Abstract

We examine the Standard and the New Physics (NP) contributions to the $ZZZ$, $ZZ\gamma$ and $Z\gamma\gamma$ neutral gauge couplings. At the one-loop level, if we assume that there is no CP violation contained in NP beyond the Standard Model one, we find that only CP conserving neutral gauge couplings are generated, either from the standard quarks and leptons, or from possible New Physics (NP) fermions. Bosonic one-loop diagrams never contribute to these couplings, while the aforementioned fermionic contributions satisfy $h_3^Z \simeq -f_5^\gamma$, $h_4^Z = h_4^\gamma = 0$. We also study examples of two-loop NP effects that could generate non vanishing $h_4^{\gamma,Z}$ couplings. We compare quantitative estimates from SM, MSSM and some specific examples of NP contributions, and we discuss their observability at future colliders.

1 Introduction

Recently there has been a renewed interest in the possible existence of anomalous neutral gauge boson self-couplings. This is due to the acquisition of new experimental results at LEP2 [1] which, together with the TEVATRON results [2], begin to produce interesting constraints on such couplings; which should further improve in the future at the next colliders [3].

This has lead to a reexamination of the phenomenological description commonly used for these couplings. The necessity of certain corrections was discovered and their implications for $ZZ$ and $Z\gamma$ production at $e^-e^+$ and hadron colliders were discussed [4].

For what concerns the quantitative theoretical predictions for each of these neutral couplings, very little has been said up to now [3, 4, 5, 6, 7], in contrary to the of the charged ($ZWW$ and $\gamma WW$) self-couplings for which several types of predictions had been given since a long time [8, 9, 10, 11]. A reappraisal of the theoretical expectations for these neutral couplings, is still lacking. Therefore, the purpose of this paper is to fill this lack and study the Standard Model (SM) predictions for these couplings, as well as the predictions arising from possible new physics beyond it.

In Section 2 we first recall some general properties following from Bose statistics, Lorentz symmetry and $SU(2) \times U(1)$ gauge invariant effective lagrangians. The most notable of them is that the neutral gauge couplings vanish whenever all three gauge boson are on-shell. Thus, at least one the gauge boson need to be off-shell, for such couplings to appear. Then, in Section 3 we consider the perturbative contributions to these couplings arising at one loop. When standard vertices for the gauge boson interactions are used, and in particular no CP violation in the photon- and $Z$- couplings to fermions is considered, then of course only CP conserving neutral gauge self-couplings can arise. At the 1-loop level, such couplings can only be induced by a fermionic triangle diagram, involving either new or SM fermions. We give the exact expression of these contributions to the real and imaginary parts of the neutral gauge couplings, in terms of the fermionic ones ($g_{\nu j}$, $g_{aj}$) and the fermion masses $M_j$, as well as the squared mass $s$ of the off-shell vector boson. To elucidate the remarkable properties of these results, we study both the high $s$ behaviour of these gauge couplings at fixed fermion mass $M_j$, as well as their high fermion-mass limit ($M_j^2 \gg s$, $m_Z^2$). As we will see, the behaviour in these limits is intimately related to the way the anomaly cancellation is realized.

The quantitative aspects of these fermionic contributions are discussed in Section 4, where we consider the SM contributions to the real and imaginary parts of the couplings, as well as the relative magnitude of the lepton- , light quark- and the top quark-contributions. We observe that the anomaly cancellation is intimately accompanied by considerable cancellation between the lepton and quark contribution to the physical neutral gauge boson couplings at high energy. We then consider the supersymmetric contributions due to the charginos and neutralinos in the MSSM. And finally we discuss the possibility of heavy fermions associated to some form of new physics (NP) with a high intrinsic scale $\Lambda_{NP}$.

Section 5 is devoted to contributions that could arise beyond the fermionic one loop
level, either though higher order perturbative diagrams or through non perturbative effects. Finally, in Section 6, we summarize our results and their consequences for the observability of neutral self-boson couplings at present and future colliders.

2 General properties of neutral self-boson couplings

Because of Bose statistics, the $Z$ and $\gamma$ self-couplings vanish identically, when all three particles are on-shell. The general form of the couplings of one off-shell boson ($V = Z, \gamma$) to a final pair of on-shell $ZZ$ or $Z\gamma$ bosons, is

$$\Gamma_{\alpha\beta\mu}^{ZV}(q_1, q_2, P) = i(s - m_V^2) \left[ f_4^V (P^\alpha g^\mu\beta + P^\beta g^\mu\alpha) - f_5^V \epsilon^{\alpha\beta\rho\sigma}(q_1 - q_2)_\rho \right],$$

$$\Gamma_{\alpha\beta\mu}^{Z\gamma V}(q_1, q_2, P) = i(s - m_Z^2) \left[ h_1^V (q_2^\mu g^{\alpha\beta} - q_2^\alpha g^{\mu\beta}) + h_2^V \frac{m_Z}{m_Z^2} P^\alpha [(P q_2)_2 g^{\mu\beta} - q_2^\mu P^{\beta}] - h_3^V \epsilon^{\alpha\beta\rho\sigma} q_2^\rho - h_4^V \epsilon^{\alpha\beta\rho\sigma} P_\rho q_2^\sigma \right],$$

where the momenta are defined as in Fig.1 and $s \equiv P^2$ is used. The expressions (1, 2) follow from the general forms written in [12, 13] and the corrections made in [4]. The forms associated to $f_4^V$, $h_1^V$, $h_2^V$ are CP-violating, whereas the ones associated to $f_5^V$, $h_3^V$, $h_4^V$ are CP-conserving.

The CP-conserving forms in (1, 2) are C- and P- violating and in this respect they are analogous to the anapole $ZW^+W^-$ and $\gamma W^+W^-$ vertices

$$\Gamma_{W^+W^-V}^{\alpha\beta\mu}(q_1, q_2, P) = i \frac{z_V}{m_W} \left[ \epsilon^{\alpha\beta\rho\sigma} P_\sigma (q_1 - q_2)_\rho P^\beta - \epsilon^{\alpha\beta\rho\sigma} P_\sigma (q_1 - q_2)_\rho P^\rho \right],$$

as well to the corresponding gauge boson-fermion anomalous anapole coupling. None of these couplings exist at tree level in the Standard Model (SM). At the one-loop SM level though, as we will see below, such couplings do appear and tend to be strongly decreasing with $s$.

