Abstract

This paper clarifies that linear implication defines a branching-time preorder, preserved in all contexts, when used to compare embeddings of process in non-commutative logic. The logic considered is a first-order extension of the proof system $\text{BV}$ featuring a de Morgan dual pair of nominal quantifiers, called $\text{BV}_1$. An embedding of $\pi$-calculus processes as formulae in $\text{BV}_1$ is defined, and the soundness of linear implication in $\text{BV}_1$ with respect to a notion of weak simulation in the $\pi$-calculus is established. A novel contribution of this work is that we generalise the notion of a ‘left proof’ to a class of formulae sufficiently large to compare embeddings of processes, from which simulating execution steps are extracted. We illustrate the expressive power of $\text{BV}_1$ by demonstrating that results extend to the internal $\pi$-calculus, where privacy of inputs is guaranteed. We also remark that linear implication is strictly finer than any interleaving preorder.

Keywords: process calculi, simulation, proof theory, calculus of structures

1. Introduction

This paper contributes to a line of work formally relating logic and process calculi. The main interest is formally relating implication in a logical system to preorders over processes. In an early work (Miller 1993), this was done by embedding processes as formulae in a fragment of linear logic, formulated in a sequent calculus, and by interpreting implication as a form of may testing preorder. We continue this investigation, but using a more general proof system based on the calculus of structures (Brünnler and Tiu 2001; Guglielmi and Straßburger 2001). The calculus of structures is a generalisation of the sequent calculus in which proof systems can be designed that cannot be expressed in the sequent calculus (Tiu 2006), notably the non-commutative logic $\text{BV}$ (Guglielmi 2007) and its extensions $\text{NEL}$ (Guglielmi and Straßburger 2011; Straßburger and Guglielmi 2011) and $\text{MAV}$ (Horne 2015).

An established result (Bruscoli 2002) is that, for an embedding of processes in a fragment of CCS as formulae in $\text{BV}$ (Milner 1989) as formulae in $\text{BV}$, linear implication is strictly finer than (completed) trace inclusion. In another work (Horne et al. 2017), a tighter result is established, showing linear implication is strictly finer than pomset ideal inclusion — a classic notion of refinement for truly concurrent processes (Gischer 1988). Pomset ideals are defined with respect to certain homomorphisms over pomsets, which have finer non-interleaving properties than traces.
Indeed BV was motivated by pomset logic (Retoré 1997), so formal links with pomsets should be no surprise.

This paper sharpens previous work on processes as formulae in two directions: firstly, we extend our embedding to more expressive process languages including the $\pi$-calculus (Milner et al. 1992); and, secondly, we establish the soundness of linear implication with respect to finer process preorders, including weak simulation. A conference paper (Horne et al. 2016) introduced a first-order extension of MAV, called MAV1, featuring additive operators modelling choice, first-order universal and existential quantifiers and a novel de Morgan dual pair of nominal quantifiers called ‘new’ and ‘wen’, denoted $\exists$ and $\forall$, respectively. For the sake of clarity, here we restrict ourselves to the system BV1, excluding the additive operators that model choice in MAV1. This work clarifies that, for embeddings of processes as formulae, linear implication in BV1 is sound with respect to a fine notion of weak simulation called complete weak open simulation, in both the $\pi$-calculus and the $\pi I$-calculus (Sangiorgi 1996a). Some general proof normalisation techniques for extracting labelled transitions from proofs of certain forms are developed, which should be applicable to many process calculi beyond the fragment of the $\pi$-calculus explicitly considered in this paper.

Summary. Section 2 recalls established results for BV and lays out a roadmap for embeddings of processes as formulae. Section 3 introduces proof system BV1 and an embedding of $\pi$-calculus processes as formulae in BV1, along with statement of the main soundness result. Section 4 contains technical proof normalisation results, generalising established results on ‘left proofs’ developed in related work. Section 5 combines lemmas regarding proof normalisation to prove the soundness of linear implication with respect to complete weak open simulation. Section 6 highlights that techniques extended to the private inputs in the $\pi I$-calculus.

2. A Roadmap for the processes-as-formulae paradigm
This section touches on the history behind the search for a logical embedding of processes. We explain in what sense the calculus of structures addresses limitations of previous embeddings. The aim of this discussion is to clarify where the current paper sits in a roadmap towards a purely logical explanation of processes in the processes-as-formulae paradigm.

2.1 Distinct logical approaches to the semantics of processes
Since the early days of linear logic (Girard 1987), applications of linear logic to modelling interactive concurrent systems have been suggested. Approaches can be classified along two major thrusts: proofs-as-process and processes-as-formulae.

The proofs-as-processes paradigm (Abramsky 1994; Bellin and Scott 1994) is inspired by the famous Curry-Howard correspondence between intuitionistic logic and typed $\lambda$-calculi. Recent work in the proofs-as-processes approach links formulae in linear logic with session types and proofs of the formulae with processes that inhabit the given session type (Caires et al. 2016). We do not follow the proofs-as-processes paradigm in this work.

In the approach we follow, the processes-as-formulae paradigm, processes are directly embedded as formulae. An early attempt at embedding of process as formulae (Miller 1993) embeds the $\pi$-calculus as a theory in linear logic. In Miller’s encoding, input and output prefixes are encoded via higher-order predicates, whose behaviour is defined via a theory in a higher-order fragment of linear logic. In that work, the semantics of a process is defined in terms of the set of formulae provable in linear logic. Miller’s approach falls short of a full processes-as-formulae embedding in the sense that input and output prefixes are not logical in nature. Also, name restriction is not handled.
Figure 1. A roadmap situating implication in the spectrum of process preorders. Arrows indicate strict soundness results. Linear implication distinguishes the most processes, while trace inclusion identifies the most processes. Weak simulation and pomset ideals are unrelated to each other.

Another related, but distinct, line of work is a deep embedding approach where process expressions are encoded as terms in a suitably expressive logic, and both the operational semantics and the process preorder or equivalence are encoded as (co-)inductive definitions (McDowell et al. 2003; Tiu and Miller 2010; Bengtson and Parrow 2009). A limitation of such deep embeddings is implication in the logic does not directly define a preorder on processes.

2.2 A purely logical approach to prefixes

The calculus of structures (Guglielmi 2007) revives research into the processes-as-formulae paradigm. The calculus of structures is sufficiently expressive to define extensions of linear logic with a non-commutative operator. As observed previously (Bruscoli 2002), for a fragment of CCS, a suitable non-commutative operator eliminates the need to use higher-order predicates to encode prefixes, as in the work (Miller 1993), discussed in the subsection immediately above.

By defining a suitable logical system in the calculus of structures, we can directly map processes to formulae in that logical system. Furthermore, unlike approaches previously discussed, embedding of processes can be compared directly by using linear implication. The existence of a purely logical preorder over processes gives rise to natural questions:

— Where is linear implication situated in the spectrum of process preorders?
— Can expressive process calculi be embedded in systems defined in the calculus of structures?
— Given that there is a strong objective justification for this process preorder (cut elimination), are there also compelling applications for this process preorder in computer science?

The above questions set a broad agenda, to which the current paper contributes.

Figure 1 elaborates on the first question above. In Figure 1, process preorders are divided along two axes: the linear-time/branching-time axis (van Glabbeek 1990) and the interleaving/causality-preserving axis (Sassone et al. 1996). At the top of Figure 1 is trace inclusion, defined by subset inclusion over the set of all traces of a process. Trace inclusion is widely considered to be the coarsest preorder over processes; hence as a minimal requirement all other preorders should be sound with respect to trace inclusion, as indicated by the arrows in the figure. Along the linear-time/branching-time axis, trace inclusion can be refined by various weak simulations which have finer properties regarding the distributivity of non-deterministic choice, indicated by $\oplus$ in this work. In the other direction, along the interleaving/causality-preserving axis, models such as pomset ideals (Gischer 1988) retain the causal relationships between events. Non-interleaving
semantics ensure, for example, that, unlike trace inclusion and weak simulation, $a \triangleleft a$ and $a \triangleright a$ do not coincide – a property referred to as **autoconcurrency** (van Glabbeek and Goltz 2001).

