On the slice-ribbon conjecture for pretzel knots

ANA G LECUONA

We give a necessary, and in some cases sufficient, condition for sliceness inside the family of pretzel knots $P(p_1, \ldots, p_n)$ with one $p_i$ even. The 3–stranded case yields two interesting families of examples: The first consists of knots for which the nonsliceness is detected by the Alexander polynomial while several modern obstructions to sliceness vanish. The second family has the property that the correction terms from Heegaard–Floer homology of the double branched covers of these knots do not obstruct the existence of a rational homology ball; however, the Casson–Gordon invariants show that the double branched covers do not bound rational homology balls.

57M25

1 Introduction

Pretzel knots have been thoroughly studied since they were first introduced by Reide-meister in [27]. In recent work, Greene and Jabuka have determined the order in the smooth knot concordance group of 3–stranded pretzel knots $P(p_1, p_2, p_3)$ with all $p_i$ odd [12, Theorem 1.1]. A corollary of their result is that the slice–ribbon conjecture proposed by Fox in [9] holds true for this family of knots. In this paper we address the question of sliceness in the family of pretzel knots $P(p_1, \ldots, p_n)$ with one $p_i$ even. Our main result, Theorem 1.1, gives a necessary condition for sliceness in this family. The condition obtained is not sufficient, but we propose a conjecture of what constraints should be added to Theorem 1.1 to obtain a complete characterisation of ribbon pretzel knots.

As a byproduct of our research we have found two interesting families of pretzel knots. The first one is a one-parameter family of knots for which most of the known slice obstructions vanish: the signature, the determinant, the Arf invariant, the $s$–invariant and the $\tau$ invariant among others. However, by using the Alexander polynomial, one can show that more than three quarters of the knots in this family are not slice. This property makes this set of knots an excellent source to test future slice invariants. The second interesting family consists of a set of pretzel knots whose double branched covers do not bound rational homology balls. The nonexistence of these balls is determined via the Casson–Gordon invariants which, for this particular family of 3–manifolds, turn...
out to be a more powerful tool than the \(d\)-invariants from Heegaard–Floer homology in obstructing the existence of a rational ball.

A knot in \(S^3\) is said to be slice if it bounds a disc smoothly embedded in the 4-ball. There are two other notions of sliceness directly related to this one. A knot is topologically slice if it bounds a topologically flat disc in \(B^4\) and algebraically slice if it is trivial in Levine’s algebraic concordance group [17; 18]. Every smoothly slice knot is topologically slice and these knots are algebraically slice. The two inclusions between these three sets are strict. Our aim is to understand which pretzel knots are slice, and a natural starting point would be to pin down algebraically slice pretzels first, and from there determine which ones are actually slice. However, this approach turns out to be very difficult for pretzel knots with one even parameter. Indeed, even though Levine constructed a complete set of invariants that establishes the algebraic concordance class of a knot \(K\), to determine their values one is required to find the irreducible symmetric factors of the Alexander polynomial of \(K\). As the question of whether or not a given polynomial is irreducible is a difficult one in general, the task of determining all the irreducible factors of a given symmetric polynomial can be quite intractable, more so as the degree of the polynomial grows. This is exactly the case for pretzel knots with one even parameter. Already inside the 3–stranded family \(P(2p + 1, 2q + 1, 2r)\) the Alexander polynomials are of arbitrarily high degree (in contrast with the knots \(P(2p + 1, 2q + 1, 2r + 1)\) which all have degree two in an appropriate normalization). Jabuka has determined the rational Witt classes of pretzel knots in [14], but which 3–stranded, one even parameter pretzels are algebraically slice is still an open question (the algebraically slice knots of the form \(P(2p + 1, 2q + 1, 2r + 1)\) are precisely those whose determinant is a negative square; this is known byproduct the work of Levine [17]). In Section 4 we will deal with a one-parameter family of 3–pretzels for which we cannot determine in general if they are slice, since we do not even know if they are algebraically slice. One last remark regarding the algebraically slice pretzels is that, whereas in the smooth setting of this paper working with 3–stranded or \(n\)–stranded pretzels does not make much of a difference, this generalization is a major difficulty when dealing with algebraically slice pretzels. Again in [14], Jabuka looks for a set of numerical conditions on the parameters defining a pretzel knot that would pinpoint their order in the rational Witt group. As he explains, the obstacle to achieving this is number-theoretic in nature and only conditions for the case of 3–strands and some special cases for 4–strands are given.

The strategy we follow in this article is as follows: use different obstructions to rule out the nonslice pretzel knots and show that the remaining knots are slice by explicitly constructing the slice discs in \(B^4\). The discs we find have the property of being ribbon, that is they have no local maxima for the radial function in \(B^4\). The slice–ribbon
On the slice-ribbon conjecture for pretzel knots

The conjecture asserts that all slice knots are ribbon and the results in the present work support this conjecture.

The first obstruction we compute comes from Donaldson’s theorem on the intersection form of definite smooth $4$–manifolds, which is further explained later in this introduction. A necessary assumption to use this obstruction is the smoothness of the discs bounded by the pretzel knots, and therefore it rules out the possibility of studying the case of topologically slice pretzel knots. Other obstructions we compute, such as the signature, the Alexander polynomial or the Casson–Gordon invariants, do not need the smoothness assumption. One could be tempted to start with these topological or algebraic invariants in order to get stronger results, but the computations for general families as the one under study are way too involved.

Given nonzero integers $p_1, \ldots, p_n$, the pretzel link $P(p_1, \ldots, p_n)$ is obtained by taking $n$ pairs of parallel strands, introducing $p_i$ half twists on the $i$th pair, with the convention $p_i > 0$ for right-handed crossings and $p_i < 0$ for left-handed crossings, and connecting the strands with $n$ pairs of bridges. The convention used to define right- and left-handed crossings is the one from Figure 1, where the first knot corresponds to $P(−5, 5, −3, 3, 7)$. If more than one of the $p_i$ is even or if $n$ is even and none of the $p_i$ are even then $P(p_1, \ldots, p_n)$ is a link. In all other cases it is a knot. Pretzel knots were the first examples of noninvertible knots (see Trotter [29]): a change of orientation of the knot changes its isotopy class. However, as far as sliceness is concerned this feature will not play any role, and thus we will ignore orientations all throughout this paper. Inside the family of pretzel knots $P(p_1, \ldots, p_n)$ we limit our considerations to those with one even parameter and moreover, from now on we fix $n \geq 3$ and $|p_i| > 1$ for all $i$. Note that if $n \leq 2$ or if $n = 3$ and one of the $p_i$ satisfies $p_i = \pm 1$, then the pretzel knot is a 2–bridge, already studied by Lisca in [19; 20].

It is well known (see Burde and Zieschang [3, Theorem 12.19]; recall that pretzel knots are a particular case of the more general family of Montesinos links) that among the $n!$ permutations of the parameters $(p_1, \ldots, p_n)$, the $2n$ of them which correspond to cyclic permutations, order-reversing permutations and compositions of these leave invariant the knot $P(p_1, \ldots, p_n)$. Two pretzel knots $K$ and $K^*$ which are not isotopic but share the same set of parameters are mutants, that is $K^*$ can be obtained from $K$ by a finite sequence of the following tangle surgeries: remove a $3$–ball from $S^3$ that meets $K$ in two proper arcs and glue it back via an involution $\tau$ of its boundary $S$, where $\tau$ is orientation preserving and leaves the set $S \cap K$ invariant. All pretzel knots defined by the same set of parameters $p_1, \ldots, p_n$ have the same double branched cover; see Bedient [2].

Our main result, Theorem 1.1, is stated for pretzel knots up to reordering of the parameters because the obstructions to sliceness that we analyze live in the double
branched cover of these knots. Up to reordering we are able to establish the sliceness of pretzel knots with one even $p_i$ except for the set of parameter sets

$$\mathcal{E} = \left\{ \left\{ a, -a - 2, -\frac{(a+1)^2}{2}, q_1, -q_1, \ldots, q_m, -q_m \right\} \right\},$$

where $m \geq 0$, $|q_i| \geq 3$ odd, and $a \geq 3$ and $a \equiv 1, 11, 37, 47, 49, 59 \pmod{60}$. Our main result is the following.

**Theorem 1.1** Let $K = P(p_1, \ldots, p_n)$ be a slice pretzel knot with one even parameter and such that $\{p_1, \ldots, p_n\} \notin \mathcal{E}$. Then, the $n$–tuple of integers $(p_1, \ldots, p_n)$ can be reordered so that it has the form

1. $(q_1, -q_1 \pm 1, q_2, -q_2, \ldots, q_{n/2}, -q_{n/2})$ if $n$ is even,
2. $(q_0, q_1, -q_1, \ldots, q_{(n-1)/2}, -q_{(n-1)/2})$ if $n$ is odd.

**Remark 1.2** Ligang Long is independently working on this problem. He has several partial results concerning the sliceness of pretzel knots with $n = 5$ and all parameters odd.

As further explained in Section 2, not all possible orders of the parameters in Theorem 1.1 yield slice knots. In Corollary 2.2 we show that for certain orders of the parameters the knots in the theorem above are actually slice. Moreover we conjecture that the orders proposed in Conjecture 2.4 are all the possible orders of the parameters in Theorem 1.1 yielding slice knots.

As detailed in Section 4.2 most of the pretzel knots in the family $P(a, -a - 2, -\frac{(a+1)^2}{2})$, $a \geq 3$ odd, are not slice. However establishing that none of them is slice is still an open challenge. There is a great amount of evidence supporting the following conjecture

**Conjecture 1.3** If $\{p_1, \ldots, p_n\} \in \mathcal{E}$ then the pretzel knot $P(p_1, \ldots, p_n)$ is not slice.

Note that a pretzel knot of the form $P(p_1, p_2, p_3)$ is independent of the order of the parameters, since cyclic permutations, order reversing permutations and compositions of these comprise all possible permutations of three elements. For 3–stranded pretzel knots whose defining parameters are not in $\mathcal{E}$, an easy corollary of Theorem 1.1 is the validity of the slice–ribbon conjecture.

In the following Corollary 1.4 the results for $P(p_1, p_2, p_3)$ with three odd parameters were already proved in [12]. Our work proves the statement for 3–stranded pretzel knots with one even parameter and leaves out the case $P(a, -a - 2, -(a + 1)^2/2)$, $a \geq 3$ odd and $a \equiv 1, 11, 37, 47, 49, 59 \pmod{60}$.
Corollary 1.4  The slice–ribbon conjecture holds true for pretzel knots of the form \( P(p_1, p_2, p_3) \), where \( p_1, p_2, p_3 \in \mathbb{Z} \) and \( \{ p_1, p_2, p_3 \} \not\in \mathcal{E} \).

In order to prove Theorem 1.1 we start using the approach of [19], which is also followed in [12]: if a pretzel knot \( K \) is slice then its double branched cover \( Y \) is the boundary of a rational homology ball \( W \); see Casson and Gordon [5, Lemma 2]. Moreover, up to considering the mirror image of \( K \), the 3–manifold \( Y \) is also the boundary of a negative definite 4–manifold \( M \) obtained by plumbing together disc bundles over spheres. We can build a closed, oriented, negative definite, 4–manifold \( X \) as \( M \cup_Y W \). By Donaldson’s celebrated theorem [7], the intersection form \( Q_X \) of \( X \) must be diagonalizable and therefore, since \( H_2(M; \mathbb{Z}) / \text{Tors} \cong H_2(X; \mathbb{Z}) / \text{Tors} \cong \mathbb{Z}^n \), there must exist a monomorphism \( \iota: \mathbb{Z}^n \rightarrow \mathbb{Z}^n \) such that \( Q_M(\alpha, \beta) = -\text{Id}(\iota(\alpha), \iota(\beta)) \) for every \( \alpha, \beta \in \mathbb{Z}^n \cong H_2(M; \mathbb{Z}) / \text{Tors} \).

The existence of \( \iota \) is enough to guarantee sliceness among 2–bridge knots [19]. In the case of pretzel knots \( P(p_1, p_2, p_3) \) with all \( p_i \) odd, this obstruction shows that there must exist some \( \lambda \in \mathbb{Z} \) such that \( -p_3 = p_1\lambda^2 + p_2(\lambda + 1)^2 \) [12, Proposition 3.1]. However, not all these pretzel knots are slice. In fact, using the Ozsváth–Szabó correction terms for rational homology spheres, Greene and Jabuka conclude that only \( D_0, 1 \) result in slice knots. In our case, for pretzel knots \( P(p_1, \ldots, p_n) \) with one even parameter, even in the case of three strands, the existence of \( \iota \) is a weaker obstruction to sliceness than in the cases studied in [12; 19]. In fact, in our setting the existence of \( \iota \) does not imply that the knot signature is zero. For example, the knot \( P(3, -4, -13) \) has signature 8, and therefore it is not slice, but \( \iota \) exists. The opposite phenomenon also arrives: the knot \( P(-5, -5, 2, 7) \) has vanishing signature but the nonexistence of \( \iota \) obstructs sliceness. Some other interesting examples are the knots \( P(3, -5, -12) \) and \( P(3, -5, -8) \). In both cases the signature vanishes and \( \iota \) exists, however a Casson–Gordon invariant shows that the first knot is not slice while the nonsliceness of the second example can be established by means of the Alexander polynomial.

The proof of Theorem 1.1 has three main steps: first we determine the pretzel knots with vanishing signature such that \( \iota \) exists. Not all the resulting knots are slice. In a second step we use the correction terms from Heegaard–Floer homology to further restrain the family of candidates to slice knots. This leaves us with two one-parameter families to further study. The sliceness of one of these families is ruled out using Casson–Gordon invariants while the other one is partially treated studying Alexander polynomials.

The rest of the paper is organized as follows. The proof of Corollary 1.4 is carried out in Section 2 assuming Theorem 1.1. An easy algorithm is given to detect ribbon pretzel
knots and we show that many of the knots from Theorem 1.1 are actually slice. In Section 3 we recall some properties of the Seifert spaces associated to pretzel knots and of the knot signature. Section 4 deals with the two interesting families of pretzel knots whose properties were described above. Finally, Sections 5 and 6 treat the general case combining Donaldson’s theorem with the knot signature and the correction terms from Heegaard–Floer homology.