Since the CP violating couplings in (1–4) can never be generated, if the NP interactions of $Z$ and photon conserve CP, we concentrate below on the CP conserving couplings $f_5^V$, $h_3^V$, $h_4^V$. As already observed these are analogous to the anapole ones. But the situation in this neutral anapole sector is rather different from the one in the sector of the general charged $ZWW$ and $\gamma WW$ couplings. This can been seen by comparing the results of the calculation of the triangular graph of Fig.2, with the generic expectations from a dimensional analysis in the effective lagrangian framework. More explicitly, the contribution of a heavy fermion of mass $\Lambda_{NP}$ to the aforementioned 1-loop triangular graph results to an $f_5^V$ or $h_3^V$ coupling, which may occasionally behave like $(m_W/\Lambda_{NP})^2$. On the other hand, when one writes the effective lagrangian in terms of $SU(2) \times U(1)$ gauge

$\epsilon^{0123} = 1$. 

3
invariant operators in the linear representation \[14\], then at the lowest non-trivial level of \(dim = 6\) operators several anomalous \(ZW W\) and \(\gamma W W\) couplings are generated \[15, 16\]. However, at this level, neither the anapole \(ZW W\) coupling of \(3\), nor any neutral gauge couplings ever appear. These couplings require higher dimensional \(dim \geq 8\) operators, which means that their magnitude should be depressed by at least one more power of \(m_W^2/\Lambda_{NP}^2\) and behave like \((m_W/\Lambda_{NP})^4\).

It is therefore interesting to examine more precisely the conditions under which such couplings can be generated and what type of NP effects determine their magnitude.

3 Fermion loop contributions

We have first looked at the perturbative ways in which the neutral couplings in \([1, 2]\) could be generated. One immediately observes that at the 1-loop level the relevant graphs are triangular ones of the type of Fig.2. For scalars or \(W^\pm\) bosons running along the loop in such graphs, with standard \(ZW W\) and \(\gamma W W\) couplings, we always get identically vanishing contributions. In particular for the CP conserving couplings, the reason is that the \(\epsilon^{\mu\nu\rho\sigma}\) tensor can never be generated from them. Only a fermionic loop (either with a single fermion \(F_j\) running along the loop, or with mixed \(F_1, F_2, \ldots\) fermionic contributions), can generate such \(\epsilon^{\mu\nu\rho\sigma}\) terms, through the axial \(Z\) coupling (see Fig.2).

To describe them, we use the standard definitions

\[
\mathcal{L} = -e Q_j A^\mu \bar{F}_j \gamma_\mu F_j - \frac{e}{2 s_W c_W} Z^\mu \bar{F}_j (\gamma_\mu g_{v12} - \gamma_\mu \gamma_5 g_{a12}) F_j \\
- \frac{e}{2 s_W c_W} Z^\mu \bar{F}_1 (\gamma_\mu g_{v21} - \gamma_\mu \gamma_5 g_{a21}) F_2 ,
\]

where \(Q_j\) is the \(F_j\) charge, while \(g_{v12}, g_{a12}\) and the mixed couplings \(g_{v12}, g_{a12}\) determine the \(Z\)-fermion interactions. If there are no CP violating NP sources, then all these couplings must be real, and hermiticity requires \(g_{v12} = g_{v21}, g_{a12} = g_{a21}\). As already said, in such a case only the CP conserving neutral gauge boson couplings in \([1, 2]\) can in principle be generated.

Using standard techniques for preserving CVC and Bose symmetry, (or equivalently for isolating the anomaly contribution) we get the 1-loop fermionic contributions to the CP conserving couplings \(h_3^{Z\gamma}\) and \(f_5^{Z\gamma}\) presented in Appendix A in terms of Passarino-Veltman functions, and in Appendix B in terms of the Feynman parametrization. These expressions are used below for computing the precise predictions of the Standard Model and of the MSSM. Before presenting these though, the following remarks are in order.

We first note that at the one-loop level, we can never generate \(h_4^{Z}\) and \(h_4^{\gamma}\), i.e.

\[
h_4^{Z} \equiv h_4^{\gamma} \equiv 0 .
\]

\(^2\)The same conclusion should also be valid if the non-linear Higgs representation is used. In this later case the \(ZWW\) anapole coupling can be generated at the dominant \(D_{chiral} = 4\) level; but the generation of neutral self-couplings still requires higher dimensional operators \([15]\).
Therefore, the neutral couplings most likely to appear are $f_5^{\gamma Z}$ and $h_3^{\gamma Z}$. From the expressions given in the Appendices A or B, it is easy to obtain their behaviour in the high and low energy limit. At high energy $s \gg M_j^2, m_Z^2$, we get

$$h_3^{Z} \simeq -f_5^{\gamma} \simeq N_F \frac{e^2 Q_j g_{\psi j} g_{\sigma j}}{8\pi^2 s_W^2 c_W^2} \left( \frac{m_Z^2}{s} \right),$$

(6)

$$f_5^{Z} \simeq -N_F \frac{g_{\psi j} [g_{\sigma j}^2 + 3g_{\psi j}^2]}{48\pi^2 s_W^2 c_W^2} \left( \frac{m_Z^2}{s} \right),$$

(7)

$$h_3^{\gamma} \simeq N_F \frac{e^2 Q_j g_{\psi j} g_{\sigma j}}{4\pi^2 s_W c_W} \left( \frac{m_Z^2}{s} \right),$$

(8)

where $M_j$ is the mass of the single fermion $F_j$ assumed to run along the loop in Fig.2 and $N_F$ is a counting factor for colour and/or hypercolour.

In both these limits, the relation

$$h_3^{Z} \simeq -f_5^{\gamma}$$

(12)

holds independently of the fermion couplings. Nevertheless, this relation cannot be exact. Indeed, as one can see from the expressions of the Feynman integrals (B.4, B.1), the approximate equality (12) is violated by the different threshold effects associated to the $Z\gamma$ and $ZZ$ final pairs, in the triangular graph in Fig.2. It turns out though that these threshold effects are rather small and moreover, they rapidly diminish as soon as $s$ goes away from threshold. In this respect, we have checked that in a high $M_j$ expansion, the violation of the equality (12) is very tiny and of the order of $m_Z^6/M_j^6$. The overall conclusion is therefore, that (12) is approximately correct for most of the range of the $s$ and $M_j$ values. This is also shown by the numerical applications presented in Section 4 below.

We next mention the fermion contribution to the anapole $ZW W$ and $\gamma WW$ couplings, since they are of the same nature as the above neutral couplings. Indeed, when one computes the triangle loop with a doublet of fermions $F, F'$ of masses $M_F, M_{F'}$, one obtains the result given in (B.21-B.23) in Appendix B. Using then (B.24-B.26) for the case of standard couplings and a degenerate fermion iso-doublet pair satisfying $M_F = $
that result simplifies to
\[
z_z \simeq -\frac{s_W}{c_W} z_\gamma = N_F \frac{e^2}{1152\pi^2 s_W c_W} \left( \frac{m_W^2}{M_F^2} \right) \left( 1 + \frac{4s + 2m_W^2}{15M_F^2} \right),
\]
(13)
for quarks, and
\[
z_z \simeq -\frac{s_W}{c_W} z_\gamma = -N_F \frac{e^2}{384\pi^2 s_W c_W} \left( \frac{m_W^2}{M_F^2} \right) \left( 1 + \frac{4s + 2m_W^2}{15M_F^2} \right),
\]
(14)
for leptons.

