the center of a group $G$. The last assertion is immediate. \hfill \Box

We use below the following fact.

5.4. **Lemma.** (Piontkowski-Van-de-Ven \cite[Thm. 6.6]{PdV99}) There is an exact sequence

\[(5.4.1) \quad 1 \to (\mathbb{G}_a)^4 \rtimes \mathbb{G}_m \to \text{Aut}(W) \to \text{Aut}(\Upsilon) = \text{PGL}_2(\mathbb{C}) \to 1.
\]

Therefore, $\text{Aut}(W)$ is a connected algebraic group.

In the next proposition we describe the algebraic Levi decomposition of $\text{Aut}(W)$.

5.5. **Proposition.**

(a) Let $R_u = R_u(\text{Aut}(W))$ be the unipotent radical of $\text{Aut}(W)$ and $L$ its reductive Levi subgroup. Then $R_u \cong (\mathbb{G}_a)^4$ and $L \cong \text{GL}_2(\mathbb{C})$. Therefore,

\[(5.5.1) \quad \text{Aut}(W) = R_u \rtimes L \cong (\mathbb{G}_a)^4 \rtimes \text{GL}_2(\mathbb{C}).\]

Furthermore, a $\text{GL}_2(\mathbb{C})$-subgroup of $\text{Aut}(W)$ is unique up to conjugation.

(b) An isomorphism $\text{Aut}(W) \xrightarrow{\cong} \text{Aut}(\mathbb{P}^4, \Gamma)$ as in Corollary 2.2.4 sends $R_u$ onto the vector group $\text{Transl}(\mathbb{C}^4) \cong (\mathbb{G}_a)^4$ of the vector space $\mathbb{C}^4 = \mathbb{P}^4 \setminus \langle \Gamma \rangle$, and the reductive Levi subgroup $L$ onto the stabilizer $\text{Aut}(\mathbb{P}^4, \Gamma, P) \cong \text{GL}_2(\mathbb{C})$ of a point $P \in \mathbb{P}^4 \setminus \langle \Gamma \rangle$.

(c) The set of reductive Levi subgroups of $\text{Aut}(W)$ coincides with the set of stabilizers of points in $W \setminus R$. Any Levi subgroup $L$ of $\text{Aut}(W)$ has a unique fixed point in $W \setminus R$, which is the unique fixed point in $W \setminus R$ of its center $z(L)$, and acts on $W \setminus R$ with a principal open orbit.

**Proof.** (a) It follows from (5.4.1) that $R_u$ coincides with the $(\mathbb{G}_a)^4$-subgroup of $\text{Aut}(W)$. The effective $\text{GL}_2(\mathbb{C})$-action on $W$ as in Remark 5.2.3 defines a $\text{GL}_2(\mathbb{C})$-subgroup, say, $L_0 \subset \text{Aut}(W)$ with $L_0 \cap R_u = \{e\}$. Thus, $L_0 \cong \text{GL}_2(\mathbb{C})$ surjects onto $\text{PGL}_2(\mathbb{C})$ with kernel being the center $z(L_0) \cong \mathbb{G}_m$. Letting $L = L_0$ we obtain (5.5.1). The last assertion of (a) follows from the Levi-Maltsev-Mostow Theorem, see, e.g., \cite{Mo56} or \cite{Hoh71}. \hfill \Box
The isomorphism Aut(W) \cong Aut(\mathbb{P}^4, \Gamma) of Corollary 2.2.4 induces an isomorphism of Levi decompositions
\[ R_u \ltimes L \cong (G_a)^4 \rtimes GL_2(\mathbb{C}) \cong \text{Transl}(\mathbb{C}^4) \rtimes \text{Aut}(\mathbb{P}^4, \Gamma, P). \]

Now (b) is straightforward.

(c) By virtue of (b), \( W \setminus R \) is the open orbit of \( R_u \) and of \( \text{Aut}(W) \). Furthermore, the unipotent radical \( R_u \cong (G_a)^4 \) acts freely (by translations) on \( W \setminus R \cong \mathbb{P}^4 \setminus \langle \Gamma \rangle \cong \mathbb{C}^4 \). The Levi subgroup \( L \cong GL_2(\mathbb{C}) \) goes onto the stabilizer \( \text{Aut}(\mathbb{P}^4, \Gamma, P) \) of a point \( P \in \mathbb{C}^4 = \mathbb{P}^4 \setminus \langle \Gamma \rangle \), hence coincides with the stabilizer of the corresponding point in \( W \setminus R \). All such stabilizers are conjugated via the action of \( R_u \cong \text{Transl}(\mathbb{C}^4) \) on \( W \setminus R \cong \mathbb{C}^4 \). The last assertion is straightforward by virtue of Lemma 5.3.

5.5.2. **Remarks.** 1. Under the identification of the triple \((\mathbb{P}^4, \Gamma, P)\) with \((\mathbb{P}(M_3 \oplus \mathbb{C}), \Gamma, P)\), see 5.1 the \( GL_2(\mathbb{C})\)-subgroup \( \text{Aut}(\mathbb{P}^4, \Gamma, P) \subset \text{Aut}(\mathbb{P}^4, \Gamma) \) is defined as in 5.1 and 5.3. The \( GL_2(\mathbb{C})\)-action by conjugation on \( R_u = \text{Transl}(\mathbb{C}^4) \cong (G_a)^4 \) is then given via the standard irreducible representation of \( GL_2(\mathbb{C}) \) on the vector space \( M_3 \cong \mathbb{C}^4 \) of binary cubic forms. This determines the structure of \( \text{Aut}(W) \) as a semidirect product. Identifying \( R_u = \text{Transl}(\mathbb{C}^4) \) with the additive group \((M_3, +)\), the action of \( \text{Aut}(W) \cong \text{Aut}(\mathbb{P}^4, \Gamma) \) on \( \mathbb{P}^4 = \mathbb{P}(M_3 \oplus \mathbb{C}) \) lifts to the action on \( M_3 \oplus \mathbb{C} \) via
\[(M_3, +) \rtimes GL_2(\mathbb{C}) \ni (h, g) : (f, z) \mapsto (f \circ g^{-1} + zh, z) \in M_3 \oplus \mathbb{C},\]
where \( g \) is defined modulo multiplication by a cubic root of unity.

2. A torus \( T \) in a connected algebraic group \( G \) is called regular if the centralizer \( C_G(T) \) is solvable, and singular otherwise. A torus \( T \subset G \) is regular if and only if it is contained just in a finite set of Borel subgroups of \( G \). The maximal tori are regular; see, e.g., [Hum75, Ch. IX, §24]. By the preceding remark we have \( C_{\text{Aut}(W)}(z(L)) = L \) and \( C_{\text{Aut}(W)}(R_u) = R_u \). Hence the center \( z(L) \) of a Levi subgroup \( L \subset \text{Aut}(W) \) uniquely determines \( L \) and is a singular torus. Using (5.5.1) it is easily seen that, conversely, any singular torus in \( \text{Aut}(W) \) is the center \( z(L) \) of a Levi subgroup \( L \subset \text{Aut}(W) \). Any two singular tori in \( \text{Aut}(W) \) are conjugated.

3. The orbits of the \( \text{Aut}(\mathbb{P}^4, \Gamma) \)-action on \( \mathbb{P}^4 \) are (see Remark 5.2.2)
\[(5.5.4) \quad \Gamma, \quad \Delta_0 \setminus \Gamma, \quad \langle \Gamma \rangle \setminus \Delta_0, \quad \mathbb{P}^4 \setminus \langle \Gamma \rangle.\]
Due to [PdV99, Thm. 6.9], the \( \text{Aut}(W) \)-action on \( W \) has as well exactly four orbits of dimensions 1, 2, 3, and 4, respectively. These orbits are:
\[(5.5.5) \quad \Upsilon, \quad \Xi \setminus \Upsilon, \quad R \setminus \Xi, \quad W \setminus R.\]

Next we examine the \( \text{Aut}(W) \)-action on \( W \).

5.6. **Proposition.** In the notation as before the following hold.

(a) The triple \((R, \Xi, \Upsilon)\) is \( \text{Aut}(W) \)-invariant.
(b) \( \text{Aut}(W) \) acts effectively on \( R \).
(c) The unipotent radical \( R_u \) of \( \text{Aut}(W) \) acts freely on \( W \setminus R \) and fixes \( \Xi \) pointwise.
(d) Let \( T = z(L) \) be a singular torus in \( \text{Aut}(W) \), where \( L \) is a reductive Levi subgroup. Then the fixed point locus \( W^T \) is \( L \)-invariant and is a disjoint union
\[ W^T = \{Q\} \cup \Psi \cup \Xi, \]
where \( Q \in W \setminus R \) is an isolated point and \( \Psi \subset R \) is a twisted cubic curve such that \( \langle \Psi \rangle \cap \Xi = \emptyset \) and \( \Psi \) meets any plane \( \Pi_\gamma, \gamma \in \Upsilon \), in a single point \( Q_\gamma \in \Pi_\gamma \).

**Proof.** Statement (a) is immediate from 2.1.2. To show (b) let \( K \) be the kernel of the restriction homomorphism \( \text{Aut}(W) \to \text{Aut}(R), \alpha \mapsto \alpha|_R \). The action of \( \text{Aut}(\mathbb{P}^4, \Gamma) \) induces a representation of this group by automorphisms of the normal bundle \( \mathcal{N}_{\Gamma/\mathbb{P}^4} \) and \( \hat{\mathcal{R}} \cong \mathbb{P}(\mathcal{N}_{\Gamma/\mathbb{P}^4}) \). The unipotent radical \( \text{Transl}(\mathbb{C}^4) \) of \( \text{Aut}(\mathbb{P}^4, \Gamma) \) acts trivially on the base \( \Gamma \). Its action on the total space \( \hat{\mathcal{R}} \) induces the \( R_u \)-action on \( R \), see Lemma 2.3.(a),(b). The latter action is effective if and only if the former is.

5.6.1. **Claim.** The induced representation of \( \text{Transl}(\mathbb{C}^4) \cong (\mathbb{G}_a)^4 \) on the normal bundle \( \mathcal{N}_{\Gamma/\mathbb{P}^4} \) is faithful.

**Proof of Claim** 5.6.1. We use Notation 5.1. Let \( \pi : (M_3 \oplus \mathbb{C}) \setminus \{0\} \to \mathbb{P}(M_3 \oplus \mathbb{C}) \) be the canonical projection, and let \( \text{Cone}(\Gamma) = \pi^{-1}(\Gamma) \) be the affine cone over \( \Gamma \) in \( (M_3 \oplus \mathbb{C}) \setminus \{0\} \). The normal bundle of \( \text{Cone}(\Gamma) \) in \( M_3 \oplus \mathbb{C} \) is the pullback \( \pi^*(\mathcal{N}_{\Gamma/\mathbb{P}^4}) \). The induced representation of \( \text{Transl}(\mathbb{C}^4) \cong (\mathbb{G}_a)^4 \) on the normal bundle \( \mathcal{N}_{\Gamma/\mathbb{P}^4} \) is faithful if and only if \( (M_3, +) \cong \text{Transl}(\mathbb{C}^4) \) acts effectively on \( \mathcal{N}_{\text{Cone}(\Gamma)}/(M_3 \oplus \mathbb{C}) \).

An element \( g \in (M_3, +) \) acts on \( M_3 \oplus \mathbb{C} \) linearly via

\[
g.(f, z) = (f + zg, z) \quad \forall (f, z) \in M_3 \oplus \mathbb{C}.
\]

It fixes \( \text{Cone}(\Gamma) \) pointwise and acts trivially on the tangent space \( T_{(f,0)} \text{Cone}(\Gamma) \). The induced action on the tangent space \( T_{(f,0)}(M_3 \oplus \mathbb{C}) \cong M_3 \oplus \mathbb{C} \) is given by the same formula

\[
dg.(u, v) = (u + vg, v) \quad \forall (u, v) \in M_3 \oplus \mathbb{C}.
\]

Fix a point \( (f, 0) = ((\alpha x + \beta y)^3, 0) \in \text{Cone}(\Gamma) \). The \( g \)-action on the normal space

\[
\mathcal{N}_{\text{Cone}(\Gamma)/(M_3 \oplus \mathbb{C}), (f, 0)} = T_{(f,0)}(M_3 \oplus \mathbb{C})/T_{(f,0)} \text{Cone}(\Gamma)
\]

is trivial if and only if \( g \in T_{(f,0)} \text{Cone}(\Gamma) \). However, one has

\[
\bigcap_{(f,0) \in \text{Cone}(\Gamma)} T_{(f,0)} \text{Cone}(\Gamma) \subset T_{(x^3,0)} \text{Cone}(\Gamma) \cap T_{(y^3,0)} \text{Cone}(\Gamma) = \{0\}.
\]

It follows that the only element of \( (M_3, +) \) acting trivially on \( \mathcal{N}_{\text{Cone}(\Gamma)/(M_3 \oplus \mathbb{C})} \) is \( g = 0 \). \( \square \)

5.6.4. **Corollary.** \( K \cap R_u = \{1\} \).

Therefore, \( \mathcal{N}_{\Gamma/\mathbb{P}^3} \) gives an embedding of \( K \) in \( \text{GL}_2(\mathbb{C}) = \text{Aut}(W)/R_u \). Since \( K \) is normal, \( K \) is contained in \( z(\text{GL}_2(\mathbb{C})) \cong \mathbb{G}_m \). The latter singular torus acts on \( \Upsilon \cong \mathbb{P}^1 \) with a fixed point, say, \( Q \). The tangent representation of the reductive group \( \mathbb{G}_m \) on \( T_Q W \) is faithful. On the other hand, \( Q \in \Xi = \text{Sing } R \), hence \( T_Q W \) is the Zariski tangent space of \( R \) at \( Q \). Thus, \( K \) acts identically on \( T_Q W \), and so, \( K = \{1\} \). This proves (b).

The first assertion of (c) follows from the correspondence of Proposition 5.3.(b). The second follows from the construction of exact sequence (5.4.1) in [PdV99, Thm. 6.6].

To prove (d) we chose coordinates in \( \mathbb{P}^4 \) so that the induced action of \( z(L) \) on \( \mathbb{P}^4 \) is given by the diagonal matrix \( \text{diag}(1,1,1,1,\lambda) \), \( \lambda \in \mathbb{C}^* \); cf. the proof of (b). This action is identical on \( (\Gamma) \cong \mathbb{P}^3 \), hence also on the normal bundle \( \mathcal{N}_{\Gamma/\mathbb{P}^3} \). However, it is effective on the normal bundle \( \mathcal{N}_{\Gamma/\mathbb{P}^4} \). This allows to decompose \( \mathcal{N}_{\Gamma/\mathbb{P}^4} \) into a direct sum of proper subbundles of ranks 2 and 1, respectively. The rank two subbundle projects in
\[ \hat{R} \cong \mathbb{P}(\mathcal{N}_{\gamma}/\mathcal{P}) \] to a \( \mathbb{P}^1 \)-subbundle, and the rank one projects to a disjoint section, say, \( \hat{\Psi} \).

In each plane \( \hat{\Pi}_\gamma, \gamma \in \Gamma \), this gives a line \( \hat{l}_\gamma \) of fixed points of \( z(L) \) and an isolated fixed point \( \hat{\Psi} \cap \hat{\Pi}_\gamma \). The image of \( \hat{l}_\gamma \) in \( \Pi_\gamma \) is the line \( l_\gamma = \Pi_\gamma \cap \Xi \). The image \( \Psi \subset R \) of the curve \( \hat{\Psi} \subset \hat{R} \) is a second irreducible component of the fixed point locus of \( z(L)|_R \). This curve \( \Psi \) is disjoint with \( \Xi \) and meets each plane \( \Pi_\gamma \) in a point. The linear projection \( \phi : \mathbb{P}^7 \dashrightarrow \mathbb{P}^4 \) with center \( \Xi \) as in (2.2.1) sends \( \Psi \) isomorphically onto the rational twisted cubic curve \( \Gamma \). The linear span \( \langle \Psi \rangle \) is sent by \( \phi \) onto \( \langle \Gamma \rangle \cong \mathbb{P}^3 \). It follows that \( \Psi \) is a rational twisted cubic curve, and \( \langle \Psi \rangle \cap \Xi = \emptyset \). \( \square \)

In the sequel we need the following simple lemma.

5.7. Lemma. Let \( \mathcal{H} \) be a subgroup of \( \text{Aut}(W) \) isomorphic either to \( \text{GL}_2(\mathbb{C}) \), or to the 2-torus \( (\mathbb{G}_m)^2 \). Then there is a unique Levi subgroup \( L \) of \( \text{Aut}(W) \) such that \( z(L) \subset \mathcal{H} \subset L \).

Proof. In the case \( \mathcal{H} \cong \text{GL}_2(\mathbb{C}) \) the assertion follows from Proposition 5.3(a). If \( \mathcal{H} \cong (\mathbb{G}_m)^2 \), then \( \mathcal{H} \) is a maximal torus in \( \text{Aut}(W) \). Being reductive, \( \mathcal{H} \) is contained in a Levi subgroup \( L \) of \( \text{Aut}(W) \) and contains its center \( z(L) \). Up to conjugation, one may suppose that \( L \) is the standard \( \text{GL}_2(\mathbb{C}) \)-subgroup of \( \text{Aut}(W) \) \( \hookrightarrow \text{Aff}(\mathbb{C}^4) \) as in 5.1 and \( \mathcal{H} \) is the diagonal torus. That is, \( W \setminus R \cong \mathbb{P}^4 \setminus \mathbb{P}^3 = \mathbb{C}^4 \) is realized as the vector space \( M_3 \) of binary cubic forms, where \( R_2 \) acts by translations and \( \text{GL}_2(\mathbb{C}) \) acts via \( h \cdot f = f \circ h^{-1} \) for any \( h \in \text{GL}_2(\mathbb{C}) \) and \( f \in M_3 \). In particular, \( \mathcal{H} \) acts via

\[
(\lambda, \mu)(a_0, a_1, a_2, a_3) = (\lambda^{-3}a_0, \lambda^{-2}a_1^{-1}a_1, \lambda^{-1}a_2^{-2}a_2, \mu^{-3}a_3).
\]

Hence \( \mathcal{H} \) has a unique fixed point, say, \( P \), which is the unique fixed point of \( L \) in \( W \setminus R \). This point determines \( L \) uniquely, see Proposition 5.3(c). \( \square \)

6. Quincet scrolls in \( W_5 \) and their stabilizers

In the next proposition we construct a special quintic scroll \( F \cong \mathbb{F}_1 \) in \( W \) contained in \( R \) and acted upon by \( \text{GL}_2(\mathbb{C}) \).

6.1. Proposition. With the notation as in 5.1 the following hold.

(a) Let \( \hat{\Delta} \) be the proper transform of \( \Delta \) in \( \hat{W} \). Then the image \( \rho(\hat{\Delta}) \subset W \) is cut out on \( W \) by a quadric.

(b) The reduced intersection \( F = (\rho(\hat{\Delta}) \cap R)_{\text{red}} \subset \mathbb{P}^6 \) is a smooth quintic scroll isomorphic to \( \mathbb{F}_1 \) and invariant under an effective \( \text{GL}_2(\mathbb{C}) \)-action on \( W \).

(c) \( F \cap \Xi = \Upsilon \) and \( \Xi \) is the only plane in \( W \) meeting \( F \cong \mathbb{F}_1 \) along a conic.

Proof. (a) Since \( \Delta \) is singular along \( \Gamma \), we have \( \hat{\Delta} \sim 4L^* - 2\hat{R} \sim 2H^* \) on \( \hat{W} \), see (2.3.1). Hence \( \rho(\hat{\Delta}) \) is cut out on \( W \) by a quadric.

(b) First we construct a special quintic scroll \( F \subset R \), and then we show that it coincides with \( (\rho(\hat{\Delta}) \cap R)_{\text{red}} \). Let \( N = \text{Cone}(\Gamma, P) \subset \mathbb{P}^4 \) be as in Remark 5.2.1 and let \( \hat{\Gamma} = \hat{N} \cap \hat{R} \) be as in Lemma 2.4. By Lemma 2.3 the normalization morphism \( \rho|_{\hat{R}} : \hat{R} \rightarrow R \) sends each fiber \( \hat{\Pi}_\gamma \) of the \( \text{P}^2 \)-bundle \( \varphi|_{\hat{R}} : \hat{R} \rightarrow \Gamma \) isomorphically onto a plane \( \Pi_\gamma \subset R = \bigcup_{\gamma \in \Gamma} \Pi_\gamma \).

The curve \( \hat{\Gamma} \subset \hat{R} \) is a section of \( \varphi|_{\hat{R}} \) meeting any plane \( \hat{\Pi}_\gamma \) in a single point, say, \( \hat{p}_\gamma \). Set \( \Psi := \rho(\hat{\Gamma}) \). By Lemma 2.4 one has \( \langle \Psi \rangle \cap \Xi = \emptyset \) and \( \Psi \) is a twisted cubic curve. Hence \( p_\gamma := \rho(\hat{p}_\gamma) \in \Pi_\gamma \setminus \Xi \). Letting \( \{q_\gamma\} = \Pi_\gamma \cap \Upsilon \), consider the one-parameter family of lines
$\Lambda_\gamma \subset \Pi_\gamma \subset R$ joining $p_\gamma$ and $q_\gamma$. Thus, any $\Lambda_\gamma$ meets the conic $\Upsilon \subset \Xi$ and the twisted cubic $\Psi \subset R \setminus \Xi$. Since $\langle \Psi \rangle \cap \langle \Upsilon \rangle = \emptyset$, the join

\begin{equation}
F = \bigcup_{\gamma \in \Upsilon} \Lambda_\gamma
\end{equation}

of corresponding points of $\Upsilon$ and $\Psi$ is a rational normal quintic scroll in $R$ ([GH94, Ch. 4, §3]).

Let us show that $F \subset (\rho(\hat{\Delta}) \cap R)_{\text{red}}$ for $F$ as in (6.1.1). Due to our choice of $\hat{\Delta}$ we have $\hat{\Delta} \cap \hat{R} \supset \hat{N} \cap \hat{R} = \hat{\Gamma}$. So, $(\rho(\hat{\Delta}) \cap R)_{\text{red}} \supset \Psi$. On the other hand, $(\rho(\hat{\Delta}) \cap \Xi)_{\text{red}}$ is a $\GL_2(\mathbb{C})$-invariant curve. Since $\Upsilon$ is the only $\GL_2(\mathbb{C})$-invariant curve in $\Xi$, one has $\Upsilon = (\rho(\hat{\Delta}) \cap \Xi)_{\text{red}} \subset (\rho(\hat{\Delta}) \cap R)_{\text{red}}$.

For any fiber $\hat{\Pi}_\gamma$ of $\varphi|_R : \hat{R} \to \Gamma$, where $\gamma \in \Gamma$, the intersection $\hat{\Pi}_\gamma \cap \hat{\Delta}$ is the projectivization of the tangent cone to $\Delta \cap \mathbb{P}^3$ at $\gamma$, where $\mathbb{P}^3 \subset \mathbb{P}^4$ is a general hyperplane passing through $\gamma$. Since the singularity of $\Delta \cap \mathbb{P}^3$ at $\gamma$ looks locally like a product of a simple cusp singularity by a smooth curve germ, this projectivization is a line $\hat{\Lambda}_\gamma$ in $\hat{\Pi}_\gamma \cong \mathbb{P}^2$. The image $\Lambda_\gamma = \rho(\hat{\Lambda}_\gamma)$ is a line in $W$ passing through the points $p_\gamma \in \Psi \cap \Pi_\gamma$ and $q_\gamma \in \Pi_\gamma \cap \Upsilon$. Thus, $F \subset (\rho(\hat{\Delta}) \cap R)_{\text{red}}$. On the other hand, $\deg(\rho(\hat{\Delta}) \cap R) = 10$ and $\deg F = 5$. Furthermore, $\Delta$ has cuspidal singularities along $\Gamma = \varphi(\hat{R})$, hence $\hat{R}$ is tangent to $\hat{\Delta}$ along $(\hat{\Delta} \cap \hat{R})_{\text{red}}$. Therefore, one has $F = (\rho(\hat{\Delta}) \cap R)_{\text{red}}$.

The hyperplane section $R$ is invariant under the $\Aut(W)$-action, and $\rho(\hat{\Delta}) \subset W$ is invariant under the $\GL_2(\mathbb{C})$-action on $W$ as in Remark 5.2.3. Hence the quintic scroll $F = (\rho(\hat{\Delta}) \cap R)_{\text{red}} \subset W$ is $\GL_2(\mathbb{C})$-invariant as well.

Indeed, by construction, $F \cap \Xi = \Upsilon$ and any plane $\Pi_\gamma$ meets $F$ along a ruling $\Lambda_\gamma$ and is not tangent to $F$ along $\Lambda_\gamma$. □

6.2. Lemma. Let $J \subset \Xi$, $J \neq \Upsilon$, be a smooth conic meeting $\Upsilon$ with even multiplicities. Then the following hold.

(a) The group $\Aut(\Xi, \Upsilon, J)$ of automorphisms of $\Xi$ which leave $\Upsilon$ and $J$ invariant is given by the following table:

| $J$     | $\Aut(\Xi, \Upsilon, J)$ |
|---------|---------------------------|
| 4.3(i)  | $\Aut(\Upsilon) \cong \PGL_2(\mathbb{C})$ |
| 4.3(ii) | $\mathbb{G}_a \rtimes (\mathbb{Z}/2\mathbb{Z})$ |
| 4.3(iii)| $\mathbb{G}_m \rtimes (\mathbb{Z}/2\mathbb{Z})$ |

(b) Up to the natural action of $\Aut(\Xi)$, there is a unique configuration $(\Upsilon, J)$ of type 4.3(ii), while the configurations of type 4.3(iii) form a one-parameter family.

Proof. [a] We leave aside the trivial case $J = \Upsilon$. If $J \neq \Upsilon$, then the action of $\Aut^0(\Xi, \Upsilon, J)$ leaves invariant $\Upsilon$, $J$, and the degenerate members of the pencil of conics $\mathcal{P}$ generated by $\Upsilon$ and $J$. Hence $\Aut^0(\Xi, \Upsilon, J)$ acts identically on the base $\mathbb{P}^1$ of $\mathcal{P}$. So, $\Aut^0(\Xi, \Upsilon, J)$ leaves invariant each member of $\mathcal{P}$.

For $J$ of type 4.3(iii) in appropriate homogeneous coordinates $(x : y : z)$ in $\Xi \cong \mathbb{P}^2$ the general member $J_{(a:b)}$ of $\mathcal{P}$ can be given by equation $ax^2 + byz = 0$. The projective transformations fixing the common points of $J$ and $\Upsilon$ are of the form $(x : y : z) \mapsto (x : \lambda y : \lambda^{-1} z)$, where $\lambda \in \mathbb{C}^*$. Thus, $\Aut^0(\Xi, \Upsilon, J) \cong \mathbb{G}_m$. The group $\Aut(\Xi, \Upsilon, J)$ is
generated by $\text{Aut}^0(\Xi, Y, J)$ and the involution
\[ \kappa : (x : y : z) \mapsto (x : z : y) \]
that interchanges the two points of the intersection $Y \cap J$.