We observe that linear implication has both branching-time and causality-preserving properties, hence is situated at the bottom of Figure 1. This work formally establishes the soundness of linear implication with respect to weak simulation, for a fragment the $\pi$-calculus.

### 2.3 Recalling established results for a purely logical embedding of processes

The first paper linking the calculus of structures with process calculi (Bruscoli 2002) embeds a fragment of $\text{CCS}$ processes into the system $\text{BV}$ in the calculus of structures. Formula $P$ is **provable** in $\text{BV}$, written $\vdash P$, whenever we have a derivation of zero or more rule instances with conclusion $P$ and premiss $\circ$ according to the rules of $\text{BV}$ in Figure 2.

**BCCS** is a fragment of $\text{CCS}$, consisting of only parallel composition and input/output prefixes. The embedding of BCCS processes as formulae in $\text{BV}$ is defined such that:

\[
\begin{align*}
\llbracket 1 \rrbracket_B &= \circ \\
\llbracket p | q \rrbracket_B &= \llbracket p \rrbracket_B \triangleright \llbracket q \rrbracket_B \\
\llbracket a.p \rrbracket_B &= a \circ \llbracket p \rrbracket_B \\
\llbracket \overline{a}.p \rrbracket_B &= \overline{a} \circ \llbracket p \rrbracket_B
\end{align*}
\]

A completed trace is defined by grammar $T ::= \circ | a \triangleleft T | \overline{a} \triangleleft T$. A process $p_0$ has completed trace $a_1 \triangleleft a_2 \ldots \triangleleft a_n$ whenever there exists a series of zero or more labelled transitions such that $p_0 \xrightarrow{a_1} p_1$, and $p_i \xrightarrow{a_{i+1}} p_{i+1}$ (skipping internal transitions due to interactions) such that $p_n$ has no further actions to execute, hence is completed. The following theorem is established connecting completed traces with BCCS processes by using provability.

**Theorem 2.1** (Bruscoli 2002). If $T$ is a completed trace and $p$ is a process in BCCS, then $\vdash T \rightarrow [p]_B$ in $\text{BV}$ if and only if $p$ has completed trace $T$.

We use negation-normal-forms where linear implication and linear negation are not primitive formulae, but instead are defined as functions that push negations to the atoms. Linear implication, $P \rightarrow Q$, is defined as $\overline{P} \triangleright Q$, where $\overline{P}$ is the linear negation of $P$, defined by the following function over formulæ.

\[
\begin{align*}
\overline{a} &= a \\
P \otimes Q &= \overline{P} \triangleright Q \\
P \triangleright Q &= P \otimes Q \\
\circ &= \circ \\
P \circ Q &= \overline{P} \triangleleft \overline{Q}
\end{align*}
\]

Linear negation defines de Morgan dualities. As in linear logic, the multiplicatives $\otimes$ and $\triangleright$ are de Morgan dual. Seq and the unit are self-dual, in the sense that their de Morgan dual operators are themselves. Cut elimination in $\text{BV}$ can be formulated as follows.

**Theorem 2.2** (Guglielmi 2007). If $\vdash C \{ P \otimes \overline{P} \}$, then $\vdash C \{ \circ \}$ in system $\text{BV}$.

Combining Theorems 2.1 and 2.2, we can establish the soundness of linear implication with respect to completed trace inclusion.

**Corollary 2.3** (soundness). For BCCS processes $p$ and $q$, if $\vdash [p]_B \rightarrow [q]_B$, then, for all completed traces $T$, if $p$ has completed trace $T$, then $q$ has completed trace $T$. 

**Figure 2.** The syntax, inference rules and structural congruence for $\text{BV}$. 
Proof. Assume that $\vdash [p]_B \rightarrow [q]_B$ holds and $p$ has completed trace $T$. By Theorem 2.1, we have that $\vdash T \rightarrow [p]_B$ holds. Hence by Theorem 2.2, $\vdash T \rightarrow [q]_B$ holds. Thereby, by Theorem 2.1, process $q$ has completed trace $T$, as required.

The original paper on BV and BCCS (Bruscoli 2002) did not explicitly state the above corollary. That paper concerned only executions rather than the more subtle semantic issues surrounding process preorders used for refining processes, as explored in this work. As observed in Figure 1, completeness of linear implication with respect to completed trace inclusion is impossible. The fact that linear implication does not exhibit autoconcurrency ($a \nrightarrow a \overset{\times}{\leftarrow} a$) is the simplest counterexample. Having no autoconcurrency is important for true-concurrency. For example, interleaving semantics, such as trace inclusion, exhibit autoconcurrency and therefore do not respect real-time. Hence linear implication is strictly finer than completed trace inclusion. Related work (Horne et al. 2017) tightens soundness by showing that linear implication is strictly finer than pomset ideals (Gischer 1988) which are finer than completed traces. That work also makes explicit how timing properties are respected by linear implication.

The rest of this paper is dedicated to both: extending the discussion to the $\pi$-calculus, which demands a treatment of name binding; and also, tightening Figure 1 by formally establishing the soundness of linear implication with respect to notions of weak simulation.

3. The first-order system BV1 and embeddings of mobile processes

We recall a first-order extension of BV, called BV1 (Horne et al. 2016), featuring a novel de Morgan dual pair of nominal quantifiers ‘new’ and ‘wen’ introduced to model private names as featured in the $\pi$-calculus. This section summarises key results required to recommend BV1 as a logical system and provides an embedding of a fragment of the $\pi$-calculus in BV1. This enables us to state the main result of the paper – that linear implication is sound with respect to weak simulation – although key lemmas are postponed until later sections.

3.1 The syntax, inference rules and structural rules of BV1

The proof system BV1 extends BV with the first-order quantifiers for all, new, wen and exists. The syntax and structural congruence are presented in Figure 3. The rules of the system, expressed as inference rules in Figure 4, can be applied in any context, where a context is a formula with a hole of the form $C\{\cdot\} := \{\cdot\} | C\{\cdot\} \odot P | P \odot C\{\cdot\} | \partial x.C\{\cdot\}$, where $\odot \in \{\times, \forall, \exists\}$ and $\partial \in \{\exists, \forall, \Pi, \forall\}$ and $\{\cdot\}$ is a hole into which any formula can be plugged. We assume that quantifiers bind tighter than binary operators, e.g., $\Pi x.P \forall Q$ denotes $(\Pi x.P) \forall Q$.

The structural congruence extends the structural congruence for BV with $\alpha$-conversion for all quantifiers and equivariance for nominal quantifiers. Equivariance allows both nested new and
wen operators to be exchanged. Note, for exists and for all, equivariance is a derived property, but equivariance must be explicitly induced in the structural congruence for nominal quantifiers.

Freshness is defined such that $x$ is fresh for a formula $P$, written $x \# P$, if and only if $x$ is not a member of the set of free variables of $P$, such that all quantifiers bind variables in their scope. A substitution is a mapping from variables to terms, which is an identity except for a finitely many variables. In this work, since we consider only name-passing calculi, we assume that the only terms in our logic are variables, but it is straightforward to extend the logic to allow function symbols as well. As standard, we assume that application of a substitution avoids capture of free variables. Application of substitutions is written in a postfix notation, e.g., $P \{v/ x\}$ denotes an application of substitution $\{v/ x\}$ to $P$.