The numerical predictions for the fermion contributions to \( f_V^1 \) and \( h_V^3 \), are strongly affected by the way the anomalies are (presumably) cancelled in the complete theory. Consequently, in the final part of this section we discuss their effect. Such anomalies are generated by triangular fermion loop diagrams. In SM they are cancelled whenever one or more complete families of leptons and quarks are considered. In the MSSM the total chargino or neutralino contributions are separately anomaly free. However, since these anomalies are proportional to the quantities
\[
\sum_j g_{v_j} g_{a_j} Q_j, \quad \sum_j g_{a_j} Q_j^2, \quad \sum_j Q_j,
\]
and independent of the masses of the fermions running along the loop, their cancellation may involve fermions with very large mass differences. Consequently three distinct possibilities arise. Either all participating fermions are almost degenerate at scale \( \Lambda_{NP} \); or they have mass differences of the electroweak size; or finally certain fermions are much lighter than others, the contributions of the heavier ones to the neutral couplings being then negligible.

These different situations lead to very different predictions for the size of the neutral couplings. In the first case, a complete family of exactly degenerate heavy fermions (for example degenerate heavy leptons and quarks with the SM structure) would lead to the vanishing of all the NP couplings. This arises because, in this case, the combination of the heavy fermion contributions is the same as in the mass independent cancelling triangle anomaly. This is the unbroken \( SU(2) \times U(1) \) situation.

If instead, one introduces mass splittings of the electroweak size (i.e. \( \simeq m_Z^2 \)) among the multiplets; like e.g. between the heavy lepton and the heavy quark doublets, then the resulting couplings are of the order \( m_Z^2/M_F^2 \), which means that they are suppressed by an extra power \( m_Z^2/M_F^2 \) as compared to (11). This case corresponds to a spontaneous broken \( SU(2) \times U(1) \) situation. Identifying \( M_F \) with \( \Lambda_{NP} \), we then indeed get a contribution of order \( 1/\Lambda_{NP}^4 \), similar to what is predicted by \( \text{dim} = 8 \) gauge-invariant operators.

Finally, if a single heavy fermion (or a partial set of heavy fermions) is much lighter than all the other fermions in the family, then the couplings are directly given by the leading terms in (11): i.e. just proportional to \( (m_Z^2/M_F^2) \). This is obviously the most favorable situation for their observability, but it would essentially mean that \( SU(2) \times U(1) \) gauge symmetry is strongly broken in the NP sector.

In the next Section we give some quantitative illustrations.
4 Contributions from Standard Model and Beyond

4.1 The Standard Model contributions

The SM contribution arises from the three families of leptons and quarks, and the anomaly cancellation occurs separately inside each family. To the couplings $h_3^{Z\gamma}$ and $f_5^{\gamma}$ only the charged fermions contribute; while $f_5^{Z}$ receives contributions from the neutrinos also. In Fig.3 we have drawn the SM contributions to the real and the imaginary parts of these couplings. The respective magnitudes of the contributions of the leptons, the five light quarks, and the top quark are also shown. The consequences of the anomaly cancellation are clearly reflected in the behaviour of the predicted couplings at high energy, e.g. for $s \gg m_Z^2, M_F^2$. Indeed it can be seen in Fig.3 that although each fermionic contribution decreases like $\sim 1/s$ in agreement with eq. (6-8), their sum decreases like $\sim \ln s/s^2$.

The neutral couplings get imaginary parts as soon as $s > 4M_F^2$ or $M_Z^2 > 4M_F^2$. After a spectacular threshold enhancement though, the imaginary contribution of each fermion behaves like $(m_Z^2 M_F^2/s^2) \ln(s/M_F^2)$ for $s \gg (M_Z^2, 4M_F^2)$. Therefore, the light fermion contribution to the imaginary parts of the couplings is strongly suppressed, and only the top quark effect is visible on Fig.3.

Summarizing, the SM neutral couplings are in general complex but the relative importance of the real and imaginary parts is strongly energy dependent. Below the $2m_t$ threshold, the imaginary part is negligible. Above $2m_t$, real and imaginary parts have a comparable magnitude; with the imaginary part being somewhat larger. In Table 1, we collect these SM contributions at LEP2 ($\sqrt{s} = 200$ GeV) and at a 500 GeV Linear Collider. The results in Fig.3 and Table 1 indicate also the extent to which (12) is approximately correct for any $s$ and $M_j$ values.

| $\sqrt{s}$ | $f_5^Z$ | $f_5^\gamma$ | $h_3^Z$ | $h_3^\gamma$ |
|------------|----------|--------------|--------|-------------|
| 200        | 2.05 - 0.15 $\times 10^{-4}$ i | 1.85 - 0.48 $\times 10^{-4}$ i | -7.21 + 0.81 $\times 10^{-2}$ i | -2.10 + 0.40 $\times 10^{-2}$ i |
| 500        | 0.25 + 0.62 i | 0.46 + 0.53 i | -0.88 - 1.82 i | -0.26 - 0.62 i |

4.2 The MSSM contributions

As a first example of new physics effect, we have computed the additional one loop contributions arising in the Minimal Supersymmetric Standard Model (MSSM). They are rather simple, as the only new fermions are charginos and neutralinos. The two charginos $\chi_{1,2}^\pm$ contribute to the four $h_3^{Z\gamma}$ and $f_5^{\gamma}$ couplings; while the four neutralinos $\chi_{1-4}^0$ contribute only to $f_5^Z$. Charginos couple to the gauge bosons through both their gaugino and higgsino components, whereas neutralinos only contribute through their higgsino components. The new feature, as compared to SM contributions, is that there now exist triangle loops with mixed contributions, for example $(F_1, F_2, F_2)$ in the chargino case.
This is caused by the non-diagonal $g_{v12}$, $g_{a12}$ Z-couplings in (4). The explicit expressions of these new contributions are also given in Appendices A and B. However, because the non-diagonal Z-couplings are generally weaker than the diagonal ones (see below), these mixed contributions turn out to be notably smaller than the unmixed contributions. Let us first discuss the chargino contributions. If $\mu$ and the soft breaking SUSY parameters are taken to be real, as would be the case if no new CP violation source, beyond the one contained in the Yukawa couplings exists; then the chargino masses are given by [18]

$$M_{\chi_{1,2}^\pm}^2 = \frac{1}{2} \left\{ M_2^2 + \mu^2 + 2m_W^2 \mp \sqrt{(M_2^2 + \mu^2 + 2m_W^2)^2 - 4(M_2\mu - m_W^2 \sin(2\beta))^2} \right\}.$$  (15)