Acknowledgments This project began while I was a PhD student under the supervision of Paolo Lisca to whom I am very grateful and from whom I still learn so much. I have had the opportunity to discuss this problem with many people who have all contributed to my better understanding of its different aspects: Benjamin Audoux, David Cimasoni, Jose F Galvan, Jose M Gamboa, Farshid Hajir, Lukas Lewark, Marco Mazzucchelli, Brendan Owens and Stepan Orevkov. Very special thanks go to Josh Greene and Slaven Jabuka, not only for their inspiring paper on this subject that introduced me to pretzel knots, but especially for their great generosity and the many hours we have shared thinking about this problem together. Finally, I thank the anonymous referee for remarking a mistake in the arguments justifying some inequalities in Section 4, and for the many suggestions that have improved the exposition of the paper.

This work is partially supported by the Spanish grant GEOR MTM2011-22435.

2 Slice pretzel knots

In this section we prove that, for certain orders of the parameters, the knots in Theorem 1.1 are actually slice. Moreover, assuming this theorem we prove Corollary 1.4 which deals with the slice-ribbon conjecture for 3–stranded pretzel knots. We start with the following proposition which explains an easy algorithm to determine whether a pretzel knot is ribbon.

Proposition 2.1 (Ribbon algorithm) Let $K = P(p_1, \ldots, p_n)$ be a pretzel knot and let $p_{n+1} := p_1$. While for some $j \in \{1, \ldots, n\}$, $p_j = -p_{j+1}$, we reduce the number of parameters to $n - 2$ and repeat with the knot $P(p_1, \ldots, p_{j-1}, p_{j+2}, \ldots, p_n)$. If at the end of the sequence of reductions we are left with a pretzel knot with exactly one parameter or with two parameters $a$ and $b$ satisfying $a = -b - 1$, then $K$ is ribbon.

Proof On a pretzel knot $K$, whenever there are two adjacent strands $p_1$ and $p_2$ with the same number of crossings but of opposite signs, we can perform the ribbon move shown in Figure 1, which simplifies the pretzel knot yielding the disjoint union of an
unknot and a new pretzel knot $K'$. The knot $K'$ is equal to $K$ without $p_1$ and $p_2$. Therefore, if $n$ is odd and after the sequence of reductions the set of parameters defining $K$ consists of only one integer, we have that after performing $(n-1)/2$ ribbon moves on $K$ we obtain the disjoint union of $(n+1)/2$ unknots. Thus, $K$ is ribbon. On the other hand, if $n$ is even and after the sequence of reductions the set of parameters defining $K$ consists of exactly two integers $a$ and $b$ satisfying $b = -a - 1$, then after performing $n/2 - 1$ ribbon moves on $K$, we obtain, since $P(a, -a - 1)$ is the unknot, the disjoint union of $n/2$ unknots. Thus again, $K$ is ribbon.

**Corollary 2.2** Let $K = P(p_1, \ldots, p_n)$ be a pretzel knot satisfying the assumptions of Theorem 1.1. Then the above ribbon algorithm shows that for certain orderings of the parameters $K$ is slice.

**Proof of Corollary 1.4** Given $K = P(p_1, p_2, p_3)$ as in the assumptions, if any of $p_1, p_2$ or $p_3$ equals $\pm 1$, then $K$ is a 2–bridge knot (see [12, Figure 2] for a proof) and by [19, Corollary 1.3], the slice–ribbon conjecture holds in this case. On the other hand, if $|p_i| \geq 2$ for every $i \in \{1, 2, 3\}$, then the parameters satisfy either $p_1, p_2, p_3 \equiv 1 \pmod{2}$ or there is exactly one even parameter. For the first possibility [12, Theorem 1.1] holds and the statement follows. In the second case, if $K = P(p_1, p_2, p_3)$ is slice then Theorem 1.1 holds and we obtain that $(p_1, p_2, p_3)$ is of the form $(p, -q, q)$ for some ordering. Since 3–stranded pretzel knots are independent from the ordering of the parameters, we have $K = P(p, q, -q)$ and Proposition 2.1 shows that $K$ is ribbon.

![Figure 1: On a pretzel knot, whenever there are two adjacent strands with the same number of crossings but of opposite sign, we can perform the ribbon move shown in this example obtaining the disjoint union of an unknot and the original pretzel knot with two strands less.](image)

**Remark 2.3** The only 3–stranded pretzel knots for which the slice-ribbon conjecture remains open are a subset of the family $P(a, -a - 2, -(a + 1)^2/2)$. We conjecture that none of these knots are slice and thus that the slice-ribbon conjecture holds for all 3–stranded pretzel knots.
Given a pretzel knot $P(p_1, \ldots, p_n)$ with $|p_i| > 1$ for all $i$ and $\{p_1, \ldots, p_n\} \notin \mathcal{E}$, the necessary condition for sliceness that we establish in this paper, namely that for some permutation $\sigma$ of the parameters, the knot $P(p_{\sigma(1)}, \ldots, p_{\sigma(n)})$ can be shown to be ribbon using Proposition 2.1, is not sufficient. For instance, in [13, Section 11] Herald, Kirk and Livingston show that the mutant $K_1 = P(3, 5, -3, -5, 7)$ of the slice pretzel knot $K_2 = P(3, -3, 5, -5, 7)$ is not slice. This result is proved using twisted Alexander polynomials associated to a higher-dimensional metabelian representation of the knot group. If a knot is slice, then these polynomials, which are elements in $\mathbb{Q}[\zeta_q][t^\pm 1]$, where $\zeta_q$ is a primitive root of unity of prime order, must have a particular factorization. Given a family of knots the computation of this obstruction is very challenging and we have not attempted to pursue it in this paper. However, we conjecture what constraints on the ordering of the parameters $(p_1, \ldots, p_n)$ need to be added to Theorem 1.1 in order to obtain a sufficient condition for sliceness. For all the examples we know (including in particular the knots $K_1$ and $K_2$ above) the ribbon algorithm of Proposition 2.1 establishes that the knot $K(p_1, \ldots, p_n)$ is actually ribbon. On the basis of these considerations we propose:

**Conjecture 2.4** The pretzel knots $P(p_1, \ldots, p_n)$ with $|p_i| > 1$ for all $i$ that are ribbon are precisely those detected by the algorithm in Proposition 2.1.

### 3 Preliminaries

#### 3.1 Double branched covers of pretzel knots

Let $\Gamma$ be a plumbing graph, that is, a tree in which every vertex $v_i$ carries an integer weight $a_i$, $i = 1, \ldots, n$. Associated to each vertex $v_i$ is the 4–dimensional disc bundle $X \to S^2$ with Euler number $a_i$. If the vertex $v_i$ has $d_i$ edges connected to it in the graph $\Gamma$, we choose $d_i$ disjoint discs in the base of $X \to S^2$ and call the disc bundle over the $j$th disc $B_{ij} = D^2 \times D^2$. When two vertices are connected by an edge, we identify $B_{ij}$ with $B_{k\ell}$ by exchanging the base and fiber coordinates and smoothing the corners. This pasting operation is called plumbing (for a more general treatment we refer the reader to Gompf and Stipsicz [11]), and the resulting smooth 4–manifold $M_\Gamma$ is said to be obtained by plumbing according to $\Gamma$.

The group $H_2(M_\Gamma; \mathbb{Z})$ has a natural basis represented by the zero-sections of the plumbed bundles. We note that all these sections are embedded 2–spheres, and they can be oriented in such a way that the intersection form of $M_\Gamma$ will be given by the
matrix $Q = (q_{ij})_{i,j=1,...,n}$ with the entries

$$q_{ij} = \begin{cases} a_i & \text{if } i = j, \\ 1 & \text{if } i \text{ is connected to } j \text{ by an edge}, \\ 0 & \text{otherwise}. \end{cases}$$

We will call $(\mathbb{Z}^n, Q)$ the intersection lattice associated to $\Gamma$.

A star–shaped graph is a connected tree with a distinguished vertex $v_0$ (called the central vertex) such that the degree of any vertex other than the central one is less than or equal to 2 (see Figure 3 for two different examples). A leg of a star–shaped graph is any connected component of the graph obtained by removing the central vertex. The boundaries of the 4–manifolds obtained by plumbing according to star shaped graphs are Seifert manifolds (see Neumann and Raymond [24, Section 5] for further references).

**Proposition 3.1** (von Randow [26]) *If $\Gamma$ is a star–shaped graph then the boundary $Y_{\Gamma} := \partial M_\Gamma$ is a Seifert space with as many singular fibers as legs of the graph $\Gamma$.***

Given a pretzel knot $K = P(p_1,\ldots,p_n)$, let $Y(p_1,\ldots,p_n)$ denote the 3–manifold obtained as the 2–fold cover of $S^3$ branched along $K$.

**Theorem 3.2** (Montesinos [21]) *The 3–manifold $Y(p_1,\ldots,p_n)$ is a Seifert fibered space with $n$ singular fibers.***

The Seifert manifold $Y(p_1,\ldots,p_n)$ can be described as the boundary of the 4–manifold obtained by plumbing according to the graph in Figure 2.

![Figure 2: Plumbing graph of a 4–manifold with boundary $Y(p_1,\ldots,p_n)$](image)

The order of the first homology group of $Y(p_1,\ldots,p_n)$ can be computed via the incidence matrix of any graph $\Gamma$ such that $Y_\Gamma = Y(p_1,\ldots,p_n) = \partial M_\Gamma$ and we have (see [24])

$$|H_1(Y_\Gamma)| = |\det Q_\Gamma| = \sum_{i=1}^{n} \frac{1}{p_i} \prod_{i=1}^{n} p_i.$$  \hspace{1cm} (1)

It will be of particular interest to describe the Seifert manifold $Y(p_1,\ldots,p_n)$ as the boundary of a plumbing $M_\Gamma$ such that the matrix $Q_\Gamma$ is negative definite. The following result establishes when is this possible.
Theorem 3.3 [24, Theorem 5.2] The Seifert space $Y(p_1, \ldots, p_n)$ can be written as the boundary of a negative definite plumbing as long as

\[
\frac{1}{p_1} + \cdots + \frac{1}{p_n} > 0.
\]

If the inequality in this last theorem holds, there is a canonical negative plumbing tree, which from now on will be denoted $\Psi$, satisfying $Y(p_1, \ldots, p_n) = \partial M_\Psi$ and $M_\Psi$ is negative definite. All the vertices in $\Psi$ have weight less than or equal to $-2$ except for the central vertex which has weight less than or equal to $-1$. The tree $\Psi$ is obtained as follows. Take the graph in Figure 2: For every $p_i$ such that $p_i > 1$ substitute its corresponding length-one leg with a ($-2$)–chain with $p_i - 1$ vertices and subtract 1 from the weight of the central vertex. In this way, we obtain a new 4–manifold, which is negative definite and has the same boundary as before the substitutions. Formally this is done by a series of blow downs and blow ups (see Neumann [23]). An example is shown in Figure 3. We call $C_i$ the ($-2$)–chain corresponding to the parameter $p_i > 1$.

Recall that if a knot $K$ is slice then its mirror image $\overline{K}$ is also slice. In the case of pretzel knots we have that for $K = P(p_1, \ldots, p_n)$ the mirror image satisfies $\overline{K} = P(-p_1, \ldots, -p_n)$. Therefore, when studying sliceness of pretzel knots, up to taking mirror images, we can always suppose that the double branched cover is the boundary of a negative definite plumbing or equivalently that the defining parameters satisfy inequality (2).

From now on we will only consider pretzel knots satisfying (2) and with one $p_i$ even. We shall divide them in the following three families:

**P1** $n$ is even and all except one of the $p_i$ are odd.

**P2** $n$ is odd, all except one of the $p_i$ are odd and the only even parameter is positive.

**P3** $n$ is odd, all except one of the $p_i$ are odd and the only even parameter is negative.

Since the Seifert space $Y = Y(p_1, \ldots, p_n)$ does not depend on the order of $p_1, \ldots, p_n$, from now on we adopt the following convention for the ordering and notation of the
parameters. We write
\[ Y = Y(a_1, \ldots, a_s; c_1, \ldots, c_t), \quad s, t \geq 0, \quad n = s + t, \]
where \( a_1, \ldots, a_s < -1 \) and \( c_1, \ldots, c_t > 1 \). Note that the central vertex in \( \Psi \) has weight \(-t\).

We label the vertices of the graph \( \Psi \) as follows: the central vertex will be called \( v_0 \); the vertices corresponding to the negative parameters \( a_1, \ldots, a_s \) will be called \( v_1, \ldots, v_s \); the vertices of the \((-2)\)-chain \( C_k, \ k \in \{1, \ldots, t\} \), will be called \( v_{1,k}, \ldots, v_{c_k-1,k} \), where \( v_0 \) is connected to \( v_{1,k} \) and \( v_{j,k} \) is connected to \( v_{j+1,k} \) for all \( j \in \{1, \ldots, t-1\} \). The number of vertices in \( \Psi \), which will be called \( m \), coincides with the rank of \( H_2(M_\Psi; \mathbb{Z}) \). It is immediate that
\[ m = |\Psi| = s + 1 + \sum_{i=1}^t (c_i - 1). \]

Let \((\mathbb{Z}^m, -\text{Id})\) be the standard negative diagonal lattice with the \( m \) elements of a fixed basis \( \mathcal{B} \) labeled as \( \{e^k_j\}_{j,k} \) (the convenience of the double script labeling of the basis vectors will become apparent later). As an abbreviation in notation let us write \( e^k_j \cdot e^l_j \) to denote \(-\text{Id}(e^k_j, e^l_j)\). If the intersection lattice \((\mathbb{Z}^m, Q_\Psi)\) admits an embedding \( \iota \) into \((\mathbb{Z}^m, -\text{Id})\), then we will omit the \( \iota \) in the notation: instead of writing \( \iota(v) = \sum_{j,k} x^k_j e^k_j \) we will directly write \( v = \sum_{j,k} x^k_j e^k_j \). If \( \iota \) exists we will call, for every \( S \subseteq \Psi \),
\[ U_S := \{e^k_j \in \mathcal{B} \mid e^k_j \cdot v \neq 0 \text{ for some } v \in S\}. \]

### 3.2 Signature of pretzel knots

It is well known (see Murasugi [22]) that slice knots have vanishing signature. For our purposes it will be convenient to express the signature of pretzel knots in terms of the associated plumbings described in the previous subsection. Indeed, in Section 5, we will find constraints on the parameters defining the Seifert spaces \( Y \), which arise as double branched covers over slice pretzel knots, combining the signature with Donaldson’s obstruction to sliceness.