Considerable creativity is permitted when defining the predicates and terms that form the atoms of the calculus. In the work on session types, atoms range over tuples containing any datatype equipped with a subtyping preorder (Ciobanu and Horne 2015). In the work on attack trees, atoms are infinitely divisible as actions are refined (Horne et al. 2017). For the $\pi$-calculus embeddings in this paper, atoms are simply pairs of first-order variables representing a channel and value passed on the given channel. Value passing extensions of the $\pi$-calculus can be embedded by extending with terms constructed from function symbols, constants and first-order variables.

Linear negation, defined by a function over formulae in Figure 3, extends the de Morgan dualities for $BV$ to quantifiers. The first-order quantifiers $\exists$ and $\forall$ are de Morgan dual, as are the nominal quantifiers $\mathcal{I}$ and $\mathcal{E}$. Linear implication is a derived connective and conservatively extends linear implication from the system $BV$ to $BV1$.

The inference rules of $BV1$ are given in Figure 4. A derivation is a sequence of zero or more inference rules, where the structural congruence can be applied at any point. We are particularly interested in proofs. Note that we overload notation where $\vdash P$, $Q$ means a derivation of any length with conclusion $P$ and premiss $Q$, as opposed to the less compact notation for derivations $P \vdash Q$ employed in the literature. If it is important that a particular rule instance is applied, we make this clear in the surrounding text.

**Definition 3.1.** A proof in $BV1$ is a derivation of the form $\vdash P$. When such a derivation exists, we say that $P$ is provable, and write $\vdash P$. 

\[
\begin{align*}
\frac{\forall x. (P \# Q) \rightarrow (P \# R)}{\forall x. (P \# Q) \rightarrow (P \# R)} & \text{ (close)} \\
\frac{\forall x. (P \# R)}{\forall x. (P \# Q) \rightarrow (P \# R)} & \text{ (tred new)} \\
\frac{\forall x. (P \# R)}{\forall x. (P \# Q) \rightarrow (P \# R)} & \text{ (tred name)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (fresh)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (new wen)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all new)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all wen)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all wen)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all wen)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all wen)} \\
\frac{\exists y. \forall x. P} {\exists y. \forall x. P} & \text{ (all wen)}
\end{align*}
\]
Figure 5. Syntax and labelled transitions for the $\pi$-calculus (plus symmetric rules for $p | q$). Function $n(\cdot)$ is such that $n(x(y)) = n(xy) = \{x, y\}$ and $n(\tau) = \emptyset$. Freshness predicate $x \# p$ is such that $x$ is fresh for $p$, where $z(x), p$ and $\nu x.p$ bind $x$ in $p$.

Cut elimination holds for $BV1$ as a consequence of cut-elimination for $MAV1$ (Horne et al. 2016). A full proof appears in a companion paper (Horne et al. 2018).

**Theorem 3.2 (cut elimination).** If $\vdash C \{ P \otimes \overline{P} \}$, then $\vdash C \{ \circ \}$ in system $BV1$.

Cut elimination is, of course, the cornerstone of a proof system. Consistency for $BV1$ can be established immediately in the sense that for any provable formula with at least one atom, the linear negation is not provable. Of particular relevance to this work is the following corollary.

**Corollary 3.3.** Linear implication defines a preorder, a reflexive and transitive relation, preserved by all contexts.

### 3.2 Embedding $\pi$-calculus processes as formulae in $BV1$

We assume that the reader is familiar with the syntax and operational semantics of the $\pi$-calculus (Milner et al. 1992). We consider a fragment of the $\pi$-calculus featuring parallel composition, input and output actions and private name binders. A (late) labelled transition system for this fragment of the $\pi$-calculus is recalled in Figure 5. A small but notable syntactic departure from the literature is the use of action $x[z]$ on labels to represent a bound output. This syntax is chosen to disambiguate semantically distinct concepts. In this paper, we would like to discuss both the input of the $\pi$-calculus and, later in this paper, the private input of the $\pi I$-calculus (Sangiorgi 1996a). Traditionally, these inputs use the same syntax but have distinct semantics. To disambiguate which input we discuss, we use $x(z)$ for the $\pi$-calculus input, which can receive both private and public names, and $x[z]$ for $\pi I$-calculus input, which can only receive a name if it is guaranteed to be private. The natural dual to private input is the output of a fresh private name, hence we also use syntax $x[z]$ for private outputs in the $\pi$-calculus. In our embeddings, the intuitive duality between $x[z]$ and $\overline{x}[z]$ is put on a precise foundation by the use of the dual operators $\Pi$ and $\mathcal{E}$.

Notice that the constant $1$ is used to indicate the successfully terminated process. We use the symbol $1$, rather than $0$ frequently used in the literature, so as to reserve $0$ for representing deadlock. Note that the use of $1$ is standard for semantics which are sensitive to the difference between a process stopping because of deadlock and stopping because it has successfully fulfilled all its obligations and has no further pending actions to execute, e.g., Bernardi and Hennessy (2013).

In the subsequent definitions, we require the following inductively defined predicate $\checkmark$, which holds whenever a process has successfully terminated.

**Definition 3.4.** $1 \checkmark$ holds, and, if $p \checkmark$ and $q \checkmark$, then $(p | q) \checkmark$ holds and $(\nu x.p) \checkmark$ holds.

This work will prove that linear implication is sound with respect to a notion of weak simulation. For weak simulations, if a process can perform a transition, then the simulating process
can perform zero or more $\tau$-transitions before matching the transition. In order to define weak simulation, we recall the following standard definitions.

**Definition 3.5.** $p_1 \leadsto p_n$ whenever $p_1 = p_n$ or there exist processes $p_2, \ldots, p_{n-1}$ such that $p_1 \xrightarrow{\tau} p_{i+1}$ for $1 \leq i < n$. If $p \leadsto q$ and $q \xrightarrow{-\tau} r$ and $r \leadsto s$, then $p \xrightarrow{\pi} s$.

For a sharper result, we consider **complete weak open simulation**. For the open part of the definition, we require the following definition of a history, where a history is a neat representation of name distinctions in open simulation (Sangiorgi 1996b) employed in related work on deep embeddings of open bisimulation using $\nabla$ quantifiers (Tiu and Miller 2010; Ahn et al. 2017).

**Definition 3.6.** A history is defined according to the grammar $h := \epsilon \mid h \cdot x^o \mid h \cdot x^i$. We denote with $n(h)$ the set of names (without the superscript $o$ and $i$) appearing in $h$. Substitution $\sigma$ respects history $h$ whenever, for all $h'$ and $h''$ such that $h = h' \cdot x^o \cdot h''$, we have $x \sigma = x$ and $x \notin n(h' \sigma)$.

Intuitively, the label $i$ on a name $x$ indicates that $x$ is a name associated with an input action, and the label $o$ indicates that it is a name associated with an output action.

For complete simulations the termination potential is preserved. In this weak setting, preserving termination potential means if a process has reached a successfully terminated state, as in Definition 3.4, then the simulating process can also perform zero or more internal $\tau$-transitions to reach a successfully terminated state. This leads us to the following version of weak simulation.

**Definition 3.7.** A complete weak open simulation is a relation between processes, indexed by a history, such that whenever $p \stackrel{h}{\sim} q$ holds, all of the following hold:

- If substitution $\sigma$ respects $h$, then $p \sigma \stackrel{h\sigma}{\sim} q \sigma$ holds.
- If $p \xrightarrow{xz} p'$, there exists $q'$ such that $q \xrightarrow{xz} q'$ and $p' \stackrel{h}{\sim} q'$.
- If $p \xrightarrow{x[z]} p'$, where variable $z$ is fresh for $p$, $q$ and $h$, then there exists process $q'$ such that $q \xrightarrow{x[z]} q'$ and $p' \stackrel{h,z}{\sim} q'$.
- If $p \xrightarrow{x(z)} p'$, where variable $z$ is fresh for $p$, $q$ and $h$, then there exists process $q'$ such that $q \xrightarrow{x(z)} q'$ and $p' \stackrel{h,z}{\sim} q'$.
- If $p \xrightarrow{\tau} p'$, then $p' \stackrel{h}{\sim} q$.