The photon couplings in (4) are then fixed by $Q_{\chi_{1,2}^\pm} = +1$. For the $Z\chi_1\chi_1$ couplings in (4) we have [18]

$$g_{v1} = \frac{3}{2} - 2s_W^2 + \frac{1}{4} \left[ \cos 2\phi_L + \cos 2\phi_R \right], \quad g_{a1} = -\frac{1}{4} \left[ \cos 2\phi_L - \cos 2\phi_R \right],$$  (16)

while for the $Z\chi_2\chi_2$ couplings

$$g_{v2} = \frac{3}{2} - 2s_W^2 - \frac{1}{4} \left[ \cos 2\phi_L + \cos 2\phi_R \right], \quad g_{a2} = \frac{1}{4} \left[ \cos 2\phi_L - \cos 2\phi_R \right],$$  (17)

where

$$\sin 2\phi_R = -\frac{2\sqrt{2}m_W(\mu \cos \beta + M_2 \sin \beta)}{D}, \quad \sin 2\phi_L = -\frac{2\sqrt{2}m_W(\mu \sin \beta + M_2 \cos \beta)}{D},$$

$$\cos 2\phi_R = -\frac{M_2^2 - \mu^2 + 2m_W^2 \cos 2\beta}{D}, \quad \cos 2\phi_L = -\frac{M_2^2 - \mu^2 - 2m_W^2 \cos 2\beta}{D},$$  (18)

with

$$D = \sqrt{(M_2^2 + \mu^2 + 2m_W^2)^2 - 4(M_2\mu - m_W^2 \sin 2\beta)^2}.$$  (19)

Finally, the mixed $Z\chi_1\chi_2$ couplings are

$$g_{v12} = -\frac{\text{Sign}(M_2)}{4} [\text{Sign}(M_2\mu - m_W^2 \sin 2\beta) \sin 2\phi_R + \sin 2\phi_L],$$

$$g_{a12} = -\frac{\text{Sign}(M_2)}{4} [\text{Sign}(M_2\mu - m_W^2 \sin 2\beta) \sin 2\phi_R - \sin 2\phi_L],$$  (20)

where $\text{Sign}(x)$ means sign of $x$. As expected, the anomaly cancellation in the chargino sector arises when one sums the mixed and unmixed contributions of the two charginos.

For the numerical applications we used the sets of parameters at the electroweak scale presented in Table 2. [19].

The main feature of the data in Table 2 is that almost always one of the chargino is considerably lighter than the other. Thus, at energies around $2M_{\chi_1}$ but considerably below $2M_{\chi_2}$, the dominant contribution comes from the lighter chargino, while the heavier
Table 2: Sets of MSSM chargino parameters at the electroweak scale.

| Set | \( M_2 \) | \( \mu \) | \( \tan \beta \) | \( M_{\chi^+} \) | \( M_{\chi^+} \) |
|-----|-----------|----------|-------------|---------------|---------------|
| (1) | 81        | \(-215\) | 2           | 94.71         | 237.94        |
| (2) | 215       | \(-81\)  | 2           | 94.71         | 237.94        |
| (3) | 120       | 300      | 2.5         | 96.13         | 328.57        |
| (4) | 200       | 800      | 4           | 193.95        | 809.43        |
| (5) | 152       | 316      | 3           | 127.89        | 345.55        |
| (6) | 150       | 263      | 30          | 132.34        | 294.88        |

one gives a weaker contribution of opposite sign. At energies higher than both chargino thresholds, these two contributions tend to cancel; the cancellation being a relic of the anomaly cancellation in the chargino sector.

More quantitatively, as the chargino couplings are of electroweak size, when one chargino is light enough (around 100 GeV or less), then their contribution is similar to the SM ones, for what concerns the real parts of the couplings. Similarly to the top quark SM case, the imaginary parts get threshold enhancements just above \( 2M_\chi \), where their magnitude is comparable to that of the real part. These features can be seen in Figs.4, 5 where we have illustrated the cases of the Sets 5 and 6. The results for the Sets 1, 2, 3 are quite similar; although it may remarked that the chargino contribution, particularly to \( f_5^Z \) or \( f_5^\gamma \), is somewhat more pronounced there. In Set 4 the chargino contribution is very small, because there, the lightest chargino is relatively heavy, and the Z-axial couplings are very small. The later is due to \( |\mu| \gg |M_2| \) in this model, which forces \( \phi_L, \phi_R \) to have similar values and thereby the Z-axial couplings to have very low values. The cases of Sets 5 and 6 are identical to the low and high \( \tan \beta \) scenarios suggested in [20] as a benchmark for SUSY studies. In Table 3 we give the precise predictions for these sets at \( \sqrt{s} = 200, 500 \text{ GeV} \).

Table 3: Chargino contributions for Set (5,6) in units of \( 10^{-4} \).

| Set | \( \sqrt{s} \) | \( f_5^\gamma \) | \( f_5^Z \) | \( h_3^\gamma \) | \( h_3^Z \) |
|-----|--------------|----------------|-------------|--------------|--------------|
| (5) | 200 GeV     | 0.29           | 0.49        | \(-0.19\)    | \(-0.31\)    |
| (5) | 500 GeV     | \(-0.17 + 0.13 \) i | \(-0.39 + 0.11 \) i | \(0.11 - 0.10 \) i | \(0.26 - 0.09 \) i |
| (6) | 200 GeV     | 0.43           | 0.70        | \(-0.29\)    | \(-0.46\)    |
| (6) | 500 GeV     | \(-0.34 + 0.25 \) i | \(-0.57 + 0.15 \) i | \(0.22 - 0.20 \) i | \(0.39 - 0.12 \) i |

In addition there is a neutralino contribution to \( f_5^Z \). It only arises from the Z couplings to the Higgsino components. In order to have an estimate of the largest possible neutralino effect, we have taken the case in which the lightest neutralinos are of Higgsino type. As the contribution to \( f_5^Z \) is proportional to the cubic power of the Z-neutralino coupling, it would become rapidly negligible if the neutralinos were not dominantly Higgsino-like. So
we have taken pure axial Z-Higgsino couplings

\[ g_{\chi_1^i} = g_{\chi_2^i} = 0, \quad g_{\chi_1^0} = -g_{\chi_2^0} = 1, \quad (21) \]

and only considered the contribution from two neutralinos. The results for the masses (in GeV) \[21\]

\[ (M_{\chi_1^0}, M_{\chi_2^0}) = (71, 130), \ (78, 165), \ (93, 165), \ (170, 195) \]

are shown in Fig.6. They are somewhat smaller than those due to charginos for comparable masses, this being due to the difference in the Z couplings. Remarkable threshold effects nevertheless appear when one neutralino is light enough. The largest effects are obtained for the couple (71,130)GeV.