Let \( K = P(p_1, \ldots, p_n) \) be a pretzel knot and let \( Y_\Gamma = \partial M_\Gamma \) be its double branched cover. Since \( K \) is a knot the determinant of the intersection form \( Q_\Gamma \) is odd and the equation
\[ Q_\Gamma(w, x) \equiv Q_\Gamma(x, x) \quad (\text{mod } 2) \quad \text{ for all } x \in H_2(M_\Gamma; \mathbb{Z}) \]
has exactly one solution in \( H_2(M_\Gamma; \mathbb{Z}_2) \). This solution admits a unique integral lift \( w \in H_2(M_\Gamma; \mathbb{Z}) \) such that its coordinates are 0 or 1 in the natural basis of \( H_2(M_\Gamma; \mathbb{Z}) \).
given by the vertices \( v_1, \ldots, v_m \) of the graph \( \Gamma \). The homology class \( w \) is called the Wu class. There is a well-defined subset \( J \subset \{ 1, \ldots, m \} \) such that
\[
w = \sum_{j \in J} v_j \in H_2(M_\Gamma; \mathbb{Z})
\]
and we define the Wu-set as \( \{ v_j \in \Gamma \mid j \in J \} \).

In Figure 4 the encircled vertices form the Wu-set of the canonical negative plumbing graphs associated to pretzel knots in the families \((p1), (p2)\) and \((p3)\). In the family \((p2)\) we assume that the only even parameter is \( c_t \), while in the family \((p3)\) the only even parameter is \( a_1 \). We have determined the Wu-set in each of these families via the following algorithm.

**Algorithm 3.4** (Computation of the Wu-set Theorem 7.1 [24]) Reduce the graph \( \Gamma \) to a collection (possibly empty) of isolated points with odd weights by a sequence of moves of type 1 and 2 below. Consider a leaf \( v \in \Gamma \) connected to the vertex \( u \in \Gamma \).

**Move 1** If the weight on \( v \) is even, then erase \( v \) and \( u \) from \( \Gamma \).

**Move 2** If the weight of \( v \) is odd, then erase \( v \) and change the parity of the weight on \( u \).

In order to determine which vertices belong to the Wu-set we undo the sequence of movements starting with the isolated vertices until we reobtain \( \Gamma \), taking the following into account.

- All the isolated vertices with odd weight obtained in the final step of the reduction of \( \Gamma \) belong to the Wu-set.
- If we undo move 1, then the vertex \( u \) does not belong to the Wu-set whereas the vertex \( v \) will belong to the Wu-set only if the weight on the vertex \( u \) and the number of adjacent vertices to \( u \) which already belong to the Wu-set do not have the same parity.
- If we undo move 2, then the vertex \( v \) will belong to the Wu-set if and only if \( u \) does not belong to the Wu-set.

The formula in the following theorem, due to Saveliev [28, Theorem 5], expresses the signature of a pretzel knot, \( \sigma(P(p_1, \ldots, p_n)) \), in terms of the intersection form \( Q_\Gamma \) and the Wu class \( w \in H_2(M_\Gamma; \mathbb{Z}) \).

**Theorem 3.5** (Saveliev) Let \( P(p_1, \ldots, p_n) \) be a pretzel knot and \( Y_\Gamma = \partial M_\Gamma \) its double branched cover where \( \Gamma \) is a tree. The equality
\[
\sigma(P(p_1, \ldots, p_n)) = \text{sign}(Q_\Gamma) - w \cdot w
\]
holds, where \( w \cdot w \) stands for \( Q_\Gamma(w, w) \).
Remark 3.6 Notice that the expression $\text{sign}(Q_\Gamma) - w \cdot w$ equals $\bar{\mu}(Y_\Gamma)$, where $\bar{\mu}$ is Neumann’s invariant.

4 Two interesting families of pretzel knots

In this section we study the sliceness of two subfamilies of pretzel knots of type (p3). Both of them stem from the detailed general study of pretzel knots developed in the remaining sections, but specific arguments are needed to prove that the knots in these families are not slice. In the first subsection we study the family $P(a, -a - 2, -a - (a^2 + 9)/2)$ with $a \geq 3$ odd. We shall prove that the double branched covers of these knots do not bound rational homology balls, in spite of the fact that the obstruction given by the $d$–invariants from Heegaard–Floer homology (see Section 6.1) vanishes. The main tool we use is the Casson–Gordon invariants. The second subsection deals with the family $P(a, -a - 2, -(a + 1)^2/2)$ with $a \geq 3$ odd. A major difficulty presented by this family is that the double branched covers of these knots are all integer homology spheres. As further explained in Section 4.2, many of the recent obstructions to knot sliceness defined from Heegard–Floer homology or Khovanov homology vanish for
this family, while the Alexander polynomial is able to detect the nonsliceness of many (perhaps all) the knots in this family.

4.1 Casson–Gordon invariants and the family $P(a, -a - 2, -a - \frac{a^2 + 9}{2})$

In 1975 Casson and Gordon introduced some knot invariants that were used to show that not all algebraically slice knots are smoothly slice. The invariants depend on a knot $K \subset S^3$ and on the choice of a character $\chi$ defined on the first homology group of the double branched cover of $K$. In [5] two different invariants, denoted $\sigma(K, \chi)$ and $\tau(K, \chi)$, are defined from the difference of the twisted signatures of some 4–manifolds associated to the couple $(K, \chi)$. We shall only deal with the properties of a specific version of $\sigma(K, \chi)$ that suits our purposes.

Since they were introduced, Casson–Gordon invariants have been thoroughly studied and generalized. In particular work of Kirk and Livingston shows that they can be interpreted as twisted Alexander polynomials [15], and they have been used to distinguish concordance classes among pretzel knots [16]. A complete study of pretzel knots from the perspective of these invariants is certainly of interest, however we will limit ourselves to the family in this subsection. Unfortunately, the general computation is out of reach with our current techniques.

Consider a slice knot $K \subset S^3$ with double branched cover $Y$. Let $p$ be a prime, $r \in \mathbb{N}$ and $\chi: H_1(Y; \mathbb{Z}) \to \mathbb{Z}/p^r$ be a character of order $p^r$. Suppose that the covering $\tilde{Y}$ induced by the character satisfies $H_1(\tilde{Y}; \mathbb{Q}) = 0$. Let $W_D$ be the double cover of $B^4$ branched over a slicing disc for $K$ and $V$ be the kernel of the map $i_*: H_1(Y; \mathbb{Z}) \to H_1(W_D; \mathbb{Z})$ induced by the inclusion.

Theorem 4.1 (Casson and Gordon) With the above assumptions, for every character $\chi$ of prime power order vanishing on $V$ we have $|\sigma(K, \chi)| \leq 1$.

We shall compute the Casson–Gordon invariants of some of the pretzel knots in the family $(p3)$ via the formula given by Cimasoni and Florens in [6, Theorem 6.7]. This formula computes $\sigma(K, \chi)$ from a surgery presentation of $Y$ regarded as a colored link and the term $\sigma_L(\omega)$ stands for the colored signature of $L$.

Theorem 4.2 (Cimasoni and Florens) Let $Y$ be the 3–manifold obtained by surgery on a framed link $L$ with $m$ components and linking matrix $Q$. Let $\chi: H_1(M; \mathbb{Z}) \to \mathbb{Z}/p^r$ be the character mapping the meridian $\mu_i$ of the $i^{th}$ component of $L$ to $n_i$ with $1 \leq n_i < p^r$ and $n_i$ coprime to $p$. Consider $L$ as an $m$–colored link and set $\omega = (n_1, \ldots, n_m)$. Then

$$\sigma(K, \chi) = \sigma_L(\omega) - \sum_{i<j} Q_{i,j} - \text{sign } Q + \frac{2}{p^{2r}} \sum_{i,j} (p^r - n_i) n_j Q_{ij}.$$
In order to use this formula to compute the Casson–Gordon invariants for the pretzel knots $K_a = P(a, -a - 2, -a - (a^2 + 9)/2)$, $a > 1$ odd, we will use the surgery presentation of the Seifert space $Y_a = Y(a, a - 2, -a - (a^2 + 9)/2)$ given by the framed link $L_a$ in Figure 5. It is obtained from the diagram associated to the canonical negative plumbing tree by blowing down the central vertex and subsequently blowing down every new $(-1)$–framed unknot.

![Diagram](image)

Figure 5: The diagram on the left corresponds to the negative definite plumbing manifold bounded by the Seifert space $Y_a = Y(a, -a - 2, -a - (a^2 + 9)/2)$. After a series of blow downs we obtain the diagram on the right that we shall use to compute the Casson–Gordon invariants. In the diagram $L_a$ the two meridians, generators of $H_1(S^3 \setminus L_a; \mathbb{Z})$, are depicted in red and the box labeled $a$ stands for $a$ right handed full twists between the strands entering the box.

From this surgery presentation of $Y_a$ we can read the following presentation of its first homology group:

$$H_1(Y_a; \mathbb{Z}) = \left\langle \mu_1, \mu_2 \mid \frac{a^2 + 9}{2} \mu_1 + a \mu_2, a \mu_1 - 2 \mu_2 = 0 \right\rangle = \left\langle \mu_1, \mu_2 \mid \frac{a + 9}{2} \mu_1 - 2\mu_2, 9 \mu_2 = 0 \right\rangle.$$

It follows that $H_1(Y_a; \mathbb{Z}) \cong \mathbb{Z}/9$ with $\mu_1$ being a generator of the group and $\mu_2 = \frac{1}{2}(a + 9)\mu_1$. We now proceed to define a character on $H_1(Y_a; \mathbb{Z})$ vanishing on the subgroup $V$, which is cyclic of order 3 generated by $3\mu_1$ (cf Remark 6.1). The character $\chi: H_1(Y_a; \mathbb{Z}) \rightarrow \mathbb{Z}/3$ such that $\chi(\mu_1) = 1$, where 1 is a generator of $\mathbb{Z}/3$, has the desired properties.

We have all the necessary ingredients to compute $\sigma(K_a, \chi)$ via the formula (5). Notice however that if $a \equiv 0$ (mod 3) then the above setting yields $\chi(\mu_2) = 0$ which is not a valid value for $n_2$ in the hypothesis of Theorem 4.2. Therefore we shall first compute $\sigma(K_a, \chi)$ for $a \not\equiv 0$ (mod 3) and later we will use yet another surgery presentation of $Y_a$ to deal with this remaining case.

The linking matrix for the link $L_a$ in Figure 5 is given by

$$Q_a = \begin{pmatrix} \frac{-a^2 + 9}{2} & a \\ a & -2 \end{pmatrix}$$
and formula (5) yields

\[
\sigma(K_a, \chi) = \sigma_{L_a}(1, n_2) - a + 2 + \frac{2}{9} \left( -\frac{a^2 + 9}{2} - 2 + a2n_2 + a(3-n_2) - 2(3-n_2)n_2 \right)
\]

\[
= \sigma_{L_a}(1, n_2) - a + 2 + \frac{2}{9} (-a^2 - 13 + a(n_2 + 3)),
\]

where the second equality is obtained substituting the two possible values of \( n_2 \), namely 1 and 2, and then rewriting a common formula for both possibilities.

Our aim is to show that the knots \( K_a \) are not slice and to do so it suffices to estimate \( |\sigma(K_a, \chi)| \) in (6) and show it is greater than 1. Indeed, all the assumptions of Theorem 4.1 are satisfied since \( H_1(Y_a; \mathbb{Z}) \) is cyclic and the character \( \chi \) is of order 3, which implies that the first rational homology of the induced covering vanishes; see Casson and Gordon [4, Lemma 4.4]. The term \( \sigma_{L_a}(1, n_2) \) is the coloured signature of the link \( L_a \) and it is defined as the signature of an \( n \times n \) hermitian matrix, where \( n \) is the rank of the first homology group of a \( C \)-complex for \( L_a \) (see [6] for the definitions and details). The \( C \)-complex for \( L_a \) depicted in Figure 6 allows us to determine \( \sigma_{L_a}(1, n_2) \in \{-a + 1, a - 1\} \).

![Figure 6: This figure presents a \( C \)-complex for \( L_3 \) with a basis of its first homology depicted in red. The evident generalization to the links \( L_a \) shows that the order of the first homology of the \( C \)-complex is \( a - 1 \) and therefore \( \sigma_{L_a} \in \{-a + 1, a - 1\} \).](image)

In the case at hand, the term \(-a^2 - 13 + a(n_2 + 3)\) attains its maximum value, \(-\frac{26}{9}\), for \( a = 5 \) and \( n_2 = 2 \). Since \( \sigma_{L_a}(1, n_2) - a + 2 \leq 1 \) we have the estimate

\[
|\sigma(K_a, \chi)| \geq \frac{2}{9} \left( a^2 + 13 - a(n_2 + 3) \right) - 1 \geq \frac{26}{9} - 1 > 1
\]

for all \( a > 1 \) odd, \( a \not\equiv 0 \pmod{3} \). This last inequality shows that the knots \( K_a \) with \( a \not\equiv 0 \pmod{3} \) are not slice.

To deal with the remaining case, the knots \( K_a \) with \( a \equiv 0 \pmod{3} \), we shall use the surgery presentation of \( Y_a \) given in Figure 7.