$p$ is simulated by $q$, written $p \preceq q$, whenever there exists a complete weak open simulation $\mathcal{R}$ such that $p \stackrel{x_0, \ldots, x_n}{\sim} q$ where $fv(p) \cup fv(q) \subseteq \{x_0, \ldots, x_n\}$, where $fv(p)$ denotes the set of free variables occurring in $p$.

We embed a fragment of the $\pi$-calculus in BV1. We assume an uninterpreted binary predicate $act$ which we use to encode action prefixes representing a channel and a message transmitted on the channel. However, for a more compact presentation, we shall simply write $xy$, where $x$ and $y$ are names, to denote $act(x, y)$.

$$\llbracket 1 \rrbracket_\pi = \circ \quad \llbracket p \mid q \rrbracket_\pi = \llbracket p \rrbracket_\pi \cdot \llbracket q \rrbracket_\pi \quad \llbracket \nu x. p \rrbracket_\pi = \forall x. \llbracket p \rrbracket_\pi \quad \llbracket x(z). p \rrbracket_\pi = \exists z. (xz \cdot \llbracket p \rrbracket_\pi) \quad \llbracket \overline{x} z. p \rrbracket_\pi = \overline{xz} \cdot \llbracket p \rrbracket_\pi$$

The main result of this paper is linear implication is sound with respect to the above notion of weak simulation, and consequently all coarser preorders (e.g. trace inclusion), including completed trace inclusion.
Theorem 3.8. For \( \pi \)-calculus processes \( p \) and \( q \), if \( \vdash [p]_\pi \rightarrow [q]_\pi \) in \( BV1 \), then \( p \leq q \).

The proof of the above theorem relies on Theorem 3.2 and results developed in the rest of this paper. We emphasise that, as for BV and BCCS, linear implication in \( BV1 \) is strictly finer than complete weak open simulation, since Definition 3.7 is still an interleaving preorder and, unlike interleaving preorders, linear implication preserves causality (cf. no autoconcurrency).

The following corollary of the above theorem emphasises a property of provable processes.

Corollary 3.9. If \( \vdash [p]_\pi \) in \( BV1 \), then \( p \) can terminate successfully.

Proof. Assuming \( \vdash [p]_\pi \), we have \( \vdash [1]_\pi \rightarrow [p]_\pi \) holds. By Theorem 3.8, we have \( 1 \leq p \), hence since, \( \exists \sqrt{ } \) and \( \forall \exists \) it must be the case that we have transitions \( p \xrightarrow{} p' \) such that \( p' \sqrt{ } \).

The above property is sometimes referred to as a multiparty compatibility property (Deniélou and Yoshida 2013) since it indicates whether a collection of endpoints can be scheduled such that, collectively, they implement a protocol without deadlocking. This observation has been exploited to provide a purely logical explanation of multiparty compatibility in session types, based on provability (Ciobanu and Horne 2015). Multiparty compatibility tells us nothing about linear implication as a notion of process refinement, hence is a much weaker property than Theorem 3.8. The above corollary does, however, emphasise an advantage of respecting ‘complete’ variants of weak simulations.

Further to the above benefit of complete simulations, observe that \( \exists x \) and \( \exists x \mid \forall y \) are unrelated according to complete weak open simulation. In contrast, if instead consider only weak open simulation, dropping the complete condition regarding termination, then \( \exists x \) would be simulated by \( \exists x \mid \forall y \) (a form of weakening property). Thus ‘complete’ simulations, just as implication in linear logic, are resource sensitive – resources are preserved by refinement.

### 3.3 Explanation for employing de Morgan dual nominal quantifiers

We illustrate why neither universal quantification nor an established self-dual nominal quantifier (Gacek et al. 2011; Miller and Tiu 2005; Pitts 2003) is capable of soundly modelling name restriction in a processes-as-formulae embedding. In the following, observe that \( \forall x. (\exists x \mid \exists x) \) outputs a fresh name twice, once on channel \( a \) and once on channel \( b \), but cannot output two distinct names in any execution. In contrast, observe \( \forall x. \exists x \mid \forall x. \exists x \) outputs two distinct fresh names before terminating, but cannot output the same name twice in any execution. Processes \( \forall x. (\exists x \mid \exists x) \) and \( \forall x. \exists x \mid \forall x. \exists x \) must not be related by weak simulation.

Suppose that universal quantifiers were unsoundly used to encode private names. In this scenario, processes \( \forall x. (\exists x \mid \exists x) \) and \( \forall x. \exists x \mid \forall x. \exists x \) are (wrongly) encoded as formulae \( \forall x. (\exists x \equiv \exists x) \) and \( \forall x. \exists x \equiv \forall x. \exists x \), respectively. The implication \( \forall x. \exists x \equiv \forall x. \exists x \rightarrow \forall x. (\exists x \equiv \exists x) \) is provable, but the respective processes are unrelated by simulation. To see why the processes are unrelated by simulation, observe both processes can output fresh names on channel \( a \) as follows.

\[
\forall x. (\exists x \mid \exists x) \xrightarrow{\bar{a}[x]} 1 \mid \exists x \quad \text{ and } \quad \forall x. \exists x \mid \forall x. \exists x \xrightarrow{\bar{a}[x]} 1 \mid \forall x. \exists x
\]

The above transitions lead to pair of processes \( 1 \mid \exists x \) and \( 1 \mid \forall x. \exists x \), where the former can only perform a free output transition \( 1 \mid \exists x \xrightarrow{\bar{b}[x]} 1 \mid 1 \), and the latter can only perform a bound output \( 1 \mid \forall x. \exists x \xrightarrow{\bar{b}[x]} 1 \mid 1 \). Hence neither process can simulate the other. Hence, under encoding of private names using universal quantifiers, implication would not be sound with respect to weak simulation, and hence Theorem 3.8 would not hold under that encoding.
Additionally, an embedding of private names must also avoid the following diagonalisation property: $\forall x.\forall y. P(x, y) \rightarrow \forall z. P(z, z)$. The self-dual nominal quantifiers of either Gabbay–Pitts or Miller–Tiu, as investigated in the calculus of structures (Roversi 2016), do successfully avoid the above diagonalisation property. However, encoding private names using any of these self-dual nominal quantifiers, say $\nabla$, leads to the following problem. Suppose that processes $\nu x.(\bar{a}x | \bar{b}x)$ and $\nu x.\bar{a}x | \nu x.\bar{b}x$ are encoded by formulae $\nabla x.(\bar{a}x \land \bar{b}x)$ and $\nabla x.\bar{a}x \land \nabla x.\bar{b}x$, respectively. In this case, linear implication $\nabla x.(\bar{a}x \land \bar{b}x) \rightarrow \nabla x.\bar{a}x \land \nabla x.\bar{b}x$ is provable.² This implication is also unsound with respect to simulation, since, as explained above, the processes are unrelated by simulation.

Our new quantifier $\Pi$, distinct from the Gabbay–Pitts operator, addresses the above limitations of universal quantification and established self-dual nominal quantifiers. In addition to avoiding diagonalisation, our $\Pi$ quantifier does not distribute over parallel composition in either direction. The formulae $\Pi x.(\bar{a}x \land \bar{b}x)$ and $\Pi x.\bar{a}x \land \Pi x.\bar{b}x$ are, correctly, unrelated by linear implication.