For this couple, at 200 and at 500 GeV, the contributions to \(f^Z_5\) in units of \(10^{-4}\), are

\[ -0.26 + 3.3i \quad \text{and} \quad -0.32 - 0.22i \]

respectively; \textit{i.e.} comparable to the SM and to chargino contributions. The same type of comments about the behaviour of the real and of the imaginary parts can be made.

Let us finally note that, if there is nearly degeneracy of the lightest chargino and neutralino, their cumulative effect in \(f^Z_5\) can be occasionally important and increase the SM contribution by a factor of 2 to 3.

### 4.3 Other NP possibilities.

The above study of the MSSM contributions gives already a good feeling of what can arise from any other perturbative NP contributions at one loop. We now want to extend the discussion by considering quantitatively, in a model-independent way, the contribution of a new fermion \(F\). Such new fermionic states arise in many extensions of the SM, like in GUTS or in TC models.

We take couplings of electroweak size, which means typical values of the order of \(g_{\nu F} = g_{a F} = \frac{1}{2}; Q_F = 1\), and keep the colour-hypercolour factor \(N_F = 1\). In Fig.7 we show how the resulting couplings depend on the fermion mass \(M_F\), at fixed energies \(\sqrt{s} = 200, \ 500 \ \text{GeV}\). The cusps in the real parts and the peaks in the imaginary parts that occur around \(M_F = \sqrt{s}/2\), are clearly visible there. They have the same structure as in the previous SM and MSSM cases and with the chosen couplings, their magnitude is similar, \textit{i.e.} a few \(10^{-4}\).

However for \(M_F \gg \sqrt{s}/2\), which is the case that we now want to discuss, the \(M_F\) dependence is smooth and the resulting neutral couplings are purely real. Thus in this limit, they can be well approximated by the energy-independent empirical formulae

\[ h^\gamma_3 = -0.02 \times 10^{-4} \left(\frac{1 \ \text{TeV}}{M_F}\right)^2, \quad (24) \]

\[ h^Z_3 = -f^Z_5 = -0.01 \times 10^{-4} \left(\frac{1 \ \text{TeV}}{M_F}\right)^2, \quad (25) \]

\[ f^Z_5 = 0.009 \times 10^{-4} \left(\frac{1 \ \text{TeV}}{M_F}\right)^2; \quad (26) \]
As they stand, these results would describe the most favorable NP case in which a single fermion is lighter than the other ones. With the chosen electroweak couplings and taking \( N_F = 1 \), such a contribution becomes nevertheless quickly unobservable when the mass \( M_F \) reaches the level of a few hundred of GeV. It could only be sizeable if the heavy fermions have enhanced couplings to the photon or to the \( Z \) (see Section 5), or if the colour-hypercolour factor \( N_F \) is large. Consequently, it is unlikely that such a new contribution (even without the depressing effect of the anomaly cancellation), can appreciably modify the SM prediction.

5 Higher orders and Non Perturbative effects

At the one-loop level we have exploited so far, only the fermionic triangle diagram can contribute to the generation of neutral gauge couplings. In such a case, the CP conserving \( h_4^{\gamma,Z} \) couplings are never generated. This is a direct consequence of the symmetries of the fermionic trace of the triangular diagram and of Shouten’s relation. It is therefore interesting to examine if there is any other way to generate such \( h_4^{\gamma,Z} \) couplings and enhance its magnitude; compare eq. (2).

Perturbatively, this may happen at a higher-loop level. We have thus explored diagrams of the form of Fig. 8a, where the hatched blob denotes a fermion 1-loop diagram generating an anapole \( ZWW \) coupling. We have found that such an anapole \( ZWW \)-vertex, inside the W-loop of Fig. 8a, generates an \( h_4^{\gamma,Z} \) coupling of the size

\[
h_4^{\gamma,Z} \sim \frac{\alpha}{4\pi} h_3^{\gamma,Z} ;
\]

i.e. the size of a typical electroweak correction to the NP prediction to \( h_3^{\gamma,Z} \). Of course the result (27) should only be considered as a rough order of magnitude expectation, since a complete model prediction would require the computation of other diagrams appearing at the same 2-loop order, like those depicted in Fig 8b.

It is conceivable that non-perturbative effects could enhance the above neutral gauge boson couplings. In this respect we may consider strong vector \( V (\rho \text{-like}) \) and axial \( A (A_1 \text{-like}) \) resonances coupled to the photon and \( Z \), like in TC models \([22]\), through the junctions

\[
\begin{align*}
eg_{\gamma V} &= e F_V M_V , \quad eg_{\gamma Z} = e \left( 1 - \frac{2s^2_W}{2s_W c_W} \right) F_V M_V , \quad eg_{A Z} = e \frac{c}{2s_W c_W} F_A M_A
\end{align*}
\]

where we expect that in the strong coupling regime \([22]\)

\[
\frac{F_{V,A}}{M_{V,A}} \simeq O(\frac{1}{\sqrt{2\pi}}) ,
\]

\( (29) \).
should hold. New strong interactions can generate non-perturbative couplings among the $V$ and $A$ vector bosons; like e.g. those expected in the Vector Dominance Model (VDM) of hadron physics for the $\rho$ and $A_1$ vector mesons [23]. Such couplings, depicted in the central bubble in Fig.9, could have the same Lorentz decomposition as in eq.(2), but with strengths determined by

$$h_{3,4}^S/\Lambda_{NP}^2, \quad h_{4}^A/\Lambda_{NP}^4,$$

where $h_{3,4}^S \sim \sqrt{4\pi}$. By multiplying these strengths by the junctions given in eq.(23) and using the corresponding $V$ or $A$ propagators according to Fig.9, one then obtains the corresponding predictions for neutral gauge couplings. For $s$, $m_Z^2 \ll M_V^2, A \equiv \Lambda_{NP}^2$, we then get

$$h_{4}^{Z,\gamma} \approx \frac{m_Z^2}{M_{V,A}^2} h_{3,4}^{Z,\gamma} \approx \alpha \left(\frac{m_Z^2}{M_{V,A}^2}\right)^2. \quad (30)$$

For vector meson masses $M_{V,A}$ not too far in the TeV range, these values may be somewhat higher than those predicted by the previous perturbative computations.