It is obtained from the diagram in Figure 5 by sliding the left handle over the handle with framing \(-2\). The new framings are obtained by applying the rules of Kirby...
On the slice-ribbon conjecture for pretzel knots

Figure 7: Starting with the link $L_a$, in which the thin curve represents the framing of the right component, we perform the indicated handle slide to obtain the second diagram. After a series of isotopies we obtain the link $\tilde{L}_a$, which is a suitable surgery presentation of $Y_a$ to compute the Casson–Gordon invariants of $K_a$ when $a \equiv 0 \pmod{3}$. Again the red curves in the last diagram are the meridians generating $H_1(S^3 \setminus \tilde{L}_a; \mathbb{Z})$.

calculus (see [11] for details). This surgery diagram yields the following presentation of the first homology group of $Y_a$:

$$H_1(Y_a; \mathbb{Z}) = \left\langle \mu_1, \mu_2 \mid \frac{-(a+2)^2+9}{2} \mu_1 - (a+2)\mu_2, -(a+2)\mu_1 - 2\mu_2 \right\rangle$$

as before $H_1(Y_a; \mathbb{Z}) \cong \mathbb{Z}/9$ is generated by $\mu_1$ and this time we have $\mu_2 = \frac{7-a}{2} \mu_1$. We choose the character $\chi: H_1(Y_a; \mathbb{Z}) \to \mathbb{Z}/3$ defined by $\chi(\mu_1) = 1$ which satisfies the assumptions of Theorem 4.1 and since $\chi(\mu_2) = 2$ we can use the formula (5) to compute $\sigma(K_a, \chi)$. This time the link $\tilde{L}_a$ of the surgery presentation in Figure 7 has linking matrix

$$Q_a = \begin{pmatrix} \frac{-(a+2)^2+9}{2} & -a - 2 \\ -a - 2 & -2 \end{pmatrix}$$

and the formula reads

$$\sigma(K_a, \chi) = \sigma_{\tilde{L}_a}(1, 2) + a + 2 + 2 + \frac{2}{9} \left( \frac{-(a+2)^2+9}{2} - (a+2)4 - (a+2) - 4 \right)$$

$$= \sigma_{\tilde{L}_a}(1, 2) + a + 4 - \frac{2}{9} (27 + 9a + a^2).$$

Similar arguments to the ones used before allow us to estimate

$$|\sigma(K_a, \chi)| \geq -2a - 5 + 6 + 2a + \frac{2a^2}{9} = \frac{2a^2}{9} + 1 > 1$$

and therefore by Theorem 4.1 we have the following statement.

**Theorem 4.3** For all odd $a > 1$ the knots in $P(a, -a - 2, -a - \frac{a^2+9}{2})$ are not slice.
Remark 4.4  In fact, we have shown something stronger than the nonsliceness of the pretzel knots in the family \( P(a, -a - 2, -a - (a^2 + 9)/2) \); the arguments in the proof of Theorem 4.1 imply that the Seifert spaces \( Y_a = Y(a, -a - 2, -a - (a^2 + 9)/2) \) do not bound rational homology balls.

### 4.2 Alexander polynomials and the family \( P(a, -a - 2, -(a+1)^2/2) \)

This section is devoted to the study of the sliceness of the pretzel knots of the form

\[
P_a = P(a, -a - 2, -(a + 1)^2/2)
\]

with \( a \geq 3 \) odd. All the knots in this family have determinant 1 and therefore the double branched covers \( Y_a \) are integer homology spheres. It follows that the Casson–Gordon invariants cannot be used to study the existence of rational homology balls bounded by the Seifert manifolds \( Y_a \). We will pursue the study of the sliceness of the knots \( P_a \) leaving open the question of the existence of rational homology balls bounded by their double branched covers.

There are several well-known obstructions to sliceness that we have computed for the knots of the form \( P_a \) but all of them vanished. In the sequel we shall not use any of the following facts but we have decided to include them for completeness. In the remaining sections we will show that each knot \( P_a \) has vanishing signature, its determinant is a square and Donaldson’s theorem does not obstruct sliceness. Moreover, we have checked that the only \( d \)–invariant of their double branched covers, which are homology spheres, vanishes. The hat version of the knot Floer homology of pretzel knots is known. The family \( P_a \) lies within the hypothesis of Eftekhary [8, Theorem 2] which combined with the Alexander polynomials computed below suffices to determine that the Ozsváth–Szabó \( \tau \) invariant is zero for all the knots in this family. Moreover, the Rasmussen \( s \)–invariant of the knot

\[
P(3, -5, -4) = 12_{n_475}
\]

is known to be zero and a crossing change argument implies that the first knot in our family, namely the knot \( P(3, -5, -8) \), also has vanishing Rasmussen invariant.

Given all this vanishing of obstructions one might be tempted to think that the knots in the family \( P_a \) are actually slice. However, we conjecture that this is not the case for any parameter \( a \) and we will show that indeed for \( a \not\equiv 1, 11, 37, 47, 49, 59 \pmod{60} \) the knot \( P_a \) does not bound a disk embedded in the 4–ball. The invariant capable of detecting the nonsliceness of these knots is the Alexander polynomial.
We have postponed the tedious computation of the Alexander polynomials $\Delta_a(t)$ of the knots $P_a$ to the Appendix. In it we show that

$$\Delta_a(t) = \frac{t^{a+2} + 1}{t+1} \frac{t^{a+1} - (a+1)^2 t^{a-1} (t-1)^2}{4}$$

$$= \prod_{d|a+2} \Phi_d(-t) \prod_{\delta|a, \delta \neq 1} \Phi_\delta(-t) - \frac{(a+1)^2}{4} t^{a-1} (t-1)^2,$$

where $\Phi_n$ stands for the $n^{th}$ cyclotomic polynomial, and $\cong$ means equality up to multiplication by $\pm t^k$ with $k \in \mathbb{Z}$.

If the knots in family $P_a$ were slice then it would follow, by Fox and Milnor’s theorem [10], that $\Delta_a(t) \cong f(t) f(t^{-1})$ for some polynomial $f(t)$. Our goal is to show that this is not the case and to this end several strategies are possible. If we showed that the polynomials $\Delta_a(t)$ are irreducible in $\mathbb{Z}[t]$, we would be done. Stepan Orevkov has kindly taken a look at this problem and informed us that he checked with the computer and up to $a = 1597$ the polynomials $\Delta_a(t)$ are in fact irreducible. However we have not found a proof to show the irreducibility of every polynomial in our family. Another possible approach is to look at these polynomials modulo $p$ for some prime and study their irreducibility in $\mathbb{F}_p[t]$. However, by Ahmadi and Vega [1, Theorem 12] the number of irreducible factors of $\Delta_a(t) \pmod{p}$ is even for every odd $p$, which implies that many (perhaps all) the polynomials $\Delta_a(t)$ are irreducible over the integers but reducible over $\mathbb{F}_p$ for every $p$.

We are not able to show that none of the polynomials $\Delta_a(t)$ satisfy the Fox–Milnor factorization but there is a lot of evidence indicating that this might be the case. Taking advantage of the rich literature on the reducibility of cyclotomic polynomials, we will prove the following statement.

**Theorem 4.5** For $a \not\equiv 1, 11, 37, 47, 49, 59 \pmod{60}$ the polynomials $\Delta_a(t)$ do not have a Fox–Milnor factorization.

**Corollary 4.6** For $a \not\equiv 1, 11, 37, 47, 49, 59 \pmod{60}$ the pretzel knots $P_a$ are not slice.

**Proof of Theorem 4.5** Since the Alexander polynomial $\Delta_a(t)$ is a self reciprocal polynomial, ie $\Delta_a(t) = t^{\deg \Delta_a} \Delta_a(t^{-1})$, its irreducible factors are all self reciprocal or come in reciprocal pairs, that is if $g | \Delta_a$ and $g$ is not self reciprocal then $g^*(t) := t^{\deg g} g(t^{-1})$ is also a factor of $\Delta_a$. Suppose that there exists a polynomial $f$ such that $\Delta_a(t) = t^{\deg f} f(t) f(t^{-1})$; then we have that the irreducible self reciprocal factors of

**Algebraic & Geometric Topology, Volume 15 (2015)**
We shall prove that in this case the polynomial $\Delta_a$ has an odd number of self reciprocal irreducible factors. We start with a prime number $p$ dividing $(a + 1)^2/4$ and consider the polynomial

\[(7) \quad \tilde{\Delta}_d(t) := \Delta_a(t) \mod p = \prod_{d|a+2, \, d \neq 1} \tilde{\Phi}_d^P(-t) \prod_{\delta|a, \, \delta \neq 1} \tilde{\Phi}_\delta^P(-t).\]

Notice that since $\gcd(p, a) = \gcd(p, a+2) = \gcd(a, a+2) = 1$ all the irreducible factors of the polynomials $\tilde{\Phi}_d^P$ and $\tilde{\Phi}_\delta^P$ in $\mathbb{F}_p[t]$ appearing in (7) have multiplicity one and are all distinct. Since cyclotomic polynomials are self reciprocal, if $\Delta_a$ satisfies the Fox–Milnor condition, it follows that every cyclotomic polynomial in (7) has an even number of irreducible factors. It is well known that the number of irreducible factors of $\tilde{\Phi}_d^P$ equals the quotient between $\varphi(d)$ and the order of $p \mod d$, where $\varphi$ is Euler’s totient function. Let us call this quotient $N_d^P$. It follows that if $\Delta_a$ has a Fox–Milnor factorization, then for every $p$ dividing $(a + 1)^2/4$ and every $d|a + 2, \, d \neq 1$, and every $\delta|a, \, \delta \neq 1$, the numbers $N_d^P$ and $N_\delta^P$ are even. The rest of the proof will consist of suitable choices of $p$ and $a$ that force $N_d^P$ or $N_\delta^P$ to be odd.

Let us consider the odd parameter $a$ modulo $12$. If $a \equiv 3, 7 \pmod{12}$, then $3$ divides either $a$ or $a + 2$ and $(a + 1)^2/4$ is even. We obtain $N_3^2 = 1$. Moreover, if $a \equiv 9 \pmod{12}$ then $3$ divides $a$ and we choose $p$ dividing $(a + 1)^2/4$ such that $p \equiv 2 \pmod{3}$. This choice is always possible since under these assumptions $(a + 1)^2/4 = (6n + 5)^2, \, n \in \mathbb{N}$ and $6n + 5 \equiv 2 \pmod{3}$. Again in this case we obtain $N_3^P = 1$. It follows that for $a \equiv 3, 7, 9 \pmod{12}$ the polynomial $\Delta_a$ does not have a Fox–Milnor factorization.

We can push the same argument further to study the cases $a \equiv 1, 11 \pmod{12}$ with less success. If $a = 12n + 11$ for some $n$ then $(a + 1)^2/4$ is even and we choose $p = 2$. The difficulty comes in the choice of $d$, since in this case there is not a common divisor for all $a$ or $a + 2$. Adding the hypothesis $n \equiv 1, 2 \pmod{5}$ we obtain that $d = 5$ divides $a$ or $a + 2$ and $N_5^2 = 1$. Similarly, if $a = 12n + 1$ and $n \equiv 1, 2 \pmod{5}$ then again $d = 5$ divides either $a$ or $a + 2$. We choose a prime $p$ dividing $(a + 1)^2/4 = (6n + 1)^2$ such that $p \equiv 2, 3 \pmod{5}$. This choice is always possible since under the current assumptions $6n + 1 \equiv 2, 3 \pmod{5}$. In this case it follows that $N_5^P = 1$. Summing up we have shown that for $a \equiv 13, 23, 25, 35 \pmod{60}$ the polynomial $\Delta_a$ does not factor as $t^{\deg f} f(t) f(t^{-1})$.

The last case we shall study is $a = 12n + 5$. This case requires a different argument. We shall prove that in this case the polynomial $t^2 + t + 1$ is a reducible factor of the mod 2 reduction of $\Delta_a$ and it has multiplicity 1. Instead of working with the previous normalization of the Alexander polynomial we shall use the Laurent polynomial
\( t^{-\deg \Delta_a/2} \Delta_a \) which we will keep calling \( \Delta_a \) to ease the notation. The irreducible factor we shall be looking at is then \( t + 1 + t^{-1} \). It is not difficult to check that we have the following identities:

\[
\Delta_5^2 = t^5 + t^3 + 1 + t^{-3} + t^{-5},
\]
\[
\Delta_{12n+5}^2(t) = \Delta_{12(n-1)+5}^2(t) + \sum_{i=1}^{6} (t^{12(n-1)+5+2i} + t^{-(12(n-1)+5+2i)}).
\]

Since these polynomials verify, in \( \mathbb{F}_2 \),

\[
t^5 + t^3 + 1 + t^{-3} + t^{-5} \equiv (t + 1 + t^{-1})(t^4 + t^3 + t^2 + 1 + t^{-2} + t^{-3} + t^{-4}),
\]
\[
\sum_{i=1}^{6} (t^{x+2i} + t^{-(x+2i)}) \equiv (t + 1 + t^{-1}) \left( \sum_{i=0}^{2} (t^{x+11-i} + t^{-(x+11-i)}) \right) + \left( \sum_{i=0}^{2} (t^{x+5-i} + t^{-(x+5-i)}) \right),
\]

an easy induction argument shows that \( t + 1 + t^{-1} \) is an irreducible factor of \( \Delta_{12n+5}^2 \) for all \( n \in \mathbb{N} \). However \( (t + 1 + t^{-1})^2 \equiv t^2 + 1 + t^{-2} \) (mod 2) is never a factor of \( \Delta_{12n+5}^2 \). Indeed, one can easily check that \( t^2 + 1 + t^{-2} \) does not divide \( \Delta_5^2 \), but on the other hand we have

\[
\sum_{i=1}^{6} (t^{x+2i} + t^{-(x+2i)}) = (t^2 + 1 + t^{-2})(t^{x+10} + t^{x+4} + t^{-(x+4)} + t^{-(x+10)}).
\]

Again and easy induction argument yields the claim and the theorem is proved. \( \square \)

**Remark 4.7** The first knot in the family \( P_a \) that is not covered by Theorem 4.5 is \( P_{11} = P(11, -13, -72) \). However it is immediate to check that in this case \( N_{11}^2 = 1 \) and therefore \( P_{11} \) is not slice. It is frustrating to accept the fact that for every single knot we have checked we have found an argument to determine its nonsliceness but that all attempts to generalize the proof to the whole family have miserably failed.

## 5 The general case: First obstructions to sliceness

We start now the study of slice pretzel knots with one even parameter in full generality. A necessary condition for a pretzel knot \( K := P(p_1, \ldots, p_n) \) to be slice is that the intersection lattice associated to its canonical negative plumbing graph \((\mathbb{Z}^m, Q_\Psi)\) admits an embedding into the standard diagonal negative lattice of the same rank. This follows, as explained in the introduction, from the fact that if \( K \) is slice, the associated Seifert space \( Y \) smoothly bounds a rational homology ball. As remarked in Section 3
up to considering mirror images we can suppose that $\sum_{i=1}^{n} 1/p_i > 0$ and thus the canonical negative plumbing graph $\Psi$ exists. Moreover, $K$ being slice implies that the invariant $\sigma(K)$ vanishes. In this section, imposing these two conditions, the existence of the embedding and the vanishing of the knot signature, we get important information on $p_1, \ldots, p_n$ and on the embedding

$$(\mathbb{Z}^m, Q_\Psi) \hookrightarrow (\mathbb{Z}^m, -\text{Id}).$$

The conclusions differ depending on whether the parameters satisfy the conditions (p1), (p2) or (p3) defined in Section 3. In fact, the existence of the embedding and the condition $\sigma(K) = 0$ totally determine $Y$ for the families (p1) and (p2) and they determine $Y$ up to one parameter for the family (p3).