### 3.4 Translating from labelled transitions to proofs (but not the converse)

Theorem 3.8 requires the following lemmas. The first follows by a trivial induction. The second translates any labelled transition into a proof and relies on cut elimination (Theorem 3.2).

**Lemma 3.10.** $[p]_{\pi'} \vdash [p\tau_{\pi'}]_{\pi}$.  

**Lemma 3.11.** The following statements hold:

- If $p \xrightarrow{x[z]} q$, then $\vdash [\nu z.\bar{x}z.q]_{\pi} \rightarrow [p]_{\pi}$.  
- If $p \xrightarrow{\bar{x}} q$, then $\vdash [\bar{x}.q]_{\pi} \rightarrow [p]_{\pi}$.  
- If $p \xrightarrow{x(z)} q$, then $\vdash [x(z).q]_{\pi} \rightarrow [p]_{\pi}$.  
- If $p \xrightarrow{\tau} q$, then $\vdash [q]_{\pi} \rightarrow [p]_{\pi}$.  

**Proof.** The proof follows by structural induction on the derivation of a labelled transition.

Consider the base cases, where a label transition holds by an axiom of the labelled transition system. For axiom $x(z).p \xrightarrow{x(z)} p$, observe $\vdash [x(z).p]_{\pi} \rightarrow [x(z).p]_{\pi}$ holds by reflexivity of linear implication (Corollary 3.3). Similarly, for axiom $\bar{x}.p \xrightarrow{\bar{x}} p$, we have $\vdash [\bar{x}.p]_{\pi} \rightarrow [\bar{x}.p]_{\pi}$.

Consider the case of the open rule:

\[
\frac{p \xrightarrow{{\bar{x}}z} q}{\nu z.p \xrightarrow{\bar{x}[z]} q} \quad \text{if } x \neq z.
\]

Assume as the induction hypothesis that $\vdash [\bar{x}.q]_{\pi} \rightarrow [p]_{\pi}$ holds, such that $x \neq z$. Using this assumption, we can establish $\vdash [x[z].q]_{\pi} \rightarrow [\nu z.p]_{\pi}$ holds, and assume $x \neq z$.

\[
\frac{\vdash [x[z].q]_{\pi} \rightarrow [\nu z.p]_{\pi}}{\Pi z.\frac{\vdash [x[z].q]_{\pi}}{\Pi z.\vdash [x[z].q]_{\pi} \rightarrow [p]_{\pi}}} \quad \text{by tidy}
\]

\[
\vdash [\nu z.\bar{x}z.q]_{\pi} \rightarrow [p]_{\pi} \quad \text{by the induction hypothesis}
\]

\[
\exists z.\left( [x[z].q]_{\pi} \rightarrow [\Pi z.[p]_{\pi} \right) \quad \text{by close.}
\]

Consider the case of the interaction rule involving a private name:

\[
\frac{p \xrightarrow{x(z)} p' \quad q \xrightarrow{\bar{x}[z]} q'}{p \mid q \xrightarrow{\tau} \nu z.(p' \mid q')}.
\]
Assume the induction hypotheses, \( \vdash [x(z).p']_\pi \rightarrow p \) and \( \vdash [\overline{x}[z].q']_\pi \rightarrow q \), hold. Now observe \( \vdash ([x(z).p']_\pi \rightarrow p) \odot ([\overline{x}[z].q']_\pi \rightarrow q) \rightarrow [vz.(p' \mid q')]_\pi \rightarrow [p \mid q]_\pi \) holds, by the following proof.

\[
\frac{\vdash [x(z).p']_\pi \rightarrow p \quad \vdash [\overline{x}[z].q']_\pi \rightarrow q}{\vdash [vz.(p' \mid q')]_\pi \rightarrow [p \mid q]_\pi}
\]

Hence by Theorem 3.2, \( \vdash [vz.(p' \mid q')]_\pi \rightarrow [p \mid q]_\pi \), as required.

Consider the interaction rule of the following form, involving a free output:

\[
\frac{p \overset{x(z)}{\rightarrow} p' \quad q \overset{\pi}{\rightarrow} q'}{p \mid q \overset{1}{\rightarrow} p' \mid q'}
\]

As the induction hypothesis assume that \( \vdash [x(z).p']_\pi \rightarrow p \) and \( \vdash [\overline{x}[y].q']_\pi \rightarrow q \) hold. Also observe \( \vdash ([x(z).p']_\pi \rightarrow p) \odot ([\overline{x}[y].q']_\pi \rightarrow q) \rightarrow [p' \mid q]_\pi \rightarrow [p \mid q]_\pi \) holds, as established by the following proof and Lemma 3.10.

\[
\frac{\vdash [x(z).p']_\pi \rightarrow p \quad \vdash [\overline{x}[y].q']_\pi \rightarrow q}{\vdash [p' \mid q]_\pi \rightarrow [p \mid q]_\pi}
\]

Hence, by Theorem 3.2, \( \vdash [p' \mid q]_\pi \rightarrow [p \mid q]_\pi \), as required.

Consider the case of the contextual rule for new names instantiated for private output:

\[
\frac{p \overset{\pi[z]}{\rightarrow} q}{v \pi.p \overset{\pi[z]}{\rightarrow} v \pi.q}
\]

As the induction hypothesis assume that \( \vdash [\pi[z].q]_\pi \rightarrow p \) holds, where \( y \) is such that \( x \neq y \) and \( z \neq y \). Using these assumptions, we can directly establish that \( \vdash [\pi[z].v \pi.q]_\pi \rightarrow [v \pi.p]_\pi \) holds, by the following proof. Note the use of the equivariance structural rule.
As the induction hypothesis assume that

\[ \vdash \exists z. (xz \triangleright [q]_\pi) \triangleright [p]_\pi \]

induction hypothesis

\[ \exists y. \exists z. (xz \triangleright [q]_\pi) \triangleright \exists y. [p]_\pi \]

close

\[ \forall z. (xz \triangleright [q]_\pi) \triangleright [y]_\pi \]

equivariance

\[ \exists z. (xz \triangleright [q]_\pi) \triangleright [y]_\pi \]

wen, since \( x \neq y \) and \( z \neq y \).

Consider the contextual rule for parallel composition, instantiated for private output:

\[ \frac{p \triangleright \bar{x}[z]}{p \triangleright q} \quad z \neq r. \]

As the induction hypothesis assume that \( \vdash \bar{x}[z].q \triangleright \bar{p} \) holds, where \( z \neq r \). By these assumptions, \( \vdash \bar{x}[z].(q \triangleright r) \triangleright \bar{p} \) holds, as established by the following proof.

\[ \vdash \exists z. (xz \triangleright [q]_\pi) \triangleright \exists y. [p]_\pi \]

reflexivity

\[ \vdash \exists z. (xz \triangleright ([q]_\pi \otimes [r]_\pi) \triangleright [r]_\pi) \triangleright \bar{p} \]

switch

\[ \vdash \exists z. (xz \triangleright ([q]_\pi \otimes [r]_\pi) \triangleright [r]_\pi) \triangleright \bar{p} \]

sequence

\[ \exists z. (xz \triangleright ([q]_\pi \otimes [r]_\pi) \triangleright [r]_\pi) \triangleright \bar{p} \]

wen, since \( z \neq r \).