For $J$ of type $4.3(ii)$, the general member $J_{(a,b)}$ of $\mathcal{P}$ can be given by the equation $a(x^2 + yz) + bz^2 = 0$. Then
\[ \text{Aut}^0(\Xi, Y, J) = \{(x : y : z) \mapsto (x + ez : y + 2ex + e^2z : z) \mid e \in \mathbb{C}\} \cong \mathbb{G}_a, \]
while $\text{Aut}(\Xi, Y, J)$ is generated by $\text{Aut}^0(\Xi, Y, J)$ and the involution
\[ \kappa : (x : y : z) \mapsto (-x : y : z). \]
The proof of (b) results from elementary computations. We leave this to the reader. □

6.3. Proposition. Fix a nondegenerate conic $J \subset \Xi$ which touches $Y$ with even multiplicities, see Figure 4.3.1. Fix also a reductive Levi subgroup $L \subset \text{Aut}(W)$. Let an $L$-invariant twisted cubic curve $\Psi$ be the set of fixed points of $z(L)$ in $R \setminus \Xi$, see Proposition 5.6(d).

(a) There exists a $z(L)$-invariant rational normal quintic scroll $F \subset R$, $F \cong \mathbb{F}_1$, with exceptional section $J = F \cap \Xi$.

(b) If $J = Y$, then $F$ as in (a) is unique and can be transformed into the scroll $(\rho(\Delta) \cap R)_{\text{red}}$ as in Proposition 6.1 by an automorphism from $R_u$. If $J \neq Y$, then there are exactly two different scrolls $F_1$ and $F_2$ as in (a). Any such scroll contains $\Psi$.

(c) Furthermore, any $F$ as in (a) is invariant under the action on $W$ of the identity component $G = G(L, J)$ of the subgroup $L \cap g^{-1}(\text{Aut}(\Xi, Y, J))$, where $g : \text{Aut}(W) \to \text{Aut}(Y) = \text{Aut}(\Xi, Y)$ is the restriction homomorphism, see (5.4.1).

(d) For $J \neq Y$, consider the involution $\kappa \in \text{Aut}(\Xi, Y, J) \setminus \text{Aut}^0(\Xi, Y, J)$ (see the proof of Lemma 6.2[a]). Let $\tilde{\kappa} \in L \cap g^{-1}(\text{Aut}(\Xi, Y, J)) \subset \text{Aut}(W)$ be such that $g(\tilde{\kappa}) = \kappa$. Then $\kappa$ interchanges $F_1$ and $F_2$. In particular, $(W, F_1) \cong (W, F_2)$.

Proof. (a) Assume first that $J = Y$. By Proposition 5.6(d), any plane $\Pi_\gamma$, $\gamma \in Y$, meets $\Psi$ in a unique point, say, $p_\gamma$, and meets $Y$ tangentially in a unique point $q_\gamma$. Indeed, $l_\gamma := \Pi_\gamma \cap \Xi$ is the tangent line to $Y$ at $q_\gamma$. The lines $(p_\gamma, q_\gamma)$ sweep up a normal rational quintic scroll $F = F(\Psi)$. This scroll $F$ is $L$-invariant and meets the plane $\Xi$ along $Y$. In particular, $F$ is $z(L)$-invariant. If $L = L_0$ comes from the standard $GL_2(\mathbb{C})$-action on $\mathbb{P}(M_3 \oplus \mathbb{C})$ as in 5.1, then $F$ coincides with $(\rho(\Delta) \cap R)_{\text{red}}$, see the proof of Proposition 6.1. Otherwise, $L = gL_0g^{-1}$ for some $g \in R_u$ such that $g(F) = (\rho(\Delta) \cap R)_{\text{red}}$.

Let further $J \neq Y$. Consider the $2:1$ morphism
\[ \delta : J \to Y, \quad \Pi_\gamma \cap J \mapsto \Pi_\gamma \cap Y = \{q_\gamma\}. \]
By our assumption, the ramification indices of $\delta$ are even. Hence $\delta$ admits two distinct sections, say, $\sigma_1, \sigma_2 : Y \to J$, see the proof of Proposition 4.4(d). Letting $t_{\gamma,i} = \sigma_i(q_\gamma)$, consider the smooth quintic scroll $F_i = F_i(J, L) \cong \mathbb{F}_1$ formed by the lines $(p_\gamma, t_{\gamma,i}, \gamma \in Y)$. The conic $J \cap \Xi$ is a common exceptional section of $F_i \to \mathbb{P}^1$, $i = 1, 2$, and $\Psi$ is a common section with $\Psi^2 = 1$. Besides, the scrolls $F_1$ and $F_2$ have common rulings passing through the points of $J \cap Y$. Since $J$ and $\Psi$ are pointwise fixed under the $z(L)$-action (see Proposition 5.4[d]), each ruling of $F_i$ is $z(L)$-invariant and represents an orbit closure of $z(L)$. Hence $F_i$ is $z(L)$-invariant for $i = 1, 2$.
Let now $F \cong \mathbb{F}_1$ be a smooth rational $z(L)$-invariant quintic scroll in $R$ with exceptional section $J \subset \Xi$. Since $z(L)$ acts identically on $\Xi$, see again Proposition 5.6(d), the $z(L)$-action on $F$ leaves invariant each ruling $\Lambda_\gamma$, where $\Lambda_\gamma$ represents a $z(L)$-orbit closure. Hence, there are exactly two fixed points of $z(L)$ on $\Lambda_\gamma$. One of these points runs over $J$ when $\gamma$ runs over $\Upsilon$, and the other one runs over $\Psi$. In particular, $\Psi \subset F$.

The line $\Lambda_\gamma$ is contained in a unique plane $\Pi_\gamma$ through the point $p_\gamma \in \Psi \cap \Lambda_\gamma$. It passes through the point $p_\gamma$ and one of the intersection points $t_{\gamma,1}, t_{\gamma,2} \in \Pi_\gamma \cap J$. It follows that $F$ coincides with one of the scrolls $F_1$ and $F_2$ constructed in (a) where $F_1 = F_2 = F$ in the case $J = \Upsilon$.

To complete the proof of (b) in the case $J = \Upsilon$, consider the standard quintic scroll $F^8 := (\rho(\hat{\Delta}) \cap R)_{\text{red}}$ with $F^8 \cap \Xi = \Upsilon$. It is invariant under the action on $W$ of a special Levi subgroup $L^s \cong GL_2(\mathbb{C})$ as in Proposition 6.1(b). The Levi subgroups $L$ and $L^s$ are conjugated via an element $g \in R_\mathbb{u}$. Clearly, $g$ conjugates their singular tori $z(L)$ and $z(L^s)$, and sends the twisted cubic curve $\Psi \subset F$ to the corresponding $z(L^s)$-fixed curve $\Psi^s \subset F^8$. By virtue of the preceding uniqueness result, it follows that $g(F) = F^8$.

Now (c) is immediate. Notice that $G$ is a connected subgroup of $L$ which leaves $J$ invariant. We claim that $G$ sends the rulings of $F$ into rulings. Indeed, these rulings are $z(L)$-orbit closures meeting $J$. Since $L = C_L(z(L))$, $L$ acts on the set of $z(L)$-orbits. Hence $G$ sends the rulings of $F$ into $z(L)$-orbit closures meeting $J$. By connectedness of $G$, it sends the rulings of $F$ into rulings. Thus, the scroll $F$ is invariant under $G$.

Now (d) Notice that $\tilde{\kappa} \in L$, $\Psi$ is $L$-invariant, and $J$ is invariant under $\kappa = \tilde{\kappa}|_\Xi$. Furthermore, $\tilde{\kappa} \in L$ commutes with $z(L)$, hence sends the $z(L)$-orbits into $z(L)$-orbits. It follows from the construction of $F_1$ and $F_2$ in (b) that $F_1 \cup F_2$ is invariant under $\tilde{\kappa}$. It can be readily seen that $\tilde{\kappa}(F_i) = F_j$ for $i \neq j$.

From Lemma 6.2(a) and Proposition 6.3(c) we deduce such a corollary.

6.3.1. **Corollary.** Consider a $z(L)$-invariant quintic scroll $F \subset R$ as in Proposition 6.3(a) along with the subgroup $G = G(L, J) \subset L$ as in 6.3(c). Then the following hold.

(a) $\text{Aut}^0(W, F) = (R_\mathbb{u} \cap \text{Aut}^0(W, F)) \rtimes G$, and

(b) $G$ is isomorphic either to $GL_2(\mathbb{C})$, or to $\mathbb{G}_a \times \mathbb{G}_m$, or to $(\mathbb{G}_m)^2$ provided the conic $J = F \cap \Xi$ is of type 4.3(i), 4.3(ii), and 4.3(iii), respectively. If $G \cong \mathbb{G}_a \times \mathbb{G}_m$, then the $\mathbb{G}_a$-subgroup of $G$ acts nontrivially on $J$, and the $\mathbb{G}_m$-subgroup preserves each ruling of $F \to \mathbb{P}^1$.

(c) Let $U = R_\mathbb{u} \cap \text{Aut}^0(W, F) \neq \{1\}$. Then $U$ acts trivially on $J$, fiberwise on $F \to \mathbb{P}^1$, and either $U \cong \mathbb{G}_a$, or $U \cong (\mathbb{G}_m)^2$. For any $t \in U$ the rational twisted cubic curve $t(\Psi) \subset F$ is pointwise fixed under the singular torus $z(L_t)$, where $L_t = t \cdot L \cdot t^{-1}$.

**Proof.** (a) We have $\text{Aut}(W) = R_\mathbb{u} \rtimes L$, see (5.5.1). Let $G$ be as in Proposition 6.3(c). Since $G \subset L \cap \text{Aut}^0(W, F)$, then

$$(R_\mathbb{u} \cap \text{Aut}^0(W, F)) \rtimes G = (R_\mathbb{u} \cap \text{Aut}^0(W, F)) \cdot G \subset \text{Aut}^0(W, F).$$

To show the opposite inclusion we proceed as follows. Let $g = r \cdot l \in \text{Aut}^0(W, F)$, where $r \in R_\mathbb{u}$ and $l \in L$.

- Since $r|_\Xi = \text{id}_\Xi$, see Proposition 5.6(c), and $g(J) = J$, then $l(J) = J$.
- Since $l(\Psi) = \Psi$ and $g(\Psi) \subset F$, then $r(\Psi) \subset F$.
- Since $r|_\Xi = \text{id}_\Xi$, then $r(\Pi_\gamma) = \Pi_\gamma \forall \gamma \in \Upsilon$.
• Since \( r(\Psi) \subset F \) and \( r(\Psi \cap \Pi) \subset F \cap \Pi = \Lambda \), then \( r(\Lambda) = \Lambda \forall \gamma \in \Upsilon \).
• Thus, \( r(F) = F \), and since \( g(F) = F \), then \( l(F) = F \).
• It follows that \( \text{Aut}^0(W, F) = (R_u \cap \text{Aut}^0(W, F)) \times (L \cap \text{Aut}^0(W, F)) \).
• Since \( R_u \cap \text{Aut}^0(W, F) \) is connected, then \( L \cap \text{Aut}^0(W, F) \) is.
• Since \( l \in (L \cap \text{Aut}^0(W, F))^0 \) and \( g(l) \in \text{Aut}^0(\Xi, \Upsilon, J) \), then \( l \in G \).
• Therefore, \( G = L \cap \text{Aut}^0(W, F) \), and so, (a) follows.

(b) is straightforward from Lemma 6.2 and the definition of \( G \).
(c) Let \( g \in (R_u \cap \text{Aut}^0(W, F)) \setminus \{1\} \), and let \( U \) be the unique one-parameter subgroup of \( R_u \) containing \( g \). Then \( U \) is the Zariski closure of the group generated by \( g \). Hence \( U \) stabilizes \( F \). We have shown before that the action of \( U = R_u \cap \text{Aut}^0(W, F) \) on \( F \) preserves each ruling and fixes \( J \) pointwise. The restriction \( U|_f \) to a general ruling \( f \equiv \mathbb{P}^1 \) acts via the unipotent part of the Borel subgroup of \( \text{Aut}(f) \cong \text{PGL}_2(\mathbb{C}) \) fixing the point \( f \cap J \). Contracting \( J \) to a point \( p \in \mathbb{P}^2 \) yields an embedding of \( U \) onto an abelian unipotent group of linear transformations fixing \( p \) and preserving each line through \( p \). Now the remaining assertions follow. □

In the following lemma we indicate the case, where the condition \( R_u \cap \text{Aut}^0(W, F) = \{1\} \) is automatically fulfilled.

6.4. Lemma. Let \( F \subset R \) be a rational normal quintic scroll which meets \( \Xi \) along a smooth conic \( J \). Then the following conditions are equivalent:

(i) \( \text{Aut}(W, F) \) contains a subgroup \( \mathcal{H} \cong \text{SL}_2(\mathbb{C}) \);
(ii) \( \text{Aut}(W, F) \cong \text{GL}_2(\mathbb{C}) \) and \( R_u \cap \text{Aut}(W, F) = \{1\} \);
(iii) \( J = \Upsilon \) and \( F \) is invariant under the action of a singular torus of \( \text{Aut}(W) \).

Proof. The implication (iii) \( \Rightarrow \) (i) is straightforward from Corollary 6.3.1(b). The implication (ii) \( \Rightarrow \) (iii) is immediate; indeed, \( \Upsilon \) is a unique \( \text{PGL}_2(\mathbb{C}) \)-invariant conic in \( \Xi \).

It remains to prove (i) \( \Rightarrow \) (ii). The \( \text{SL}_2(\mathbb{C}) \)-subgroup \( \mathcal{H} \subset \text{Aut}(W, F) \) is contained in a unique reductive Levi subgroup \( L \cong \text{GL}_2(\mathbb{C}) \) of \( \text{Aut}(W) \). Let \( T := z(L) \). The center \( z(\mathcal{H}) \) has an isolated fixed point on \( \Pi_\gamma \setminus \Xi, \forall \gamma \in \Upsilon \). Therefore, \( z(\mathcal{H}) \) has a curve of fixed points \( \Psi \subset R \setminus \Xi \). Since \( z(\mathcal{H}) \subset T \), the points of \( \Psi \) are fixed by \( T \), see Proposition 5.6(d). The lines joining the corresponding points of \( J \) and \( \Psi \) are \( T \)-orbits. Therefore, \( \Psi, J = F \cap \Xi, \) and \( F \) are \( L \)-invariant.

The subgroup \( L \subset \text{Aut}(W, F) \) normalizes both \( \text{Aut}(W, F) \) and \( R_u \cong (\mathbb{G}_a)^4 \). Hence it normalizes the intersection \( K := \text{Aut}(W, F) \cap R_u \). Since \( K \) is normalized by \( L \) and \( R_u \), it is a normal subgroup in \( \text{Aut}(W) \). However, \( K \) cannot be a proper subgroup of \( R_u \). Indeed, the representation of \( L \cong \text{GL}_2(\mathbb{C}) \) on \( R_u \cong \mathbb{C}^4 \) by conjugation is irreducible, see Remark 5.5.2. Therefore, there is an alternative: either \( \text{Aut}(W, F) = L \), or \( \text{Aut}(W, F) = \text{Aut}(W) \). The latter is impossible since \( R \setminus \Xi \) is an orbit of \( \text{Aut}(W) \), see (5.5.5). This proves (ii). □

6.4.1. Corollary. Let \( F_1, F_2 \subset R \) be two quintic scrolls meeting \( \Xi \) along smooth conics. If \( \text{Aut}(W, F_i) \cong \text{GL}_2(\mathbb{C}) \) for \( i = 1, 2 \), then \( F_2 = g(F_1) \) for some \( g \in R_u \). Consequently, the pairs \( (V_1, S_1) \) and \( (V_2, S_2) \) linked to \( (W, F_1) \) and \( (W, F_2) \), respectively, are isomorphic.

Proof. Due to Lemma 6.4 for \( i = 1, 2 \) one has \( F_i \cap \Xi = \Upsilon \), \( L_i := \text{Aut}(W, F_i) \) is a Levi subgroup in \( \text{Aut}(W) \), and so, \( z(L_i) \) stabilizes \( F_i \). Letting \( \Psi_i \) be the component of the fixed point set of \( z(L_i)|_{F_i} \) different from \( \Upsilon \), we see that all the assumptions of Proposition 6.3(b)

23
are satisfied for $F_1$ and $F_2$. By this proposition, both $F_1$ and $F_2$ can be transformed into $(\rho(\tilde{\Delta}) \cap R)_{\text{red}}$ by suitable automorphisms from $R_u$. Now the assertions follow. \hfill \Box

In the next lemma we construct some $L$-invariant cubic cone in $W$.

6.5. Lemma. Let $L$ be a reductive Levi subgroup of $\text{Aut}(W)$, let $Q$ be the unique fixed point of the singular torus $T = z(L)$ in $W \backslash R$, and let $\Psi \subset R \setminus \Xi$ be the one-dimensional component of the fixed point set $W^T$, see Proposition 5.6(d). Consider the cubic cone $\text{Cone}(\Psi, Q) \subset \mathbb{P}^7$ over $\Psi$ with vertex $Q$. Then $\text{Cone}(\Psi, Q)$ is contained in $W$ and $L$-invariant.

Proof. It is easy to see that there is a one-dimensional family of lines in $W$ passing through $Q$ (cf. [Isk77, Proposition 5.3], [KPS16, Lemma 2.2.6]). The union of these lines form an $L$-invariant surface $S_Q$, which is a cone with vertex $Q$. Moreover, $S_Q = W \cap T_Q W$ because $W = W_5 \subset \mathbb{P}^7$ is an intersection of quadrics. The singular torus $T$ has a curve of fixed points on $S_Q$, and this curve must coincide with $S_Q \cap R = \Psi$. Therefore, $S_Q = \text{Cone}(\Psi, Q)$. \hfill \Box

6.6. Let us fix the following setup. Consider two linked pairs $(W, F)$ and $(V, S)$ as in Corollary 4.5.1. That is, $F \subset R$ is a smooth rational normal quintic scroll such that $F \cong \mathbb{P}_1$, $J = F \cap \Xi$ is a smooth conic touching $\Upsilon$ with even multiplicities, $V$ is a smooth Fano-Mukai fourfold of genus 10, and $S \subset V$ is a cubic cone with $\text{Aut}^0(V, S) \cong \text{Aut}^0(W, F)$. Suppose that $F$ is invariant under a singular torus $z(L)$, where $L \subset \text{Aut}(W)$ is a reductive Levi subgroup, see Remark 5.5.2.2. Via the above isomorphism, the identity component $G_L$ of $L \cap \text{Aut}(W, F)$ acts effectively on $V$ stabilizing $S$ (cf. Corollary 6.3.1). In the following lemma we construct a pair of disjoint $G_L$-invariant cubic cones in $V$.

6.6.1. Lemma. In the setting of 6.6 the following hold.

(a) There exists a unique $G_L$-invariant cubic cone $S' \subset V$ disjoint with $S$.

(b) If $R_u \cap \text{Aut}^0(W, F) = \{1\}$, then $S'$ in (a) is $\text{Aut}^0(V, S)$-invariant.

(c) If $R_u \cap \text{Aut}^0(W, F) \neq \{1\}$, then there exists a one-parameter family $(S'_t)$ of cubic cones in $V$ disjoint with $S$.

Proof. [a] Let $Q$ be the unique fixed point of $z(L)$ in $W \backslash R$, and let $\Psi \subset R \setminus \Xi$ be the 1-dimensional component of the fixed point set of $z(L)$. Consider the $L$-invariant cubic cone $S'_W := \text{Cone}(\Psi, Q) \subset W$, see Lemma 6.5. Since $S'_W$ meets the hyperplane section $R$ transversely along $\Psi$, the proper transform $S''_W$ of $S'_W$ in $\tilde{W}$ is isomorphic to $S'_W$ and disjoint with $\tilde{R} \subset \tilde{W}$. Then the image $S' := \xi(S''_W) \subset V$ is disjoint with $S = \xi(\tilde{R})$ and $G$-invariant. The linear projection $\theta : \mathbb{P}^{12} \dashrightarrow \mathbb{P}^7$ with center $\langle S \rangle$ sends $S'$ isomorphically onto $S''_W$. Therefore, $S'$ is a cubic cone disjoint with $S$. This yields the existence in [a].

Let $S'' \subset V$ be a $G_L$-invariant cubic cone disjoint with $S$. Then $S''_W = \theta(S'') \subset W$ is a $G_L$-invariant cubic cone in $W$. The hyperplane section $A = A_S \subset V$ as in 3.1.1 meets $S''$ along a $G_L$-invariant rational twisted cubic curve. Its image $\Psi'' \subset F$ under $\theta$ is also a $G_L$-invariant rational twisted cubic curve and a section of the ruling $F \rightarrow J$. Since $z(L) \subset G_L$, see 6.6 $\Psi''$ is $z(L)$-invariant. It follows that $\Psi''$ is a component of the fixed point set of $z(L)$ in $\tilde{R} \setminus \Xi$, hence $\Psi'' = \Psi$. The vertex $Q'' \in W \setminus R$ of $S''_W$ coincides with the unique isolated fixed point $Q$ of $z(L)$. Thus, $S''_W = \text{Cone}(\Psi'', Q'') = \text{Cone}(\Psi, Q) = S'_W$. Therefore, $S'' = S'$. This proves the uniqueness in [a].
Lemma 6.5, the cubic cone $S_{W} = \text{Cone}(\Psi, Q) \subset W$ is $\text{Aut}^{0}(W, F)$-invariant. Then $S'$ is $\text{Aut}^{0}(V, S)$-invariant, because diagram (3.1.1) is $\text{Aut}^{0}(W, F)$-equivariant.

[c] If $R_{u} \cap \text{Aut}^{0}(W, F) \neq \{1\}$, then the Sarkisov link (3.1.1) provides a one-parameter family of cubic cones in $V$ disjoint with $S$, see Corollary 6.3.1(c). □

6.7. Construction. Let us investigate more closely the rational normal quintic scrolls $F \subset R$ with $F \cong \mathbb{P}_{1}$ and $R_{u} \cap \text{Aut}^{0}(W, F) \neq \{1\}$. We use the notation from Lemma 2.3 and Proposition 5.6. The proper transform $\tilde{F}$ of $F$ in $\tilde{W}$ (see diagram (2.2.1)) is a smooth scroll which meets $\tilde{S} \cong \mathbb{P}^{1} \times \mathbb{P}^{1}$ along a nondegenerate conic, say, $J$. The morphism $\varphi|_{\tilde{F}} : \tilde{F} \to \Gamma$ induces on $\tilde{F}$ a structure of a $\mathbb{P}^{1}$-bundle of the $\mathbb{P}^{2}$-bundle $\varphi|_{\tilde{R}} : \tilde{R} \to \Gamma$, see Lemma 2.3(a).

This is the projectivization of a rank 2 vector subbundle $L \to \mathbb{P}_{4}$. In each fiber of $\mathcal{M}_{F}/\mathbb{P}^{4}$, $L$ is transversal to the rank 2 vector subbundle $\mathcal{M}_{F}/\mathbb{P}^{3}$, where $\mathbb{P}^{3} = \mathbb{P}(M_{3} \oplus \{0\})$. The pullback $\tilde{L}$ of $L$ in the tangent bundle $T\mathbb{P}_{4}$ is a vector subbundle of corank 1 containing the tangent bundle of $\Gamma$.

Consider the canonical projection $\pi : (M_{3} \oplus \mathbb{C}) \setminus \{0\} \to \mathbb{P}(M_{3} \oplus \mathbb{C}) \cong \mathbb{P}^{4}$ along with the affine cone (with the vertex removed) $\text{Cone}(\Gamma) \subset (M_{3} \oplus \mathbb{C}) \setminus \{0\}$, cf. the proof of Proposition 5.6(b). The pullback $\tilde{\mathcal{L}}^{*} := \pi^{*}\tilde{L}$ is a vector subbundle of corank 1 of the trivial vector bundle $T(M_{3} \oplus \mathbb{C})|_{\text{Cone}(\Gamma)} \cong (M_{3} \oplus \mathbb{C}) \setminus \{0\} \times \text{Cone}(\Gamma)$ over $\text{Cone}(\Gamma)$. This subbundle is invariant under the natural $\mathbb{G}_{m}$-action on $(M_{3} \oplus \mathbb{C}) \setminus \{0\}$ and contains the tangent bundle $T(\text{Cone}(\Gamma))$. The fibers of $\tilde{\mathcal{L}}^{*}$ define a one-parameter family of hyperplanes $(\tilde{\mathcal{L}}_{\gamma})_{\gamma \in \Gamma}$ of the vector 5-space $M_{3} \oplus \mathbb{C}$ transversal to $\tilde{E} := M_{3} \oplus \{0\} = \langle \text{Cone}(\Gamma) \rangle$.

In the following lemma we provide a criterion as to when $F$ is invariant under the action of a nontrivial subgroup of the unipotent radical $R_{u} = R_{u}(\text{Aut}(W))$.

6.7.1. Lemma. In the notation as in 6.7 consider the family $(H_{\gamma})_{\gamma \in \Gamma}$ of projective planes in the projective 3-space $\mathbb{P}(\tilde{E}) = \mathbb{P}(M_{3})$, where $H_{\gamma} := \mathbb{P}(\tilde{\mathcal{L}}^{*}_{\gamma} \cap \tilde{E})$. Then the following holds.

- $R_{u} \cap \text{Aut}^{0}(W, F) \neq \{1\}$ if and only if the planes $H_{\gamma}$ pass through a common point;
- $\dim(R_{u} \cap \text{Aut}^{0}(W, F)) \geq 2$ if and only if the planes $H_{\gamma}$ vary in a pencil.

Proof. The unipotent radical $R_{u}$ of $\text{Aut}(W)$ can be identified with the group of translations $(M_{3}, +) \cong \text{Transl}(\mathbb{C}^{4})$ acting on $M_{3} \oplus \mathbb{C}$ via

$$(M_{3}, +) \ni g : (f, z) \mapsto (f + zg, z) \in M_{3} \oplus \mathbb{C},$$

see (5.6.2). This action is trivial on the tangent space $T_{(f, 0)}(\text{Cone}(\Gamma))$, where $(f, 0) = ((\alpha x + \beta y)^{3}, 0) \in \text{Cone}(\Gamma)$. The tangent action on $T_{(f, 0)}(M_{3} \oplus \mathbb{C}) \cong M_{3} \oplus \mathbb{C}$ is given by $dg : (u, v) \mapsto (u + vg, v)$, see (5.6.3).