Given $\Psi$, we are interested in whether an embedding into the standard negative lattice exists. With the notation established in Section 3 in the following lemma we prove that, up to a change of basis, the images under the embedding of the $(-2)$–chains and of the central vertex are totally determined.

**Lemma 5.1** Let $Y := Y(a_1, \ldots, a_s; c_1, \ldots, c_t)$ be a Seifert manifold which is the boundary of a negative definite canonical plumbing $M_\Psi$, whose associated intersection lattice $(\mathbb{Z}^m, Q_\Psi)$ admits an embedding into $(\mathbb{Z}^m, -\text{Id})$. Moreover, suppose that the associated pretzel link is a knot. Then, up to a change of basis, we have the following.

1. For every $k \in \{1, \ldots, t\}$, the image of the vertices $v_{1,k}, \ldots, v_{c_k-1,k}$ of the $(-2)$–chain $C_k$ is $v_{i,k} = e_i^k - e_{i+1}^k$, for every $i \in \{1, \ldots, c_k - 1\}$. In particular, $U_{C_k} \cap U_{C_\ell} = \emptyset$ for every $k, \ell \in \{1, \ldots, t\}$ with $k \neq \ell$.

2. The central vertex satisfies $v_0 = -e_1^1 - e_2^1 - \cdots - e_1^t$, with $e_i^k$ defined in (1).

3. $s \geq t - 1$.

**Proof** We start by proving (1) using the same argument as in [12]. The only linear combinations of the $\{e_i^k\}_{i,k}$ which yield vectors of square $-2$ are of the form $\pm e_i^k \pm e_j^\ell$. Since $v_{1,k}$ has square $-2$, up to reindexing the basis of $\mathbb{Z}^m$ and up to scaling by $-1$, we must have $v_{1,k} = e_1^k - e_2^k$. If $c_k > 2$, then there exists $v_{2,k}$, which has also square $-2$, and since $v_{1,k} \cdot v_{2,k} = 1$, one of the vectors appearing in $v_{2,k}$ must be either $-e_1^k$ or $e_2^k$. Thus, again up to reindexing and rescaling, we are forced to define $v_{2,k} = e_2^k - e_3^k$. So far we have proved (1) for $c_k = 2$ or $c_k = 3$. In the proof of [12, Lemma 3.1] it is explained how to proceed by induction to show that (up to a change of basis) we are forced to make the assignment $v_{i,k} = e_i^k - e_{i+1}^k$ for all $i \in \{1, \ldots, c_k - 1\}$, provided $c_k \geq 5$. Therefore, we are left with the case $c_k = 4$. It is easy to check that this time...
there is a second possibility for the embedding of the \((-2)\)–chain \(C_k\), namely

\[
  v_{1,k} = e_1^k - e_2^k, \\
  v_{2,k} = e_2^k - e_3^k, \\
  v_{3,k} = -e_1^k - e_2^k.
\]

However, since \(v_{1,k} \cdot v_0 = 1\) we must have \(\{e_1^k, e_2^k\} \cap U_{v_0} \neq \emptyset\), which is not compatible with \(v_0 \cdot v_{3,k} = 0\).

In order to complete the proof of (1) suppose by contradiction that for two different indices \(k, \ell \in \{1, \ldots, t\}\) there exist \(i, j\) and \(e_s^r\) such that \(e_s^r \in U_{v_i,k} \cap U_{v_j,\ell}\). Since \(v_{i,k} \cdot v_{j,\ell} = 0\), there must exist some other basis vector, say \(e_s^x\), in \(U_{v_i,k} \cap U_{v_j,\ell}\) and since \(v_{i,k} \cdot v_{i,k} = v_{j,\ell} \cdot v_{j,\ell} = -2\), we have \(U_{v_i,k} = U_{v_j,\ell} = \{e_s^r, e_s^x\}\). By assumption \(P(a_1, \ldots, a_s, c_1, \ldots, c_t)\) is a knot, which implies in particular that at most one parameter among \(c_1, \ldots, c_t\) is equal to 2 and therefore, at least one of the chains \(C_k\) and \(C_\ell\) has length strictly greater than one; say it is \(C_k\). It follows from the above arguments that exactly one basis vector between \(e_s^r\) and \(e_s^x\) belongs to either \(U_{v_{i-1,k}}\) or \(U_{v_{i+1,k}}\). Let us fix, without loss of generality, that \(e_s^r \in U_{v_{i+1,k}}\); then we have that \(v_{i+1,k} \cdot v_{j,\ell} \neq 0\). This contradiction proves (1).

Next, all the \((-2)\)–chains \(C_1, \ldots, C_t\) are connected to the central vertex and therefore \(|U_{v_0} \cap U_{C_k}| \geq 1\) for every \(k\). Since there are exactly \(t\) \((-2)\)–chains and the weight of the central vertex is \(-t\), we have \(|U_{v_0} \cap U_{C_k}| = 1\) for every \(k\). Hence, up to reindexing and scaling by \(-1\), we have that for every \(k \in \{1, \ldots, t\}\) the vector \(-e_1^k\) is a summand in the expression of \(v_0\). Thus, (2) is proved.

We are left with (3), which follows from a straightforward computation. In fact, from (1) we know that for each \(k \in \{1, \ldots, t\}\), the image of the chain \(C_k\) is contained in the span of \(c_k\) vectors of the basis \(\{e_i^k\}_{i,k}\). Moreover, for every \(k, \ell \in \{1, \ldots, t\}, k \neq \ell\), the images of \(C_k\) and \(C_\ell\) are disjoint. Therefore, the rank of the image of the embedding, which in the statement is called \(m\), must be at least equal to \(\sum_{k=1}^t c_k\).

On the other hand, since \(\Psi\) the canonical negative plumbing graph, we know that

\[
m = s + 1 + \sum_{k=1}^t (c_k - 1).
\]

Hence, \(s \geq t - 1\) and (3) holds. \(\square\)

Once established in Lemma 5.1 the convention on the embedding of the \((-2)\)–chains and the central vertex, we study in Lemmas 5.3, 5.4 and 5.5 the embedding of the
whole lattice associated to $\Psi$. In the three lemmas we will assume the following slice conditions:

**Lemma 5.3** Assume $(SC)$ and that $j$ is an embedding of a ball. Taking as $Q$ of $M$ that $w$ is negative definite imply, by (4), that $k$ is negative definite and among $a_1, \ldots, a_s, c_1, \ldots, c_t$ odd, we can consider the equation (3) defining $w$ in $(\mathbb{Z}^m, Q)$ in the lattice $(\mathbb{Z}^m, -1)$ via $\iota$:

$$-	ext{Id}(\iota(w), x) \equiv -\text{Id}(x, x) \pmod{2}$$

for all $x \in H_2(X; \mathbb{Z})$,

where $X$ is the smooth closed 4–manifold obtained glueing $M_\Psi$ to a rational homology ball. Taking as $x$ in the above formula each of the basis vectors $e^k_j$, we see that the embedding of $w$ into $(\mathbb{Z}^m, -1)$ must be of the form $w = \sum_{j,k} \beta^k_j e^k_j$ with all $\beta^k_j$ odd. Since $w \cdot w = -m$ we conclude that $\beta^k_j \in \{\pm 1\}$.

Let us write the embedding of the $v_i$ as $v_i = \sum_{j,k} x(i)^k_j e^k_j$, where $x(i)^k_j \in \mathbb{Z}$. The equation $w \cdot v_i = v_i \cdot v_i$ implies

$$-\sum_{j,k} \beta^k_j x(i)^k_j = -\sum_{j,k} (x(i)^k_j)^2.$$ 

Thus, $\beta^k_j x(i)^k_j \in \{0, 1\}$ and for every $i$, the vector $v_i$ is a linear combination of exactly $|a_i|$ vectors of the basis $\{e^k_j\}_{j,k}$ with coefficients $\pm 1$. Moreover, since for every $i, j \in \{1, \ldots, s\}$ with $i \neq j$, we have $v_i \cdot v_j = 0$ from the equality $w = \sum_{i=1}^s v_i = \sum_{j,k} \beta^k_j e^k_j$.
we deduce easily that $U_{v_i} \cap U_{v_j} = \emptyset$. Furthermore, it follows that for each $(-2)$--chain $C_k$, $k \in \{1, \ldots, t\}$, there must exist one and only one $i(k) \in \{1, \ldots, s\}$ such that $U_{v_{i(k)}} \cap U_{C_k} \neq \emptyset$. Notice that we do not yet exclude the possibility $i(k) = i(k')$ for $k \neq k'$. Since $C_k$ is orthogonal to $v_{i(k)}$, it follows that $U_{C_k} \subseteq U_{v_{i(k)}}$, which implies in particular that $c_k \leq |a_{i(k)}|$ for every $k$.

Consider the set $\Delta := \{v_i \subset w \mid U_{v_i} \cap U_{C_k} = \emptyset \text{ for all } k\}$. Observe that $s \leq |\Delta| + t$. By Lemma 5.1(1), it holds that

$$|U_{w \Delta}| \geq \sum_{k=1}^{t} c_k,$$

and therefore, since $U_{v_i} \cap U_{v_j} = \emptyset$ for every $v_i, v_j \subset w, i \neq j$, we have

$$|U_{\Delta}| \leq m - \sum_{k=1}^{t} c_k = s + 1 + \sum_{k=1}^{t} (c_k - 1) - \sum_{k=1}^{t} c_k = s + 1 - t.$$

Since, for every $i, \ell \in \{1, \ldots, s\}$ with $i \neq \ell$ it holds $a_i \leq -2$, $U_{v_i} \cap U_{v_\ell} = \emptyset$ and $|x(i)_{j}^{k}| \leq 1$ for every $j, k$, it follows that the embedding in the statement is possible only if $2|\Delta| \leq |U_{\Delta}|$. Hence, only if $s \leq t + 1$. On the other hand, the embedding
of the \((-2)\)-chains requires, by Lemma 5.1(3), that \(s \geq t - 1\). Since, by assumption (p1), we have \(n = s + t \equiv 0 \pmod{2}\) it follows that \(s = t\). Furthermore, this last equality implies that \(\Delta = \emptyset\) and that for each \(i \in \{1, \ldots, s\}\), there exists at most one \(k \in \{1, \ldots, t\}\) such that \(U_\psi \cap U_{C_k} \neq \emptyset\). In fact, assume by contradiction that there exist \(i, k, k'\), with \(k \neq k'\), such that \(U_{C_k} \cup U_{C_{k'}} \subseteq U_\psi\); then \(|\Delta| \geq s - t + 1\) and the inequality \(2|\Delta| \leq |U_\psi|\) gives \(s \leq t - 1\). This contradiction shows that if \(k \neq k'\), then \(i(k) \neq i(k')\) and also that \(s \in \{t, t + 1\}\). From now on, we assume without loss of generality that \(i(k) = k\) for every \(k\).

Equality \(s = t\) forces

\[
1 + \sum_{k=1}^{t} c_k = m = -\text{sign}(Q_\psi) = -\sigma(P_\psi) - w \cdot w = \sum_{k=1}^{t} |a_k|.
\]

Since \(c_k \leq |a_k|\), we must have \(c_k = |a_k|\) for all parameters except one. Without loss of generality we fix that \(a_k = -c_k\) for \(k \in \{1, \ldots, t - 1\}\) and \(a_t = -c_t - 1\). Notice that, by assumption (p1), either \(a_t\) or \(c_t\) is the only even parameter among \(a_1, \ldots, a_t, c_1, \ldots, c_t\). At this point, after fixing the embedding of the \((-2)\)-chains and the central vertex applying Lemma 5.1, it is straightforward to check that the embedding is as claimed.

\[\square\]

**Lemma 5.4** Assume (SC) and that \(a_1, \ldots, a_s, c_1, \ldots, c_t\) satisfy (p2). Then \(s = t - 1\),

\[
Y = Y(-c_1, \ldots, -c_{t-1}; c_1, \ldots, c_t)
\]

and the embedding into the diagonal negative lattice is, up to a change of basis, the one in Figure 9.

**Proof** By assumption, the parameters defining \(Y\) verify (p2) and therefore there is exactly one even parameter and moreover, it is positive. Without loss of generality, we fix it to be \(c_t\). The homology Wu class \(w\), depicted in Figure 4, is

\[
w = v_{1,t} + v_{3,t} + \cdots + v_{c_t-1,t} + \sum_{i=1}^{s} v_i,
\]

where \(v_i\) is the vertex in the graph \(\Psi\) with weight \(a_i\) and \(v_{2j-1,t} \in C_t\) for all \(j \in \{1, \ldots, c_t/2\}\).

From the assumptions \(\sigma(P_\psi) = 0\) and the existence of an embedding of the intersection lattice associated to \(\Psi\) into the standard negative diagonal lattice of rank \(m\), it follows, exactly as in the proof of Lemma 5.3, that for every \(i, \ell \in \{1, \ldots, s\}\) with \(i \neq \ell\), the vector \(v_i\) is the linear combination of exactly \(|a_i|\) vectors from the basis \(e_j^k\) with
we obtain the condition

\[ A(8) \]

Following the proof of Lemma 5.3, define \( c \) in particular that \( U \subset C \). Since \( 2 \in \mathbb{Z} \) the basis of \( Z \) being \( \{ e_j^k \} \) where \( k \in \{ 1, \ldots, t \} \) and \( j \in \{ 1, \ldots, c \} \).

coefficients \( \pm 1 \) and that \( U_{v_i} \cap U_{v_j} = \emptyset \). Since \( w = \sum_{j,k} \beta_{jk}^k e_j^k \), where \( \beta_{jk}^k \in \{ \pm 1 \} \), it follows that \( U_{C_k} \cap U_{v_j} = \emptyset \) for every \( i \). Moreover, we deduce that for each \((-2)\)-chain \( C_k \), \( k \in \{ 1, \ldots, t-1 \} \), there must exist one and only one \( i(k) \in \{ 1, \ldots, s \} \) such that \( U_{v_{i(k)}} \cap U_{C_k} \neq \emptyset \). Notice that we do not yet exclude the possibility \( i(k) = i(k') \) for \( k \neq k' \). Since \( C_k \) is orthogonal to \( v_{i(k)} \), it follows that \( U_{C_k} \subseteq U_{v_{i(k)}} \), which implies in particular that \( c_k \leq |a_{i(k)}| \) for every \( k \in \{ 1, \ldots, t-1 \} \).