Remaining cases for the contextual rules instantiated with free output, \( \tau \) and input are similar to the previous two cases. Hence, by induction on the structure of the derivation of a labelled transition, a corresponding provable formula can be constructed as required. \( \square \)

**Remark 3.12.** Interestingly, the equivariance structural rule (Figure 3) is a design decision in the sense that cut elimination is still provable for BV1 without equivariance. However, equivariance is a requirement for soundly embedding the labelled transitions of the \( \pi \)-calculus (Lemma 3.11). Consider labelled transition \( v_y.v_x.\bar{x}.\bar{w}_y.\bar{x}.\bar{y} \triangleright v_y.\bar{w}_y \). The implication corresponding to the labelled transition: \( \vdash v_y.v_x.\bar{x}.\bar{w}_y \triangleright \bar{p} \) is provable only if we have equivariance.

The converse of each statement in Lemma 3.11 does not necessarily hold. Hence, although we can embed labelled transitions as proofs, the same techniques cannot be applied to extract labelled transitions from proofs. Additional techniques developed in the next section are required.

**4. Left proofs and normalisation properties required for establishing the main result**

This section provides technical devices required to establish the soundness of linear implication with respect to weak simulation (Theorem 3.8). These techniques, which are forms of proof normalisation properties, permit greater control of where in a proof the interaction of atoms, instantiation of existential quantifiers and extrusion of quantifiers each occur. These lemmas are critical for extracting labelled transitions from proofs in subsequent sections.
4.1 Generalising established observations on left proofs in BV

Before tackling BV1, we begin by generalising some established result for BV (Bruscoli 2002). The proof of Proposition 2.1 concerning BCCS employs a normalisation result transforming certain proofs in BV to 'left proofs'. In BV, a left proof is such that atomic interaction can only be applied inside left contexts, where the hole appears to the left of binary connectives, as follows: \( L\{ \cdot \} := \{ \cdot \} \mid L\{ \cdot \} \circ P \mid L\{ \cdot \} \bowtie P \mid L\{ \cdot \} \otimes P \). For example, the formula \( (a \circ (b \bowtie c)) \bowtie ((\overline{a} \bowtie \overline{b}) \bowtie \overline{c}) \) has a left proof where the atomic interaction rule must apply first to \( a \) before \( b \), then finally \( c \). The following established result is restricted to formulae in BV in which \emph{times} \( \otimes \) never appears.

\textbf{Proposition 4.1 (Bruscoli 2002).} If formula \( P \) contains no times operator and \( \vdash P \) in BV, then there exists \( Q \) such that there is a derivation \( \vdash \) using the sequence rule only and \( Q \) is provable using only the atomic interaction rule applied in left contexts.

The following example shows there are formulae for which there is no left proof:

\[ \vdash \left( \left( (\overline{a} \bowtie \overline{b}) \otimes (\overline{d} \bowtie \overline{e}) \right) \bowtie \left( \overline{c} \bowtie \overline{f} \right) \right) \bowtie (a \circ ((b \bowtie c) \otimes (\overline{g} \bowtie \overline{h}))) \bowtie \left( d \circ \left( (e \circ f) \otimes (\overline{h} \bowtie \overline{h}) \right) \right). \]

The above formula has no left proof in BV, where interaction is restricted to left contexts. The difficulty is that the atoms \( g \) and \( h \) must interact before associativity can be applied to allow the sequence rule to be correctly applied, as follows:

\[
\begin{array}{c}
\begin{array}{c}
(\left( (\overline{a} \bowtie \overline{b}) \otimes (\overline{d} \bowtie \overline{e}) \right) \bowtie \left( \overline{c} \bowtie \overline{f} \right) )
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{reflexivity}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
(\left( (\overline{a} \bowtie \overline{b}) \otimes (\overline{d} \bowtie \overline{e}) \right) \bowtie \left( \overline{c} \bowtie \overline{f} \right) )
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{sequence}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
(\left( (\overline{a} \bowtie \overline{b}) \otimes (\overline{d} \bowtie \overline{e}) \right) \bowtie \left( \overline{c} \bowtie \overline{f} \right) )
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{atomic interaction.}
\end{array}
\end{array}
\]

Fortunately, although there exist formulae with no left proof, it is possible to generalise Proposition 4.1 to formulae of the form \( P \rightarrow Q \), where \( P \) and \( Q \) contain no \emph{times} operator and \emph{switch} may be applied along with \emph{sequence}.

\textbf{Proposition 4.2 (generalisation of Proposition 4.1).} For formulae \( P \) and \( Q \) in which no \emph{times} operator occurs, if \( \vdash P \rightarrow Q \) in BV, then there exists a left proof of \( P \rightarrow Q \) in BV.

Now observe that embeddings of BCCS processes do not use the \emph{times} operator. Hence, by the above observation, for any BCCS processes \( p \) and \( q \), if \( \vdash [p]_B \rightarrow [q]_B \), then we can always construct a left proof of the same formula. For example, \([b \mid c]_B \rightarrow [\overline{a} \bowtie \overline{b} \cdot d \mid a \cdot c \cdot d]_B\) has the following left proof.

\[
\begin{array}{c}
\begin{array}{c}
\left( \overline{b} \bowtie \overline{b} \right) \bowtie \left( \overline{c} \bowtie \overline{c} \right) \bowtie \left( \overline{d} \bowtie \overline{d} \right)
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{atomic interaction}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\left( \overline{a} \bowtie \overline{a} \right) \bowtie \left( \overline{b} \bowtie \overline{b} \right) \bowtie \left( \overline{c} \bowtie \overline{c} \right) \bowtie \left( \overline{d} \bowtie \overline{d} \right)
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{atomic interaction}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\left( \overline{a} \bowtie \overline{a} \right) \bowtie \left( \overline{b} \bowtie \overline{b} \right) \bowtie \left( \overline{c} \bowtie \overline{c} \right) \bowtie \left( \overline{d} \bowtie \overline{d} \right)
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{atomic interaction}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\left( \overline{a} \bowtie \overline{a} \right) \bowtie \left( \overline{b} \bowtie \overline{b} \right) \bowtie \left( \overline{c} \bowtie \overline{c} \right) \bowtie \left( \overline{d} \bowtie \overline{d} \right)
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{switch}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\left( \overline{a} \bowtie \overline{a} \right) \bowtie \left( \overline{b} \bowtie \overline{b} \right) \bowtie \left( \overline{c} \bowtie \overline{c} \right) \bowtie \left( \overline{d} \bowtie \overline{d} \right)
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\text{sequence.}
\end{array}
\end{array}
\]
Furthermore, from a left proof, we know how to establish the soundness of linear implication with respect to complete weak simulation suitably defined for BCCS. For example, from the above proof, we can use a procedure to construct a complete weak simulation $S$, defined to be the least relation containing the following pairs of processes:

\[(b \mid c) S (\overline{a} \cdot \overline{b} \mid a \cdot c \cdot d) \quad (1 \mid c) S (\overline{a} \cdot \overline{c} \mid d) \quad (b \mid 1) S (\overline{b} \cdot \overline{a} \mid d) \quad (1 \mid 1) S (\overline{a} \cdot \overline{d}).\]

In the interest of space, we proceed immediately to the $\pi$-calculus, rather than explaining this procedure on BCCS. The procedures for each calculus are similar, except the $\pi$-calculus requires additional mechanisms for handling quantifiers.

### 4.2 Extending the concept of left proofs to BV1

Here we define left proofs in BV1, by adapting the definition of left proofs for BV such that quantifiers are accommodated. The concept of a left context in BV1 is defined as follows.

**Definition 4.3.** A left context $L\{ \cdot \}$ is defined according to the following grammar:

\[L\{ \cdot \} ::= \{ \cdot \} \mid L\{ \cdot \} \triangleright P \mid L\{ \cdot \} \triangleright P \mid L\{ \cdot \} \otimes P \mid \text{Hx}.L\{ \cdot \} \mid \forall x.L\{ \cdot \}\]

The interaction fragment of BV1 consists of the rules atomic interaction, tidy1 and tidy name. The cooling fragment consists of all other rules of BV1. A left derivation is a derivation where rules of the interaction fragment are applied only in a left context. A left proof of formula $P$ in BV1 is a proof established using a left derivation.