Let $\gamma = \pi(f, 0) \in \Gamma$. We claim that $dg|_{T_{(f, 0)}(M_{3} \oplus \mathbb{C})}$ preserves the hyperplane $\tilde{\mathcal{L}}_{\gamma}^{*} \subset T_{(f, 0)}(M_{3} \oplus \mathbb{C}) \cong M_{3} \oplus \mathbb{C}$ if and only if $(g, 0) \in \tilde{\mathcal{L}}_{\gamma}^{*} \cap \tilde{E}$. Indeed, $\tilde{\mathcal{L}}_{\gamma}^{*}$ can be given in $T_{(f, 0)}(M_{3} \oplus \mathbb{C}) = M_{3} \oplus \mathbb{C}$ by equation of the form $\langle u, w \rangle + \delta v = 0$, where $w \in \tilde{E} = M_{3} \oplus \{0\}$ is a nonzero vector and $\delta \in \mathbb{C}$. Let $(u, v) \in \tilde{\mathcal{L}}_{\gamma}^{*}$. Then $dg(u, v) = (u + vg, v) \in \tilde{\mathcal{L}}_{\gamma}^{*}$ if and only if $v \cdot \langle g, w \rangle = 0$. Since $\tilde{\mathcal{L}}_{\gamma} \neq \tilde{E}$ then $v \neq 0$ for a general $(u, v) \in \tilde{\mathcal{L}}_{\gamma}^{*}$. So, $dg(u, v) \in \tilde{\mathcal{L}}_{\gamma}^{*}$ for any $(u, v) \in \tilde{\mathcal{L}}_{\gamma}^{*}$ if and only if $(g, 0) \in \tilde{\mathcal{L}}_{\gamma}^{*} \cap \tilde{E}$. Now the claim follows.
Therefore, \( dg \) preserves the subbundle \( \tilde{\mathcal{L}}^* \subset T(M_3 \oplus \mathbb{C})_{|\text{Cone(}\Gamma\text{)}} \) if and only if \((g,0) \in \left( \bigcap_{\gamma \in \Gamma} \tilde{\mathcal{L}}^*_\gamma \right) \cap \tilde{E} \). Applying this with \( g \neq 0 \) yields the first assertion. To show the second, if suffices to apply the same argument to a pair of non-collinear vectors \((g_1,0)\) and \((g_2,0)\) from \( \tilde{E} = M_3 \oplus \{0\} \cong \mathbb{R}^u \).

The following simple lemma should be classically known. For a lack of reference, we provide an elementary argument.

6.7.2. **Lemma.** Consider the tangent developable quartic surface \( \Delta_0 \subset \mathbb{P}^3 \) of the twisted cubic curve \( \Gamma \), cf. 5.1. Then any line \( l \) on \( \Delta_0 \) is a tangent line to \( \Gamma \).

**Proof.** Assuming the contrary, consider the projection \( \pi : \mathbb{P}^3 \dashrightarrow \mathbb{P}^2 \) with center at a general point of \( l \). The image \( \pi(\Gamma) \) is a rational plane cubic such that the tangent lines to \( \pi(\Gamma) \) at smooth points pass all through the same point \( \pi(l) \). However, this cannot happen in characteristic zero by the duality argument. \( \square \)

6.7.3. **Corollary.** Let \( F \subset \mathcal{R} \) be a rational normal quintic scrolls such that \( J = F \cap \Xi \) is a smooth conic. Then \( \dim(\mathcal{R}_u \cap \text{Aut}^0(W,F)) \leq 1 \).

**Proof.** Assuming the contrary, by Lemma 6.7.1 the planes \( H_\gamma, \gamma \in \Gamma \), contain a common line \( l \). Besides, each plane \( H_\gamma \) contains the tangent line \( l_\gamma \) to \( \Gamma \) at the point \( \gamma \in \Gamma \), see 6.7. Hence \( l \) meets each \( l_\gamma \). Since distinct tangent lines \( l_\gamma \) are disjoint, \( l \subset \Delta_0 \) is different from any \( l_\gamma \). Now Lemma 6.7.2 gives a contradiction. \( \square \)

7. **G\(_2\)-construction**

In this section we exploit the description of the Fano-Mukai fourfolds of genus 10 based on a beautiful construction of S. Mukai ([Muk88], see Theorem 7.1). Using a lemma due to Kapustka and Ranestad [KR13, Lem. 1] we find the stabilizers of elements in the Lie algebra of the exceptional group \( G_2 \), and interpret these in terms of the automorphism groups of Fano-Mukai fourfolds \( V_{18} \). Let us start by recalling the following result.

7.1. **Theorem** ([Muk89]). Let \( G_2 \) be the simple algebraic group of exceptional type \( G_2 \). Consider the adjoint variety \( \Omega = G_2/P \subset \mathbb{P}^g \mathfrak{g}_2 = \mathbb{P}^{13} \), where \( P \subset G_2 \) is a parabolic subgroup of dimension 9 corresponding to a long root, and \( \mathfrak{g}_2 \) is the Lie algebra of \( G_2 \). Then any Fano-Mukai fourfold of genus 10 is isomorphic to a hyperplane section of the homogeneous fivefold \( \Omega \).

7.2. **Notation.** We let \( \mathfrak{g}_2 \) be the Lie algebra of \( G_2 \), \( \mathfrak{h} \) be a fixed Cartan subalgebra of \( \mathfrak{g}_2 \), and \( \Delta \subset \mathfrak{h}^\vee \) be the corresponding root system. Choose a base of simple roots \( \alpha_1, \alpha_2 \) of \( \Delta \) satisfying ([Bou02])

\[
(\alpha_1, \alpha_1) = 2, \quad (\alpha_2, \alpha_2) = 6, \quad (\alpha_1, \alpha_2) = -3.
\]

The Dynkin diagram \( G_2 \) looks like

(7.2.1)

7.3. Recall that \( G_2 \) has dimension 14, rank 2, and its center is trivial. It can be realized as the automorphism group of the octonion algebra \( \mathcal{O} \) over \( \mathbb{C} \). Let \( \mathcal{O}_0 \subset \mathcal{O} \) be the hyperplane of pure octonions. Then the adjoint variety \( \Omega \) can be realized as the subvariety in the
Grassmannian $\text{Gr}(2, \mathcal{O}_0)$ of the isotropic two-dimensional subspaces $\Lambda \subset \mathcal{O}_0$ with respect to the multiplication in $\mathcal{O}$. The latter means that the multiplication restricts as zero to such a subspace.

In the presentation $\Omega = G_2/P$ (cf. Theorem 7.1) one can choose for $P$ the parabolic subgroup of $G_2$ with Lie algebra

$$\mathfrak{p} = \mathfrak{h} \oplus \left( \bigoplus_{\alpha \in \Delta^+} \mathfrak{g}_{\alpha} \right) \oplus \mathfrak{g}_{-\alpha_1} = \mathfrak{b} \oplus \mathfrak{g}_{-\alpha_1},$$

where $\mathfrak{b}$ stands for a Borel subalgebra of $\mathfrak{g}_2$. A reductive Levi subgroup of $P$ is, e.g., the $\text{GL}_2(\mathbb{C})$-subgroup with Lie algebra $\mathfrak{h} \oplus \mathfrak{g}_{\alpha_1} \oplus \mathfrak{g}_{-\alpha_1}$. Respectively, the $\text{SL}_2(\mathbb{C})$-subgroup with Lie algebra $[\mathfrak{g}_{\alpha_1}, \mathfrak{g}_{-\alpha_1}] \oplus \mathfrak{g}_{\alpha_1} \oplus \mathfrak{g}_{-\alpha_1}$ is a semisimple Levi subgroup of $P$ (cf. [Muk88 § 1], [HM02 § 1], and also [LM03 § 2.3]).

7.4. By [Muk88], $\Omega$ is a Fano-Mukai fivefold of Fano index 3 with $\text{rk}\text{Pic}(\Omega) = 1$. The linear system $[-\frac{1}{3}K_{\Omega}]$ defines an embedding $\Omega \hookrightarrow \mathbb{P}^{13}$ onto a variety of degree $\text{deg} \, \Omega = \left(-\frac{1}{3}K_{\Omega}\right)^5 = 18$. By the adjunction formula and the Lefschetz hyperplane section theorem, any smooth hyperplane section $V = \Omega \cap \mathbb{P}^{12} \subset \mathbb{P}^{13}$ is a Fano-Mukai fourfold of genus 10. According to Theorem 7.1 any such variety occurs to be a hyperplane section of $\Omega \subset \mathbb{P}^{13}$.

By definition, the adjoint variety $\Omega$ is the orbit of the highest weight vector in the projectivized adjoint representation of $G_2$. This is the projectivized minimal (nonzero) nilpotent orbit of the $\text{Ad}(G_2)$-action on $\mathfrak{g}_2$ ([CMG93 Thm. 4.3.3]). The adjoint variety $\Omega$ contains the points $\mathbb{P}(\mathfrak{g}_\alpha)$, where $\alpha$ runs over the set $\Delta \subset \Delta$ of long roots ([Tev05 § 8.5]). The dual variety $D_\ell := \Omega^* \subset \mathbb{P}(\mathfrak{g}_2)^\vee$ of $\Omega$, that is, the locus of hyperplanes in $\mathbb{P}(\mathfrak{g}_2)$ which define singular hyperplane sections of $\Omega$, is $\text{Ad}(G_2)$-invariant. In fact, $D_\ell$ is an irreducible hypersurface in $\mathbb{P}(\mathfrak{g}_2^\vee)$ of degree 6. The latter follows, e.g., from the classification of defective varieties of small dimension (see [Tev05 § 7.3.3]), or, alternatively, by comparing [Lev05 Thm. 7.47] with Proposition 8.1(e) below.

We let $\delta_\ell$ be a homogeneous polynomial of degree 6 defining $D_\ell$. There exists a second $\text{Ad}(G_2)$-invariant sextic hypersurface $D_s$ in $\mathbb{P}(\mathfrak{g}_2^\vee)$ given by a homogeneous polynomial $\delta_s$ of degree 6, where $\delta_\ell$ and $\delta_s$ are elements of the graded subalgebra $\mathbb{C}[\mathfrak{g}_2]^{\text{Ad}(G_2)}$ of $\text{Ad}(G_2)$-invariant functions on $\mathfrak{g}_2$, see [Tev05 § 8.5]. Indeed, let $\mathbb{C}[\mathfrak{h}]^W$ be the graded subalgebra of $\mathbb{C}$-invariant functions on $\mathfrak{h}$, where $W$ is the Weyl group of $G_2$. It is known (see, e.g., [Bou92 Ch. VI, § 12, Table IX, Summary 32-33]) that $\mathbb{C}[\mathfrak{h}]^W = \mathbb{C}[f_2, f_6]$, where $\text{deg} \, f_2 = 2$ and $\text{deg} \, f_6 = 6$. In particular, the graded piece $(\mathbb{C}[\mathfrak{h}]^W)_6$ of dimension 2 is spanned by $f_2^3$ and $f_6$. By the Chevalley restriction theorem ([CG97 Thm. 3.1.38]) the restriction map gives an isomorphism of graded algebras

$$\mathbb{C}[\mathfrak{g}_2]^{\text{Ad}(G_2)} \cong \mathbb{C}[\mathfrak{h}]^W.$$  

Hence $(\mathbb{C}[\mathfrak{g}_2]^{\text{Ad}(G_2)})_6 \cong (f_2^3, f_6)$ is spanned by a pair $(\delta_\ell, \delta_s)$ of irreducible invariants chosen so that ([Tev05 Thm. 8.25])

$$\delta_\ell|_{\mathfrak{h}} = \prod_{\alpha \in \Delta_\ell} \alpha \quad \text{and} \quad \delta_s|_{\mathfrak{h}} = \prod_{\beta \in \Delta_s} \beta,$$

where $\Delta_s$ stands for the set of short roots.
7.5. Let $G$ be a simple algebraic group of rank $r$ with Lie algebra $\text{Lie}(G)$. For an element $g \in \text{Lie}(G)$ we let $\text{Stab}_G(g)$ stand for the stabilizer of $g$ in $G$ under the adjoint representation. The Lie algebra of $\text{Stab}_G(g)$ is the centralizer of $g$ in $\text{Lie}(G)$. The element $g$ is called regular if $\dim \text{Stab}_G(g) = r$ and singular otherwise. We have the following facts.

7.5.1. **Proposition.** For an element $g \in \text{Lie}(G)$ the following hold.

(a) ([SS70, 1.3]) The stabilizer $\text{Stab}_G(g)$ contains an abelian subgroup of dimension $r = \text{rk} G$.

(b) ([Kur83 Thms. A and α]; cf. [SS70, 1.4, 1.16-1.18]) $g$ is regular if and only if the stabilizer $\text{Stab}_G(g)$ is abelian.

(c) ([Ste65 Cor. 3.4]) If $g$ is singular, then $\dim \text{Stab}_G(g) \geq r + 2$.

(d) ([SS70, 1.7, 3.9]) If $g$ is semisimple, then $\text{Stab}_G(g)$ is a reductive group. A semisimple $g$ is regular if and only if $\text{Stab}_G(g)^0$ is a maximal torus of $G$.

7.5.2. An element $g \in \text{Lie}(G)$ with $\dim \text{Stab}_G(g) = r + 2$ is called subregular. The orbit of $g$ in $\text{Lie}(G)$ is also called subregular. It should be noted that an orbit $\mathcal{O}$ of the adjoint $G$-action on $\text{Lie}(G)$ is conic if and only if $\mathcal{O}$ is a nilpotent orbit ([CMG93 Lem. 4.3.1]). The image of a nilpotent orbit $\mathcal{O}$ in $\mathbb{P}(\text{Lie}(G))$ is an orbit of the same dimension as the one of $\mathcal{O}$ in $\text{Lie}(G)$. In contrast, for a non-nilpotent orbit $\mathcal{O} \subset \text{Lie}(G)$, its image in $\mathbb{P}(\text{Lie}(G))$ is an orbit of the same dimension as the one of $\mathcal{O}$.

7.6. **Notation.** We identify $g_2$ and $g_2^\perp$ via the Killing form. Under this identification, the adjoint representation $\text{Ad}(G_2)$ and its dual have the same orbits.

For a nonzero element $g \in g_2$ we let $[g]$ be the image of $g$ in $\mathbb{P}(g_2)$. Let $V^g_\mathbb{P} = \Omega \cap \mathbb{P}(g_2^\perp)$ be the section of $\Omega$ by the projectivized hyperplane $g_2^\perp$ orthogonal to $g$ with respect to the Killing form.

Using Proposition 7.5.1 and Lemma 1 in [KR13] we deduce the following results.

7.7. **Proposition (KR13).** Consider the pencil $\mathcal{D}$ of $\text{Ad}(G_2)$-invariant sextic hypersurfaces in $\mathbb{P}(g_2^\perp) = \mathbb{P}(g_2)$ generated by $D_\ell$ and $D_s$. Then the following hold.

(a) For any $D \in \mathcal{D}$ different from $D_\ell = \delta_\ell(0)$ and $D_s = \delta_s^*(0)$ the complement $D \setminus D_\ell$ is the $\text{Ad}(G_2)$-orbit of $[g]$, where $g \in g_2$ is regular semisimple with an abelian group $\text{Stab}_{G_2}(g)$ and with $\text{Stab}_{G_2}(g)^0 \cong (\mathbb{G}_m)^2$.

(b) The complement $D_s \setminus D_\ell$ is a union of exactly two $\text{Ad}(G_2)$-orbits, the orbit of $[g_s]$ and the orbit of $[g_s + g_n]$, where $g_s, g_n \in g_2$ are commuting elements such that

- $g_s$ is subregular semisimple, $g_n \neq 0$ is nilpotent, and $g_s + g_n$ is regular;
- the orbit $\text{Ad}(G_2).[g_s + g_n]$ is an open, dense subvariety of $D_s \setminus D_\ell$;
- the orbit $\text{Ad}(G_2).[g_s]$ is a closed subvariety of $D_s \setminus D_\ell$ of codimension 2;
- the stabilizer $\text{Stab}_{G_2}(g_s + g_n)$ is abelian, and $\text{Stab}_{G_2}(g_s + g_n)^0 \cong \mathbb{G}_a \times \mathbb{G}_m$;
- the stabilizer $\text{Stab}_{G_2}(g_s)$ is a non-abelian reductive group of dimension 4 and of rank 2.

**Proof.** [a] By [KR13] Lem. 1(2), for $D \neq D_s, D_\ell$, the complement $D \setminus D_\ell$ coincides with the orbit of some $[g] \in \mathbb{P}(g_2)$. On the other hand ([Tev05 § 8.5]), $g \in g_2$ is regular semisimple if and only if $[g] \notin D_\ell \cup D_s$. Now [a] follows by Proposition 7.5.1(b) and (d).

[b] By [KR13] Lem. 1(1) and its proof, $D \setminus D_\ell$ is a union of a semisimple subregular orbit $O_1 = \text{Ad}(G_2).[g_s]$ and a mixed regular orbit $O_2 = \text{Ad}(G_2).[g_s + g_n]$, where $g_n \neq 0$ is nilpotent and commutes with $g_s$. Thus, $\text{codim}_{\mathbb{P}(g_2)} O_1 = 3$ and $\text{codim}_{\mathbb{P}(g_2)} O_2 = 1$, see 7.5.2. In particular, $O_2$ is open and dense in $D_s \setminus D_\ell$, and its complement $O_1$ in $D_s \setminus D_\ell$
is closed of codimension 2, see [KR13, Rem. 1]. Since $g_s$ is subregular, Stab$_{G_2}(g_s)$ is a non-abelian reductive group of dimension 4 and of rank 2 with semisimple part $\operatorname{SL}_2(\mathbb{C})$, see [CMG93] and Proposition 7.5.1(d)

Since $g_s + g_n$ is regular, Stab$_{G_2}(g_s + g_n)$ is an abelian group of dimension 2, see Proposition 7.5.1(b). The unipotent radical of Stab$_{G_2}(g_s + g_n)^0$ contains the one-parameter unipotent subgroup $\exp(tg_n)$, $t \in \mathbb{C}$. On the other hand, the semisimple element $g_s$ centralizes $g_s + g_n$, hence Stab$_{G_2}(g_s + g_n)^0$ is not unipotent. It follows that Stab$_{G_2}(g_s + g_n)^0 \cong \mathbb{G}_a \times \mathbb{G}_m$.

### 7.8. Lemma

The stabilizer Stab$_{G_2}(g)$ acts effectively on the hyperplane section $V = V_{18}^g$.

The proof starts with the following claim.

#### 7.8.1. Claim

*The kernel of the natural homomorphism Stab$_{G_2}(g) \to \operatorname{Aut}(V)$ is contained in the unipotent radical of Stab$_{G_2}(g)$.*

**Proof.** The simple group $G_2$ acts effectively on $\Omega$. If $h \in \operatorname{Stab}_{G_2}(g)$ acts trivially on $V$, then it acts trivially on the hyperplane $\langle V \rangle \subset \mathbb{P}(g_2)$. Hence the adjoint action of $h$ on $g_2$ has at most two distinct eigenvalues $\lambda_1$ and $\lambda_2$ of multiplicity 13 and 1, respectively. Since $h(g) = g$, one has $\lambda_2 = 1$. The Lie algebra $g_2$ being semisimple, one has det $h = 1 = \lambda_1^{13}$. Up to equivalence, the adjoint representation is a unique irreducible representation of $G_2$ of dimension 14. Hence it is equivalent to the coadjoint representation. It follows that $h$ and $h^{-1}$ are conjugated, and so, $\operatorname{tr}(h) = \operatorname{tr}(h^{-1})$. Thus, $13\lambda_1 + 1 = 13\lambda_1^{-1} + 1$, which implies $\lambda_1 = 1$. Then the semisimple part of $h$ equals 1, and $h$ is unipotent. Finally, the kernel of the representation Stab$_{G_2}(g) \to \operatorname{Aut}(V)$ is a normal closed subgroup of Stab$_{G_2}(g)$ consisting of unipotent elements. \(\square\)

The next claim ends the proof of Lemma 7.8.

#### 7.8.2. Claim

*The unipotent radical of Stab$_{G_2}(g)$ acts effectively on $V$.*

**Proof.** It suffices to show that any one-parameter unipotent subgroup $U = \{\exp(tN)\}_{t \in \mathbb{C}} \subset \operatorname{Stab}_{G_2}(g)$, where $N \in g_2$ is nilpotent, acts effectively on $V$. Suppose this is not the case. Then $N$ vanishes on the affine hyperplane $g_1 \subset g_2$. Since it also vanishes on the line $Cg$, one has $N = 0$. \(\square\)

#### 7.8.3. Corollary

*Let $V = V_{18}^g$, where $g \in g_2 \setminus \{0\}$ and $[g] \notin D_6$. Assume that $V$ contains an $\operatorname{Aut}^0(V)$-invariant cubic cone $S$. Then the following hold.

(i) If $g$ is singular semisimple, then $\operatorname{Aut}^0(V) \cong \operatorname{GL}_2(\mathbb{C})$;

(ii) if $g$ is regular non-semisimple, then $\operatorname{Aut}^0(V) \supset \mathbb{G}_a \times \mathbb{G}_m$;

(iii) if $g$ is regular semisimple, then $\operatorname{Aut}^0(V) \supset (\mathbb{G}_m)^2$.

In particular, if $\operatorname{rk}(\operatorname{Aut}^0(V)) = 1$ then we are in case (ii). Any two Fano-Mukai fourfolds satisfying (i) (resp., (ii)) are isomorphic via an automorphisms of $\Omega$ provided by the Ad$(G_2)$-action on $\Omega$.***

**Proof.** Statements (ii) and (iii) are straightforward from Propositions 7.5.1(a), (b) and and Lemma 7.8. By Propositions 7.5.1(b) - (c) and 7.7(b) and Lemma 7.8 in case (i) $\operatorname{Aut}^0(V)$ contains a non-abelian reductive subgroup of dimension 4 and of rank 2. Hence $V$ admits a nontrivial $\operatorname{SL}_2(\mathbb{C})$-action. Let $(W, F)$ be the pair linked to $(V, S)$ via an $\operatorname{Aut}^0(V)$-equivariant Sarkisov link (3.1.1). Due to Lemma 6.4 one has $\operatorname{Aut}^0(V) \cong \operatorname{Aut}^0(W, F) \cong \operatorname{GL}_2(\mathbb{C})$. 29
By (i), (iii) the equality \( \text{rk}(\text{Aut}^0(V)) = 1 \) implies that \( g \) is regular non-semisimple. According to Proposition 7.7(b) any two such elements \( g_1, g_2 \in g_2 \) belong to the same \( \text{Ad}(G_2) \)-orbit. Hence the corresponding smooth hyperplane sections \( V_{18}^{g_1} \) and \( V_{18}^{g_2} \) of \( \Omega \) are isomorphic under the \( \text{Ad}(G_2) \)-action on \( \Omega \). The same argument applies in case (i) (alternatively, see Lemma 6.4.1). □

7.8.4. Notation. We let \( V_{18}^s \) and \( V_{18}^a \), respectively denote a unique, up to isomorphism, Fano-Mukai fourfold \( V_{18}^{g_1} \) as in Corollary 7.8.3(i) and (ii), respectively. The existence of these fourfolds is guaranteed by Proposition 7.7(b). Thus, \( \text{Aut}^0(V_{18}^s) \cong \text{GL}_2(\mathbb{C}) \) and \( \text{Aut}^0(V_{18}^a) \supset \mathbb{G}_a \times \mathbb{G}_m \).

8. Lines in \( V_{18} \)

To study the lines in a Fano-Mukai fourfold \( V_{18} \), let us first investigate the Fano variety of lines in the homogeneous space \( \Omega = G_2/P \).

8.1. Proposition. Let \( \Omega = G_2/P \) be as above. Then the following hold.

(a) \( \Omega \) contains a line.
(b) For any line \( l \subset \Omega \) one has

\[ 8.1.1 \quad N_{l/\Omega} \cong \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(1) \]

(c) The Hilbert scheme \( \Sigma(\Omega) \) of lines on \( \Omega \) is a non-singular variety of dimension 5.
(d) Consider the universal family of lines on \( \Omega \)

\[ 8.1.2 \quad \mathcal{L}(\Omega) \leftarrow \Sigma(\Omega) \rightarrow \Omega \]

where \( \mathcal{L}(\Omega) \to \Sigma(\Omega) \) is a \( \mathbb{P}^1 \)-bundle. Then any fiber of \( \mathcal{L}(\Omega) \to \Omega \) is one-dimensional.
(e) For any point \( p \in \Omega \) the union \( L_{\Omega}p \) of the lines in \( \Omega \) passing through \( p \) is a cone over a rational twisted cubic curve.

Proof. (a) It suffices to show that a general section \( \Omega \cap \mathbb{P}^{11} \) contains a line. However, the latter follows from Shokurov’s theorem [Sho80].

(b) Let \( l \) be a line on \( \Omega \subset \mathbb{P}^{13} \). Since \( \Omega \) is a homogeneous space, the tangent bundle \( T_\Omega \) is generated by global sections (that is, the vector fields from the corresponding Lie algebra). Hence the vector bundles \( T_{\Omega|l} \) and \( N_{l/\Omega} = T_{\Omega|l}/T_l \) are also generated by global sections. This means that the integers \( a, b, c, d \) in the decomposition

\[ \mathcal{N}_{l/\Omega} = \mathcal{O}_{\mathbb{P}^1}(a) \oplus \mathcal{O}_{\mathbb{P}^1}(b) \oplus \mathcal{O}_{\mathbb{P}^1}(c) \oplus \mathcal{O}_{\mathbb{P}^1}(d) \]

are all non-negative. On the other hand,

\[ \deg \mathcal{N}_{l/\Omega} = -K_\Omega \cdot l - 2 + 2 g(l) = 1. \]

This implies (8.1.1), (c) follows from (8.1.1) and the standard facts of the deformation theory. Indeed, we have \( H^1(V, \mathcal{N}_{l/\Omega}) = 0 \) and \( \dim H^0(V, \mathcal{N}_{l/\Omega}) = 5 \). Statement (d) follows from the facts that \( \Omega \) is homogeneous and the diagram (8.1.2) is equivariant. To show (e) we note that \( L_\Omega p = T_p \Omega \cap \Omega \) is the tangent cone and \( T_p \Omega \cap \Omega \) is a cone over a rational twisted cubic curve, see [HM02, § 1, Prop. 1] or [KR13, Proof of Lemma 3]. □
Next we study the lines in a Fano-Mukai fourfold $V_{18}$.

8.2. Proposition. Let $V = V_{18} \subset \mathbb{P}^{12}$ be a smooth Fano-Mukai fourfold of genus 10. Then the following hold.

(a) $V$ contains a line.

(b) For any line $l \subset V$ one has

\begin{equation}
\mathcal{N}_{l/V} \cong \begin{cases} \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} & (\ast) \\ \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(1) & (\ast\ast) \end{cases}
\end{equation}

(c) The Hilbert scheme $\Sigma(V)$ of lines on $V$ is a non-singular variety of dimension 3.

(d) Consider the universal family of lines on $V$

\begin{equation}
\begin{array}{ccc}
\Sigma(V) & \leftarrow & \mathcal{L}(V) \\
\mathbb{P}^1 & \leftarrow & V
\end{array}
\end{equation}

where $r : \mathcal{L}(V) \to \Sigma(V)$ is a $\mathbb{P}^1$-bundle. Then $s$ is a generically finite morphism of degree 3. Consequently, $V$ is covered by lines.

(e) For $p \in V$, let $LV_p$ be the union of all lines in $V$ passing through $p$. If $\dim LV_p = 2$, then $LV_p$ is a cubic cone. Otherwise, $LV_p$ is nonempty and consists of at most three lines.

(f) A general line $l$ on $V$ has normal bundle of type $(\ast)$ in (8.2.1). Any line $l$ on $V$ with normal bundle of type $(\ast\ast)$ is contained in the branching divisor $B \subset V$ of $s$.

(g) Any line $l$ on $V$ contained in a cubic cone has normal bundle of type $(\ast\ast)$.