Following the proof of Lemma 5.3, define \( \Delta := \{ v_i \cup w \mid U_{v_i} \cap U_{C_k} = \emptyset \text{ for all } k \in \{ 1, \ldots, t-1 \} \} \). Observe that this time we have \( |\Delta| \geq s - t + 1 \). Arguing as in Lemma 5.3 we obtain the condition \( 2|\Delta| \leq |U_\Delta| \), which gives \( s \leq t - 1 \). On the other hand, the embedding of the \((-2)\)-chains requires, by Lemma 5.1(3), that \( s \geq t - 1 \). Moreover, \( s = t - 1 \) implies that for every \( i \in \{ 1, \ldots, s \} \), there exists at most one \( k \in \{ 1, \ldots, t-1 \} \) such that \( U_{v_i} \cap U_{C_k} \neq \emptyset \) (hence \( \Delta = \emptyset \)). Indeed, if this were not the case, then \( |\Delta| \geq s - t + 2 \) and the inequality \( 2|\Delta| \leq |U_\Delta| \) would lead to the contradiction \( s \leq t - 3 \). Therefore, from now on, we assume without loss of generality that \( i(k) = k \) for every \( k \in \{ 1, \ldots, t-1 \} \).

We have the following equalities:

\[
\sum_{k=1}^{t-1} c_k + c_t = m - \sigma(P_\psi) - w \cdot w = - \sum_{k=1}^{t-1} a_k + c_t = \sum_{k=1}^{t-1} |a_k| + c_t.
\]
Recall that, for every \( k \in \{1, \ldots, t - 1\} \), it holds \( c_k \leq |a_k| \). Then, (8) forces \( c_k = |a_k| \) for every \( k \in \{1, \ldots, t - 1\} \), while \( c_t \), the only even parameter, has no constraints. In this way we have proved the relationship among the parameters \( a_1, \ldots, a_{t-1}, c_1, \ldots, c_t \) claimed in the statement. The embedding of the \((-2\)-chains and of the central vertex follows from Lemma 5.1 and at this point it is immediate to check that the rest of the embedding must be as suggested in Figure 9.

Lemma 5.5 Assume (SC) and that \( a_1, \ldots, a_s, c_1, \ldots, c_t \) satisfy (p3). Then \( s = t + 1 \) and

\[
Y = Y(-c_1 - \lambda^2 - (c_1 - \lambda)^2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)
\]

for some \( \lambda \in \mathbb{Z} \). Moreover, the embedding into the diagonal negative lattice is, up to a basis change, the one in Figure 10.

\[
\begin{align*}
  & e_1 + e_2 + \cdots + e_{c_1} - \lambda e_0 - (c_1 - \lambda) e_2^0 \\
  & e_1 + e_2 + \cdots + e_{c_1} + e_1^0 + e_2^0 \\
  & e_1^t + e_2^t + \cdots + e_{c_t}^t
\end{align*}
\]

Figure 10: Up to a change of basis the embedding of a plumbing graph in the family (p3): the basis of \( \mathbb{Z}^m \) is \( \{e_0^0, e_0^1, e_j^k\} \) where \( k \in \{1, \ldots, t\} \) and \( j \in \{1, \ldots, c_k\} \).

Proof By assumption (p3), among \( a_1, \ldots, a_s, c_1, \ldots, c_t \) there is exactly one even parameter and this parameter is negative. Without loss of generality we fix it to be \( a_1 \). The homology Wu class \( w \), depicted in Figure 4, is \( w = \sum_{i=2}^t v_i \).

We start with the same argument of Lemma 5.3. From the assumptions \( \sigma(P_\Psi) = 0 \) and the existence of an embedding of the intersection lattice associated to \( \Psi \) into the
standard negative diagonal lattice of rank $m$, it follows that for every $i, \ell \in \{2, \ldots, s\}$ with $i \neq \ell$, $v_i$ is the linear combination of exactly $|a_i|$ vectors from the basis $e^k_j$ with coefficients $\pm 1$ and that $U_{v_i} \cap U_{v_\ell} = \emptyset$.

Next, by Lemma 5.1(3) the embedding of the $(-2)$–chains is possible only if $s \geq t - 1$. On the other hand, being $\Psi$ the canonical negative plumbing graph, it holds $v_0 \cdot v_0 = -t$. This implies, since for every $i, j \in \{2, \ldots, s\}$ with $i \neq j$ we have $v_i \cdot v_0 = 1$ and $U_{v_i} \cap U_{v_j} = \emptyset$, that $s - 1 \leq t$. Hence, $s \in \{t - 1, t, t + 1\}$. Moreover, by assumption (p3), we know $s + t \equiv 1 \pmod{2}$, which forces $s \in \{t - 1, t + 1\}$.

We assume first $s = t - 1$. In this case the Wu-set of $\Psi$ consists of the $t - 2$ vertices $v_2, \ldots, v_{t-1}$. These vertices are connected to the central vertex, which has weight $-t$. Recall that for every $i, j \in \{2, \ldots, t - 1\}$ with $i \neq j$, we have $U_{v_i} \cap U_{v_j} = \emptyset$ and that $m = |U_w|$. It follows that either

1. there exist two different indices $i, j \in \{2, \ldots, t - 1\}$ such that $|U_{v_i} \cap U_{v_0}| = |U_{v_j} \cap U_{v_0}| = 2$, or
2. there exists exactly one $i \in \{2, \ldots, t - 1\}$ such that $|U_{v_i} \cap U_{v_0}| = 3$.

We will show that both (1) and (2) lead to contradiction. In fact, if (1) holds, call $e^k_r, e^\ell_s$ the two basis vectors in $U_{v_j} \cap U_{v_0}$. Then, the equalities $|e^k_r \cdot v_j| = |e^k_r \cdot v_0| = |e^\ell_s \cdot v_j| = |e^\ell_s \cdot v_0| = 1$ are incompatible with $v_j \cdot v_0 = 1$. Suppose now that (2) holds and consider the vertex $v_1$. Since $v_1 \cdot v_0 = 1$, there exists $h \in \{2, \ldots, t - 1\}$ and $k \in \{1, \ldots, t\}$ such that $U_{v_h} \cap U_{C_k} \cap U_{v_1} \neq \emptyset$. Moreover, since $v_1$ and $v_h$ are orthogonal to $C_k$, we have that $U_{C_k} \subseteq U_{v_1} \cap U_{v_h}$. The index $h$ must be the index $i$ in the statement of (2); otherwise we would have $U_{v_h} = U_{C_k}$, which leads $v_h \cdot v_1 \neq 0$. At this point, there are two possibilities.

- $|U_{v_1} \cap U_{v_i} \cap U_{v_0}| = 2$: in this case there are two $(-2)$–chains, say $C_k$ and $C_\ell$, such that $U_{C_k \cup U_{C_\ell}} \subseteq U_{v_1}$. Since $v_1 \cdot v_0 = 1$ and $v_1$ is orthogonal to $C_k$ and $C_\ell$, there must exist some $\lambda \in \mathbb{Z}$ such that

$$v_1 = -\lambda e^k_1 - \ldots - \lambda e^k_{c_k} + (\lambda + 1)e^\ell_1 + \cdots + (\lambda + 1)e^\ell_{c_\ell},$$

where we use the convention fixed in Lemma 5.1 for the embedding of the $(-2)$–chains. Since by assumption the parameters $a_1, \ldots, a_{t-1}; c_1, \ldots, c_t$ satisfy (p3), we have that $a_1$ is even and $c_k, c_\ell$ are odd. However, $v_1 \cdot v_1 = -\lambda^2 c_k - (\lambda + 1)^2 c_\ell$, which is in contradiction with $a_1$ being even.

- $|U_{v_1} \cap U_{v_i} \cap U_{v_0}| = 3$: this time we have three $(-2)$–chains, say $C_k, C_\ell$ and $C_p$, such that

$$v_1 = \lambda e^k_1 + \cdots + \lambda e^k_{c_k} + \rho e^\ell_1 + \cdots + \rho e^\ell_{c_\ell} + \delta e^p_1 + \cdots + \delta e^p_{c_p}$$
for some \( \lambda, \rho, \delta \in \mathbb{Z} \). Since \( a_1 \) is even and \( c_k, c_\ell \) and \( c_p \) are odd, there are two possibilities for the coefficients \( \lambda, \rho \) and \( \delta \): the three of them are even or two of them are odd and one is even. In both cases we have \( v_1 \cdot v_0 = \lambda + \rho + \delta \neq 1 \).

After this final contradiction we conclude that, under the assumptions of the statement, it is not possible to have \( s = t - 1 \).

We are only left with analyzing the case \( s = t + 1 \). Since \( m = |U_w| \) and since for every \( i, j \in \{2, \ldots, t + 1\} \) with \( i \neq j \), we have \( U_{v_i} \cap U_{v_j} = \emptyset \), we deduce that for each \((-2)\)-chain \( C_k, k \in \{1, \ldots, t\} \), there must exist one and only one \( i(k) \in \{2, \ldots, s\} \) such that \( U_{v_i(k)} \cap U_{C_k} \neq \emptyset \). Moreover, since there are \( t \) vertices in the Wu-set and the central vertex has weight \(-t\), it also holds that if \( i(k) = i(k') \), then \( k = k' \). We fix, without loss of generality, that \( i(k) = k + 1 \) for every \( k \in \{1, \ldots, t\} \). Since \( C_k \) is orthogonal to \( v_{k+1} \), it follows that \( U_{C_k} \subseteq U_{v_{k+1}} \), which implies in particular that \( c_k \leq |a_{k+1}| \) for every \( k \).

The assumption \( s = t + 1 \) and Lemma 5.1(1) imply that

\[
m = s + 1 + \sum_{k=1}^{t} (c_k - 1) = 2 + \sum_{k=1}^{t} c_k = 2 + \sum_{k=1}^{t} |U_{C_k}|.
\]

Therefore, since \( m = |U_w| \), there are exactly two basis vectors, say \( e_1^0 \) and \( e_2^0 \), such that \( e_1^0, e_2^0 \in U_w \) and for every \( k \in \{1, \ldots, t\} \) we have \( e_1^0, e_2^0 \not\in U_{C_k} \). Since \( w = \sum_{i=2}^{t} v_i = \sum j, \ell \beta_j^\ell e_j^\ell \) with \( \beta_j^\ell \in \{\pm 1\} \) and \( a_2, \ldots, a_{t+1} \) are odd, we necessarily have that there exists one vector, say \( v_2 \), such that \( e_1^0, e_2^0 \in U_{v_2} \). Note that this implies that for every \( i \in \{3, \ldots, t + 1\} \), we have \( a_i = -c_{i-1} \). At this point, using Lemma 5.1 to fix the embedding of the \((-2)\)-chains and the central vertex, it follows that the embedding of \( v_0, v_3, \ldots, v_{t+1}, C_1, \ldots, C_t \) is as claimed in Figure 10.

In order to conclude, we must determine the embedding of \( v_1 \) and \( v_2 \). Since \( v_2 \subseteq w \) and \( \{e_1^0, e_2^0\} \cup U_{C_1} = U_{v_2} \) it follows that, up to the sign of \( e_1^0 \) and \( e_2^0 \), we have \( v_2 = e_1^0 + \cdots + e_{c_1}^0 + e_1^0 + e_2^0 \). The vector \( v_1 \), which is the only one with even square, is connected to the central vertex, and since it is orthogonal to all the other vertices, we necessarily have \( U_{C_1} \subseteq U_{v_1} \) and \( U_{v_1} \cap U_{v_i} = \emptyset \) for every \( i \in \{3, \ldots, t + 1\} \). Since \( v_1 \cdot v_2 = 0 \) we deduce that there exist \( \lambda \in \mathbb{Z} \) such that \( v_1 = e_1^0 + \cdots + e_{c_1}^0 - \lambda e_1^0 - (c_1 - \lambda)e_2^0 \). \( \square \)

### 6 Remaining cases

Lemmas 5.3 and 5.4 proved in the last section imply Theorem 1.1 for pretzel knots in the families \((p1)\) and \((p2)\). The “only” thing left now is to understand what happens
with the Seifert spaces from Lemma 5.5. In this section we introduce the correction terms from Heegaard–Floer homology and explain how to use them in combination with Donaldson’s theorem to get further obstructions to sliceness. This enhanced obstruction suffices to reduce the candidates to Seifert spaces bounding rational homology balls in Lemma 5.5 to the double branched covers of the knots studied in Section 4.

6.1 Correction terms from Heegaard–Floer homology

Ozsváth and Szabó, using techniques from Heegaard–Floer homology, showed that if $Y$ is a rational homology sphere bounding a rational homology ball $W$, then, for each Spin$^c$–structure $s$ on $Y$ which extends over $W$, the so-called correction term $d(Y, s)$ vanishes. Details can be found in [25]. We summarize here, following [12], a particular way of using this information as an obstruction for a Seifert space to bound a rational homology ball.

We denote by Spin$^c(W)$ the set of Spin$^c$ structures on the manifold $W$. This set admits a free transitive action of the group $H^2(W; \mathbb{Z})$ and the following diagram, where the horizontal arrows give the action, $r$ is the restriction and $i^*$ is induced by the inclusion, commutes:

$$
\begin{array}{ccc}
H^2(W; \mathbb{Z}) \times \text{Spin}^c(W) & \longrightarrow & \text{Spin}^c(W) \\
(i^*, r) & \downarrow & \\
H^2(Y; \mathbb{Z}) \times \text{Spin}^c(Y) & \longrightarrow & \text{Spin}^c(Y)
\end{array}
$$

After fixing a reference Spin$^c$ structure on $W$, say $s_0$, we are able to identify $H^2(W; \mathbb{Z})$ with Spin$^c(W)$ as Spin$^c(W) = s_0 + H^2(W; \mathbb{Z})$ and analogously Spin$^c(Y) = r(s_0) + H^2(Y; \mathbb{Z})$. Therefore, it follows from the above diagram and Ozsváth and Szabó’s result that if $Y$ bounds a rational homology ball $W$ then for every $s \in r(\text{Spin}^c(W)) \subseteq \text{Spin}^c(Y)$ the correction term $d(Y, s)$ vanishes and we can identify $r(\text{Spin}^c(W))$ with $r(s_0) + i^*(H^2(W; \mathbb{Z}))$. We shall denote by $V$ the subgroup $i^*(H^2(W; \mathbb{Z})) \subseteq H^2(Y; \mathbb{Z})$.