We require a number of technical lemmas to establish the key normalisation property, Proposition 4.11. Firstly, observe that instances of atomic interaction can be pushed upwards in a proof until they are in a left context. In order to achieve this in BV1, we should first permute all tidy rules upwards, since they may obstruct an atomic interaction from beingpermuted upwards. To see how this obstruction can happen, consider the following proof.

\[
\begin{align*}
\begin{array}{c}
\circ \\
(\overline{ab} \triangleright ab) \quad \text{atomic interaction} \\
(\overline{ab} \triangleright ab) \triangleright \text{Iz}.\circ \\
(\overline{ab} \triangleright ab) \triangleright \text{Iz}.(\overline{cz} \triangleright cz) \quad \text{atomic interaction} \\
(\overline{ab} \triangleright ab) \triangleright \text{Iz}.(\overline{cz} \triangleright \exists y . cy) \quad \text{select1} \\
(\overline{ab} \triangleright ab) \triangleright (\text{Iz}.\overline{cz} \triangleright \exists y . cy) \quad \text{extrude new} \\
(\overline{ab} \triangleright ab) \triangleright (\text{Iz}.\overline{cz} \triangleright \exists y . cy) \quad \text{sequence} \\
(\overline{ab} \triangleright \text{Iz}.\overline{cz}) \triangleright (ab \triangleleft \exists y . cy) \quad \text{select1}. \\
\end{array}
\end{align*}
\]

In the above proof, the tidy name rule followed by one of the atomic interaction rules can be permuted upwards until they are in a left context. The last three lines of the above proof can thereby be transformed to the following proof, where rules are only applied in left contexts.

\[
\begin{align*}
\begin{array}{c}
\circ \\
(\overline{ab} \triangleright ab) \quad \text{atomic interaction} \\
(\overline{ab} \triangleright ab) \triangleleft \text{Iz}.(\overline{cz} \triangleright cz) \quad \text{atomic interaction} \\
\end{array}
\end{align*}
\]
There is a critical subtlety: a restriction is, as in \(\text{BV}\), rules of the interaction fragment do not permute over all other rules. In particular, we should take care about where the \(\text{times}\) operator appears in derivations. To see why, consider the following derivation involving \(\text{tidy name}\), \(\text{medial new}\) and the \(\text{times}\) operator.

\[
\begin{align*}
C\{ \text{II}x.(P \bowtie Q) & \bowtie \text{II}x.(R \bowtie S) \} \\
\rightarrow & \\
C\{ \text{II}x.(P \bowtie Q \bowtie R \bowtie S) \} & \text{medial new} \\
\rightarrow & \\
C\{ \text{II}x.(P \bowtie (\text{II}y.\bowtie S) \bowtie \text{II}y.\bowtie \text{II}y.\bowtie R \bowtie \text{II}y.\bowtie S) \} & \text{tidy name}
\end{align*}
\]

The \(\text{tidy name}\) rule in the above derivation cannot be permuted above the \(\text{medial new}\) rule in \(\text{BV1}\).

For formulae in \(\text{BV1}\) without \(\text{times}\), the following normalisation property holds.

**Lemma 4.4.** Assume that \(P\) and \(R\) contain no \(\text{times}\) operator. If there is a derivation \(\overrightarrow{\varphi}\) in \(\text{BV1}\), then there exists \(Q\) such that: there is a derivation \(\overrightarrow{\psi}\) in the cooling fragment of \(\text{BV1}\) and a derivation \(\overrightarrow{\varphi}\) in the interaction fragment of \(\text{BV1}\).

In contrast to the above, notice that \(\text{times}\) may appear in the formula in the following.

**Lemma 4.5.** If \(P\) is provable in the interaction fragment of \(\text{BV1}\), then \(P\) has a left proof in \(\text{BV1}\).

A key case for the above lemma, known already for \(\text{BV}\), is the following derivation.

\[
\begin{align*}
C\{ \bowtie \} & \\
\rightarrow & \\
C\{ \text{a} \bowtie a \} & \text{atomic interaction} \\
\rightarrow & \\
C\{ a \bowtie (b \bowtie (b \bowtie b)) \} & \text{atomic interaction}.
\end{align*}
\]

Observe that, in the derivation above, the atoms \(b\) do not interact in a left context. To ensure that \(\text{atomic interaction}\) is always applied in a left context, the above derivation can be transformed to the derivation below.

\[
\begin{align*}
C\{ \bowtie \} & \\
\rightarrow & \\
C\{ b \bowtie b \} & \text{atomic interaction} \\
\rightarrow & \\
C\{ (a \bowtie a) \bowtie (b \bowtie b) \} & \text{atomic interaction} \\
\rightarrow & \\
C\{ a \bowtie (a \bowtie (b \bowtie b)) \} & \text{sequence}.
\end{align*}
\]

No further problematic cases are introduced by quantifiers.

As a technical device, we define a form of restricted context called a \(\text{killing context}\) (Chaudhuri et al. 2011) consisting of a hole surrounded by quantifiers \(\forall\) and \(\Pi\).

**Definition 4.6 (killing context).** Grammar \(\mathcal{K}\{ \cdot \} ::= \{ \cdot \} | \forall x.\mathcal{K}\{ \cdot \} | \Pi x.\mathcal{K}\{ \cdot \}\) defines killing contexts.

Splitting, proven in a companion paper as the main technical lemma required for proving cut elimination (Horne et al. 2018), is formulated as follows for \(\text{BV1}\). Traditionally, in the sequent calculus, any connective can be selected and a corresponding rule applied. Splitting normalises proofs to generalise this feature of sequents to the calculus of structures.

**Lemma 4.7 (splitting).** The following statements hold.
— For any atom \( \alpha \), if \( \vdash \alpha \otimes Q \), there exists killing context \( K \{ \cdot \} \) such that if \( x \) appears in \( K \{ \cdot \} \), then \( x \neq \alpha \), and there exists derivation \( \vdash_{Q} \).

— For any atom \( \alpha \), if \( \vdash \alpha \otimes Q \), there exists killing context \( K \{ \cdot \} \) such that if \( x \) appears in \( K \{ \cdot \} \), then \( x \neq \alpha \), and there exists derivation \( \vdash_{Q} \).

— If \( \vdash (P \otimes Q) \otimes R \), then there exist formulae \( V \) and \( W \) such that \( \vdash P \otimes V \) and \( \vdash Q \otimes W \), and killing context \( K \{ \cdot \} \) such that \( \vdash_{Q} \) and if \( x \) appears in \( K \{ \cdot \} \), then \( x \neq (P \otimes Q) \).

— If \( \vdash (P \circ Q) \otimes R \), then there exist formulae \( V \) and \( W \) such that \( \vdash P \otimes V \) and \( \vdash Q \otimes W \), and killing context \( K \{ \cdot \} \) such that \( \vdash_{Q} \) and if \( x \) appears in \( K \{ \cdot \} \), then \( x \neq (P \circ Q) \).

— If \( \vdash \exists x. P \otimes Q \), then there exist formulae \( V \) and \( W \) where \( x \neq V \) and \( \vdash P \otimes W \) and either \( V = W \) or \( V = \exists x. W \), such that we have \( \vdash_{Q} \).

— If \( \vdash \exists x. P \otimes Q \), then there exist formulae \( V \) and \( W \) where \( x \neq V \) and \( \vdash P \otimes W \) and either \( V = W \) or \( V = \exists x. W \), such that we have \( \vdash_{Q} \).