Proof. (a) The proof is similar to the one of 8.1(a).

(b) From the standard exact sequence

\[ 0 \to \mathcal{N}_{l/V} \to \mathcal{N}_{l/\Omega} \to \mathcal{N}_{V/\Omega}|_l \to 0 \]

one deduces that all the summands in a decomposition of $\mathcal{N}_{l/V}$ into a sum of line bundles are of degree $\leq 1$, and there is at most one summand of degree 1. Thus (8.1.1) implies (8.2.1).

(c) follows from (8.2.1).

(d) Recall that $V$ is a section of $\Omega \subset \mathbb{P}^{13}$ by a hyperplane $H$. For $p \in V$, the subvariety $LV_p$ is a hyperplane section of $L\Omega_p$, that is,

\[ LV_p = L\Omega_p \cap V = L\Omega_p \cap H. \]

By Proposition 8.1(e), $L\Omega_p$ is a cubic cone, that is, a cone over a rational twisted cubic curve. Hence, $LV_p$ is non-empty, $\dim LV_p \leq 2$, and $\dim LV_p = 2$ if and only if $LV_p = L\Omega_p$. Thus, $s$ is dominant. So, this is a generically finite morphism of degree 3. Indeed, for a general point $p \in V$, $H$ cuts the cubic cone $L\Omega_p$ on $V$ with vertex $p$ along three distinct lines. The last assertion in (e) is now immediate.

(f) To any line $l \in \Sigma(V)$ there corresponds a smooth rational curve $l' \subset \mathcal{L}(V)$. Clearly, the restriction $s|_{l'} : l' \to l \subset V$ is an isomorphism. Consider the differential

\begin{equation}
ds : \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} = \mathcal{N}_{l'/\mathcal{L}(V)} \to \mathcal{N}_{l/V}.\end{equation}

In case $(\ast\ast)$ the map $ds$ has cokernel of rank 1 along $l'$. Hence $s$ is ramified along $l'$. 

31
Consider a line \( l \subset S \), where \( S \subset V \) is a cubic cone. Then \( l \) lifts to a ruling \( l' \) of a scroll \( S' \cong \mathbb{F}_3 \) in \( \mathcal{L}(V) \). The map \( s|_{S'} : S' \to S \) contracts the exceptional section of \( S' \) to the vertex \( p \) of \( S \). Therefore, the cokernel of \( ds \) in (8.2.3) in nontrivial at \( p \), and so, \( N_{l/V} \not\cong \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1} \).

9. Cubic scrolls in \( V_{18} \)

In this section we study the cubic scrolls in a Fano-Mukai fourfold \( V = V_{18} \) of genus 10. The following facts are proven in [KR13, Prop. 1 and 2 and the proof of Prop. 4].

9.1. Theorem. For any Fano-Mukai fourfold \( V = V_{18} \) of genus 10 the following hold.

(a) Let \( \Sigma(V) \) be the Hilbert scheme of lines in \( V \). Then \( \Sigma(V) \) is isomorphic to a smooth divisor of bidegree \((1,1)\) on \( \mathbb{P}^2 \times \mathbb{P}^2 \).

(b) Let \( \mathcal{I}(V) \) be the Hilbert scheme of cubic scrolls in \( V \). Then \( \mathcal{I}(V) \) is isomorphic to a disjoint union of two projective planes.

9.1.1. Remarks. (i) By the Lefschetz hyperplane section theorem we have Pic(\( \Sigma(V) \)) = \( \mathbb{Z} \cdot [\mathcal{F}_1] \oplus \mathbb{Z} \cdot [\mathcal{F}_2] \), where \( \mathcal{F}_i \), \( i = 1,2 \), are the pull-backs of lines on the corresponding factors of \( \mathbb{P}^2 \times \mathbb{P}^2 \).

(ii) Note that the embedding \( \Sigma(V) \subset \mathbb{P}^2 \times \mathbb{P}^2 \) onto a smooth divisor \( D \) of bidegree \((1,1)\) guaranteed by Theorem 9.1(a) is defined canonically. Indeed, the projections \( \text{pr}_i : \Sigma(V) \to \mathbb{P}^2 \), \( i = 1,2 \), to the factors of \( \mathbb{P}^2 \times \mathbb{P}^2 \) are extremal contractions. By (i) the projections \( \text{pr}_1 \) and \( \text{pr}_2 \) are the only extremal contractions of the threefold \( \Sigma(V) \). It follows that the Aut\(^0(\Sigma(V))\)-action on \( \Sigma(V) \) induces an action of Aut\(^0(\Sigma(V))\) on the factors of \( \mathbb{P}^2 \times \mathbb{P}^2 \) making the morphisms \( \text{pr}_i \), \( i = 1,2 \), equivariant.

(iii) One can treat \( \Sigma(V) \subset (\mathbb{P}^2)^\vee \times \mathbb{P}^2 \) as the variety of full flags in \( \mathbb{P}^2 \). Using this representation, it can be easily seen that the maps Aut\(^0(\Sigma(V))\) \to Aut((\mathbb{P}^2)^\vee)) and Aut\(^0(\Sigma(V))\) \to Aut(\mathbb{P}^2) are isomorphisms.

We use below the following facts.

9.2. Lemma. Given a cubic scroll \( S \in \mathcal{I}(V) \), there is a unique hyperplane section \( A_S \) of \( V \) with Sing(\( A_S \)) = \( S \). This hyperplane section \( A_S \) coincides with the union of lines in \( V \) which meet \( S \). Given a point \( P \in A_S \setminus S \), there is a unique line in \( A_S \) through \( P \) which meets \( S \).

Proof. By Proposition 3.1 there is a hyperplane section \( A = A_S \) of \( V \) with Sing(\( A_S \)) = \( S \). The linear projection \( \theta : V \to W \) in diagram (3.1.1) sends \( A \) to a smooth quintic scroll \( F \subset W \) contracting the lines meeting \( S \) and not contained in \( S \). These lines correspond to the rulings of \( \eta|_A : \tilde{A} \to F \) in (3.1.1). It follows that \( A = \xi(\tilde{A}) \) is covered by such lines. Since through any point in \( \tilde{A} \setminus B \) passes a unique ruling of \( \eta|_A : \tilde{A} \to F \), the last statement follows.

9.3. Lemma. A line \( l \in V \) can be a common exceptional section for at most two smooth cubic scrolls in \( V \), and can be contained in at most finite number of cubic cones. Consequently, the morphism \( s^{-1}(l) \to l \) (see diagram (8.2.2)) is generically finite.

Proof. We claim that \( l \) cannot be a common exceptional section of three or more smooth cubic scrolls. Indeed, assuming the contrary, through a general point \( p \) of \( l \) pass at least 4 distinct lines in \( V \). By Proposition 8.3(c) this implies that \( p \) is a vertex of a cubic cone in \( V \). So, the cubic cones with vertices on \( l \) form a one-parameter family, say, \( \mathcal{C}(l) \). By
Lemma 9.2 for any pair of cubic cones \( S', S'' \) through \( l \) one has \( S'' \subset A_{S'} \) and \( S' \subset A_{S''} \). Hence for any \( S' \in \mathcal{C}(l) \) there is a Zariski dense open subset of \( A_{S'} \) swept up by the cubic cones in \( \mathcal{C}(l) \). Therefore, \( A_{S'} \) and \( S' = \text{Sing}(A_{S'}) \) do not depend on the choice of \( S' \), a contradiction. \( \square \)

By virtue of Theorem 9.1 and the next lemma, a general cubic scroll in \( V \) is smooth.\(^3\)

9.4. **Lemma.** Any cubic cone in \( V \) is contained in the branching divisor \( B \) of \( s : \mathcal{L}(V) \to V \). The family of cubic cones in \( V \) is at most one-dimensional.

**Proof.** The first statement is immediate from Proposition 8.2(f)–(g).

To show the second, suppose the contrary. Then an entire component of \( \mathcal{S}(V), \) say, \( \mathcal{S}_i(V), \) \( i \in \{1,2\} \), consists of cubic cones. By Proposition 8.2(e) the vertices of these cones are all distinct and cover a surface, say, \( T_i \subset \mathcal{B} \).

The pull-back \( \tilde{T}_i = s^{-1}(T_i) \subset \mathcal{L}(V) \) is \( \mathbb{P}^1 \)-fibered over \( T_i \). Indeed, let \( S_i \subset \mathcal{B} \) be the cubic cone with vertex \( t \in T_i \). Then the fiber \( s_t = s^{-1}(t) \cong \mathbb{P}^1 \) parameterizes the family of lines in \( V \) through \( t \), that is, the family of rulings of \( S_t \).\(^4\) Thus, \( \tilde{T}_i \) is a component of the ramification divisor \( \mathcal{R} \) of \( s \).

By Proposition 8.2(e), a general line in \( V \) is not contained in \( \mathcal{B} \). Hence the image \( r(\tilde{T}_i) \) is a proper subvariety in \( \Sigma(V) \), see diagram (8.2.2). So, \( r|_{\tilde{T}_i} : \tilde{T}_i \to r(\tilde{T}_i) \) is a \( \mathbb{P}^1 \)-fibration over a surface \( r(\tilde{T}_i) \subset \Sigma(V) \). The points of this surface parametrize a family of lines in \( V \) contained in \( T_i \). So, there is a one-parameter family of lines passing through a general point \( t \in T_i \). These lines sweep up the cubic cone \( S_t \) with vertex \( t \), see again Proposition 8.2(e). Thus, \( S_t = T_i \) for a general \( t \in T_i \). Hence \( S_t \) does not depend on \( t \), a contradiction. \( \square \)

9.5. **Proposition.** Each component \( \mathcal{S}_i(V), \) \( i = 1,2 \), of the Hilbert scheme \( \mathcal{S}(V) \) of cubic scrolls in \( V \) (see Theorem 9.1(b)) contains at least one \( \text{Aut}^0(V) \)-invariant cubic cone.

In the proof we use the following auxiliary results.

9.5.1. **Lemma.** Any morphism \( f : \mathbb{P}^2 \to \Sigma(V) \) is constant.

**Proof.** We regard \( \Sigma(V) \) as a smooth divisor in \( \mathbb{P}^2 \times \mathbb{P}^2 \) of bidegree \((1,1)\). Suppose to the contrary that \( T := f(\mathbb{P}^2) \subset \Sigma(V) \) is not a point. Then \( \dim T = 2 \) and \( f : \mathbb{P}^2 \to T \) is a finite morphism of degree, say, \( d \). By Remark 9.1(i), one has \( T \sim a_1F_1 + a_2F_2 \) for some integers \( a_1, a_2 \geq 0 \). There are relations

\[
F_1^3 = F_2^3 = 0, \quad F_1^2 \cdot F_2 = F_1 \cdot F_2^2 = 1.
\]

Since \( \Sigma(V) \) is smooth, in suitable bihomogeneous coordinates \((x_0 : x_1 : x_2 ; y_0 : y_1 : y_2)\) in \( \mathbb{P}^2 \times \mathbb{P}^2 \) the equation of \( \Sigma(V) \) can be written as

\[
F_1 x_0 y_0 + x_1 y_1 + x_2 y_2 = 0.
\]

Hence any fiber of the projections to the factors \( \text{pr}_i|_{\Sigma(V)} : \Sigma(V) \to \mathbb{P}^2, \) \( i = 1,2 \), is isomorphic to \( \mathbb{P}^1 \). It follows that the restrictions \( \pi_i = \text{pr}_i|_{T} : T \to \mathbb{P}^2, \) \( i = 1,2 \), are finite morphisms. Indeed, \( \pi_i(T) \) is neither a point, nor a curve, since \( \mathbb{P}^2 \) does not admit any dominant morphism to a curve. In particular, \( T \cdot F_i^2 > 0, \) \( i = 1,2 \), hence \( a_1, a_2 > 0 \).

\(^3\)In [PZ13, Cor. 5.13] we constructed a pair \((V,S)\) such that \( S \in \mathcal{S}(V) \) is a smooth cubic scroll.

\(^4\)In fact, \( s_t \) is the exceptional section of a surface \( \tilde{S}_t \cong F_3 \) in \( \mathcal{L}(V) \). The restriction \( s|_{\tilde{S}_t} : \tilde{S}_t \to S_t \) is the minimal resolution of singularity of the cubic cone \( S_t \).
The degree of $\pi_1 \circ f : \mathbb{P}^2 \to \mathbb{P}^2$ equals $(\deg f)(\deg \pi_1) = d(T \cdot F) = da_2$, while $\deg(\pi_2 \circ f) = da_1$. Identifying $\Sigma(V)$ with a smooth hyperplane section $D_0 \subset \mathbb{P}^7$ of the image of $\mathbb{P}^2 \times \mathbb{P}^2$ under the Segre embedding, we obtain $\theta_T(1) = \theta_T(F_1 + F_2)$. It follows that

$$\deg T = (F_1 + F_2)^2 \cdot T = 3(a_1 + a_2).$$

On the other hand, $f^* \theta_T(F_1) = \theta_{\mathbb{P}^2}(da_2)$ and $f^* \theta_T(F_2) = \theta_{\mathbb{P}^2}(da_1)$. So, $f^* \theta_T(1) = \theta_{\mathbb{P}^2}(da_1 + da_2)$, and

$$\deg T = \frac{1}{d}(da_1 + da_2)^2 = (a_1 + a_2)^2.$$

Thus, $d(a_1 + a_2) = 3$. Up to a translation in indices, the only possibility is $d = 1$, $a_1 = 2$, $a_2 = 1$. In particular, $f$ and $\pi_1$ are birational, hence $T \cong \mathbb{P}^2$. Since $T$ is an ample divisor on $\Sigma(V)$, by the Lefschetz theorem, the restriction map $\text{Pic}(\Sigma(V)) \to \text{Pic}(T)$ is injective, a contradiction.

**Proof of Proposition 9.5.** By Lemma 9.4, for $i = 1, 2$ there is an $\text{Aut}^0(V)$-invariant Zariski dense, open subset $\mathcal{U}_i$ of $\mathcal{S}(V)$, whose points correspond to smooth cubic scrolls in $V$. So, each point in $\mathcal{S}(V) \setminus \mathcal{U}_i$ corresponds to a cubic cone. Any smooth cubic scroll contains a unique distinguished line, which is its exceptional section. This provides an $\text{Aut}^0(V)$-equivariant rational map

$$\zeta : \mathcal{S}(V) \cong \mathbb{P}^2 \dashrightarrow \Sigma(V) \hookrightarrow \mathbb{P}^2 \times \mathbb{P}^2$$

sending a smooth cubic scroll to its exceptional section. This map is regular on $\mathcal{U}_i$. By Lemma 9.3 the restriction $\zeta|_{\mathcal{U}_i} : \mathcal{U}_i \to \zeta(\mathcal{U}_i)$ has finite fibers. Hence $\dim \zeta(\mathcal{U}_i) = 2$, $i = 1, 2$.

In particular, $\zeta$ is non-constant. By Lemma 9.5.1, $\zeta$ cannot be a morphism. So, its indeterminacy set is a nonempty subset of $\mathcal{S}(V) \setminus \mathcal{U}_i$ of dimension zero. It consists of isolated fixed points of $\text{Aut}^0(V)$ that correspond to $\text{Aut}^0(V)$-invariant cubic cones in $V$. \hfill \Box

9.5.5. **Lemma.** Two general cubic scrolls in $V$ either are disjoint, or meet transversely in a single point.

**Proof.** By Lemma 9.4 it is enough to deal with a pair of smooth cubic scrolls in $V$. Given a smooth cubic scroll $S$ in $V$, consider the family $\mathcal{S}(S)$ of all $S' \in \mathcal{S}(V)$ such that $S' \subset A_S$. We claim that $\mathcal{S}(S)$ is at most one-dimensional. Indeed, starting with the pair $(V, S)$ one can produce a diagram (3.1.1). If $\widetilde{S} \subset \widetilde{A}_S$ is the proper transform of $S'$ in $\widetilde{W}$, then $\eta(\widetilde{S}) \subset \eta(\widetilde{A}_S) = F$. Suppose that $\widetilde{S}$ dominates $F$ under $\eta$. Then $\widetilde{S}$ meets each ruling $f_p = \eta^{-1}(p)$, $p \in F$, of $\eta : \widetilde{A}_S \to F$. Hence $S'$ meets each line $\xi(f_p) \subset A_S$. Thus, $\xi(f_p) \subset A_{S'}$ for any $p \in F$. This family of lines covers $A_S$, and so, $A_S = A_{S'}$. Then also the singular loci $S$ and $A_S = A_{S'}$ coincide, a contradiction.

Thus, $\eta(\widetilde{S}') = \theta(S')$ is an irreducible curve in $F$, which can be either a line, or a smooth conic. Anyway, $\widetilde{S}'$ belongs to a one-parameter family of ruled surfaces in $\widetilde{A}_S$. Hence $\dim \mathcal{S}(S) \leq 1$.

It follows that $S' \not\subset A_S$ for a general pair of cubic scrolls $(S, S')$ in $V$. Then $\theta|_{S'} : S' \to \theta(S') \subset W$ is birational. Hence $\dim(\langle S \rangle \cap \langle S' \rangle) \leq 1$. If $\dim(\langle S \rangle \cap \langle S' \rangle) = 1$, then $\theta(\langle S' \rangle)$ is a plane in $\mathbb{P}^7$. Then $\theta(S') \subset W$ is as well a plane, which belongs to a one-parameter family of planes in $W$. Therefore, for a general $S' \in \mathcal{S}(V)$ one has $\dim(\langle S \rangle \cap \langle S' \rangle) \leq 0$. So, either $S$ and $S'$ are disjoint, or they meet transversely in a single point. \hfill \Box
Next we describe the middle cohomology group of $V$.

9.6. **Proposition.** The group $H^4(V,\mathbb{Z})$ is generated by the classes of two cubic scrolls $S_1$ and $S_2$ from different components of $\mathcal{S}(V)$. In the cohomology ring $H^*(V,\mathbb{Z})$ these classes satisfy the relations $[S_1]^2 = [S_2]^2 = 1$, $[S_1] \cdot [S_2] = 0$.

The proof is preceded by the following lemma.

9.6.1. **Lemma.** For any cubic scroll $S$ in $V$ one has $S^2 = 1$ in $H^*(V,\mathbb{Z})$.

**Proof.** By Lemma 9.4 one can choose $S \in \mathcal{S}(V)$ to be smooth. Consider the corresponding diagram (3.1.1). For the exceptional divisor $\tilde{B} \sim H^* - \tilde{A}$ of $\xi : \tilde{W} \to V$ one has ([PZ16 Lem. 2.3])

\begin{equation}
\tilde{B}^4 = c_2(V) \cdot S + K_V|_S \cdot K_S - c_2(S) - K_V^2 \cdot S.
\end{equation}

Letting $s_0$ and $f$ be the exceptional section and a ruling of $S \cong \mathbb{P}_1 \to \mathbb{P}_1$, respectively, one computes

\begin{equation}
K_V^2 \cdot S = (2H^2) \cdot S = 12, \quad c_2(S) = 4, \quad K_V|_S \cdot K_S = -2(s_0+2f)(-2s_0-3f) = 10.
\end{equation}

Plugging (9.6.3) in (9.6.2) gives

\begin{equation}
B^4 = S^2 - 6.
\end{equation}

From the exact sequence

\[ 0 \to T_S \to T_V|_S \to \mathcal{N}_{V/S} \to 0 \]

one deduces a relation for the Chern classes

\[ (1 - K_S t + c_2(S)t^2)(1 + c_1(\mathcal{N}_{V/S})t + c_2(\mathcal{N}_{V/S})t^2) = 1 - K_V|_S t + c_2(V)|_S t^2. \]

This yields a system

\[
c_1(\mathcal{N}_{V/S}) = K_S - K_V|_S, \]

\[
c_2(V) \cdot S = c_2(S) - K_S \cdot c_1(\mathcal{N}_{V/S}) + c_2(\mathcal{N}_{V/S}) = c_2(S) - K_S^2 + K_S \cdot K_V|_S + S^2.
\]

Using (9.6.3) one obtains the relation $c_2(V) \cdot S = S^2 + 6$. It follows by (9.6.4) that $\tilde{B}^4 = S^2$.

Finally, from [PZ15 Lem. 5.5] one gets

\[ S^2 = \tilde{B}^4 = (H^* - \tilde{A})^4 = (H^*)^4 + 6(H^*)^2 \cdot \tilde{A}^2 - 4H^* \cdot \tilde{A}^3 + \tilde{A}^4 = 1. \]

\[ \square \]

9.6.5. **Lemma.** For any two cubic scrolls $S_i \in \mathcal{S}(V)$, $i = 1, 2$, one has $S_1 \cdot S_2 = 0$.

**Proof.** By Lemma 9.6.1 any two disjoint cubic scrolls belong to different components of $\mathcal{S}(V)$. According to Proposition 6.3(b) and Lemma 6.6.1 there is a Fano-Mukai fourfold $V = V_{18}$ of genus 10, which contains two disjoint cubic cones. By Theorem 7.1 any Fano-Mukai fourfold of genus 10 appears as a smooth hyperplane section of the adjoint variety $\Omega \subset \mathbb{P}^{13}$. Since the family of such hyperplane sections of $\Omega$ is irreducible, the lemma follows. \[ \square \]
Proof of Proposition 9.6. Using diagram (3.1.1) one derives isomorphisms
\[ H^4(V, \mathbb{Z}) \cong H^4(W, \mathbb{Z}) \cong \mathbb{Z} \oplus \mathbb{Z}, \]
see [PZ15] Lem. 3.4. By Lemmas 9.6.1 and 9.6.5 the classes \([S_1]\) and \([S_2]\) are independent and generate \(H^4(V, \mathbb{Z})\). □

Let us introduce the following notation.

9.7. Notation. Given a cubic scroll \(S \in \mathcal{S}(V)\), consider the following objects:
- the variety \(\Lambda(S) \subset \Sigma(V)\) of rulings of \(S\) (clearly, \(\Lambda(S) \cong \mathbb{P}^1\));
- the variety \(\Sigma(S) \subset \Sigma(V)\) of lines in \(V\) which meet \(S\).

9.7.1. Lemma. \(\Sigma(S)\) is a divisor on \(\Sigma(V)\).

Proof. The statement is immediate from Lemma 9.2. □

9.7.2. Lemma. Consider the standard projections \(\text{pr}_i : \Sigma(V) \to \mathbb{P}^2, i = 1, 2\) (see Theorem 9.1(a)). Then for any \(S \in \mathcal{S}(V)\) the variety \(\Lambda(S) \subset \Sigma(V)\) is a fiber of one of these projections, while \(\Sigma(S)\) is the pull-back of a line in \(\mathbb{P}^2\) under the other one. In particular, \(\Sigma(S) \cong \mathbb{F}_1\), and \(\Lambda(S) \subset \Sigma(S)\) is the exceptional section.

Proof. Let \(S_1 \in \mathcal{S}_1(V)\). For a general cubic scroll \(S_2 \in \mathcal{S}_2(V)\), by Lemma 9.5.5 and Proposition 9.6 one has \(S_1 \cap S_2 = \emptyset\). Therefore, \(\Sigma(S_1) \cdot \Lambda(S_2) = 0\). Similarly, for a general \(S'_1 \in \mathcal{S}_1(V)\) one has \(\Sigma(S_1) \cdot \Lambda(S'_1) = 1\). In the notation of Remark 9.1.1(i) modulo reindexing \(\mathcal{S}(V)\) one obtains \(\Sigma(S_1) \sim \mathcal{F}_1\). Thus, \(\Sigma(S_1)\) is the pull-back of a line under a projection \(\Sigma(V) \to \mathbb{P}^2\). This shows as well that \(\Lambda(S_1)\) is a fiber of the other projection. □

The following corollary of (9.5.2) and 9.7.2 is immediate, cf. [KR13, proof of Prop. 2].

9.7.3. Corollary. (i) Any line \(l \in \Sigma(V)\) is a common ruling of exactly two cubic scrolls \(S_1(l)\) and \(S_2(l)\), where \(S_i(l) \in \mathcal{S}_i(V), i = 1, 2\). In particular, \(V\) is covered by the cubic scrolls contained in \(V\).
(ii) If \(l\) is contained in a third cubic scroll \(S \neq S_i(l), i = 1, 2\), then \(S\) is smooth, and \(l\) is the exceptional line of \(S\).
(iii) Two distinct cubic scrolls \(S', \neq S\) in \(V\) can have at most one common ruling.

The possible intersections of two cubic cones are as follows.

9.7.4. Corollary. Two distinct cubic cones \(S, S'\) in \(V\) either are disjoint, or meet transversally in one point, or finally contain a common ruling which is the only one-dimensional component of their intersection. 

Proof. By Proposition 9.6, if the intersection \(S \cap S'\) is finite, then either it is empty, or \(S\) and \(S'\) meet transversally at a single point, depending on whether \(S, S'\) belong to different components of \(\mathcal{S}(V)\) or not.

Assume that \(\dim(S \cap S') = 1\). Then any ruling of \(S'\) meets \(S\) and so it is contained in \(A_S\). Therefore, \(S' \subset A_S\). Since through any point of \(A_S \setminus S\) passes exactly one line in \(A_S\) meeting \(S\) (see Lemma 9.2), the vertex \(v(S')\) lies on \(S\). By symmetry, \(v(S)\) lies on \(S'\). Thus, the line \(l\) joining \(v(S)\) and \(v(S')\) is a common ruling.

It follows that \(v(S') \in \langle S\rangle\), and so, \(\langle S\rangle \cap S'\) is a union of lines in \(V\) passing through \(v(S')\). By symmetry, \(\langle S'\rangle \cap S\) is a union of lines passing through \(v(S)\). One concludes that
\[ S \cap S' = (\langle S'\rangle \cap S) \cap (\langle S\rangle \cap S') \]
is a union of lines in V passing through both ν(S) and ν(S'). Since ν(S) \neq ν(S'), see Proposition 8.2(e), l is the only one-dimensional component of S ∩ S'. □

We can now reinterpret the embedding Σ(V) ⊆ P^2 × P^2 as follows.

9.7.5. Corollary. In the notation of 9.7.3(i) the morphism
\[ \varrho : \Sigma(V) \to \mathcal{I}_1(V) \times \mathcal{I}_2(V) \cong \mathbb{P}^2 \times \mathbb{P}^2, \quad l \mapsto (S_1(l), S_2(l)), \]
realizes Σ(V) as a smooth (1,1)-divisor in \mathbb{P}^2 × \mathbb{P}^2.

We use below the following notation and terminology.

9.8. Notation. Given a line l in V, consider the following objects:
- the family \Sigma(l) ⊂ Σ(V) of lines in V which meet l;
- the union Θ(l) ⊂ V of lines from Σ(l);
- the morphism π : Σ(l) \setminus \{l\} → l, l' ↦ l' \cap l.

It is known ([KR13, proof of Prop. 2]) that Σ(l) \setminus \{l\} is a curve in Σ(V) of bidegree (1,1). Due to Proposition 8.4(e) and Lemma 9.3, π is generically 2 : 1 or 1 : 1. So, Σ(l) consists of at most two components. Then also Θ(l) consists of at most two components of pure dimension 2.