**Remark 6.1** Notice that the group $V$ defined above coincides with the group $V$ in Theorem 4.1. There is in fact a striking formal similarity between the Casson–Gordon invariants and the $d$–invariants of a 3–manifold. Nevertheless these two invariants detect different phenomena. For example we shall see in the next subsection that the correction terms do not obstruct the existence of a rational homology ball bounded by $Y(a, -a - 2, -a - (a^2 + 9)/2)$ while the Casson–Gordon invariants do obstruct (cf Section 4.1 and Remark 4.4).
Given a slice knot \( K \subset S^3 \), the 2–fold cover of \( D^4 \) branched over a slicing disc \( D \) of \( K \) is a rational homology ball \( W_D \) [5, Lemma 2]. Hence, we can specialize the above discussion to \( W_D \) and \( Y = \partial W_D \), which is the 2–fold cover of \( S^3 \) branched over \( K \). In the case \( K \) is a Montesinos knot, let \( \Gamma \) be its associated plumbing graph with \( m \) vertices, and let us further assume that the associated incidence matrix \( Q_\Gamma \) is negative definite. Let us call \( Y = Y_\Gamma = \partial M_\Gamma \) the boundary of the plumbing 4–manifold \( M_\Gamma \) associated to \( \Gamma \).

The manifold \( M_\Gamma \cup Y_\Gamma \) (\( W_D \)) is a closed, oriented, negative definite, 4–manifold and hence, by Donaldson’s theorem, there exists a basis \( \tilde{\epsilon}_1, \ldots, \tilde{\epsilon}_m \) of \( H^2(M_\Gamma \cup Y_\Gamma ; \mathbb{Z}) \) with respect to which the intersection pairing is represented by \( -\text{Id} \). Let \( \Sigma_1, \ldots, \Sigma_m \in H_2(M_\Gamma ; \mathbb{Z}) \) be a basis determined by the \( m \) 2–handles of \( M_\Gamma \) and let \( D_1, \ldots, D_m \in H_2(M_\Gamma, Y_\Gamma ; \mathbb{Z}) \) be a dual basis determined by their cocores. With these choices of bases, the map \( \eta: H_2(M_\Gamma; \mathbb{Z}) \to H_2(M_\Gamma, Y_\Gamma; \mathbb{Z}) \) is represented by the incidence matrix \( Q_\Gamma \) of the graph \( \Gamma \). The application in cohomology, \( \gamma: H^2(M_\Gamma, Y_\Gamma; \mathbb{Z}) \to H^2(M_\Gamma; \mathbb{Z}) \), is again represented by the matrix \( Q_\Gamma \), when we consider in \( H^2(M_\Gamma, Y_\Gamma; \mathbb{Z}) \) the basis \( \Sigma_1^*, \ldots, \Sigma_m^* \) of the Poincaré duals of the \( \Sigma_i \) and in \( H^2(M_\Gamma; \mathbb{Z}) \) the basis \( \tilde{\Sigma}_1, \ldots, \tilde{\Sigma}_m \) of the Hom-duals of the \( \Sigma_i \): \( \tilde{\Sigma}_i(\Sigma_j) = \delta_{ij} \).

The long exact sequence in cohomology of the pair \((M_\Gamma, Y_\Gamma)\),

\[
0 \rightarrow H^2(M_\Gamma, Y_\Gamma; \mathbb{Z}) \overset{Q_\Gamma}{\rightarrow} H^2(M_\Gamma; \mathbb{Z}) \overset{\delta}{\rightarrow} H^2(Y_\Gamma; \mathbb{Z}) \rightarrow 0
\]

(9)

\[
\begin{array}{ccc}
\mathbb{Z}^m & \overset{Q_\Gamma}{\rightarrow} & \mathbb{Z}^m \\
\oplus & \overset{\delta}{\rightarrow} & \mathbb{Z}^m/ Q_\Gamma \mathbb{Z}^m,
\end{array}
\]

allows us to identify \( H^2(Y_\Gamma; \mathbb{Z}) \) with the cokernel of \( Q_\Gamma \) via \( \delta \). Therefore, we can further identify \( \text{Spin}^c(Y) = r(s_0) + \text{coker } Q_\Gamma \). Using some algebraic topology one can obtain [12, Theorem 3.4], which in our notation states:

**Theorem 6.2** (Greene, Jabuka) Let \( K, W_D, Y_\Gamma, M_\Gamma, Q_\Gamma \) be as above. Then, with the above fixed bases, \( H^2(M_\Gamma \cup Y_\Gamma \cup Y_\Gamma (-W_D); \mathbb{Z}) \to H^2(M_\Gamma; \mathbb{Z}) \) has a matrix representative \( A \), which leads to a factorization \( Q_\Gamma = -AA^t \). Moreover, \( \delta \) in (9) induces an isomorphism

\[
(\text{im } A)/(\text{im } Q_\Gamma) \cong i^*(H^2(W_D; \mathbb{Z})) \subseteq H^2(Y_\Gamma; \mathbb{Z})/\text{coker } Q_\Gamma.
\]

From the above discussion we know that \( d(Y_\Gamma, s) = 0 \) for every \( s = r(s_0) + v \), where \( v \in V = i^*(H^2(W_D; \mathbb{Z})) \). Therefore, we must have at least \( |V| \) Spin\^c–structures
on $Y_\Gamma$ for which the invariant $d$ vanishes. By Theorem 6.2 we can calculate $|V|$ as

$$ (10) \quad |V| = |(\text{im} \ A)/(\text{im} \ Q_\Gamma)| = |(AZ^m)/(AA^tZ^m)|$$

$$ = |Z^m/(AA^tZ^m)| = |\det A^t|. $$

For $3$–manifolds $Y$ obtained as boundaries of $4$–dimensional plumblings specified by certain graphs, Ozsváth and Szabó give in [25] an explicit formula to calculate $d(Y, s)$. The class of graphs that they consider includes all star-shaped graphs $\Gamma$ such that $Q_\Gamma$ is negative definite. In order to state the formula we need to introduce some definitions and notation. With the above fixed basis, a covector $v \in H^2(M_\Gamma; \mathbb{Z})$ is called characteristic for $Q_\Gamma$ if it is congruent modulo $2$ to the vector $(Q_{\Gamma_{11}}, \ldots, Q_{\Gamma_{mm}})$, whose coordinates in the basis $\tilde{\Sigma}_1, \ldots, \tilde{\Sigma}_m$ are the elements in the diagonal of $Q_\Gamma$. We will denote by $\text{Char}(Q_\Gamma) \subseteq H^2(M_\Gamma; \mathbb{Z})$ the set of all characteristic covectors for $Q_\Gamma$. Given a cohomology class $v \in H^2(M_\Gamma; \mathbb{Z})$ we will write $[v]$ to denote its equivalence class in $\text{coker} \ Q_\Gamma$. For a given $s \in \text{Spin}^c(Y_\Gamma)$ we define the set

$$ \text{Char}_s(Q_\Gamma) := \{ v \in \text{Char}(Q_\Gamma) \mid s = r(s_0) + [v] \}. $$

With these conventions and definitions in place, we are ready to state the formula we use for computing correction terms (see [25, Corollary 1.5]):

$$ (11) \quad d(Y_\Gamma, s) = \max_{v \in \text{Char}_s(Q_\Gamma)} \frac{v^t Q_\Gamma^{-1} v + |\Gamma|}{4}. $$

We already know that for every $s \in r(s_0) + V$ we have $d(Y_\Gamma, s) = 0$. Nevertheless, let us compute $d(Y_\Gamma, s)$ for $s \in r(s_0) + V$ with equality (11). Greene and Jabuka’s result, Theorem 6.2, shows $V \cong (\text{im} \ A)/(\text{im} \ Q_\Gamma)$, so we consider a cohomology class $v = Ax \in H^2(M_\Gamma; \mathbb{Z})$. In this case, the term $v^t Q_\Gamma^{-1} v$ from (11) simplifies to

$$ v^t Q_\Gamma^{-1} v = -x^t A^t (AA^t)^{-1} A x = -x^t A^t (A^t)^{-1} A^{-1} A x = -|x|^2, $$

and therefore

$$ (12) \quad d(Y_\Gamma, s) = \max_{Ax \in \text{Char}_s(Q_\Gamma)} \frac{-|x|^2 + m}{4}, $$

where $m$ is the number of vertices in $\Gamma$. The requirement that $v = Ax$ be characteristic can be expressed as a condition on $x$ itself. In fact, by definition $v = \sum_{i=1}^m v_i \tilde{\Sigma}_i$ is characteristic if and only if $v_i \equiv Q_\Gamma_{ii} (\text{mod} \ 2)$ for all $i$. Since, by Theorem 6.2, $Q_\Gamma = -AA^t$, we have that $v = Ax$ is characteristic if and only if

$$ (13) \quad \sum_{j=1}^m A_{ij} x_j \equiv \sum_{j=1}^m A_{ij}^2 \equiv \sum_{j=1}^m A_{ij} \equiv 0 \quad (\text{mod} \ 2) \quad \text{for all} \ i = 1, \ldots, m. $$

Algebraic & Geometric Topology, Volume 15 (2015)
Since \( \det(Q_\Gamma) \) is the determinant of the knot \( K \), it follows that \( \det(A) \) is odd and therefore the matrix \( A \) is invertible (mod 2). Hence, the vector \( x \) (mod 2) is uniquely determined by equivalence (13). At the same time, it is clear that taking \( x_i \equiv 1 \) (mod 2) for all \( i \), the equivalences in (13) are satisfied, so it must be the unique solution. Now, since \( d(Y_\Gamma, s) = 0 \), equation (12) forces \( x_i \in \{ \pm 1 \} \) for all \( i \in \{1, \ldots, m\} \). Notice that there are \( 2^m \) such vectors \( v = Ax \) in \( \text{im} A \), while the number \( |V| \) of equivalence classes of these vectors \( [v] \) in \( V \approx (\text{im} A)/(\text{im} Q_\Gamma) \) might be significantly smaller.

In the next subsection we shall compute, for the Seifert spaces in Lemma 5.5, an upper bound \( N \) on the number of Spin\(^c\) structures with vanishing correction terms. The above arguments imply that the inequality \( |V| \leq N \) must hold, which will give further constraints on the invariants defining Seifert spaces in family \( (p3) \) that bound rational homology balls.

### 6.2 Further study of family \( (p3) \)

**Lemma 6.3** Let \( a = \lambda + \rho > 1 \) be an odd integer, \( \lambda, \rho \in \mathbb{Z} \) with \( \lambda, \rho \geq 0 \). If the Seifert space \( Y = Y(–a – \lambda^2 – \rho^2, –a – 2; a) \) bounds a rational homology ball, then either \( Y = Y(–a – (a^2 + 1)/2, –a – 2; a) \) or \( Y = Y(–a – (a^2 + 9)/2, –a – 2; a) \).

**Proof** Since \( Y \) is the boundary of a rational homology ball, the intersection lattice of its associated canonical negative plumbing graph \( \Psi \), which is easily seen to be negative, admits an embedding into \((\mathbb{Z}^m, –\text{Id})\), where \( m = a + 2 \). Let us label the vertices in \( \Psi \) as follows: let \( v_1, \ldots, v_{a-1} \) be the vertices in the \((-2)\)-chain corresponding to the parameter \( a \), where \( v_1 \) is connected to the central vertex; let \( v_a \) be the central vertex; let \( v_{a+1} \) be the vertex with weight \(-a – 2\) and finally let \( v_{a+2} \) be the remaining vertex. The \( 2\)-handles represented by the vertices \( \{v_1, \ldots, v_{a+2}\} \) form a basis of \( H_2(M_{\Psi}; \mathbb{Z}) \). With respect to this basis, the incidence matrix of the graph \( Q_{\Psi} \) is the matrix of the intersection pairing on \( M_{\Psi} \). Since \( Y \) satisfies the assumptions of Lemma 5.5 we know explicitly the factorization \( Q_{\Psi} = AA^t \):

\[
A^t := \begin{pmatrix}
1 & 0 & 0 & 0 & -1 & 1 & 1 & \\
-1 & 1 & -1 & 0 & 0 & 1 & 1 & \\
0 & -1 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
\vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \\
0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \\
\end{pmatrix}
\]
By assumption, there exists a rational homology ball $W$ such that $Y = \partial W$. With the notation and conventions fixed in Section 6.1, we have that every $s \in \text{Spin}^c(Y)$ which extends to $W$ is of the form $r(s_0) + v$, where $v \in V \subset H^2(Y; \mathbb{Z})$. Greene and Jabuka’s result, Theorem 6.2, states that $V \cong (\text{im} \, A)/(\text{im} \, Q_{\Psi})$ and by (10) we have

$$|V| = |\det A| = \sqrt{|\det Q_{\Psi}|} = \sqrt{|(1/a - a - 2 - 1/a - \lambda^2 - \rho^2)\lambda(-a - 2)(-a - \lambda^2 - \rho^2)|} = |\lambda - \rho|.$$ 

Notice that we have used equality (1) to calculate $|\det Q_{\Psi}|$.