6 Concluding Remarks

We have studied various ways to generate neutral triple gauge boson couplings among the photon and $Z$. Since these couplings are actually form factors involving at least one off-shell vector boson, they depend on the corresponding energy-squared variable $s$. The simplest way to generate them is through a fermionic triangle loop, involving fermions with arbitrary vector and axial gauge couplings. Such diagrams only generate CP-conserving couplings satisfying

$$h_3^Z \simeq -f_3^Z, \quad h_4^Z \equiv h_4^\gamma \equiv 0, \quad (31)$$

for almost any $s$ and fermion mass.

We have then studied the high energy behaviour of these couplings at a fixed fermion mass; as well as the high fermion mass limit at current energies. This last case allows us to illustrate different possible situations, that depend on the NP mass spectrum and on the way the anomaly cancellation takes place. The most favorable situation arises whenever one of the states needed to cancel the anomaly is much lighter than the rest.

To acquire a feeling of the expected magnitudes we have presented in Fig.3 the SM prediction for these couplings as a function of the energy $\sqrt{s}$. These SM predictions are found to be at the level of a few 10$^{-4}$ for LEP (200GeV), while for LC(500GeV) they reduce to a few 10$^{-5}$; see Table 1. Just above the $2m_t$ threshold, an imaginary part of the order of 10$^{-4}$ appears due to top quark contribution. According to a previous study [4], such values should be unobservable at LEP2, but marginally observable at a high luminosity LC [24].

Subsequently, we have computed the supersymmetric (chargino and neutralino) contributions in MSSM, varying the input masses inside the currently reasonable ranges appearing in Table 2 and eq.(22). The results strongly depend on the mass of the lightest
SUSY state (chargino or neutralino). If this is close to 100 GeV, then the SUSY contribution can be comparable to or even larger (if the chargino and neutralino effects cumulate) than the contribution from the top quark, or even the total SM one; compare Figs.4,5 with Fig.3 and the results in Table 3. As in the SM top case, a non negligible imaginary part is again generated just above the chargino or neutralino thresholds.

To summarize, the "low mass" contributions, both in SM and in MSSM, predict complex and strongly energy dependent values for these couplings, with remarkable cusp and peak effects which could however only be observed at a high luminosity LC. Note also that for such small values of the couplings no effect from the imaginary parts should be observable in ZZ or Zγ production cross sections, because there is no imaginary tree level contribution with which they could interfere, see [4].

To acquire a somewhat more model-independent feeling, we have also considered the contributions of a single heavy fermion, supposed to be the lightest one of a new physics spectrum. Keeping its gauge couplings to photon and Z as standard, we have studied its contribution versus its mass $M_F$. Results are presented in Fig.7 for medium values of $M_F$, while empirical formulae have been established for higher values. Obviously, as soon as the fermion is too heavy to be produced in pairs, no imaginary part is generated by such NP. The real parts decrease like $1/M_F^2$ and become of the order of $10^{-6}$ for a mass $M_F$ in the TeV range; compare (24-26). So one would need either a large colour-hypercolour factor or enhanced couplings of the heavy fermion to the photon or to the Z, in order to get observable NP contributions of this type.

Finally we have discussed how high order effects could feed the couplings $h_V$, which are still vanishing at one loop. However such contributions are always accompanied by an additional $\alpha/4\pi$ factor, which make them totally unobservable. Thus the only chance to generate $h_V$ is through some kind of non perturbative contributions. An example of such effect based on analogy with low energy hadronic Physics and the Vector Dominance Model has been considered. But even such a rather extreme model only leads to

$$\frac{h_V}{h_3} \sim \frac{m_Z^2}{\Lambda_{NP}^2},$$

which for reasonable values of $\Lambda_{NP}$ should render $h_V$ unobservable.

Our overall conclusion is that it is very unlikely that the neutral gauge couplings would depart in an observable way from SM prediction; provided of course that the new states couple to the photon and Z through standard gauge couplings. Exceptions to this statement could come, either from low-lying (order 100 GeV) new states (for example light charginos or neutralinos); or from enhanced photon-new fermion or Z-new fermion couplings, (for example due to some resonant states of the VDM type).
Appendix A: Fermion loop contributions in terms of Passarino-Veltman functions.

Using the short-hand notation of the Passarino-Veltman functions \(^{25}\)

\[ B_0(s; ij) = B_0(s; M_i, M_j) \]  
\[ B_Z(s; ij) \equiv B_0(s; M_i, M_j) - B_0(m_Z^2 + i\epsilon; M_i, M_j) \]  
\[ C_{ZZ}(s; jik) \equiv C_0(m_Z^2, m_Z^2, s; M_i, M_j, M_k) \]  
\[ C_{Z\gamma}(s; ijk) \equiv C_0(m_Z^2, 0, s; M_i, M_j, M_k) \]

where \(s \equiv P^2\), and observing the symmetry relations

\[ B(s; ij) = B(s; ji) \]  
\[ C_{ZZ}(s; ijk) = C_{ZZ}(s; kji) \]

we get for the contribution of \(F_j\)-fermion loop

\[ f_5^\gamma(j) = -\frac{N_F e^2 m_Z^2 g_{aj} g_{vj}}{8 \pi^2 s_W^2 s_W^2 (s - 4m_Z^2)^2 s} \left\{ 2B_Z(s; jj)m_Z^2(s + 2m_Z^2) + (s - 2m_Z^2)(s - 4m_Z^2) \right\} \]  
\[ f_5^Z(j) = -\frac{N_F e^2 m_Z^2 g_{aj}}{16 \pi^2 s_W^4 c_W^4 (s - 4m_Z^2)^2} \left\{ \frac{(3g_{vij}^2 + g_{aj}^2)(s - 4m_Z^2)}{3} ight\} \]  
\[ h_3^\gamma(j) = \frac{N_F e^2 Q_j g_{vij} g_{aj} m_Z^2}{4 \pi^2 c_W s_W (s - m_Z^2)} \left\{ 1 + 2m_Z^2 C_{Z\gamma}(s; jij) + \frac{m_Z^2}{s - m_Z^2} B_Z(s; jj) \right\} \]  
\[ h_3^Z(j) = \frac{N_F e^2 Q_j g_{vij} g_{aj} m_Z^2}{4 \pi^2 s_W^2 c_W^2 (s - m_Z^2)^2} \left\{ \frac{s m_Z^2}{s - m_Z^2} B_Z(s; jj) \right\} + \frac{s + m_Z^2}{2} [2C_{Z\gamma}(s; jij) m_j^2 + 1] \]

where \(M_j\) is the \(F_j\) mass, and \(N_F\) denotes any (colour hypercolour) counting factor.