A line l ∈ Σ(V) will be called a splitting line, or an s-line for short, if Θ(l) splits into two components Θ_1(l) and Θ_2(l). We let Σ_s(V) ⊂ Σ(V) denote the subvariety of s-lines in V. Clearly, Σ_s(V) is a closed subset in Σ(V). We consider it with its reduced structure.

The proof of Proposition 2 in [KR13] shows that Θ_1(l) and Θ_2(l) belong to different components of \mathcal{I}(V). We adopt the convention Θ_i(l) ∈ \mathcal{I}_i(V), i = 1, 2. Adopting a terminology from [KR13], we call a line l in a cubic scroll S exceptional if either S is smooth and l is the exceptional section of S, or S is a cone and l is a ruling of S.

Since (Θ(l))_{l ∈ Σ(V)} is a flat family over an irreducible base, the function l ↦ deg Θ(l) on Σ(V) is constant. In statement [a] of the following lemma we determine this constant.

9.9. Lemma. (a) For any line l ∈ Σ(V) one has deg Θ(l) = 6. If l is an s-line with Θ(l) = Θ_1(l) ∪ Θ_2(l), then Θ_i(l), i = 1, 2, are cubic scrolls.
(b) Let l ∈ Σ(V). Then l ∈ Σ_s(V), that is, l is an s-line, if and only if l is an exceptional line of a cubic scroll.
(c) An s-line l is contained in \mathcal{B} if and only if l is a ruling of a cubic cone.

Proof. [a] Consider the rational surfaces \( T_i = \zeta(U_i) \subset \Sigma(V), i = 1, 2, \) where \( U_i \subset \mathcal{I}_i(V) \) is the subset of smooth scrolls, and \( \zeta : U_i \to \Sigma(V) \) sends a scroll \( S \in U_i \) to its exceptional section, c.f. the proof of Proposition 9.5. It is easy to see that any two exceptional divisors on Σ(V) meet. Hence, \( T_1 \cap T_2 \neq \emptyset. \)

Let \([l] \in T_1 \cap T_2 \subset \Sigma(V). \) We claim that Θ(l) = S_1 ∪ S_2 for some \( S_i \in \mathcal{I}_i(V), i = 1, 2. \) Indeed, one has \( l = \lim_{j \to \infty} l_{i,j}, \) where for any \( j \geq 1, l_{i,j} \in \zeta(U_i) \) is the exceptional line of a smooth cubic scroll \( S_{i,j} \in \mathcal{I}_i, i = 1, 2. \) Passing to subsequences one may assume that \( \lim_{j \to \infty} S_{i,j} = S_i \in \mathcal{I}_i, i = 1, 2. \) If \( S_i \) is smooth, then \( l \subset S_i \) is the exceptional line of \( S_i. \) In any case, \( S_1 \cup S_2 \subset \Theta(l). \) Since Θ(l) consists of at most two components, see 9.8, one has Θ(l) = S_1 ∪ S_2, as claimed. So, deg Θ(l) = 6 ∀l ∈ Σ(V). Now the second assertion follows as well. Indeed, Ω (and then also V) contains neither a plane, nor a quadric surface ([KR13, Lem. 3]). Moreover, since V is an intersection of quadrics ([Isk77, Lem. 2.10]), V does not contain any cubic surface F with \langle F \rangle \cong P^3. \)
To show the “if” part, observe that in both cases the corresponding cubic scroll is a component of $\Theta(l)$. Due to (a) $l$ is an $s$-line. The “only if” part follows from the definition.

A line $l$ on $V$ is contained in $B$ if and only if through a general point of $l$ pass at most 2 lines in $V$ including $l$ itself. For an $s$-line $l$ this is the case if and only if at least one of the components $\Theta_1(l)$ and $\Theta_2(l)$ is a cubic cone. 

9.9.1. Corollary. One has $\dim \Sigma_s(V) = 2$.

Proof. This follows from Lemma 9.9. Indeed, $\Sigma_s(V)$ consists of the exceptional lines of smooth cubic scrolls and of the rulings of cubic cones. The first family of lines is purely two-dimensional, and the second is at most two-dimensional due to Lemma 9.4.

9.10. Proposition. For any $S \in \mathcal{I}(V)$ one has

(a) $\Lambda(S) \subset \Sigma_s(V)$ if and only if $S$ is a cubic cone;
(b) $\Lambda(S) \cdot \Sigma_s(V) = 1$ for any $S \in \mathcal{I}(V)$;
(c) $\Sigma_s(V) \sim \mathcal{F}_1 + \mathcal{F}_2$.

Proof. (a) is immediate from Lemma 9.9. (b) Let $S \in \mathcal{I}(V)$ be smooth. Let us show that exactly one ruling of $S$ is an $s$-line. For such a ruling $l$ one has $\Theta(l) = S_1 \cup S_2$, where $S_i \in \mathcal{I}_i(V)$, $S_i \neq S$, $i = 1, 2$. Due to Corollary 9.7.3(iii) at least one of $S_1$, $S_2$ is smooth. Since each ruling of $S_i$ meets $S$, one has $S_i \subset A_S$, $i = 1, 2$.

Starting with the pair $(V, S)$ we construct diagram (3.1.1). The proper transform $\tilde{S}_i$ of $S_i$ in $\tilde{W}$ is a ruled surface contained in $\tilde{A}_S$, and its image $\theta(S_i) \subset W$ under the linear projection $\theta : \mathbb{P}^{12} \dashrightarrow \mathbb{P}^7$ with center $\langle S \rangle$ is a curve contained in $F$.

Assume first that $\langle S \rangle \cap \langle S_i \rangle = l$ for some $i \in \{1, 2\}$. Then $J := \theta(S_i)$ is a smooth conic. Indeed, if $S_i$ is smooth, then $\theta(S_i)$ is the image of a conic section of $S_i \rightarrow \mathbb{P}^1$ disjoint with $l$, and if $S_i$ is a cubic cone, then $\theta(S_i)$ is the image of a twisted cubic in $S_i$, which meets $l$ once and transversely. The rational normal quintic scroll $F$, which contains a nondegenerate conic $J$, is isomorphic to $\mathbb{P}_1$, and $J$ is its exceptional section. Hence $S_i$ is the only component of $\Theta(l)$ with $\langle S \rangle \cap \langle S_i \rangle = l$. Moreover, $l$ is a unique splitting line in $S$, because $S_i$ does not contain two distinct rulings of $S$, see Corollary 9.7.3(iii). Thus, in this case $\Lambda(S) \cap \Sigma_s(V)$ consists of a single point.

Assume further that $\dim(\langle S \rangle \cap \langle S_i \rangle) = 2$ for $i = 1, 2$. Then $f_i := \theta(S_i)$ is a line in $F$ for $i = 1, 2$. These lines cannot be both rulings of $F$. Indeed, otherwise $\eta^{-1}(f_i)$, $i = 1, 2$, would be ruled surfaces in $\tilde{W}$ from the same irreducible family of ruled surfaces. Hence also $S_1$ and $S_2$ would belong to the same family of surfaces in $\tilde{V}$ over an irreducible base. However, $S_1$ and $S_2$ belong to different components of $\mathcal{I}(V)$ ([KR13] proof of Prop. 2). Due to Proposition 9.6 we obtain a contradiction.

So, one of the $f_i$, say, $f_1$ should be the exceptional line of $F \cong \mathbb{P}_3$, while $f_2$ should be a ruling of $F$. Once again, $S_1$ is uniquely determined and does not contain two distinct rulings of $S$. Hence $\Lambda(S) \cap \Sigma_s(V)$ is a single point in this case as well.

This follows by (b) and 9.7.2.

9.10.1. Corollary. If two distinct cubic cones $S$ and $S'$ in $V$ have a common ruling $l$, then they belong to different components of $\mathcal{I}(V)$.
Proof. Indeed, $\Lambda(S)$ and $\Lambda(S')$ are two lines in $\Sigma_s(V)$, which meet in a point $[l]$. If $S$ and $S'$ were in the same component, say, $\mathcal{S}_i(V)$ of $\mathcal{S}(V)$, then these lines would project to the same point $\text{pr}_j([l]) \in \mathbb{P}^2$, where $j \neq i$. The latter means that $S = S'$, a contradiction. □

10. Cubic cones in $V_{18}$ and lines on singular del Pezzo sextics

In this section we associate to each Fano-Mukai fourfold $V = V_{18}$ of genus 10 a certain (singular) del Pezzo sextic surface. The cubic cones in $V$ occur to be in a one-to-one correspondence with the lines on this sextic.

10.1. Lemma ([Dol12 § 8.1.1, § 8.4.2], [CT88 Prop. 8.3]). Let $X \subset \mathbb{P}^6$ be a linearly nondegenerate normal surface of degree 6, and let $\tilde{X}$ be the minimal desingularization of $X$. Let $\Gamma(\tilde{X})$ be the dual graph of the configuration of $(-1)$- and $(-2)$-curves in $\tilde{X}$. Suppose that $X$ admits two different birational contractions onto $\mathbb{P}^2$. Then the following hold.

(a) $X$ has at worst Du Val singularities.
(b) $X$ admits a canonical embedding in $\mathbb{P}^2 \times \mathbb{P}^2$.
(c) $X$ is one of the following:
   (i) a smooth del Pezzo sextic surface, with $\Gamma(\tilde{X})$ being a cycle of six $(-1)$-vertices;
   (ii) a del Pezzo sextic surface with a unique singular point of type $A_1$ and with
   \[
   \Gamma(\tilde{X}) : \begin{array}{cccccc}
   -1 & -1 & -2 & -1 & -1 & -1 \\
   \end{array}
   \]
   where the black vertices correspond to the lines in $X$;
   (iii) a del Pezzo sextic surface with a unique singular point of type $A_2$ and with
   \[
   \Gamma(\tilde{X}) : \begin{array}{cc}
   -2 & \circ \\
   \circ & -2 \\
   -1 & \end{array}
   \]
   (d) The number of lines in $X$ is 6 for type (c)(i), 4 for type (c)(ii), and 2 for type (c)(iii). There exists a unique divisor $G_X \in |-K_X|$ whose support coincides with the union of lines on $X$.

Abusing the language we say that a del Pezzo sextic $X$ in (c)(ii) (resp., $X$ in (c)(iii)) is of type $A_1$ (resp., of type $A_2$).

One has the following result.

10.2. Proposition. $\Sigma_s(V)$ is a sextic surface. If it is reducible, then this is the union $\mathcal{F}_1 \cup \mathcal{F}_2$ of two cubic scrolls, where $\mathcal{F}_i$ is the pullback of a line in $\mathbb{P}^2$ under the projection $\text{pr}_i : \Sigma(V) \to \mathbb{P}^2$, $i = 1, 2$. If it is irreducible, then $\Sigma_s(V)$ is a del Pezzo sextic which is either smooth, or of type $A_1$, or of type $A_2$.

Proof. By Proposition 9.10(c) $\Sigma_s(V)$ is a sextic hyperplane section of $\Sigma(V)$ with respect to the polarization on $\Sigma(V)$ induced by the Segre embedding $\mathbb{P}^2 \times \mathbb{P}^2 \hookrightarrow \mathbb{P}^8$. Moreover, if the surface $\Sigma(V)$ is reducible, then $\Sigma_s(V) = \mathcal{F}_1 \cup \mathcal{F}_2$. Assume that $\Sigma_s(V)$ is irreducible. Again by Proposition 9.10(c) the restrictions $p_i|_{\Sigma_s(V)} : \Sigma_s(V) \to \mathcal{S}_i(V) = \mathbb{P}^2$, $i = 1, 2$, yield two birational contractions, whose exceptional divisors do not possess any common component. Moreover, any ruling of $p_i$ passing through a singular point of $\Sigma_s(V)$ is
If it is finite, then any cubic cone \( \Sigma \) contained in \( \Sigma(V) \). Therefore \( \Sigma(V) \) is normal. The rest of the proof is straightforward from Lemma 10.1(c).

10.2.1. Corollary. The set of cubic cones in \( V \) is finite if and only if \( \Sigma(V) \) is irreducible. If it is finite, then any cubic cone \( S \subset V \) is invariant under the \( \text{Aut}^0(V) \)-action.

10.3. Notation. Up to an automorphism of \((\mathbb{P}^2)^{\vee} \times \mathbb{P}^2\), which does not interchange the factors, one may assume that \( \Sigma(V) \) coincides with the variety \( \Sigma \) of complete flags in \( \mathbb{P}^2 \) given in \((\mathbb{P}^2)^{\vee} \times \mathbb{P}^2 \) by equation (9.3.1). Up to an automorphism of \( \Sigma(V) \) one may suppose that \( (\mathcal{F}_1, \mathcal{F}_2) \) is one of the following:

\begin{itemize}
  \item[(i)] \( \mathcal{F}_1 = \{x_0 = 0\} \) and \( \mathcal{F}_2 = \{y_0 = 0\} \);
  \item[(ii)] \( \mathcal{F}_1 = \{x_0 = 0\} \) and \( \mathcal{F}_2 = \{y_1 = 0\} \).
\end{itemize}

We say that a pair \( (\mathcal{F}_1, \mathcal{F}_2) \) is of the first (resp., second) kind if it is equivalent to a pair \( (i) \) (resp., \( (ii) \)). For a pair \( (\mathcal{F}_1, \mathcal{F}_2) \) of the first kind in \( (i) \) the intersection \( C = \mathcal{F}_1 \cap \mathcal{F}_2 \) is the \((1,1)\)-conic in \((\mathbb{P}^1)^{\vee} \times \mathbb{P}^1 \) given by equation \( x_1 y_1 + x_2 y_2 = 0 \). The projection \( p_{2|\mathcal{F}_1}: \mathcal{F}_1 \to \mathcal{F}_2(V) \cong \mathbb{P}^2 \) sends birationally \( \mathcal{F}_1 \) onto \( \mathbb{P}^2 \) contracting the exceptional section \( s_1 \) of \( \mathcal{F}_1 \cong \mathbb{P}_1 \) (disjoint with \( s_1 \)) to the line \( h_2 = \{y_0 = 0\} \), and sends the conic section \( C \subset \mathcal{F}_1 \) (disjoint with \( s_1 \)) to the line \( h_2 = \{y_0 = 0\} \), and symmetrically for the projection \( p_{1|\mathcal{F}_2}: \mathcal{F}_2 \to \mathcal{F}_1(V) \cong \mathbb{P}^2 \).

For a pair \( (\mathcal{F}_1, \mathcal{F}_2) \) of the second kind the intersection \( C = \mathcal{F}_1 \cap \mathcal{F}_2 \) is reducible and consists of two lines \( s_1 \cup s_2 \), where \( s_1 \) (resp. \( s_2 \)) is the exceptional section of \( \mathcal{F}_1 \) (resp. \( \mathcal{F}_2 \)) and a ruling of \( \mathcal{F}_2 \) (resp. \( \mathcal{F}_1 \)). Thus, \( p_2(s_1) = q_2 \in h_2 = \{y_1 = 0\} \), and \( p_1(s_2) = q_1 \in h_1 = \{x_0 = 0\} \). The lines \( s_1 \) and \( s_2 \) meet at a single point.

10.3.1. Lemma. Assume that \( \Sigma(V) = \mathcal{F}_1 \cup \mathcal{F}_2 \). Let \( (W, F) \) be the pair linked to \( (V, S_2) \). Suppose also that the group \( \text{Aut}^0(W, F) \) contains a singular torus \( z(L) \) of \( \text{Aut}(W) \), where \( L \subset \text{Aut}(W) \) is a Levi subgroup. Then \( (\mathcal{F}_1, \mathcal{F}_2) \) is a pair of the first kind. This holds, in particular, if \( \text{Aut}(V) \supset (\mathbb{G}_m)^2 \).

Proof. Suppose to the contrary that \( (\mathcal{F}_1, \mathcal{F}_2) \) is a pair of the second kind. By Corollary 10.3.2(b) the cubic cones \( S_1 \) and \( S_2 \) are \( \text{Aut}^0(V) \)-invariant. Since \( z(L) \subset \text{Aut}^0(W, F) \), then \( \mathcal{F}_1(V) \) contains a cubic cone \( S_i \) disjoint with \( S_2 \), see Lemma 6.6.1. The cones \( S_1 \) and \( S_2 \) have a common ruling, hence \( S' \neq S_1 \). So, \( S'_1 \) corresponds to a rulings \( \Lambda(S_{1,t}) \) of \( \mathcal{F}_1 \) for some \( t \in \mathbb{P}^1 \), see Corollary 10.3.2(b). However, the cones \( S_2 \) and \( S'_1 \) as well have a common ruling. This gives a desired contradiction.

From Proposition 10.1 we deduce

10.3.2. Corollary. (a) If \( \Sigma(V) \) is irreducible, then every component \( \mathcal{F}_i(V) \), \( i = 1, 2 \), contains exactly 3, 2 or 1 cubic cone(s) according to types \( (c)(i) \) and \( (c)(ii) \) in Lemma 10.1, respectively.

(b) If \( \Sigma(V) = \mathcal{F}_1 \cup \mathcal{F}_2 \), then the following hold.

\begin{itemize}
  \item For \( i = 1, 2 \) the subvariety \( \mathcal{C}_i(V) \) of \( \mathcal{F}_i(V) \cong \mathbb{P}^2 \) whose points correspond to cubic cones in \( V \) consists of a line \( h_i \subset \mathbb{P}^2 \) and a reduced \( \text{Aut}^0(V) \)-invariant point \( q_i = [S_i] \). For a pair \( (\mathcal{F}_1, \mathcal{F}_2) \) of the first kind, \( q_i \notin h_i \), otherwise \( q_i \in h_i \).
  \item Each ruling \( l_i,t \) of \( S_i \), \( t \in \mathbb{P}^1 \), is a common ruling of \( S_i \) and of a unique cubic cone \( S_{j,t} \in \mathcal{C}_j(V) \), \( j \neq i \).
  \item If \( (\mathcal{F}_1, \mathcal{F}_2) \) is a pair of the first kind, then \( S_j \) does not contain the vertex of \( S_i \), \( i \neq j \).
\end{itemize}

Proof. Statement \( (a) \) is straightforward from Proposition 9.1[a].
(b) By Proposition 9.10(a), the cubic cones in $\mathcal{F}(V)$ correspond to the lines in $\Sigma_a(V) = \mathcal{F}_1 \cup \mathcal{F}_2$ contracted under the projection $p_i : \Sigma_a(V) \to \mathcal{F}(V) = \mathbb{P}^2$, $i, j = 1, 2$. Hence they correspond to the rulings of $\mathcal{F}_i$ and the exceptional sections $s_i$ of $\mathcal{F}_i$, $i = 1, 2$. This gives an isomorphism $\mathcal{C}(V) \cong h_i \cup \{q_i\}$ and the equalities $[S_i] = \{q_i\}$ and $s_j = \Lambda(S_i) = p_i^{-1}(q_i)$, $i, j = 1, 2$, $j \neq i$. Any ruling of $p_i : \mathcal{F}_i \to h_i$ meets the exceptional section $s_i$ in a point, which corresponds to the unique common ruling of the assigned cubic cones, cf. Corollary 9.7.3. This proves the first two assertions of (b).

To show the last one, we let $v_i$ be the vertex of the cone $S_i$, $i = 1, 2$. Suppose to the contrary that $v_i \in S_j$ for some choice of $i, j \in \{1, 2\}$, $i \neq j$. Let $l$ be the unique ruling of $S_j$ passing through $v_i \neq v_j$. Since any line in $V$ through $v_i$ is a ruling of $S_i$, see Proposition 11.2(e), $l$ is a common ruling of $S_i$ and $S_j$. However, for a pair $(\mathcal{F}_1, \mathcal{F}_2)$ of the first kind both $\Lambda(S_1) \subset \mathcal{F}_2$ and $\Lambda(S_2) \subset \mathcal{F}_1$ are disjoint with the common conic section $C = \mathcal{F}_1 \cap \mathcal{F}_2$. Hence, $S_1$ and $S_2$ do not have any ruling in common, a contradiction. $\square$

11. Automorphism groups of singular del Pezzo sextics

In this section we prove the following proposition.

11.1. Proposition. For any Fano-Mukai fourfold $V = V_{18}$ of genus 10 one of the following cases $\square$ occurs.

| $\Sigma_a(V)$ | $\text{Aut}(V)$ |
|-------------|----------------|
| $1^o$ a union of two smooth cubic scrolls meeting along a smooth conic | $\text{GL}_2(\mathbb{C}) \subset \text{Aut}(V) \subset \text{GL}_2(\mathbb{C}) \rtimes (\mathbb{Z}/2\mathbb{Z})$ |
| $2^o$ a del Pezzo sextic of type $A_1$ | $\mathbb{G}_a \times \mathbb{G}_m \subset \text{Aut}(V) \subset (\mathbb{G}_a \times \mathbb{G}_m) \rtimes (\mathbb{Z}/2\mathbb{Z})$ |
| $3^o$ a smooth del Pezzo sextic | $(\mathbb{G}_m)^2 \subset \text{Aut}(V) \subset (\mathbb{G}_m)^2 \rtimes (\mathbb{Z}/6\mathbb{Z})$ |
| $4^o$ a union of two smooth cubic scrolls meeting along a pair of intersecting lines | $\mathbb{G}_a \times \mathbb{G}_m \subset \text{Aut}(V) \subset B(\text{PGL}_3(\mathbb{C})) \rtimes (\mathbb{Z}/2\mathbb{Z})$, where $B(\text{PGL}_3(\mathbb{C}))$ is a Borel subgroup of $\text{PGL}_3(\mathbb{C})$ |

In Cases $1^o$ and $3^o$ the variety $V$ contains two one-parameter families of cubic cones and two $\text{Aut}^0(V)$-invariant cubic cones $S_i \in \mathcal{F}(V)$, $i = 1, 2$. The number of cubic cones in $V$ equals 4 in Case $2^o$ and 6 in Case $3^o$; all of these cones are $\text{Aut}^0(V)$-invariant.

In fact, Case $4^o$ does not occur, see Corollary 12.5.2 in the next section. The proof of Proposition 11.1 is done in 11.5. It is preceded by some preliminary facts and constructions.

11.2. Lemma. (a) The induced $\text{Aut}(V)$-action on $\Sigma(V)$ is effective and leaves invariant the divisor $\Sigma_a(V) \subset \Sigma(V)$.

(b) $\text{Aut}^0(V)$ acts effectively on any component of $\Sigma_a(V)$.

(c) The action of $\text{Aut}(V)$ on $\Sigma_a(V)$ is effective.

Proof. (a) By Proposition 8.2(d), there are exactly three lines passing through a general point of $V$. This allows to reconstruct the $\text{Aut}(V)$-action on $V$ from the induced $\text{Aut}(V)$-action on $\Sigma(V)$. So, the latter action is effective. Now the assertion is straightforward.

(b) One may identify $\Sigma(V) \subset (\mathbb{P}^2)^\vee \times \mathbb{P}^2$ with the variety $\Sigma$ of complete flags in $\mathbb{P}^2$, see 10.3. The duality permutes the factors $(\mathbb{P}^2)^\vee$ and $\mathbb{P}^2$ inducing an involution $i$ of $\Sigma$. Thus, $\text{Aut}(\Sigma) = \text{Aut}^0(\Sigma) \rtimes (\mathbb{Z}/2\mathbb{Z})$, where $\text{Aut}^0(\Sigma) \cong \text{Aut}(\mathbb{P}^2)$.}

41
For $i = 1, 2$ the action of $\text{Aut}^0(\Sigma(V))$ on the ruling $p_i : \Sigma(V) \to \mathcal{I}_i(V)$ induces an isomorphism $\text{Aut}^0(\Sigma(V)) \cong \text{Aut}(\mathcal{I}_i(V))$ and also an injection $\text{Aut}^0(V) \hookrightarrow \text{Aut}(\mathcal{I}_i(V))$. For any irreducible component $\mathcal{T}$ of the divisor $\Sigma_s(V)$, at least one of the projections $p_i|_{\mathcal{T}} : \mathcal{T} \to \mathcal{I}_i(V)$, $i = 1, 2$, is dominant. Hence the representation $\text{Aut}^0(V) \to \text{Aut}(\mathcal{T})$ is faithful.

Assume that $\alpha \in \text{Aut}(V)$ induces the identity on $\Sigma_s(V)$. In particular, any ruling of $p_i : \Sigma(V) \to \mathcal{I}_i(V)$ contained in $\Sigma_s(V)$ is invariant under $\alpha$. The rulings on $\Sigma_s(V)$ correspond to the cubic cones in $V$, and they do exist, see, e.g., Corollary 10.3.2. It follows that $\alpha(\mathcal{I}_i(V)) = \mathcal{I}_i(V)$, $i = 1, 2$, that is, $\alpha$ does not interchange the factors of $(\mathbb{P}^2)^\vee \times \mathbb{P}^2$. Since the projections $p_i|_{\Sigma_s(V)} : \Sigma_s(V) \to \mathcal{I}_i(V)$, $i = 1, 2$, are dominant and $\alpha$-equivariant, $\alpha$ acts identically on the factors of $(\mathbb{P}^2)^\vee \times \mathbb{P}^2$, hence also on $\Sigma$. By $(a)$ $\alpha = \text{id}_V$. □

The following corollary is straightforward.

11.2.1. **Corollary.** There is an embedding

$$\text{Aut}(V) \hookrightarrow \text{Aut}((\mathbb{P}^2)^\vee \times \mathbb{P}^2, \Sigma(V), \Sigma_s(V)) = \text{Aut}(\Sigma(V), \Sigma_s(V)).$$

**Proof.** Indeed, the pair of projections of $(\mathbb{P}^2)^\vee \times \mathbb{P}^2$ to the factors being canonical (see 9.1.1), the inclusion $\text{Aut}((\mathbb{P}^2)^\vee \times \mathbb{P}^2, \Sigma(V)) \subset \text{Aut}(\Sigma(V))$ is in fact the equality. □

The Hilbert scheme of lines $\Sigma(V)$ admits the following alternative description.

11.2.2. **Construction 1.** For a vector $y \neq 0$ in a vector space $U = \mathbb{C}^{n+1}$, we let $[y]$ denote the image of $y$ in $\mathbb{P}(U) = \mathbb{P}^n$. Consider the Segre embedding

$$\nu : (\mathbb{P}^n)^\vee \times \mathbb{P}^n \hookrightarrow \mathbb{P}^{n^2-1}, \quad ([x^\ast], [y]) \longmapsto [x^\ast \otimes y], \quad x^\ast \in (U)^\vee, \ y \in U, \ x^\ast \otimes y \neq 0.$$

Using the standard isomorphism $U^\vee \otimes U \cong \text{End}(U) = \mathfrak{gl}(U)$, we regard $U^\vee \otimes U$ as the vector space of square matrices of order $n+1$ over $\mathbb{C}$. We let $(e_0, \ldots, e_n)$ be the standard basis of $U = \mathbb{C}^{n+1}$ and $(e^*_0, \ldots, e^*_n)$ be its dual, so that $e^*_i \otimes e_j = E_{i,j}$ is the elementary matrix with the only nonzero entry $e_{i,j} = 1$. Under this identification, the image of $U^\vee \times U$ in $\mathfrak{gl}(U)$ consists of matrices of rank 1:

$$(11.2.3) \quad x^\ast \otimes y = \begin{pmatrix} x_0y_0 & \cdots & x_0y_n \\ \vdots & \ddots & \vdots \\ x_ny_0 & \cdots & x_ny_n \end{pmatrix},$$

where $x^\ast = x_0e_0^* + \ldots + x_ne_n^*$ and $y = y_0e_0 + \ldots + y_ne_n$.