From the discussion in Section 6.1 we know that, for every cohomology class $v = Ax \in \text{im} \, A$ for which $s = r(s_0) + v$ satisfies $d(Y, s) = 0$, it holds that $x = (x_1, \ldots, x_m)$ has coordinates $x_i \in \{\pm 1\}$ for all $i$. While there are $2^m$ such $v = Ax$ in $\text{im} \, A$, there are significantly fewer equivalence classes of such vectors $[v]$ in $V = (\text{im} \, A)/(\text{im} \, Q_{\Psi})$. In fact, observe that any two cohomology classes, $v = Ax$ and $v' = Ax'$, satisfy $[v] = [v']$ if and only if there exists some $y$ such that $A(x - x') = -AA^t \cdot y$. Namely, if and only if $x - x' \in \text{im} \, A^t$. The first $a + 1$ columns $\text{col}_1, \ldots, \text{col}_{a + 1}$ of $A^t$ generate the kernel of $\ell: \mathbb{Z}^m \to \mathbb{Z}$, where $\ell(x_1, \ldots, x_{a+2}) = x_{a+1} - x_{a+2}$. In fact, since $\ell(\text{col}_i) = 0$ for $i = 1, \ldots, a + 1$ we have $\text{span}(\text{col}_1, \ldots, \text{col}_{a+1}) \subseteq \ker \ell$. On the other hand, for every $y = (y_1, \ldots, y_{a+2}) \in \ker \ell$, $y_{a+1} = y_{a+2}$ and since the determinant of the leading principal minor of $A^t$ is $-1$, it follows that $\text{span}(\text{col}_1, \ldots, \text{col}_{a+1}) = \ker \ell$. Therefore, $\ker \ell \subset \text{im} \, A^t$ and hence, if $\ell(x) = \ell(x')$ then $[v] = [v']$. The functional $\ell$, when restricted to the set $\{x \in \mathbb{Z}^{a+2} \mid x_i \in \{\pm 1\}\}$, only takes 3 different values. Thus, $d(Y, s)$ vanishes for at most 3 Spin$^c$ structures in $r(s_0) + V$. On the other hand, we know that all the Spin$^c$ structures of the form $s = r(s_0) + v$, with $v \in V$, extend to $W$ and therefore, they all have vanishing correction terms. We conclude that $|V| = |\lambda - \rho| \leq 3$. Since $a$ is odd we cannot have $\lambda = \rho + 2$, and therefore $\lambda = \rho + 1$ or $\lambda = \rho + 3$. Taking into account that $a = \lambda + \rho$ and making the pertinent substitutions we obtain the Seifert spaces in the statement.

**Corollary 6.4** Every Seifert space in Lemma 5.5 bounding a rational homology ball is either of the form $Y = Y(-c_1 - (c_1^2 + 1)/2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)$ or $Y = Y(-c_1 - (c_1^2 + 9)/2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)$.

**Proof** The Seifert spaces in Lemma 5.5 are of the form

$$Y = Y(-c_1 - \lambda^2 - \rho^2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)$$

for some $\lambda, \rho \in \mathbb{Z}$ such that $\lambda + \rho = c_1$. Since $Y$ is invariant under any change of order of the parameters, it is the double cover of $S^3$ branched over the pretzel knot

$$K := P(-c_2, c_2, -c_3, c_3, \ldots, -c_t, c_t, -c_1 - \lambda^2 - \rho^2, -c_1 - 2, c_1).$$
Adding to the projection of \( K \) the band shown in Figure 1 and performing a ribbon move along it, we obtain the disjoint union of an unknot and the pretzel knot

\[
K_2 := P(-c_3, c_3, \ldots, -c_t, c_t, -c_1 - \lambda^2 - \rho^2, -c_1 - 2, c_1).
\]

Therefore \( K \sim K_2 \), where \( \sim \) stands for concordance equivalence. Since concordance is an equivalence relation, we have \( K \# - K_2 \sim K_2 \# - K_2 \) and hence \( K \# - K_2 \) is slice. It follows that its double branched cover, the 3–manifold \( Y \# - Y_2 \), is the boundary of a rational homology ball, and therefore there exists a rational homology cobordism between \( Y \) and

\[
Y_2 := Y(-c_3, c_3, \ldots, -c_t, c_t, -c_1 - \lambda^2 - \rho^2, -c_1 - 2, c_1).
\]

Obviously, we can repeat the same construction \( t - 1 \) times showing that there exists a rational homology cobordism between \( Y \) and the Seifert space with three exceptional fibers \( Y(-c_1 - \lambda^2 - \rho^2, -c_1 - 2, c_1) \). Among these spaces, by Lemma 6.3 the only ones that possibly bound rational homology balls are of the form \( Y = Y(-c_1 - (c_1^2 + 1)/2, -c_1 - 2; c_1) \) and \( Y = Y(-c_1 - (c_1^2 + 9)/2, -c_1 - 2; c_1) \).

\[\square\]

**Remark 6.5** The above corollary shows that the Seifert space

\[
Y(a_1, \ldots, a_k, \alpha_1, \ldots, \alpha_r, -\alpha_1, \ldots, -\alpha_r),
\]

where \( a_i, \alpha_j \in \mathbb{Z} \), bounds a rational homology ball if and only if \( Y(a_1, \ldots, a_k) \) does.

### 6.3 Proof of main theorem

In this last section we prove Theorem 1.1 putting together the conclusions of the preceding sections. We shall give two nearly equivalent statements of our main result: one regarding the sliceness of pretzel knots, as stated in the introduction, and another one focusing on the Seifert spaces bounding rational homology balls. Notice that in this second case our results are slightly weaker since we were able to determine, in Section 4, that many of the knots in the family \( P(a, -a - 2, -(a + 1)^2/2) \), \( a \geq 3 \) odd, are not slice but this does not imply that the double branched covers do not bound rational homology balls.

**Proof of Theorem 1.1** Up to considering mirror images we can suppose that the double branched cover of the slice knot \( K \) bounds a negative definite 4–manifold. Since \( K \) is slice \( \sigma(K) = 0 \) and its double branched cover \( Y \) bounds a rational homology ball. It follows that the slice condition (SC) from Section 5 are satisfied.

If \( K \) is of type (p1) or (p2) then the theorem is an immediate corollary of Lemmas 5.3 and 5.4, since the Seifert spaces determine the pretzel knots up to reordering of the parameters.
If $K$ belongs to (p3) then its double branched cover $Y$ is one of the Seifert spaces in Corollary 6.4. If $Y = Y(-c_1 - (c_1^2 + 9)/2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)$ then by Remarks 6.5 and 4.4 it does not bound a rational homology ball and therefore $K$ is not slice. Finally, if $Y = Y(-c_1 - (c_1^2 + 1)/2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t)$ then it is the double branched cover of all pretzel knots with defining parameters $\{-c_1 - (c_1^2 + 1)/2, -c_1 - 2, -c_2, \ldots, -c_t; c_1, \ldots, c_t\}$. Since the Alexander polynomial is invariant under mutation, all the different pretzel knots with the same set of parameters have the same Alexander polynomial. By assumption $K$ is slice and therefore its Alexander polynomial has a Fox–Milnor factorization. It then follows that the Alexander polynomial of any knot concordant to $K$ also has a Fox–Milnor factorization. Since the pretzel knot $P(c_1, -c_1 - 2, -(c_1 + 1)^2/2, c_2, -c_2, \ldots, c_t, -c_t)$ is clearly concordant to $P(c_1, -c_1 - 2, -(c_1 + 1)^2/2)$ and by assumption $\{c_1, -c_1 - 2, -(c_1 + 1)^2/2\} \not\in \mathcal{E}$, by Theorem 4.5 we conclude that $K$ is not slice.

As far as Seifert spaces bounding rational homology balls are concerned we have the following result which is just a rephrasing of Theorem 1.1.

**Theorem 6.6** Consider a Seifert space of the form $Y = Y(p_1, \ldots, p_n)$ with $n \geq 3$, $p_1$ even and $p_i$ odd for $i = 2, \ldots, n$. If $Y$ is the boundary of a rational homology ball, then the set of parameters $\mathcal{P} = \{p_1, \ldots, p_n\}$ satisfies one of the following:

1. $n$ is even and $\mathcal{P}$ can be written as $\{p_1, -p_1 \pm 1, q_1, -q_1, \ldots, q_{n/2}, -q_{n/2}\}$.
2. $n$ is odd and $\mathcal{P}$ can be written as $\{p_1, q_1, -q_1, \ldots, q_{(n-1)/2}, -q_{(n-1)/2}\}$.
3. $n$ is odd and $\mathcal{P}$ can be written as
   
   (a) $\{a, -a - 2, -(a + 1)^2/2, q_1, -q_1, \ldots, q_{(n-3)/2}, -q_{(n-3)/2}\}$ or
   (b) $\{-a, a + 2, (a + 1)^2/2, q_1, -q_1, \ldots, q_{(n-3)/2}, -q_{(n-3)/2}\}$,

where $a \geq 3$ and $|p_1| = (a + 1)^2/2$.

Moreover, in the two first cases the rational homology ball exists.

**Appendix**

In this appendix we compute the Alexander polynomial of the pretzel knots

$$P_a = P(a, -a - 2, -(a + 1)^2/2),$$

where $a > 1$ odd. To this end we shall heavily rely on Jabuka’s theorem [14, Theorem 3.1] which gives in particular a symmetrized linking form $\mathcal{L} + \mathcal{L}^\tau$ of the pretzel
knots $P_a$ associated to the Seifert surfaces given in [14, Figure 2]. We shall use the following notation, where $A_n$ is a square matrix of size $n$:

$$
A_n = \begin{pmatrix}
  t-1 & -1 & -1 & \cdots & -1 & -1 \\
  t & t-1 & -1 & \cdots & -1 & -1 \\
  t & t & t-1 & \cdots & -1 & -1 \\
  : & : & : & \ddots & : & : \\
  t & t & t & \cdots & t-1 & -1 \\
  t & t & t & \cdots & t & -1 \\
\end{pmatrix}
$$

**Theorem A.1** (Jabuka) The Alexander polynomial $\Delta_a(t)$ of the knots in family $P_a$ satisfies $\Delta_a(t) \doteq \det \Theta_a$, where

$$
\Theta_a = L - tL^T = \begin{pmatrix}
  A_{a+1} & 0 & -1 & 0 \\
  \vdots & \vdots & \vdots & \vdots \\
  -1 & 0 & \vdots & \vdots \\
  1 & 0 & \vdots & \vdots \\
  0 & -A_{a-1} & \vdots & \vdots \\
  t & \cdots & t & -t & \cdots & -t & 0 & -t \\
  0 & \cdots & 0 & 0 & \cdots & 0 & 1 & \frac{(a+1)^2}{4} - (1-t) \\
\end{pmatrix}.
$$

Expanding the determinant of $\Theta_a$ by the last column we obtain

(1) \quad $\Delta_a(t) \doteq \det \Theta_a = t \det A_{a+1} \det A_{a-1} + \frac{(a+1)^2}{4} (1-t) \det B_a$,

where $B_a$ equals $\Theta_a$ with the last row and column removed. In the following two lemmas we shall compute the determinants of $A_n$ and $B_n$ for all $n \in \mathbb{N}$.

**Lemma A.2** We have $\det A_n = \sum_{i=0}^{n} (-1)^{n-i} t^i$.

**Proof** The statement is trivially true for $A_1$. Let us suppose the lemma holds for $A_1, \ldots, A_{n-1}$ and we will show that it is then true for $A_n$, finishing the proof. After subtracting the second row from the first in $A_n$, expand the determinant by the first row to obtain

$$
\det A_n = - \det A_{n-1} + t \det C_{n-1},
$$

where the entries of the matrix $C_n$ are defined as

$$(c_n)_{ij} = \begin{cases}
(c_n)_{11} = t, \\
(c_n)_{ij} = (a_n)_{ij} & \text{for } (i, j) \neq (1, 1).
\end{cases}$$
Remark that the determinant of $C_n$ satisfies $\det C_n = t \det C_{n-1}$ and thus $\det C_n = t^n$. We have then $\det A_n = -\det A_{n-1} + t^n$, concluding the proof. □

**Lemma A.3** We have $\det B_n = t^{n+1} - t^n$.

**Proof** Subtracting row $n + 1$ to each of the preceding rows, and subtracting column $n + 1$ to each of the preceding columns in $B_n$, changes the first diagonal block into a matrix $A'_{n+1}$, whose determinant coincides with that of $A_{n+1}$ (since $A'$ is obtained from $A$ by elementary row and column operations). An analogous row and column operation changing the block $-A_{n-1}$ into $-A'_{n-1}$ yield the matrix

$$
B'_n = \begin{pmatrix}
A'_{n+1} & 0 & 0 \\
0 & -A'_{n-1} & 0 \\
0 & 0 & 1 \\
\vdots & \vdots & \ddots
\end{pmatrix}.
$$

Note that the described row and column operations have the property that for every $i < n + 1$ the matrix $A'_i$, the submatrix formed by the elements in the first $i$ rows and columns of $A'_{n+1}$, is exactly $A_i$. Indeed, the row operations change every entry of $A_i$ into $(a_{ij} - t)$ for $i, j = 1, \ldots, n - 1$, while the first $i$ entries in the last column of $A_{n+1}$ become all equal to $-t$. The following column operations, yielding $A'_{n+1}$, change the entries $(a_{ij} - t)$ to $(a_{ij} - t + t)$ and the claim follows. A completely analogous argument shows that the relevant submatrices of $-A'_{n-1}$ are actually equal to the corresponding $-A_i$. Taking all this into account we expand the determinant of $B'_n$ by the last column to obtain

$$
\det B_n = -(-t \det A_{n+1} \det(-A_{n-2}) + t \det C_1)
+ (-1)^{n+1}((-1)^{n-1} t \det A_n \det(-A_{n-1}) - t \det C_2),
$$

where $C_1$ and $C_2$ are easily seen to have vanishing determinant. By the proof of Lemma A.2 it then follows that

$$
\det B_n = (-1)^n t (\det A_{n+1} \det A_{n-2} - \det A_n \det A_{n-1})
= (-1)^n t ((t^{n+1} - \det A_{n+2}) \det A_{n-2} - \det A_n (t^{n-1} - \det A_{n-2}))
= (-1)^n t^n (t^2 \det A_{n-2} - \det A_n) = (-1)^n t^n ((-1)^n (t - 1)) = t^{n+1} - t^n. □

Algebraic & Geometric Topology, Volume 15 (2015)
Notice that for \( n \) even we have \( \det A_n = (t^{n+1} + 1)/(t + 1) \). Substituting in the expression (1) the results of the last two lemmas we obtain, since \( a \) is odd,

\[
\Delta_a(t) = \frac{t^{a+2} + 1}{t+1} \frac{t^{a+1} + 1}{t+1} - \frac{(a+1)^2}{4} t^{a-1}(t-1)^2
\]

\[
= \prod_{d|a+2, d \neq 1} \Phi_d(-t) \prod_{d|a, d \neq 1} \Phi_d(-t) - \frac{(a+1)^2}{4} t^{a-1}(t-1)^2,
\]

where \( \Phi_n \) stands for the \( n^{th} \) cyclotomic polynomial.