The mixed term contribution arises when two different fermions, having the same charge but mixed \(ZF_1F_2\)-couplings, are running along the loop in Fig. We consider mixed \(ZF_1F_2\) couplings of the type appearing in the second line of (10), which arise e.g. in the chargino and neutralino cases\(^3\). Thus, for the \(ZZ\gamma^*\) case we obtain

\[ f_5^\gamma(12) = -\frac{N_F Q_1 e^2 m_Z^2 g_{a12} g_{v12}}{8 \pi^2 s_W^2 c_W^4 (s - 4m_Z^2)^2 s} R_{ZZ\gamma^*} \]

\(^3\)For simplicity we disregard the case, that three different fermions run along the loop in Fig. which could in principle only arise in the case of three light neutralino states.
where

\[ R_{ZZ\gamma} = 4(s - m_Z^2)(M_1^2 - M_2^2)[B_0(s; 11) - B_0(s; 22)] + 2(s - 2m_Z^2)(s - 4m_Z^2) \]
\[ + 2m_Z^2(s + 2m_Z^2)[B_0(s; 11) + B_0(s; 22) - 2B_0(m_Z^2 + i\epsilon; 12)] \]
\[ + 4(s - m_Z^2)(M_1^4 + M_2^4 + m_1^4 - 2M_1^2M_2^2 - 2M_1^2m_Z^2 - 2M_2^2m_Z^2)[C_{ZZ}(s; 121) + C_{ZZ}(s; 212)] \]
\[ + 2s(s + 2m_Z^2)[M_2^2C_{ZZ}(s; 121) + M_1^2C_{ZZ}(s; 212)] \]  
(A.12)

and \( Q_1 = Q_2 \) is the common charge of \( F_1, F_2 \).

Correspondingly for the \( ZZZ^* \) case we get

\[ f_{3}^Z(12) = - \frac{N_F e^2 m_Z^2}{16\pi^2 s_W^2 c_W^2 (s - 4m_Z^2)} \left\{ [g_{a1}(g_{a12}^2 + g_{v12}^2) + 2g_{a12}g_{v12}g_{v1}]R_{a} \right. \\
\[ + [g_{a1}(g_{a12}^2 + g_{v12}^2) - 2g_{a12}g_{v12}g_{v1}]R_{b} + g_{a1}(g_{a12}^2 - g_{v12}^2)R_{c} + (1 \leftrightarrow 2) \right\} , \]
(A.13)

where

\[ R_{a} = 1 + \frac{2(M_1^2 - M_2^2)(s + 2m_Z^2)}{s(s - 4m_Z^2)}[B_0(m_Z^2; 12) - B_0(m_Z^2; 11)] \]
\[ - \frac{1}{(s - m_Z^2)(s - 4m_Z^2)} \left\{ C_{ZZ}(s; 112) \left[ - 2M_1^2 s^3 - s^2 \left( M_1^2(M_1^2 - M_2^2) - m_Z^2(7M_1^2 + 3M_2^2 - 4m_1^2) \right) + 4s m_2^2 (M_1^2 M_2^2 - 2M_1^2 m_Z^2 - M_2^4 + m_1^4) + 4m_2^4 (M_1^2 - M_2^2)^2 \right] \\
- C_{ZZ}(s; 121) \left[ s^2 M_2^2 + s(M_1^4 - 3M_1^2 M_2^2 - 3M_1^2 m_Z^2 + 2M_2^4 - 2M_2^2 m_Z^2 + 2m_2^2) \right] \right\} , \]
(A.14)
\[ R_{b} = \frac{M_2^2}{s - m_Z^2} \left\{ (M_1^2 - M_2^2 - m_Z^2)[C_{ZZ}(s; 112) - C_{ZZ}(s; 121)] \right. \\
\[ + (s - m_Z^2)C_{ZZ}(s; 112) + B_2(s; 11) + 2B_2(s; 12) \right\} , \]
(A.15)
\[ R_{c} = \frac{M_1 M_2}{s - m_Z^2} \left\{ (2M_1^2 - 2M_2^2 + s)[C_{ZZ}(s; 112) - C_{ZZ}(s; 121)] \right. \\
\[ + 2(s - m_Z^2)C_{ZZ}(s; 121) + 2B_2(s; 11) + 4B_2(s; 12) \right\} . \]
(A.16)

Finally for the \( Z\gamma Z^* \) mixed case we have

\[ h_{3}^{Z}(12) = \frac{N_F e^2 Q_{1} g_{a12} g_{a12} m_Z^2}{4\pi^2 s_W c_W^2 (s - m_Z^2)^2} \left\{ \frac{2 s m_Z^2}{s - m_Z^2} B_2(s; 12) \right. \\
\[ + (s + m_Z^2)[M_2^2 C_2(s; 122) + M_2^2 C_Z(s; 211) + 1] \right\} . \]
(A.17)

We note that there is no mixed contribution for \( h_{3}^{Z} \).
Appendix B: Fermion loop contributions in terms of Feynman integrals.

The contributions of a single \( F_j \)-fermion loop in terms of Feynman integrals are:

\[
\begin{align*}
\gamma_5^j (j) &= N_F \frac{e^2 Q_j g_{v_j} g_{a_j}}{4\pi^2 s_W^2 c_W^2} I_5^\gamma, \\
\gamma_5^5 (j) &= -N_F \frac{e^2 g_{a_j}}{96\pi^2 s_W^2 c_W} \left( [g_{a_j}^2 + 3g_{v_j}^2] I_5^{Z1} + [g_{v_j}^2 - g_{a_j}^2] I_5^{Z2} \right), \\
\gamma_3^j (j) &= - N_F \frac{e^2 Q_j^2 g_{a_j}}{2\pi^2 s_W c_W} I_3^\gamma, \\
\gamma_3^5 (j) &= - N_F \frac{e^2 Q_j g_{a_j} g_{a_j}}{4\pi^2 s_W^2 c_W} I_3^\gamma,
\end{align*}
\] (B.1)

with

\[
\begin{align*}
I_5^\gamma &= \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{x_1 (1-x_1-x_2) m_Z^2}{D_{ZZ}(s)}, \\
I_5^{Z1} &= \frac{6m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \cdot \\
& \quad \left\{ [(1-x_1-x_2)(m_Z^2 x_2^2 - s x_1^2) + x_2 (1-3x_1)(s x_1 + m_Z^2 (2x_2 - 1))] \\
& \quad \quad \frac{D_{ZZ}(s)}{D_{ZZ}(m_Z^2)} \\
& \quad - \frac{m_Z^2 [(1-x_1-x_2)(x_2^2 - x_1^2) + x_2 (1-3x_1)(x_1 + 2x_2 - 1)]}{D_{ZZ}(m_Z^2)} \right\}, \\
I_5^{Z2} &= \frac{6M_F^2 m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{(1-3x_1)}{D_{ZZ}(s)},
\end{align*}
\] (B.5)

where \( D_{ZZ}(s) \equiv M_j^2 + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_2 - 1) \), (B.8)

and

\[
\begin{align*}
I_3^\gamma &= \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{x_1 (1-x_1-x_2) m_Z^2}{D_{Z\gamma}(s)}, \\
I_3^Z &= \frac{m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \frac{(s x_1 - m_Z^2 x_2)(1-x_1-x_2)}{D_{Z\gamma}(s)},
\end{align*}
\] (B.10)

where \( D_{Z\gamma}(s) \equiv M_j^2 + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_1 + x_2 - 1) \). (B.11)