In the sequel we let $n = 2$, so that $\mathfrak{gl}(U) = \mathfrak{gl}_3(\mathbb{C})$. Assuming that $\Sigma(V)$ is realized as the subvariety of complete flags in $\mathbb{P}^2$ embedded in $(\mathbb{P}^2)^\vee \times \mathbb{P}^2$ with equation (9.5.3)

$$x_0y_0 + x_1y_1 + x_2y_2 = 0,$$

its image $\Sigma$ in $\mathbb{P}^8 = \mathbb{P}(\mathfrak{gl}(U))$ lies in the hyperplane $\mathfrak{sl}(U) = \mathfrak{sl}_3(\mathbb{C})$ of matrices with zero trace. We identify $\Sigma(V)$ with $\Sigma$. In this way, $\Sigma(V)$ is realized as a smooth hyperplane section of $\nu((\mathbb{P}^2)^\vee \times \mathbb{P}^2) \subset \mathbb{P}^8$, where $\nu$ stands for the Segre embedding, and, alternatively, as the projectivization of the cone of $(3 \times 3)$-matrices of rank 1 with zero trace.

For a square matrix $M$ of order 3 and of rank 1 one has:

$$\text{tr}(M) = 0 \iff M^2 = 0 \iff \text{im}(M) \subset \ker(M).$$

Thus, for $M \in \Sigma(V)$, $\text{im}(M)$ is a line in the plane $\ker(M)$, and $\mathbb{P}(\text{im}(M)) \subset \mathbb{P}(\ker(M)) \subset \mathbb{P}^2$. 42
is a complete flag in \( \mathbb{P}^2 \). The maps \( M \mapsto \ker(M) \) and \( M \mapsto \im(M) \) yield the projections \( \Sigma(V) \to \mathbb{P}^2 \) and \( \Sigma(V) \to \mathbb{P}^2 \), respectively.

2. The \( \text{GL}_3(\mathbb{C}) \)-action on \( \mathfrak{gl}_3(\mathbb{C}) \) by conjugation: \( (A, M) \mapsto AMA^{-1} \) descends to a \( \text{PGL}_3(\mathbb{C}) \)-action on \( \mathbb{P}^8 = \mathbb{P}^{\mathfrak{gl}_3(\mathbb{C})} \). The Segre embedding is equivariant with respect to the latter \( \text{PGL}_3(\mathbb{C}) \)-action on \( \mathbb{P}^8 \) and the \( \text{PGL}_3(\mathbb{C}) \)-action on \( (\mathbb{P}^2)^{\vee} \times \mathbb{P}^2 \) given by
\[
(A, ([x^*], [y^*])) \mapsto ([A^{-1}x^*], [Ay^*]).
\]

Any square matrix \( M \) of order 3 and of rank 1 with zero trace has Jordan form \( \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \).

Therefore, the induced \( \text{PGL}_3(\mathbb{C}) \)-action on \( \Sigma \) is transitive. In fact, \( \Sigma \cong \text{PGL}_3(\mathbb{C})/B_0 \), where \( B_0 \subset \text{PGL}_3(\mathbb{C}) \) is the Borel subgroup of upper triangular matrices.

Recall that \( \text{Aut}(\Sigma) \cong \text{PGL}_3(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z}) \), see the proof of Lemma 11.2. One can take the matrix transposition for the generator of \( \mathbb{Z}/2\mathbb{Z} \) interchanging the factors of \( \mathbb{P}^2 \) and \( \mathbb{P}^8 \). The (maximal) diagonal torus \( T_0 = (G_m)^2 \) of \( B_0 \) acts effectively on \( \Sigma \). Any \( (G_m)^2 \)-subgroup of \( \text{Aut}(\Sigma) \) is conjugate to \( T_0 \) in \( \text{PGL}_3(\mathbb{C}) \).

3. To a square matrix \( C \neq 0 \) of order 3 one can associate a hyperplane \( H_C \) in the vector space \( \mathfrak{gl}_3(\mathbb{C}) \), where
\[
H_C = \{ M \in \mathfrak{gl}_3(\mathbb{C}) \mid \text{tr}(M \cdot C) = 0 \}.
\]

If \( C \neq 0 \) is a scalar matrix, then \( H_C \) coincides with the subspace \( \mathfrak{sl}_3(\mathbb{C}) \subset \mathfrak{gl}_3(\mathbb{C}) \) of matrices with zero trace. Since the bilinear form \( (A, B) \mapsto \text{tr}(A \cdot B) \) on \( \mathfrak{sl}_3(\mathbb{C}) \) is nondegenerate, any hyperplane in \( \mathfrak{sl}_3(\mathbb{C}) \) coincides with \( H_C \) for a suitable \( C \in \mathfrak{sl}_3(\mathbb{C}) \).

4. According to Proposition 9.10(c), \( \Sigma(V) \) is a hyperplane section of \( \Sigma(V) = \Sigma \) in \( \mathbb{P}^8 \).

Therefore, there exists a \( (3 \times 3) \)-matrix \( C = C(V) \) with zero trace such that
\[
\Sigma(V) = \Sigma \cap \mathbb{P}(H_C) = \nu ((\mathbb{P}^2)^{\vee} \times \mathbb{P}^2) \cap \mathbb{P}(\mathfrak{sl}_3(\mathbb{C}) \cap H_C).
\]

Such a matrix \( C \) is defined uniquely up to a nonzero scalar factor. The \( \text{PGL}_3(\mathbb{C}) \)-action on \( \mathbb{P}^8 = \mathbb{P}(\mathfrak{gl}_3(\mathbb{C})) \) by conjugation leaves the pair \( (\nu((\mathbb{P}^2)^{\vee} \times \mathbb{P}^2), \Sigma) \) invariant. Replacing \( C \) (defined up to a scalar factor) by its Jordan form, any hyperplane section \( X \) of \( \Sigma \) can be sent by an automorphism of \( \Sigma \) to one of the sections
\[
X_{(a,b)} = \Sigma \cap H_{C_{(a,b)}}, \quad (a, b) \neq (0, 0), \quad \text{and} \quad X_i = \Sigma \cap H_{C_i}, \quad i = 1, 2, 3,
\]

where
\[
C_{(a,b)} = \text{diag}(a, b, -a - b), \quad C_1 = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}, \quad C_2 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad C_3 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

5. Consider the group \( \widetilde{\text{GL}}_n(\mathbb{C}) = \text{GL}_n(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z}) \), where the generator \( \tau \) of \( \mathbb{Z}/2\mathbb{Z} \) acts on \( \text{GL}_n(\mathbb{C}) \) via the Cartan involution \( A \mapsto (A^t)^{-1} \). The action of \( \text{GL}_n(\mathbb{C}) \) via conjugation on \( \mathfrak{gl}(U) \) with \( U = \mathbb{C}^n \) extends to an action of \( \widetilde{\text{GL}}_n(\mathbb{C}) \), where \( \tau \) acts on \( \mathfrak{gl}(U) \) via \( C \mapsto C^t \). Let also
\[
\text{PCent}_{\text{GL}_n(\mathbb{C})}(C) = \left\{ \tilde{A} \in \widetilde{\text{GL}}_n(\mathbb{C}) \mid \tilde{A} \cdot C = \alpha C \right\}, \quad \alpha \in \mathbb{C}^*,
\]
\[
\text{PGL}_n(\mathbb{C}) = \text{GL}_n(\mathbb{C})/z(\text{GL}_n(\mathbb{C})) \cong \text{PGL}_n(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z}),
\]
\[
\text{PCent}_{\text{PGL}_n(\mathbb{C})}(C) = \text{PCent}_{\text{GL}_n(\mathbb{C})}(C)/z(\text{GL}_n(\mathbb{C})).
\]
11.3. **Lemma.** For a hyperplane section \( X_C = \Sigma \cap H_C \), where \( C \in \frak{sl}_3(\mathbb{C}) \), \( C \neq 0 \), one has

\[
\text{Aut}(\Sigma, X_C) = \text{PCent}_{\text{PGL}_3(\mathbb{C})}(C) \subset \text{PGL}_3(\mathbb{C}).
\]

**Proof.** We have \( \text{Aut}(\Sigma) = \text{PGL}_3(\mathbb{C}) \). Clearly, \( g \in \text{PGL}_3(\mathbb{C}) \) induces an automorphism of \((\Sigma, X_C)\) if and only if \( g(H_C) \) is a member of the pencil generated by \( H_C \) and \( H_0 \), if and only if \( g.C = \alpha C + \beta E \) for some \( \alpha, \beta \in \mathbb{C} \). For \( A \in \text{GL}_3(\mathbb{C}) \) one has \( AC = AC^t A^{-1} \) and \( A \tau C = AC^t A^{-1} \). Anyway, under the latter condition, \( \text{tr}(\alpha C + \beta E) = \text{tr}(C) = 0 \), hence \( \beta = 0 \). Now the claim follows. \( \square \)

11.4. **Lemma.** Given a matrix \( C \) as in \((11.2.5)\), the following hold.

| \( C \) | \( \text{Sing}(X_C) \) | \( \text{Aut}(\Sigma, X_C) \) |
|------|------------------|------------------|
| (a) \( C_{(1,1)}, C_{(1,-2)}, C_{(-2,1)} \) | a smooth conic | \( \text{GL}_2(\mathbb{C}) = \text{GL}_2(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z}) \) |
| (b) \( C_{(1,0)}, C_{(-1,0)} \) | \( \emptyset \) | \( (\mathbb{G}_m)^2 \times (\mathbb{Z}/6\mathbb{Z}) \) |
| (c) \( C_{(1,0)}, b \notin \{-2, -1/2\}, b^3 \neq 1 \) | \( \emptyset \) | \( (\mathbb{G}_m)^2 \times (\mathbb{Z}/2\mathbb{Z}) \) |
| (d) \( C_1 \) | \( A_1 \) | \( (\mathbb{G}_a \times \mathbb{G}_m) \times (\mathbb{Z}/2\mathbb{Z}) \) |
| (e) \( C_2 \) | \( A_2 \) | \( ((\mathbb{G}_a)^2 \times \mathbb{G}_m) \times (\mathbb{Z}/2\mathbb{Z}) \) |
| (f) \( C_3 \) | two intersecting lines | \( B(\text{PGL}_3(\mathbb{C})) \times (\mathbb{Z}/2\mathbb{Z}) \) |

where \( B(\text{PGL}_3(\mathbb{C})) \) stands for a Borel subgroup of \( \text{PGL}_3(\mathbb{C}) \), in Cases \( \text{[c]} \) and \( \text{[d]} \) the generator of \( \mathbb{Z}/2\mathbb{Z} \), acts by the inversion \( g \mapsto g^{-1} \) on the first factor, and in Case \( \text{[e]} \) the group \( \text{Aut}(\Sigma, X_C) \) does not contain the product \( \mathbb{G}_a \times \mathbb{G}_m \).

**Proof.** \[ \text{[a]} \] Let \( C \in \{ \text{diag}(1,1, -2), \text{diag}(1, -2, 1), \text{diag}(-2, 1, 1) \} \). The hyperplane section \( X_{(1,1)} = \{ x_2 y_2 = 0 \} \cap \Sigma \) has two irreducible components given by \( x_2 = 0 \) and \( y_2 = 0 \), respectively. Hence \( X_{(1,1)} \) is a union \( \mathcal{F}_1 \cup \mathcal{F}_2 \) of the first kind (see \( 10.3 \)), and similarly \( X_{(1,-2)} \) and \( X_{(-2,1)} \) are. By the spectral mapping theorem \((\text{EL04})\) one obtains

\[
\text{PCent}_{\text{GL}_3(\mathbb{C})}(C) = \text{Cent}_{\text{GL}_3(\mathbb{C})}(C) \cong \text{GL}_2(\mathbb{C}) \times z(\text{GL}_3(\mathbb{C})).
\]

Now the assertion follows from Lemma \( 11.3 \).

\[ \text{[b]} \] For \( C = \text{diag}(1, \zeta, \zeta^2) \), where \( \zeta \neq 1 \) and \( \zeta^3 = 1 \), one has

\[
\text{PCent}_{\text{GL}_3(\mathbb{C})}(C) = \mathbb{T}(3) \times ((\mathbb{Z}/3\mathbb{Z}) \times (\mathbb{Z}/2\mathbb{Z})),
\]

where \( \mathbb{T}(3) = \text{Cent}_{\text{GL}_3(\mathbb{C})}(C) \) is the diagonal 3-torus of \( \text{GL}_3(\mathbb{C}) \), the factor \( \mathbb{Z}/3\mathbb{Z} \) is generated by the cyclic permutation matrix \( \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \), and \( \mathbb{Z}/2\mathbb{Z} = \langle \tau \rangle \) acts on \( \mathbb{T}(3) \) by the inversion. Passing to the quotient by the center \( z(\text{GL}_3(\mathbb{C})) \subset \mathbb{T}(3) \) gives the result, see Lemma \( 11.3 \). One can easily check that \( X_C \) is smooth.

The proof of \( \text{[c]} \) is similar.

\[ \text{[d]} \] For \( C_1 \) as in \((11.2.5)\) one has

\[
\text{PCent}_{\text{GL}_3(\mathbb{C})}(C_1) = \text{Cent}_{\text{GL}_3(\mathbb{C})}(C_1) = \left\{ \begin{pmatrix} \lambda & a & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \mu \end{pmatrix}, \begin{pmatrix} a & \lambda & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \mu \end{pmatrix} \cdot \tau \bigg| \lambda, \mu \in \mathbb{C}^*, \ a \in \mathbb{C} \right\}.
\]
This group contains the center \( z(\tilde{ GL}_3(\mathbb{C})) \cong \mathbb{G}_m \) and an element \( \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \tau \) of order 2. The quotient by the center is isomorphic to \((\mathbb{G}_a \times \mathbb{G}_m) \times (\mathbb{Z}/2\mathbb{Z})\). The generator of the factor \( \mathbb{Z}/2\mathbb{Z} \) acts by the inversion \( g \mapsto g^{-1} \) on \( \mathbb{G}_a \times \mathbb{G}_m \).

We use the notation \( X_i = X_{C_i}, i = 1, 2, 3 \), see (11.2.4). The hyperplane section \( \mathfrak{S}_{X_1} \in |-K_{X_1}| \) as in Lemma 10.1(d) is given by \( X_1 \cap H_{C_{1;1}} \). It is easy to see that \( X_1 \cap H_{C_{1;1}} \) consists of four lines. Then by Lemma 10.3(d) the surface \( X_1 \) is a singular del Pezzo sextic of type \( A_1 \).

Similarly, for \( C_2 \) as in (11.2.5) one has

\[
\text{PCent}_{\tilde{ GL}_3(\mathbb{C})}(C_2) = \left\{ \begin{pmatrix} \mu^2 \lambda & \mu a & b \\ 0 & \mu \lambda & a \\ 0 & 0 & \lambda \end{pmatrix}, \begin{pmatrix} b & \mu a & \mu^2 \lambda \\ a & \mu \lambda & 0 \\ \lambda & 0 & 0 \end{pmatrix} \cdot \tau \mid \lambda, \mu \in \mathbb{C}^*, a, b \in \mathbb{C} \right\}.
\]

This group contains the center \( z(\tilde{ GL}_3(\mathbb{C})) = \{ \lambda E \}_{\lambda \in \mathbb{C}^*} \) and an element \( \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \cdot \tau \) of order 2. The quotient \( \text{PCent}_{\tilde{ GL}_3(\mathbb{C})}(C_2)/z(\tilde{ GL}_3(\mathbb{C})) \) is isomorphic to \((\mathbb{G}_a)^2 \times \mathbb{G}_m) \times (\mathbb{Z}/2\mathbb{Z})\).

None of the one-parameter unipotent subgroups is centralized by a \( \mathbb{G}_m \)-subgroup, as stated. The corresponding surface \( X_2 \) contains exactly two lines given by \( X_2 \cap H_{C_{2;1}} \). We conclude as in (d) that \( X_2 \) is an \( A_2 \)-surface.

The matrix \( C_3 \) is conjugate to \( C_2^2 \) with centralizer

\[
\text{PCent}_{\tilde{ GL}_3(\mathbb{C})}(C_2^2) = \left\{ \begin{pmatrix} \lambda & a_0 & a_1 \\ 0 & \lambda_1 & a_2 \\ 0 & 0 & \lambda_2 \end{pmatrix}, \begin{pmatrix} a_1 & a_0 & 0 \\ a_2 & \lambda_1 & 0 \\ 0 & 0 & \lambda_2 \end{pmatrix} \cdot \tau \mid \lambda_i \in \mathbb{C}^*, a_i \in \mathbb{C}, i = 0, 1, 2 \right\}.
\]

Thus, \( \text{PCent}_{\tilde{ PGL}_3(\mathbb{C})}(C_3) \cong B(\tilde{ PGL}_3(\mathbb{C})) \times (\mathbb{Z}/2\mathbb{Z}) \). By Lemma 11.3 the latter group is isomorphic to \( \text{Aut}(\Sigma, X_3) \). The hyperplane section \( X_3 = \{ x_1 y_0 = 0 \} \cap \Sigma \) has two irreducible components given by \( x_1 = 0 \) and \( y_0 = 0 \), respectively. Hence \( X_3 \) is a union \( \mathcal{F}_1 \cup \mathcal{F}_2 \) of the second kind, see 10.3.

11.5. Proof of Proposition 11.1. According to 11.2.2, the pair \((\Sigma(V), \Sigma_3(V))\) is equivalent to one of the pairs \((\Sigma, X_{(a:b)})\) and \((\Sigma, X_1)\), \( i = 1, 2, 3 \). The automorphism groups of the latter pairs are described in Lemma 11.4. By Corollary 11.2.1 \( \text{Aut}(V) \) embeds in one of these groups. On the other hand, due to Corollary 7.8.3 and Proposition 9.5 \( \text{Aut}(V) \) contains one of the groups \( \tilde{ GL}_3(\mathbb{C}), \mathbb{G}_a \times \mathbb{G}_m \), and \( (\mathbb{G}_m)^2 \), which is not the case for \( \text{Aut}(\Sigma, X_2) \). Hence either \( \text{Aut}(V) \hookrightarrow \text{Aut}(\Sigma, X_{(a:b)}) \), or \( \text{Aut}(V) \hookrightarrow \text{Aut}(\Sigma, X_i), i \in \{1, 2, 3\} \).

Inspecting Lemma 11.4 we see that, if \( \text{GL}_2(\mathbb{C}) \subset \text{Aut}(V) \), there then is an embedding \( \text{Aut}(V) \hookrightarrow \text{Aut}(\Sigma, X_{(1,1)}) \cong \text{GL}_2(\mathbb{C}) \). Furthermore, in this case \( \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}) \), see Lemma 6.4 and \( \Sigma_3(V) \) is a union \( \mathcal{F}_1 \cup \mathcal{F}_2 \) of the first kind, see Lemma 11.4(a). The \( \text{GL}_2(\mathbb{C}) \)-action on \( \Sigma_3(V) = \mathcal{F}_1 \cup \mathcal{F}_2 \) preserves two disjoint lines, which are the exceptional sections of the cubic scrolls \( \mathcal{F}_i \cong \mathbb{F}_1, i = 1, 2 \). These lines correspond to the families of rulings \( \Lambda(S_i), i = 1, 2 \), where the cubic cones \( S_1 \in \mathcal{S}_1(V) \) and \( S_2 \in \mathcal{S}_2(V) \) are \( \text{Aut}^0(V) \)-invariant and have no common ruling, see Proposition 9.10. Since \( S_1 \cdot S_2 = 0 \) in \( H^*(V, \mathbb{Z}) \), see Proposition 9.6, then \( S_1 \cap S_2 = \emptyset \) due to Corollary 9.7. This corresponds to Case 1" of Proposition 11.1.

Suppose now that \( \text{rk} \text{Aut}(V) \geq 2 \), but \( \text{GL}_2(\mathbb{C}) \not\subset \text{Aut}(V) \). By Lemma 11.4 one of the following holds: either, for a suitable \( (a:b) \in \mathbb{P}^1 \),

\[
(\mathbb{G}_m)^2 \subset \text{Aut}(V) \subset \text{Aut}(\Sigma, X_{(a:b)}) \subset (\mathbb{G}_m)^2 \times (\mathbb{Z}/6\mathbb{Z}),
\]
or

\[(11.5.1) \quad (\mathbb{G}_m)^2 \subset \text{Aut}(V) \subset \text{Aut}(\Sigma, X_3) = B(\text{PGL}_3(\mathbb{C})) \times (\mathbb{Z}/2\mathbb{Z}).\]

In the latter case, by Lemma 11.4(d) one has \(\Sigma_s(V) \cong X_3 = \text{Y}_{(0:1)} = \mathcal{F}_1 \cup \mathcal{F}_2\) is a union of the second kind. However, the latter contradicts Lemma 10.3.1. In the former case, by Lemma 11.4(b)(c) \(\Sigma_s(V)\) is a smooth del Pezzo sextic. This corresponds to Case 3\(^{o}\) of Proposition 11.1.

Assume further that \(\text{rk Aut}(V) = 1\). By Lemma 11.4 either (11.5.1) holds and we are in Case 4, or there are embeddings

\[\mathbb{G}_a \times \mathbb{G}_m \hookrightarrow \text{Aut}(V) \hookrightarrow \text{Aut}(\Sigma, X_1) = (\mathbb{G}_a \times \mathbb{G}_m) \times (\mathbb{Z}/2\mathbb{Z}),\]

and \(\Sigma_s(V) \cong X_1\) is a normal del Pezzo sextic of type \(A_1\), see Lemma 11.4(d). The latter corresponds to Case 2\(^{o}\) of Proposition 11.1 \(\square\)

11.5.2. \textbf{Remark.} According to Lemma 11.4(b) for the matrix \(C = \text{diag}(1, \zeta, \zeta^2)\), where \(\zeta\) is a primitive cubic root of unity, one has \(\text{Aut}(\Sigma, X_C) \cong (\mathbb{G}_m)^2 \times (\mathbb{Z}/2\mathbb{Z})\). However, we do not know whether this group can be realized as the automorphism group \(\text{Aut}(V)\) for some Fano-Mukai fourfold \(V = V_{18}\). In other words, we ignore whether \(X_C\) is equivalent to some \(\Sigma_s(V)\) under the \(\text{Aut}(\Sigma)\)-action on \(\Sigma\).

12. \textbf{Automorphism groups of } \(V_{18}\)

Let \(V = V_{18}\) be a Fano-Mukai fourfold of genus 10. By Proposition 11.1, \(\text{Aut}^0(V)\) is one of the groups \(\text{GL}_2(\mathbb{C}), \mathbb{G}_a \times \mathbb{G}_m, \) and \((\mathbb{G}_m)^2\). The central result of this section is the following theorem.

12.1. \textbf{Theorem.} \textit{Given an }\text{Aut}^0(V)\text{-invariant cubic cone }S \subset V\text{, consider the pair } (W, F_S) \text{ linked to } (V, S)\text{, and let } J_S = F_S \cap \Sigma\text{. With this notation, Case 4\(^{o}\) of Proposition 11.1 does not occur, that is, } \Sigma_s(V) \text{ cannot be a union } \mathcal{F}_1 \cup \mathcal{F}_2 \text{ of the second type. Moreover, one of the following possibilities occurs:}

| \text{Aut}^0(V) | V | \Sigma_s(V) | (\Upsilon, J_S) |
|----------------|----------------|----------------|----------------|
| (i) \text{GL}_2(\mathbb{C}) | V_{18}^a | \mathcal{F}_1 \cup \mathcal{F}_2 \text{ of the first kind} | \Upsilon = \Upsilon |
| (ii) \mathbb{G}_a \times \mathbb{G}_m | V_{18} | \text{an }A_1\text{-del Pezzo sextic} | 4.3(ii) for a suitable choice\(^5\) of \(S\) |
| (iii) \((\mathbb{G}_m)^2\) | \not\in V_{18}^{a} \text{, } V_{18}^{a} | \text{a smooth del Pezzo sextic} | 4.3(iii) for any choice of \(S\) |

\(^5\)The cubic cones \(S \subset V\) such that \((\Upsilon, J_S)\) is of type 4.3(ii) correspond actually to the two outer \((-1)\)-vertices in diagram (10.1.1). The two inner \((-1)\)-vertices in (10.1.1) correspond to the cubic cones \(S \subset V\) with \((\Upsilon, J_S)\) of type 4.3(iii) see Remark 13.3.2

For the proof of the first assertion see Corollary 12.5.2. Then the equivalence between the first and the third properties in (i)(iii) follows from Proposition 11.1. The proof of the remaining statements is done in 12.9 after a certain preparation and several auxiliary results.

12.2. \textbf{Lemma.} \textit{Suppose that }\text{Aut}(V) \supset \text{SL}_2(\mathbb{C})\text{. Then any component } \mathcal{J}_i(V), \ i = 1, 2, \text{ of } \mathcal{J}(V) \text{ contains a unique } \text{Aut}^0(V)\text{-fixed point, and this point corresponds to an } \text{Aut}^0(V)\text{-invariant cubic cone } S_i \in \mathcal{J}_i(V)\text{. Furthermore, one has } S_1 \cap S_2 = \emptyset\text{.}
Proof. The existence of an $\text{Aut}^0(V)$-fixed point in $\mathcal{F}_i(V)$ that corresponds to a cubic cone is established in Proposition 9.5. We claim that an $\text{SL}_2(\mathbb{C})$-fixed point in $\mathcal{F}_i(V)$ is unique;
then, of course, this point is a unique $\text{Aut}^0(V)$-fixed point as well.

Suppose to the contrary that the $\text{SL}_2(\mathbb{C})$-action on $\mathcal{F}_i(V) \cong \mathbb{P}^2$ admits at least two fixed points. Since the group $\text{SL}_2(\mathbb{C})$ is simply connected, the induced $\text{SL}_2(\mathbb{C})$-action on $\mathbb{P}^2$ can be lifted to a linear $\text{SL}_2(\mathbb{C})$-action on $\mathbb{C}^3$ trivial on the one-dimensional subspaces which correspond to the fixed points. Due to the complete reducibility, such an $\text{SL}_2(\mathbb{C})$-action on $\mathbb{C}^3$ is trivial. This is a contradiction.

By Lemma 6.4 under our assumptions one has $\text{Aut}^0(V) = \text{GL}_2(\mathbb{C})$.

Due to the uniqueness, the unordered pair $(S_1, S_2)$ coincides with the pair $(S, S')$ of $\text{Aut}^0(V)$-invariant cubic cones as in Lemma 6.6.1(a). However, the latter cones are disjoint. □

12.3. Lemma. Assume that $\Sigma_s(V) = \mathcal{F}_1 \cup \mathcal{F}_2$. For $i = 1, 2$ let $S_i \in \mathcal{F}_i(V)$ be the $\text{Aut}^0(V)$-invariant cubic cone provided by the exceptional section of the ruling $\mathcal{F}_i \to \mathbb{P}^1$, $j \neq i$, see Corollary 10.3.2(b). Let $(W, F)$ be the pair linked to $(V, S_2)$. Suppose that $\text{Aut}^0(W, F)$ contains a singular torus of $\text{Aut}^0(W)$. Then the following hold.

(a) $(\mathcal{F}_1, \mathcal{F}_2)$ is a pair of the first kind;
(b) $R_u \cap \text{Aut}^0(W, F) = \{1\}$, and $\text{Aut}^0(V)$ is isomorphic to one of the groups $\text{GL}_2(\mathbb{C})$, $\mathbb{G}_a \times \mathbb{G}_m$, and $(\mathbb{G}_m)^2$.

Proof. [a] By Lemma 6.6.1(a) there exists a cubic cone $S' \subset V$ disjoint with $S_2$. Since $S' \cdot S_2 = 0$, these cubic cones belong to different components of $\mathcal{F}(V)$, see Proposition 9.6. Thus, $S' \in \mathcal{F}_i(V)$, and so, $\Lambda(S') \subset \Sigma_s(V)$ is either a ruling of $\mathcal{F}_1$, or the exceptional section of $\mathcal{F}_2$. However, if $(\mathcal{F}_1, \mathcal{F}_2)$ were a pair of the second kind, then in both cases $S'$ and $S_2$ would possess a common ruling, a contradiction. This proves [a].

[b] Therefore, $(\mathcal{F}_1, \mathcal{F}_2)$ is a pair of the first kind. Since the cubic cone $S_1$ is $\text{Aut}^0(V)$-invariant, its vertex $v_1$ is fixed under the action of $\text{Aut}^0(V)$ on $V$. By Corollary 10.3.2(b), $v_1 \notin S_2$. It follows that $\theta(v_1) \notin R$, see diagram (3.1.1), where $B = R$. The projection $\theta : V \to W$ with center $\langle S_2 \rangle$ as in diagram (3.1.1) sends $v_1$ to a fixed point $\theta(v_1)$ of $\text{Aut}^0(W, F)$. However, by Proposition 5.4(c) the unipotent radical $R_u$ of $\text{Aut}^0(W)$ acts freely in $W \setminus R$. Thus, $R_u \cap \text{Aut}^0(W, F) = \{1\}$. The last assertion follows from Corollary 6.3.1(a)(b). □

12.3.1. Corollary. Suppose that $\Sigma_s(V) = \mathcal{F}_1 \cup \mathcal{F}_2$ is a pair of the second kind. Let $(W, F)$ be linked to $(V, S)$, where $S \subset V$ is an $\text{Aut}^0(V)$-invariant cubic cone. Then the following hold.

- $\text{rk} \text{Aut}(V) = 1$;
- $\text{Aut}(V) \supset \mathbb{G}_a \times \mathbb{G}_m$;
- Any $\mathbb{G}_m$-subgroup of $\text{Aut}(W, F)$ acts nontrivially on $J = F \cap \Xi$.

Proof. Suppose to the contrary that $\text{rk} \text{Aut}(V) = 2$. Then $\text{Aut}^0(W, F)$ contains a singular torus of $\text{Aut}^0(W)$, and so, by Lemma 12.3(a) $(\mathcal{F}_1, \mathcal{F}_2)$ is a pair of the first kind, a contradiction.

---

6Alternatively, one can notice that the cones $S_1$ and $S_2$ correspond to the disjoint exceptional sections of the components $\mathcal{F}_1$ and $\mathcal{F}_2$ of $\Sigma_s(V)$. It follows that $S_1 \cap S_2$ is zero-dimensional, hence empty since $S_1 \cdot S_2 = 0$ in $H^*(V, \mathbb{Z})$, see Proposition 9.6 and Corollary 9.7.4.
Since $\text{Aut}(V)$ of rank 1 contains one of the groups $\text{GL}_2(\mathbb{C})$, $\mathbb{G}_a \times \mathbb{G}_m$, $(\mathbb{G}_m)^2$, it contains $\mathbb{G}_a \times \mathbb{G}_m$.

Suppose that there is a $\mathbb{G}_m$-subgroup, say, $Z \subset \text{Aut}(W, F)$ acting trivially on $J$. Then $Z$ is contained in the kernel $R_z \times z(L)$ of the homomorphism $\varrho : \text{Aut}(W, F) \to \text{PGL}_2(\mathbb{C})$ in (5.4.1). Hence $Z$ is a singular torus of $\text{Aut}(W)$. Since $F$ is $Z$-invariant, this leads again to a contradiction with Lemma 12.3(a). \hfill \square

12.4. Lemma. Let $S \subset V$ be a cubic cone, let $(W, F)$ be linked to $(V, S)$, and let $J = F \cap \Xi$ be the exceptional section of $F$. Then the following hold.

(a)

\begin{equation}
\dim \text{Aut}^0(W, F) = \dim \text{Aut}^0(V, S) \geq \begin{cases} 
2 & \text{if } J \neq \Upsilon, \\
4 & \text{if } J = \Upsilon.
\end{cases}
\end{equation}

(b) Let $\mathcal{F}_J$ be the family of all rational normal quintic scrolls $F' \subset R$ with exceptional section $J$. Then the equality in (12.4.1) holds if and only the orbit of $F \in \mathcal{F}_J$ under the natural $\text{Stab}_{\text{Aut}(W)}(J)$-action on $\mathcal{F}_J$ is open.

Proof. We claim that $\mathcal{F}_J$ is of pure dimension 4. Indeed, by a deformation argument the family of twisted cubics in $R \setminus \Xi = R \setminus \text{Sing}(R)$ has dimension 6. Given a scroll $F \in \mathcal{F}_J$, the twisted cubic curves $\Psi$ contained in $F$ are the sections of $F \to \mathbb{P}^1$ disjoint with $J$, that is, the sections with $\Psi^2 = 1$. Therefore, the family of twisted cubic curves $\Psi \subset F$ is two-dimensional. Now the claim follows.

The group $\text{Aut}(\Upsilon) \cong \text{PGL}_2(\mathbb{C})$ acts naturally on the plane $\Xi \cong \mathbb{P}^2$ viewed as the symmetric square of $\Upsilon \cong \mathbb{P}^1$. By Lemma 6.2(a) one has

$$
\dim \text{Stab}_{\text{Aut}(\Xi, \Upsilon)}(J) = \begin{cases} 
1 & \text{if } J \neq \Upsilon, \\
3 & \text{if } J = \Upsilon.
\end{cases}
$$

The stabilizer $\mathcal{G} := \text{Stab}_{\text{Aut}(W)}(J)$ acts on $\mathcal{F}_J$. From (5.4.1) and Proposition 5.6(c) one can deduce the equalities

\begin{equation}
\dim \mathcal{G} = 5 + \dim \text{Stab}_{\text{Aut}(\Xi, \Upsilon)}(J) = \begin{cases} 
6 & \text{if } J \neq \Upsilon, \\
8 & \text{if } J = \Upsilon.
\end{cases}
\end{equation}

Notice that $\text{Aut}(W, F)$ is the stabilizer of $F \in \mathcal{F}_J$ under the $\mathcal{G}$-action on $\mathcal{F}_J$. For the dimension of the orbit $\mathcal{G}.F$ of $F$ under this action one has

\begin{equation}
\dim \mathcal{G}.F = \dim \mathcal{G} - \dim \text{Stab}_{\mathcal{G}}(F) = \dim \mathcal{G} - \dim \text{Aut}^0(W, F) \leq \dim \mathcal{F}_J = 4.
\end{equation}

Then (12.4.2) and (12.4.3) imply (12.4.1). This gives (a). Now (b) is straightforward. \hfill \square

12.5. Lemma. Suppose that $\Sigma_0(V)$ is a union $\mathcal{F}_1 \cup \mathcal{F}_2$ of the second kind. Then $\text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m$.

Proof. According to Proposition 9.5, there exists an $\text{Aut}^0(V)$-invariant cubic cone $S \subset V$. Let $(W, F_S)$ be the pair linked to $(V, S)$, and let $J_S = F_S \cap \Xi$. Assume to the contrary that $\text{Aut}^0(V) \cong \text{Aut}^0(W, F_S) \not\cong \mathbb{G}_a \times \mathbb{G}_m$. By Corollary 12.3.1, $\text{Aut}^0(W, F_S) \cong \text{Aut}^0(V)$ has rank 1, and any $\mathbb{G}_m$-subgroup of $\text{Aut}^0(W, F_S)$ acts nontrivially on $J_S$. Hence either $J_S = \Upsilon$ is of type 4.3(i) or $(\Upsilon, J_S)$ is of type 4.3(iii). Furthermore, by Corollary 12.3.1, $\text{Aut}^0(W, F_S)$ contains $\mathbb{G}_a \times \mathbb{G}_m$. 

48
Suppose first that $J_S = Y$. Consider the unipotent radical $R_u(\text{Aut}^0(W,F_S))$ of the solvable group $\text{Aut}^0(W,F_S) \cong \text{Aut}^0(V) \subset B(\text{GL}_3(\mathbb{C}))/\pi(\text{GL}_3(\mathbb{C}))$ of rank 1, see Case 4 of Proposition 11.1. By Lemma 12.4 in our case $\dim \text{Aut}^0(W,F_S) \geq 4$. Hence $\dim R_u(\text{Aut}^0(W,F_S)) \geq 3$. The image of $R_u(\text{Aut}^0(W,F_S))$ in $\text{Aut}(Y) = \text{PGL}_2(\mathbb{C})$ is contained in the unipotent radical $R_u(B(\text{PGL}_2(\mathbb{C})) \cong \mathbb{G}_a$ of a Borel subgroup. The exact sequence (5.4.1) reads:

$$1 \longrightarrow R_u \times z(L) \longrightarrow \text{Aut}(W) \overset{\varrho}{\longrightarrow} \text{Aut}^0(Y) = \text{PGL}_2(\mathbb{C}) \longrightarrow 1.$$ 

It follows that the kernel of $\varrho|_{R_u(\text{Aut}^0(W,F_S))}$ has dimension $\geq 2$ and is contained in $R_u$. Therefore, $\dim(R_u \cap \text{Aut}^0(W,F_S)) \geq 2$. The latter contradicts Corollary 6.7.3.

Thus, $(Y,J_S)$ is a pair of type 4.3(iii), $\varrho(\text{Aut}^0(W,F_S)) = \text{Aut}^0(Y,J_S) \cong \mathbb{G}_m$, and $\ker(\varrho|_{\text{Aut}^0(W,F_S)}) \cong \mathbb{G}_a$, see Corollary 6.7.3. Finally, one has $\text{Aut}^0(V) \cong \text{Aut}^0(W,F_S) \cong \mathbb{G}_a \times \mathbb{G}_m$. □

12.5.2. Corollary. Case 4 of Proposition 11.1 does not occur.

Proof. Assume to the contrary that $\Sigma_a(V)$ is a union $\mathcal{F}_1 \cup \mathcal{F}_2$ of the second kind. By Lemma 12.5, we have $\text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m$. This implies that any cubic cone $S$ in $V$ is $\text{Aut}^0(V)$-invariant. Indeed, notice that $\text{Aut}(V,S) = \text{Aut}(V,v(S))$ is the stabilizer in $\text{Aut}(V)$ of the vertex $v(S)$ of $S$, see Proposition 8.2(e). If $S$ were not $\text{Aut}^0(V)$-invariant, then the $\text{Aut}^0(V)$-orbit of $v(S)$ would be a curve in $V$, see Lemma 9.4. Hence the stabilizer of $S$ in $\text{Aut}^0(V)$ would have codimension 1, so $\dim \text{Aut}^0(V,S) = 1$. The latter contradicts (12.4.1). Thus, the cubic cones in $V$ are $\text{Aut}^0(V)$-invariant.

It follows that the $\text{Aut}^0(V)$-action on $\Sigma_a(V)$ preserves any ruling $f_{i,t}$ of $\mathcal{F}_i \rightarrow \mathbb{P}^1$, $i = 1,2$, see Proposition 9.10(a). If the factor $\mathbb{G}_m$ of $\text{Aut}^0(V) = \mathbb{G}_a \times \mathbb{G}_m$ acts non-trivially on a general ruling $f_{i,t}$ of $\mathcal{F}_i$, then its two fixed points must be fixed by the $\mathbb{G}_a$-subgroup. Anyway, at least one of the factors $\mathbb{G}_a$ and $\mathbb{G}_m$ of $\text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m$ acts trivially on $\mathcal{F}_i$. The latter contradicts Lemma 11.2. □

We can remove now an extra assumption in Lemma 6.4(iii).

12.5.3. Corollary. Let $S$ be an $\text{Aut}^0(V)$-invariant cubic cone in $V$, and $(W,F_S)$ be the pair linked to $(V,S)$. Let $J_S = F_S \cap \Xi$. Then $\text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C})$ if and only if $J_S = Y$.

Proof. The “only if” part follows from Lemma 6.4. The “if” part follows from Proposition 11.1 and Corollary 12.5.2. □

In the next lemma we examine the cubic cones in $V$ which are not $\text{Aut}^0(V)$-invariant.

12.6. Lemma. Let $S \subset V$ be a cubic cone, and let $(W,F_S)$ be the pair linked to $(V,S)$. Let $J_S = F_S \cap \Xi$. Assume that $S$ is not $\text{Aut}^0(V)$-invariant. Then $\text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C})$ and $(Y,J_S)$ is a pair of type 4.3(iii) see Figure 4.3.1. Furthermore,

$$\text{Aut}^0(V,S) \cong \text{Aut}^0(W,F_S) \cong \mathbb{G}_a \times (\mathbb{G}_m)^2 \cong (\mathbb{G}_a \times \mathbb{G}_m) \times \mathbb{G}_m,$$

where $\mathbb{G}_a = R_u \cap \text{Aut}^0(W,F_S)$, a non-abelian subgroup $\mathbb{G}_a \times \mathbb{G}_m \subset \text{Aut}^0(V,S)$ acts on $F_S$ preserving the rulings, and the $\mathbb{G}_m$-subgroup centralizing the $\mathbb{G}_a$-subgroup acts effectively on $J_S$.

Proof. By Proposition 11.1 and Corollary 12.5.2 one has $\Sigma_a(V) = \mathcal{F}_1 \cup \mathcal{F}_2$, where $(\mathcal{F}_1, \mathcal{F}_2)$ is a pair of the first kind, and $\text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C})$. By Lemma 12.2 there are exactly two $\text{Aut}^0(V)$-invariant cubic cones $S_1, S_2$ in $V$; these correspond to the exceptional sections.
of $F_1$ and $F_2$. Under the $\text{Aut}^0(V)$-action, the cone $S \neq S_1, S_2$ varies in a one-parameter family of cubic cones, which correspond to the rulings of a scroll $F_i, i \in \{1, 2\}$. It follows that $\dim \text{Aut}^0(V, S) = \dim \text{Aut}^0(V) - 1 = 3$. By Corollary 12.5.3, $J_S \neq \varnothing$. Since $\text{Aut}^0(V)/\text{Aut}^0(S, V) \cong \mathbb{P}^1$, then $\text{Aut}^0(V, S) \cong B$ is a Borel subgroup of $\text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C})$. Hence (12.6.1) holds, and $\text{Aut}^0(W, F_S) \cong B$ contains a singular torus of $\text{Aut}(W)$.

The maximal torus of $\text{Aut}^0(W, F_S)$ acts on $J_S$ non-identically with exactly two fixed points. It follows by Lemma 6.3.1(a) that $J_S \neq \varnothing$ is of type [4.3(ii)] and the $G$-subgroup of $\text{Aut}^0(W, F_S)$ acts identically on $J_S$. Hence it preserves each ruling of $F_S$. In the notation of Corollary 6.3.1 one has $R_u \cap \text{Aut}^0(W, F_S) \cong G_a$ and $G \cong (G_m)^2$. Now the remaining assertions are immediate. □

12.7. Lemma. Let $S \subset V$ be a cubic cone, let $(W, F_S)$ be the pair linked to $(V, S)$, and let $J_S = F_S \cap \Xi$. Assume that $(\varnothing, J_S)$ is of type [4.3(2)] and $F_S$ is $Z$-invariant, where $Z \subset \text{Aut}(W)$ is a singular torus. Then the cone $S$ is $\text{Aut}^0(V)$-invariant, $R_u \cap \text{Aut}^0(W, F_S) = \{1\}$, and $\text{Aut}^0(V) \cong G_a \times G_m$.

Proof. Due to Corollary 6.3.1(a)(b) and its proof one has

\[(12.7.1) \quad \text{Aut}^0(V, S) \cong \text{Aut}^0(W, F_S) \cong (R_u \cap \text{Aut}^0(W, F_S)) \rtimes (G_a \times G_m),\]

where the $G_m$-subgroup $Z$ preserves the rulings of $F_S$ and the $G_a$-subgroup centralized by the $G_m$-subgroup acts effectively on $J_S$. In particular, $\text{rk} \text{Aut}^0(V, S) = 1$.

If the cone $S$ is $\text{Aut}^0(V)$-invariant, then $\text{rk} \text{Aut}^0(V) = 1$, and so, $\text{Aut}^0(V) \cong G_a \times G_m$ by Proposition 11.1. Hence $R_u \cap \text{Aut}^0(W, F_S) = \{1\}$ due to (12.7.1).

Otherwise, $\dim \text{Aut}^0(V) = \dim \text{Aut}^0(V, S) + 1 \geq 3$. Hence by Proposition 11.1 $\text{Aut}^0(V) = \text{GL}_2(\mathbb{C})$. So, Lemma 12.6 applies to the pair $(V, S)$. According to this lemma, $\text{rk} \text{Aut}^0(V, S) = 2$ contrary to (12.7.1). □

12.8. We use the notation $V_{18}^s$ and $V_{18}^a$ introduced in 7.8.4. Let as before $g_2 = \text{Lie}(G_2)$. Recall that $V_{18}^s = V_{18}^s (V_{18}^a = V_{18}^a)$, respectively for a singular semisimple element $g_s \in g_2$ (a regular non-semisimple element $g_a \in g_2$, respectively). Due to Proposition 7.7(b), such nonzero elements $g_s$ and $g_a$ do exist, and their images $[g_s]$ and $[g_a]$ in $\mathbb{P}(g_2)$ form two distinct orbits of the induced $\text{Ad}(G_2)$-action on $\mathbb{P}(g_2)$. Therefore, the Fano-Mukai fourfolds $V_{18}^s$ and $V_{18}^a$ of genus 10 do exist and are unique up to isomorphism. By Corollary 7.8.3 one has $\text{Aut}^0(V_{18}^s) \cong \text{GL}_2(\mathbb{C})$ and $\text{Aut}^0(V_{18}^a) \cong G_a \times G_m$. Moreover, the following hold.

12.8.1. Lemma. Assume that $V \cong V_{18}^s$. Then $\text{Aut}^0(V) = G_a \times G_m$, and any cubic cone $S \subset V$ is $\text{Aut}^0(V)$-invariant. Let $(W, F_S)$ be the pair linked to $(V, S)$. Then, for a suitable choice of $S$, $J_S = F_S \cap \Xi$ is of type [4.3(ii)], and $F_S$ is invariant under a singular torus $z(L) \subset \text{Aut}(W)$.

Proof. Fix a smooth conic $J' \subset \Xi$ of type [4.3(ii)] and a Levi subgroup $L$ of $\text{Aut}(W)$. By Proposition 6.3(a) there exists a $z(L)$-invariant quintic scroll $F' \subset R$ such that $J' = F' \cap \Xi$. Let $(V', S')$ be the pair linked to $(W, F')$. Then by Lemma 12.7 the cone $S'$ is $\text{Aut}^0(V')$-invariant, and $\text{Aut}^0(V') \cong G_a \times G_m$.

By Theorem 7.1 $V' = V_{18}^g$ for some $g \in g_2$. By Corollary 7.8.3 $g$ is regular non-semisimple. Hence $V' \cong V_{18}^s \cong V$, and so, $\text{Aut}(V) \cong \text{Aut}(V') \cong G_a \times G_m$. We identify $V$ and $V'$ via this isomorphism.

By Proposition 11.1 $\Sigma_a(V)$ is irreducible and contains exactly 4 lines. Therefore, $V$ contains exactly 4 cubic cones, which are all $\text{Aut}^0(V)$-invariant. By construction, the cone $S \subset V$ which corresponds to $S' \subset V'$ satisfies the conditions of the lemma. □
12.9. Proof of Theorem 12.1 Corollary 12.5.3 yields the equivalence

\[ J_S = \Upsilon \iff \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}). \]

If \( V \cong V_{18}^s \), then \( \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}) \) by Corollary 7.8.3(i). Conversely, suppose that \( \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}) \). By Theorem 7.1 \( V = V_{18}^g \) for some \( g \in \mathfrak{g}_2 \), where \( g \) is singular semisimple, see Proposition 7.5.1(a)(c). Hence \( V \cong V_{18}^s \), see Proposition 7.7. This yields the equivalence

\[ (12.9.1) \quad \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}) \iff V \cong V_{18}^s. \]

Combining with Proposition 11.1 this ends the proof of 12.1(i).

Suppose further that \( \text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m \), and let \( V = V_{18}^g \) for some \( g \in \mathfrak{g}_2 \). By Proposition 7.5.1 and Corollary 7.8.3, \( g \) is regular non-semisimple, that is, \( V \cong V_{18}^a \). By Lemma 12.8.1 this gives the equivalence

\[ (12.9.2) \quad \text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m \iff V \cong V_{18}^a. \]

From (12.9.1) and (12.9.2) we deduce

\[ \text{Aut}^0(V) \cong (\mathbb{G}_m)^2 \iff V \not\cong V_{18}^a, V_{18}^1. \]

If \( \text{Aut}^0(V) \cong (\mathbb{G}_m)^2 \), then the pair \((\Upsilon, J_S)\) is of type 4.3(iii) for any cubic cone \( S \subset V \). Thus, if for some \( \text{Aut}^0(V) \)-invariant cubic cone \( S \subset V \) the corresponding pair \((\Upsilon, J_S)\) is of type 4.3(ii), then \( \text{rk} \text{Aut}^0(V) = 1 \) and \( \text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m \). By Lemma 12.8.1 we have the converse implication, and so, the equivalence

\[ \text{Aut}^0(V) \cong (\mathbb{G}_m)^2 \iff (\Upsilon, J_S) \text{ is of type } 4.3(ii) \text{ for a cubic cone } S \subset V. \]

Together with Proposition 11.1 and Corollary 12.5.2 this proves 12.1(ii).

From 12.1(i) and 12.1(ii) we deduce the equivalence

\[ \text{Aut}^0(V) \cong (\mathbb{G}_m)^2 \iff (\Upsilon, J_S) \text{ is of type } 4.3(iii) \text{ for any cubic cone } S \subset V. \]

Due to Proposition 11.1 and Corollary 12.5.2 this completes the proof of 12.1(iii) \( \square \).

12.9.3. Remark. By virtue of Proposition 6.3(b) for a conic \( J \subset \Xi \) touching \( \Upsilon \) with even multiplicities and a Levi subgroup \( L \) of \( \text{Aut}(W) \) there is a unique \( z(L) \)-invariant scroll \( F \subset R \) with \( J = F \cap \Xi \) if \( J = \Upsilon \), and exactly two distinct such scrolls otherwise. Since the singular tori in \( \text{Aut}(W) \) are conjugated under the \( R_u \)-action, the quintic scrolls \( F \subset R \) with given \( J = F \cap R \) are equivalent under the \( R_u \)-action on \( W \) up to passing to the “conjugate” scroll in the case \( J \neq \Upsilon \). The variety \( \mathcal{F}_J \) of such rational quintic scrolls is isomorphic to \( \mathbb{C}^4 \) if \( J = \Upsilon \). For \( J \) of type 4.3(ii), \( \mathcal{F}_J \) consists of two disjoint components isomorphic to \( \mathbb{C}^4 \). For \( J \) of type 4.3(iii), \( \mathcal{F}_J \) has two disjoint components isomorphic to \( \mathbb{C}^4 \), and then eventually also some number of lower-dimensional components. Anyway, the automorphism \( \tilde{\kappa} \) as in Proposition 6.3(d) interchanges these two \( \mathbb{C}^4 \)-components. Cf. also Lemma 12.4(b).

13. Proofs of the main theorems and beyond

In this section we prove Theorems 1.1–1.3 from the Introduction. Besides, Remark 13.4 and Theorem 13.5 complement the main results.
13.1. Proof of Theorem 1.1. By Proposition 9.5, $V$ contains two distinct $\text{Aut}^0(V)$-invariant cubic cones $S_i \in \mathcal{S}(V)$, $i = 1, 2$. To the pair $(V, S_i)$ there corresponds an $\text{Aut}^0(V)$-equivariant Sarkisov link (3.1.1). Now Theorem 1.1 follows immediately from Corollary 4.5.2.

13.2. Proof of Theorem 1.2. By Proposition 7.7 and Theorem 12.1, for any $g \in G_2$ such that $[g] \notin D_{\ell}$ one has $\text{Aut}^0(V^g) = \text{Stab}_{G_2}(g)^0$. Now the result follows.

From the proof we deduce the following corollary (cf. 15.1 below).

13.2.1. Corollary. For each $g \in G_2$ such that $[g] \notin D_{\ell}$ the group $\text{Aut}^0(V^g)$ is the identity component of the stabilizer of $V^g$ in $\text{Aut}^0(\Omega) \cong G_2$.

13.3. Proof of Theorem 1.3. The existence and the uniqueness in Theorem 1.3(iii) follow from 12.8 by virtue of Theorem 12.1. Since $\text{Aut}^0(V_{18}^s) \cong \text{GL}_2(\mathbb{C})$ comes from a Levi subgroup $L \subset \text{Aut}(W)$, and $L$ acts on $W$ with a principal open orbit, see Proposition 5.5(c), then the latter holds as well for the induced $\text{GL}_2(\mathbb{C})$-action on $V_{18}^s$. As for the description of the fixed points in (i) see Theorem 13.5(d) below. Inclusions 13.3(iii) follow from Proposition 11.1 and Theorem 12.1. Let us show (1.3.1) and (1.3.2).

Suppose that $\text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C})$, that is, $V \cong V_{18}^s$. We claim that there is an exact sequence

$$1 \longrightarrow \text{Aut}^0(V) \longrightarrow \text{Aut}(V) \longrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 0. \tag{13.3.1}$$

Indeed, let $(S_1, S_2)$ be the unique pair of $\text{Aut}^0(V)$-invariant cubic cones, see Lemma 12.2. By Corollary 6.4.1 there exists an isomorphism $\tau_V : (V, S_1) \overset{\cong}{\longrightarrow} (V, S_2)$. Due to the uniqueness of the pair $(S_1, S_2)$ one has $\tau_V(S_2) = S_1$. Therefore, $\tau_V \in \text{Aut}(V, S_1)$. Since the group $\text{Aut}(V, S_1) \cong \text{GL}_2(\mathbb{C})$ is connected, one obtains $\tau_V^2 \in \text{Aut}^0(V)$. Moreover, $\text{Aut}^0(V)$ and $\tau_V$ generate $\text{Aut}(V)$. This proves our claim.

Thus, $\text{Aut}(V)/\text{Aut}^0(V) \cong \mathbb{Z}/2\mathbb{Z}$. It follows that the embedding $\text{Aut}(V) \hookrightarrow \text{GL}_2(\mathbb{C}) \times (\mathbb{Z}/2\mathbb{Z})$ in Case 1 of Proposition 11.1 is an isomorphism. The last assertion of Theorem 1.3 (i) is straightforward.