16
The mixed contributions due to two different fermions (with the same charge) around the loop are:

$$H_Z^2(12) = - \frac{e^2 Q_1 g_{\mu 12} g_{a 12}}{4 \pi^2 s_W c_W^2} I_3^Z + (1 \leftrightarrow 2) \ , \quad (B.12)$$

where $I_3^Z$ is given by (B.10) with $D_{Z \gamma} (s)$ replaced by

$$D'_{Z \gamma} (s) \equiv M_1^2 + (M_2^2 - M_1^2) (1 - x_1 - x_2) + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_1 + x_2 - 1) \ . \quad (B.13)$$

Correspondingly

$$f_5^Z(12) = \frac{e^2 Q_1 g_{\mu 12} g_{a 12}}{4 \pi^2 s_W c_W^2} I_5^Z + (1 \leftrightarrow 2) \ , \quad (B.14)$$

where $I_5^Z$ is given by the same expression as in (B.12) with $D_{ZZ} (s)$ replaced by

$$D'_{ZZ} (s) \equiv M_1^2 + (M_2^2 - M_1^2) x_2 + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_2 - 1) \ . \quad (B.15)$$

Finally,

$$f_5^Z(12) = - \frac{e^2}{96 \pi^2 s_W c_W^2} \left( [g_{a 1} (g_{a 12}^2 + g_{v 12}^2) + 2 g_{v 1} g_{a 12} g_{a 12}] I_5^Z + M_1^2 [g_{a 1} (g_{a 12}^2 + g_{v 12}^2) - 2 g_{v 1} g_{a 12} g_{a 12}] I_5^Z + 2 M_1 M_2 g_{a 1} (g_{v 12}^2 - g_{a 12}^2) I_5^Z \right) + (1 \leftrightarrow 2) , \quad (B.16)$$

with

$$I_5^{Z a} = \frac{3 m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_c^{1 - x_1} dx_2 \left\{ [s x_1 (1 - x_1 - x_2) (x_2 - 1) + m_Z^2 x_2^2 (1 - x_2)] \right\} \left( \frac{1}{D_1} + \frac{2}{D_2} \right) + (1 - 3 x_2) (ln D_1 + 2 ln D_2) \right\} \quad (B.17)$$

$$I_5^{Z b} = \frac{3 m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_0^{1 - x_1} dx_2 \left\{ \frac{1 - x_1}{D_1} - \frac{2 x_2}{D_2} \right\} \quad (B.18)$$

$$I_5^{Z c} = \frac{3 m_Z^2}{s - m_Z^2} \int_0^1 dx_1 \int_0^{1 - x_1} dx_2 \left\{ \frac{2 x_2}{D_1} - \frac{2 (1 - 2 x_2)}{D_2} \right\} \quad (B.19)$$

and

$$D_1 = M_1^2 + (M_2^2 - M_1^2) x_2 + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_2 - 1) , \quad D_2 = M_1^2 + (M_2^2 - M_1^2) x_1 + s x_1 (x_1 + x_2 - 1) + m_Z^2 x_2 (x_2 - 1) \ , \quad (B.20)$$

Some of the unmixed parts of these expressions can be derived from the results obtained in [4]. We have checked by doing a direct numerical integration, that they agree with the numerical results obtained from the Passarino-Veltman expressions and the FF-package [40].
It is easy, from the above analytic expressions, to derive the asymptotic expressions given in eqs.(3,5) and (3,14).

For comparison we also give the fermion doublet contribution to the \(\gamma WW\) and \(ZWW\) anapole couplings defined in (3). Denoting the “up” and “down” fermions as \(F\) and \(F'\) and defining their Z-couplings as in (4), we get

\[
\begin{align*}
  z_Z &= - N_F \frac{e^2}{32\pi^2 s_W c_W} \left[ (g_{eF} + g_{aF}) I_F + (g_{eF'} + g_{aF'}) I_F' \right], \\
  z_\gamma &= - N_F \frac{e^2}{16\pi^2 s_W^2} \left( Q_F I_F + Q_{F'} I_{F'} \right),
\end{align*}
\]

(B.21) (B.22)

where

\[
I_F = \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \cdot \frac{x_1(1-x_1-x_2)m_W^2}{M_F^2 + s x_1(x_1 + x_2 - 1) + m_W^2 x_2(x_1 + x_2 - 1) + (M_F^2 - M_{F'}^2)x_2}
\]

(B.23)

and \(I_{F'} = I_F (M_F^2 \rightarrow M_{F'}^2)\). In the case of a degenerate doublet \(M_F = M_{F'}\), with standard doublet couplings, this result simplifies to

\[
\begin{align*}
  z_Z &= - \frac{s_W}{c_W} z_\gamma = N_F \frac{e^2}{48\pi^2 s_W c_W} I_W, \\
  z_\gamma &= - \frac{s_W}{c_W} z_Z = - N_F \frac{e^2}{16\pi^2 s_W c_W} I_W,
\end{align*}
\]

(B.24) (B.25)

for a doublet of quarks, and

\[
\begin{align*}
  z_Z &= - \frac{s_W}{c_W} z_\gamma = - N_F \frac{e^2}{16\pi^2 s_W c_W} I_W, \\
  z_\gamma &= - \frac{s_W}{c_W} z_Z = - N_F \frac{e^2}{16\pi^2 s_W c_W} I_W,
\end{align*}
\]

(B.26)

for a doublet of leptons, with

\[
I_W = \int_0^1 dx_1 \int_0^{1-x_1} dx_2 \cdot \frac{x_1(1-x_1-x_2)m_W^2}{M_F^2 + s x_1(x_1 + x_2 - 1) + m_W^2 x_2(x_1 + x_2 - 1)}.
\]

which, for \(M_F \gg m_W\), leads to eqs.(13,14).

Note that for a completely degenerate standard family (a doublet of lepton and a doublet of coloured quarks) the total contribution vanishes.