Similarly, we claim that (13.3.1) still holds in the case where $V \cong V_{18}^a$, and so, (1.3.2) follows by Case 2 of Proposition 11.1.

Indeed, among the four cubic cones contained in $V$, there is a unique pair of disjoint cones. Namely, these are the cubic cones $S_1, S_2$ which do not contain the ruling corresponding to the singular point of $\Sigma_a(V)$, see diagram (10.1.1).

Consider the pair $(W, F_2)$ linked to $(V, S_2)$. The image of $S_1$ in $W$ is a cubic cone $S_{1,W}$, which meets $F_2$ along a twisted cubic section $\Psi$. The construction being $\text{Aut}^0(V)$-equivariant, the image of $\text{Aut}^0(V) \cong \mathbb{G}_a \times \mathbb{G}_m$ in $\text{Aut}(W)$ is contained in the stabilizer of the vertex $v(S_{1,W}) \in W \setminus R$.

The latter stabilizer is a Levi subgroup, say, $L_2 \subset \text{Aut}(W)$, see Proposition 5.5(c). The $\mathbb{G}_a$-subgroup of $\text{Aut}^0(V)$ cannot preserve the rulings of $S_{1,W}$ and $F_2$, respectively. Indeed, otherwise on such a ruling $l$ it would have two fixed points $l \cap \Psi$ and $v(S_{1,W})$ ($l \cap \Psi$ and $l \cap \Xi$, respectively). In particular, $\text{Aut}^0(V)$ would act identically on $S_1$, which is impossible. It follows that the $\mathbb{G}_m$-subgroup of $\text{Aut}^0(V)$ corresponds to the singular torus $z(L_2)$ fixing $\Psi$ and $J_2 := F_2 \cap \Xi$ pointwise and preserving the rulings of both $S_{1,W}$ and $F_2$. By contrast, the $\mathbb{G}_a$-subgroup of $\text{Aut}^0(W, F_2) \cong \text{Aut}^0(V)$ acts effectively on $J_2$. Hence $(\Psi, J_2)$ is a pair of type 4.3(ii).
Symmetrically, for the pair \((W, F_1)\) linked to \((V, S_1)\) the \(\mathbb{G}_m\)-subgroup of \(\text{Aut}^0(W, F_1) \cong \mathbb{G}_a \times \mathbb{G}_m\) acts trivially on \(J_1 = F_1 \cap \Xi\), while the \(\mathbb{G}_a\)-subgroup acts effectively. So, \((\Upsilon, J_1)\) is as well a pair of type 4.3(ii).

We claim that the pairs \((W, F_1)\) and \((W, F_2)\) are isomorphic. Indeed, the corresponding Levi subgroups \(L_1\) and \(L_2\) are conjugate in \(\text{Aut}(W)\). Hence, up to an automorphism of \(W\), one may suppose that \(L_1 = L_2 =: L\). By Lemma 6.3(b) the pairs \((\Upsilon, J_1)\) and \((\Upsilon, J_2)\) of type 4.3(ii) are isomorphic under the \(\text{Aut}(\Xi, \Upsilon)\)-action. This isomorphism can be realized by an element of \(L\). Hence one may suppose also that \(J_1 = J_2 =: J\). By virtue of Proposition 6.3(b) and (d) under these assumptions there is an isomorphism of pairs \((W, F_1) \cong (W, F_2)\), as claimed.

The latter isomorphism induces an isomorphism of linked pairs \(\tau_V : (V, S_1) \cong (V, S_2)\). Since \(\{S_1, S_2\}\) is the only pair of disjoint cubic cones in \(V\), one has \(\tau_V^* \in \text{Aut}(V, S_i)\), \(i = 1, 2\). Since \(\text{Aut}^0(V) \subset \text{Aut}(V, S_i)\) and \([\text{Aut}(V) : \text{Aut}^0(V)] \leq 2\), see Proposition 11.1.2 we deduce (13.3.1), as desired.

13.3.2. **Remark.** Let again \(V \cong V_{18}^a\), and let \(\{S'_1, S'_2\}\) be the pair of cubic cones in \(V\) with a common ruling, which corresponds to the unique singular point of \(\Sigma_a(V)\), cf. diagram (10.1.1). For the corresponding linked pairs \((W, F'_j)\), \(j = 1, 2\), one has \(\text{Aut}^0(W, F'_j) \cong \text{Aut}^0(V, S'_j) \cong \mathbb{G}_a \times \mathbb{G}_m\). The argument in the proof above shows that the \(\mathbb{G}_m\)-subgroup of \(\text{Aut}^0(W, F'_j)\) acts nontrivially on \(J'_j = F'_j \cap \Xi\), while the \(\mathbb{G}_a\)-subgroup acts identically on \(J'_j\). It follows that \(R_a \cap \text{Aut}^0(W, F'_j) \cong \mathbb{G}_a\), and \((\Upsilon, J'_j)\) is a pair of type 4.3(iii) for \(j = 1, 2\).

13.4. **Remark.** It is a folklore that the moduli space \(\mathcal{M}_{18}\) of the Fano-Mukai fourfolds of genus 10 is one-dimensional. Indeed, this can be seen as follows.

Identify \(G_2\) with its image in \(\text{Aut}(\mathbb{P}(g_2^2)) \cong \text{PGL}_{14}(\mathbb{C})\) under the dual of the adjoint representation. The open set \(U = \mathbb{P}(g_2^2) \setminus (D_e \cup D_s)\) is \(G_2\)-invariant. Each point \([g] \in U\) corresponds to the hyperplane section \(V^g = \Omega \cap g^{-1}\); the latter is a Fano-Mukai fourfolds of genus 10 with \(\text{Aut}^0(V^g) \cong (\mathbb{G}_m)^2\), see Theorem 1.3(iii). Then \(\mathcal{M}_{18}\) is dominated by the one-dimensional quotient \(U / G_2\), see Proposition 7.7. The fiber of \(U \to U / G_2\) through a point \([g] \in U\) is isomorphic to \(G_2 / \text{Stab}_{G_2}(V^g)\). By Corollary 13.2.1 one has

\[
\text{Aut}^0(V^g) = \text{Stab}_{G_2}(V^g) \cap \text{Stab}_{G_2}(V^g) \subset \text{Aut}(V^g).
\]

The fiber of the morphism \(U / G_2 \to \mathcal{M}_{18}\) through the image of \([g]\) in \(U / G_2\) is isomorphic to \(\text{Aut}(V^g) / \text{Stab}_{G_2}(V^g)\). The latter is a cyclic group whose order is a factor of 6, see (1.3.3). Hence \(U / G_2 \to \mathcal{M}_{18}\) is a finite morphism, and so, \(\dim \mathcal{M}_{18} = 1\).

Notice, however, that the moduli space \(\mathcal{M}_{18}\) does not exist as a separated scheme. Indeed, the points \([V_{18}^a]\) and \([V_{18}^a]\) do not admit disjoint neighborhoods in \(\mathcal{M}_{18}\), as follows from Proposition 7.7.

In addition to Theorem 1.3(i) we have the following results. Item (f) will be used in the next section.

13.5. **Theorem.** Let \(V = V_{18}^a\) be the Fano-Mukai fourfold as in Theorem 1.3(i) and let \(S_1, S_2 \subset V\) be the unique \(\text{Aut}^0(V)\)-invariant cubic cones (see Lemma 12.2). Let \(A_i = A_{S_i}, i \in \{1, 2\}\) be the unique \(\text{Aut}^0(V)\)-invariant hyperplane section with \(\text{Sing}(A_i) = S_i\). Then the following hold.
(a) For $i \neq j$, $A_i$ cuts $S_j$ along a rational twisted cubic curve $\Gamma_j \subset S_i$. The curves $\Gamma_1$ and $\Gamma_2$ are disjoint, the union $\Gamma_1 \cup \Gamma_2$ is an $Aut(V)$-orbit contained in $A_1 \cap A_2$ and pointwise fixed under the $z(Aut^0(V))$-action.

(b) For $j = 1, 2$ consider the family $(S_{j,t})_{t \in \mathbb{P}^1}$ of cubic cones on $V$ such that $\Lambda(S_{j,t})$ is a ruling of $\mathcal{F}_j \to \mathbb{P}^1$ (see Corollary 10.3.2(b)). Then each point of $\Gamma_j$ is the vertex $v_{j,t} = v(S_{j,t})$, and for $j \neq i$ one has $A_i = \bigcup_{t \in \mathbb{P}^1} S_{j,t}$.

(c) The twisted cubics $\Gamma_1$ and $\Gamma_2$ are sections of a rational normal scroll $D$ of degree 6 which is the image of $\mathbb{P}^1 \times \mathbb{P}^1$ embedded to $\mathbb{P}^7 \subset \mathbb{P}^{12}$ by the linear system of bidegree $(1, 3)$. One has $(A_1 \cap A_2)_{red} = D$.

(d) The vertices $v(S_i)$ for $i = 1, 2$ are the unique $GL_2(\mathbb{C})$-fixed points in $V$. Furthermore, $D \setminus (\Gamma_1 \cup \Gamma_2)$ is an orbit of $GL_2(\mathbb{C})$.

(e) $A_1$ and $A_2$ are two components of the branching divisor $\mathcal{B}$ of the morphism $s : \mathcal{L}(V) \to V$ in (8.2.2).

(f) The Fano fourfold $V$ is covered by the affine charts
\begin{equation}
U_i = V \setminus A_i \cong \mathbb{C}^4 \quad \text{and} \quad U_{i,t} = V \setminus A_{i,t} \cong \mathbb{C}^4, \quad t \in \mathbb{P}^1, \quad i = 1, 2,
\end{equation}
where $A_{i,t} = A_{S_{i,t}}$ is the unique hyperplane section of $V$ with $Sing(A_{i,t}) = S_{i,t}$.

\begin{proof}[Proof] Since $S_1 \cap S_2 = \emptyset$ one has $v(S_j) \notin A_i$ for $j \neq i$. This yields the first assertion. The cones $S_1$ and $S_2$ being disjoint (see Lemma 12.2) also the curves $\Gamma_1$ and $\Gamma_2$ are. Since $\Gamma_i \subset S_j \subset A_j$ one has $\Gamma_i \subset A_i \cap A_j$, $i = 1, 2$.

The factor $\mathbb{Z}/2\mathbb{Z}$ of $Aut(V)$ in Theorem 13.4 is generated by an involution $\tau \in Aut(V) \setminus Aut^0(V)$ interchanging $S_1$ and $S_2$. Then $\tau$ switches also $\Gamma_1$ and $\Gamma_2$. Since both $A_i$ and $S_j$ are $Aut^0(V)$-invariant then $\Gamma_i = A_i \cap S_j$ is. The curve $\Gamma_i$ is an orbit of $Aut^0(V)$. It is pointwise fixed under the $z(Aut^0(V))$-action, and $\Gamma_1 \cup \Gamma_2$ is an orbit of $Aut(V)$.

(b) Since $S_{j,t}$ and $S_i$ contain a common ruling one has $v(S_{j,t}) \in S_i$, and so, $S_{j,t} \subset A_i$ (recall that $A_i$ is the union of lines in $V$ meeting $S_i$, see Lemma 9.2). The union $\bigcup_{t \in \mathbb{P}^1} S_{j,t} \subset A_i$ is a closed subvariety of dimension 3. Since $A_i$ is irreducible of dimension 3 one has $A_i = \bigcup_{t \in \mathbb{P}^1} S_{j,t}$. The set of vertices $\{v(S_{j,t})\}_{t \in \mathbb{P}^1} \subset S_i$ is $Aut^0(V)$-invariant, hence, $\{v(S_{j,t})\}$ is a closed one-dimensional $Aut^0(V)$-orbit in $S_i$. The center $z(Aut^0(V))$ acts nontrivially on any ruling $l$ of $S_i$ with just two fixed points, $v(S_i)$ and $\Gamma_i \cap l$. Therefore, $\Gamma_j = S_i \cap A_j$ is the only one-dimensional $Aut^0(V)$-orbit in $S_i$. It follows that $\{v(S_{j,t})\} = \Gamma_j$.

(c) The conic $C = \mathcal{F}_1 \cap \mathcal{F}_2 \subset \Sigma(S)$ parameterizes a family of lines $(l_t)_{t \in \mathbb{P}^1}$ in $V$, where $l_t \in S_{1,t} \cap S_{2,t}$. Since $v(S_{j,t}) \in \Gamma_j \cap l_t$, $j = 1, 2$, the line $l_t$ meets both $S_1$ and $S_2$, hence is contained in $A_1 \cap A_2$. Thus, $D = \bigcup_{t \in \mathbb{P}^1} l_t \subset A_1 \cap A_2$ is a rational normal scroll.

According to Corollary 10.3.2(b) the exceptional section $\Lambda(S_2)$ of $\mathcal{F}_1$ and a ruling $\Lambda(S_{2,t})$ of $\mathcal{F}_2$ project to two distinct points of $\mathcal{E}(V) \cong \mathbb{P}^2$. Since $S_2$ and $S_{2,t}$ are members of the same family $\mathcal{F}_2(V)$ one has $S_2 \cdot S_{2,t} = 1$, see Proposition 9.6. Since they have no common ruling, they meet transversally in one point, say, $P_{2,t}$, which is smooth on both $S_2$ and $S_{2,t}$, see Corollary 9.7.4. Hence there is a unique ruling $l_{2,t} \ni P_{2,t}$ of $S_{2,t}$ which meets $S_2$. By symmetry, there is a unique ruling $l_{1,t}$ of $S_1,t$ which meets $S_1$. Notice that the unique common ruling $l_t$ of $S_{1,t}$ and $S_{2,t}$ meets both $S_1$ and $S_2$, hence $l_{1,t} = l_{2,t} = l_t \subset D \subset A_1 \cap A_2$, see the proof of (b).

The hyperplane section $A_t$ passes through the vertex $v_{1,t} \in \Gamma_1 \cap S_{1,t} \subset A_2$ cutting $S_{1,t}$ along a union of at most 3 rulings. Since $v_{1,t} \in l_t \subset \Gamma_1 = A_1 \cap S_2$ each of these rulings meets $S_2$. It follows by the preceding that the ruling of $S_{1,t}$ which meets $S_2$ is unique and coincides with $l_t$. We conclude that $l_t$ is a triple intersection of $S_{1,t} \subset A_2$ and $A_1$.\end{proof}
Therefore, \( A_1 \cap A_2 = 3D \), and so, \((A_1 \cap A_2)_\text{red} = D\), as stated. We leave to the reader to check the remaining statements of (e).

(d) Since \( S_1, S_2 \) are \( \text{Aut}^0(V) \)-invariant their vertices \( v(S_1) \) and \( v(S_2) \) are two distinct fixed points of \( \text{Aut}^0(V) \). The hyperplane sections \( A_1 \) and \( A_2 \) are \( \text{Aut}^0(V) \)-invariant. For \( i = 1, 2 \) the center \( z(\text{Aut}^0(V)) \) acts on \( V \setminus A_i \cong \mathbb{C}^4 \) via homotheties with a unique fixed point \( v(S_i) \). According to (a) and (b), \( z(\text{Aut}^0(V)) \) fixes also the vertex \( v_{j,t} \) of each cone \( S_{j,t} \) leaving the cone invariant.

We claim that \( z(\text{Aut}^0(V)) \) acts nontrivially on each ruling \( l_t \) of \( D \). Indeed, suppose to the contrary that \( z(\text{Aut}^0(V)) \) acts identically on \( l_t \). The latter is true for any \( t \in \mathbb{P}^1 \) due to the rigidity of the reductive group actions. Since \( l_t \) is a ruling of the cone \( S_{1,t} \), then also \( z(\text{Aut}^0(V)) \) acts identically on any ruling of \( S_{1,t} \). Hence it acts identically on the cone \( S_{1,t} \) for any \( t \in \mathbb{P}^1 \). By (b) one has \( A_2 = \bigcup_{t \in \mathbb{P}^1} S_{2,t} \). It follows that \( z(\text{Aut}^0(V)) \) acts identically on \( S_2 \subset A_2 \). However, \( z(\text{Aut}^0(V)) \) acts via homotheties in \( V \setminus A_1 \cong \mathbb{C}^4 \) with the unique fixed point \( v_2 = v(S_2) \). This gives a contradiction.

Hence each ruling \( l_t \) of \( D \) is \( z(\text{Aut}^0(V)) \)-invariant and contains just two \( z(\text{Aut}^0(V)) \)-fixed points \( l_t \cap (\Gamma_1 \cup \Gamma_2) \). Now the absence of fixed points of \( \text{Aut}^0(V) \cong \text{GL}_2(\mathbb{C}) \) both in \( D \) and in \( V \setminus (D \cup \{ v(S_1), v(S_2) \}) \) follows. The second assertion is now straightforward.

(e) is also straightforward by virtue of (b) and Lemma 9.4.

(f) Notice first of all that any affine chart in \( (13.5.1) \) is isomorphic indeed to \( \mathbb{C}^4 \) by Corollary 4.5.2. Suppose to the contrary that there is a point \( P \in V \), which is not covered by any of the affine charts in \( (13.5.1) \). Thus, all the hyperplane sections \( A_i, A_{i,t} \) pass through \( P \). In particular, \( P \in D = (A_1 \cap A_2)_{\text{red}}, \) see (c) and so,

\[ P \in B := D \cap \bigcap_{i=1,2, t \in \mathbb{P}^1} A_{i,t}. \]

Let us show that \( B \) should contain a point of \( \Gamma_1 \cup \Gamma_2 \). Indeed, \( D \setminus (\Gamma_1 \cup \Gamma_2) \) is an orbit of \( \text{Aut}^0(V) \), see the proof of (d). If this orbit contains a point \( P \in B \), then \( B \), being \( \text{Aut}^0(V) \)-invariant, contains the whole orbit \( D \setminus (\Gamma_1 \cup \Gamma_2) \). Thus, also \( B \supset D \) since \( B \) is closed.

Therefore, one may assume that, say, \( P \in \Gamma_1 \subset B \). By (b) the curve \( \Gamma_1 \) is filled in by the vertices of the cones \( S_{1,t} \). We claim that for any \( t_1 \neq t_2 \) the cones \( S_{1,t_1} \in \mathcal{J}(V) \) and \( S_{2,t_2} \in \mathcal{J}(V) \) are disjoint. Indeed, by Proposition 9.6 one has \( S_{1,t_1} \cdot S_{2,t_2} = 0 \). Since these cones have no common ruling, our claim follows by Corollary 9.7.4.

Let us show that the vertex \( v_{1,t_1} \) of \( S_{1,t_1} \) cannot lie on \( A_{2,t_2} \), hence also in \( B \), which gives a desired contradiction. Indeed, otherwise there is a line through \( v_{1,t_1} \), meeting \( S_{2,t_2} \). The only lines through \( v_{1,t_1} \) are the rulings of \( S_{1,t_1} \). However, as we have seen, the latter rulings are disjoint with \( S_{2,t_2} \). 

14. Flexibility of affine cones over Fano-Mukai fourfolds \( V_{18} \)

14.1. An affine variety \( X \) of dimension at least 2 is called flexible (in the sense of [AFK+13]) if the subgroup \( \text{SAut}(X) \subset \text{Aut}(X) \) generated by all the unipotent algebraic subgroups of \( \text{Aut}(X) \) acts transitively on the smooth locus \( X_{\text{reg}} \). We say that \( X \) is flexible in codimension one if \( \text{SAut}(X) \) admits an open orbit \( O_X \) whose complement has codimension at least 2 in \( X \). In the latter case \( \text{SAut}(X) \) acts \( m \)-transitively on \( O_X \) for any natural \( m \) ([AFK+13, Theorem 2.2]).
Actions of unipotent groups on affine cones over Fano varieties was recently a subject of intensive studies. Several families of smooth Fano fourfolds were examined from this viewpoint; see, e.g., [PZ13, PZ16] and the references therein. Using a criterion in [KPZ13], one can deduce from [PZ15] and Theorem 1.1 such a corollary.

14.1. Corollary. Let $V = V_{18} \subset \mathbb{P}^{12}$ be a Fano-Mukai fourfold of genus 10, and let $A$ be a hyperplane section of $V$ containing either a smooth cubic scroll, or a cubic cone. Then $V \setminus A$ contains a principal open cylinder $U \cong \mathbb{C} \times \mathbb{C}$, where $\dim \mathbb{C} = 3$. Consequently, any affine cone $X = \text{Cone}_H(V)$, where $H$ is an ample polarization of $V$, admits an effective $\mathbb{G}_a$-action.

Flexibility of affine cones over Fano varieties was studied recently in [MPS16]. Theorem 1.4 and Remark 1.2 in [ibid] lead to the following criterion.

14.2. Proposition. Let $V$ be a projective variety with a very ample polarization $H$. Suppose that $V$ contains a Zariski open subset $U$ whose complement $V \setminus U$ has codimension at least 2 in $V$ and such that $U = \bigcup_{\alpha} U_\alpha$ is covered by a collection $(U_\alpha)$ of smooth, flexible principal open subsets $U_\alpha = V \setminus H_\alpha$, where $H_\alpha \in |H|$. Then the corresponding affine cone $X = \text{Cone}_H(V)$ is flexible in codimension one. More precisely, the pullback of $U$ in $X$ is contained in the open orbit of $\text{SAut}(X)$. In particular, if $U = V$ then $X$ is flexible.

Applying this criterion in the setting of Theorem 1.1 one obtains the following result.

14.3. Theorem. The affine cone over any polarized Fano-Mukai fourfold $V = V_{18}$ of genus 10 is flexible in codimension one. For $V = V_{18}$ this cone is flexible.

Proof. Let $A_i$ be the hyperplane sections of $V$ with $\text{Sing}(A_i) = S_i$, $i = 1, 2$, where $S_1, S_2$ are two distinct cubic cones in $V$, see Theorem 1.1. Then the principal open subsets $U_i := V \setminus A_i \cong \mathbb{C}^4$, $i = 1, 2$, are flexible, and $\text{codim}_{\mathbb{C}^4}(U_i \cap U_j) = 2$. Since $\text{Pic}(V) \cong \mathbb{Z}$ the criterion of Proposition 14.2 applies and gives the result.

If $V = V_{18}$ then by Theorem 15.111, $V$ is covered by the affine charts isomorphic to $\mathbb{C}^4$. Once again, the flexibility of the cone $\text{Cone}_H(V)$ follows from Proposition 14.2.

15. Final remarks and open questions

15.1. Given a simple affine algebraic group $G$ over $\mathbb{C}$ of adjoint type and a parabolic subgroup $P \subset G$, consider the flag variety $G/P$. It is known (see [Dem77], [Akh95] Theorem 2 in §3.3 and the subsequent remark) that $\text{Aut}^0(G/P) \cong G$ (for certain three cases). In the exceptional cases $G' := \text{Aut}^0(G/P)$ is again a simple affine algebraic group of adjoint type, and $G/P = G'/P'$ for a parabolic subgroup $P' \subset G'$. In particular, for $G = G_2$ and $G/P = \Omega$ as in Section 7, one has $\text{Aut}^0(G/P) = G_2$. A similar phenomenon might occur as well for smooth hyperplane sections of adjoint varieties.

15.2. Problem. Consider a flag variety $G/P$, where $G$ is a semisimple affine algebraic group with trivial center and $P \subset G$ is a parabolic subgroup. Choose $G$ and $P$ suitable so that $\text{Aut}^0(G/P) \cong G$. Let $\iota : G/P \hookrightarrow \mathbb{P}^n$ be a $G$-equivariant embedding with linearly nondegenerate image. Since $\text{Pic}(G/P)$ is discrete, one may identify $G \cong \text{Aut}^0(G/P)$ with $\text{Aut}^0(\mathbb{P}^n, \iota(G/P))$. We wonder as to when for any smooth hyperplane section $H$ of $\iota(G/P)$ one has $\text{Aut}^0(H) = \text{Stab}^0_G(H)$.

Theorem 12 says that this is indeed the case for $G = G_2$ and for the adjoint orbit $\Omega = G_2/P$. By [EH16, Lem. 8.2(i)] this is the case for any irreducible hermitian symmetric
space $G/P$ of compact type, provided the embedding $\iota: G/P \hookrightarrow \mathbb{P}^n$ is given by the ample generator of the Picard group $\text{Pic}(G/P) \cong \mathbb{Z}$. See [FH16, Prop. 8.4 and Thm. 8.5] for concrete examples.

One can ask the same question more generally for the smooth linear sections $L$ of $\iota(G/P)$ provided the Picard group of $L$ is isomorphic to $\mathbb{Z}$. See [PdV99, Thm. 1.2, Cor. 1.3 and its proof].

15.3. Question. It is known that for any compactification $(V, A)$ of $\mathbb{C}^3$ with $b_2(V) = 1$ the middle Betti number $b_3(V)$ vanishes. In all known examples in dimension 4, that is, for $\mathbb{P}^4$, $Q^4 \subset \mathbb{P}^5$, the examples in [Pro94], and the ones in Theorem 1.1, the middle Betti number satisfies the inequality $b_4(V) \leq 2$. We wonder whether this inequality still holds for any compactification $(V, A)$ of $\mathbb{C}^4$ with $b_2(V) = 1$.

15.4. Problem. Describe explicitly the involution acting on $V = V_{18}^a$ ($V = V_{18}^s$, respectively) and interchanging the $\text{Aut}^0(V)$-invariant cubic cones $S_1, S_2 \subset V$. Determine the discrete groups $\text{Aut}(V)/\text{Aut}^0(V)$ for the Fano-Mukai fourfolds $V \not\cong V_{18}^a, V_{18}^s$ of genus 10.

15.5. Remark. The group $\text{Aut}(V_{18}^a) \cong (\mathbb{G}_a \times \mathbb{G}_m) \rtimes (\mathbb{Z}/2\mathbb{Z})$ being non-abelian, the involution of $V_{18}^a$ interchanging the $\text{Aut}^0(V)$-invariant cubic cones $S_1, S_2$ does not admit an extension to an element of $\text{G}_2$ acting on $\Omega$, see Propositions 7.5.1(b) and 7.7(b). However, we ignore if it can be extended to an automorphism of $\Omega$.

15.6. Problem. Which Fano-Mukai fourfolds $V_{18}$ of genus 10 admit a Kähler-Einstein metric ([Tia15])? Notice that the group $\text{Aut}^0 V_{18}^a \cong \mathbb{G}_a \times \mathbb{G}_m$ is not reductive, see Theorem 1.3(ii). Hence, according to Matsushima’s theorem ([Mat57]), the variety $V_{18}^a$ does not admit such a metric.

15.7. Problem. Study singular Fano-Mukai fourfolds of type $V_{18}$ (cf. [Pro15, Pro16]).

Acknowledgments. The paper started during the first author’s stay at the Institute Fourier, Grenoble, in June of 2016. He thanks the institute for its hospitality. The authors are grateful to Alexander Kuznetsov for useful discussions, to Michel Brion, Jun-Muk Hwang, and Laurent Manivel for important remarks around the material of Sect. 7 and to Ivan Arzhantsev and Alexander Perepechko for a pertinent remark concerning the material of Section 14. Our thanks are due also to a referee for his remarks improving the style of the paper.