— If \( \vdash \exists x. P \otimes Q \), then there exist formulae \( V \) and value \( v \) such that \( \vdash P \{v/\alpha\} \otimes V \), and killing context \( K \{ \cdot \} \) such that \( \vdash_{Q} \) and if \( y \) appears in \( K \{ \cdot \} \), then \( y \neq (\exists x. P) \).

— If \( \vdash \forall x. P \otimes Q \), then, for any term \( t \), \( \vdash P \{t/\alpha\} \otimes Q \).

Although splitting was developed to establishing cut elimination, the technique has proven to be useful for solving other problems. Essentially, splitting can be used to guide a proof that proceeds by induction over the structure of formulae. Such structural induction is trivial in the sequent calculus, since rules in sequents can only be applied to the root connective of a formula in a sequent. Hence, splitting can be seen as a recovering part of the power of the sequent calculus in the more expressive setting of the calculus of structures.

A derivation over contexts \( \frac{c(\cdot|\cdot)}{c(\cdot|\cdot)} \) means, for all formulae \( U \), \( \frac{c(\cdot|\cdot)}{c(\cdot|\cdot)} \), i.e., no rule is applied to the formula inserted in the hole. The following lemma ensures that rules of the interaction fragment can be confined to parts of formulae of a certain form.

**Lemma 4.8.** Assume that, for \( \otimes \in \{ \otimes, \circ, \otimes \} \), we have derivation \( \frac{K \{ Q_{0} \otimes Q_{1} \}}{s} \) in the interaction fragment. There exist context \( c(\cdot|\cdot) \) and formulae \( S_{0} \) and \( S_{1} \), such that, in the interaction fragment, \( \frac{K_{1}}{S_{0}}, \frac{K_{2}}{S_{1}}, \frac{K_{3}}{S_{2}} \), and \( c(\cdot|\cdot) \); and also \( \frac{c(\cdot|\cdot)}{s} \) in the cooling fragment.

Assume \( \frac{K_{1}}{s} \) in the interaction fragment, where \( \tilde{D} \in \{ \vee, \square, \exists, \forall \} \). There exist context \( c(\cdot|\cdot) \) and formula \( R \) such that both \( \frac{c(\cdot|\cdot)}{Q} \) and \( c(\cdot|\cdot) \) in the interaction fragment, and \( \frac{c(\cdot|\cdot)}{s} \) in the cooling fragment.

We also require the following technical lemmas, used to break down certain derivations.

**Lemma 4.9.** Assume \( \frac{K_{1}}{c(\cdot|\cdot)} \) using only the interaction fragment, and \( K \{ \cdot \} \) is a killing context. In this situation, there exists left context \( L \{ \cdot \} \) such that we can construct a left derivation \( \frac{L_{1}}{c(\cdot|\cdot)} \) and, also, derivation \( \frac{L_{1}}{C_{1}(\cdot|\cdot)} \) using only the interaction fragment.

To understand the above lemma, consider context \( (\overline{a} \otimes a) \circ (\overline{b} \otimes b) \). There is no way to transform this context to \( (\cdot | \cdot) \), by applying interaction rules only in left contexts. However, we can first apply atomic interaction in a left context \( (\overline{a} \otimes a) \circ (\overline{b} \otimes b) \), observing we obtain a premiss...
forming another left context. Assuming that a formula $P$ with a left proof is plugged into the context, we can construct a left proof $\mathcal{L}(\alpha \|$$_{\beta \gamma \delta})$. Thereby interactions to the right of the hole in the context are suspended to the end of the proof.

The following property is a simple distributivity property satisfied by left contexts.

**Lemma 4.10.** Let $\mathcal{L}(\alpha \|$$_{\beta \gamma \delta})$, using the cooling fragment, for all left contexts $\mathcal{L} \{ \cdot \}$, such that for all variables $y$ appearing as binders in $\mathcal{L} \{ \cdot \}$ we have $y \neq Q$.

Although we cannot construct a left proof for all formulae containing $times$, as discussed for BV, we can handle a large class of formulae. The class of formulae we are concerned with is those formulae of the form $\mathcal{K} \{ P \rightarrow Q \}$, where $P$ and $Q$ contain no $times$ operator and $\mathcal{K} \{ \cdot \}$ is a killing context. Fortunately, this class includes all formulae required for comparing embeddings of processes using linear implication. By combining the above technical lemmas, we obtain the following more general property transforming proofs into left proofs.

**Proposition 4.11.** Assume that $P$ and $Q$ contain no $times$ operator and $\mathcal{K} \{ \cdot \}$ is a killing context. If $\mathcal{K} \{ P \rightarrow Q \}$ has a proof in BV1, then $\mathcal{K} \{ P \rightarrow Q \}$ has a left proof in BV1.

**Proof.** The trick in this proof is, since $\mathcal{P}$ contains no $par$ operator, we can proceed by induction on the structure of $\mathcal{P}$ in $\vdash \mathcal{P} \rightarrow Q$, applying splitting (Lemma 4.7) at each step. Also observe that the killing context can be trivially removed by repeatedly applying splitting.

Consider the base case where $P = \alpha$, and $\vdash \alpha \nabla Q$. Since $Q$ contains no $times$ operator, by Lemma 4.4, there exists $R$ such that we have derivation in the cooling fragment $\mathcal{R} \{ \cdot \}$ and a proof of $R$ in the interaction fragment. Since the proof of $R$ is in the interaction fragment, by Lemma 4.5, there is a left proof of $R$, and hence a left proof of $\alpha \nabla Q$.

In the base case for atoms, $\vdash \alpha \nabla Q$ where $Q$ contains no $times$. By splitting (Lemma 4.7), for some killing context $\mathcal{K} \{ \cdot \}$, such that if $y$ appears in $\mathcal{K} \{ \cdot \}$, then $y \neq \alpha$, we have a derivation $\mathcal{K} \{ \pi \} \vdash_{\mathcal{P}} \mathcal{Q} \{ \cdot \}$. Hence, by Lemma 4.4, for some $\mathcal{L} \{ \cdot \}$ we have $\mathcal{L} \{ \pi \} \vdash_{\mathcal{P}} \mathcal{Q} \{ \cdot \}$ in the cooling fragment and $\mathcal{K} \{ \pi \} \vdash_{\mathcal{L}} \mathcal{K} \{ \pi \}$ in the interaction fragment. By Lemma 4.9, there exists left context $\mathcal{L} \{ \cdot \}$ such that we have left derivation $\mathcal{L} \{ \pi \} \vdash_{\mathcal{L}} \mathcal{K} \{ \pi \}$ and in the interaction fragment we have derivation $\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}} \mathcal{L} \{ \alpha \nabla \pi \}$. Now observe $\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}} \mathcal{L} \{ \alpha \nabla \pi \}$.

is provable in the interaction fragment as follows: $\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}} \mathcal{L} \{ \alpha \nabla \pi \}$. Therefore, by Lemma 4.5, there is a left proof of $\mathcal{L} \{ \alpha \nabla \pi \}$. By using the left proof of $\mathcal{L} \{ \alpha \nabla \pi \}$, a left proof of $\alpha \nabla Q$ can be constructed as follows. Note that Lemma 4.10 can be applied, since for all $y$ appearing in $\mathcal{K} \{ \cdot \}$ we have $y \neq \alpha$, and in the derivation from $\mathcal{L} \{ \cdot \}$ to $\mathcal{K} \{ \cdot \}$ only the interaction fragment is applied; hence for all $y$ appearing as binders in $\mathcal{L} \{ \cdot \}$, we have $y \neq \alpha$.

\[
\begin{array}{l}
\frac{\alpha \nabla Q}{\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}}} \quad \text{in the cooling fragment (Lemma 4.10)} \\
\frac{\frac{\alpha \nabla Q}{\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}}}}{\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}}} \quad \text{in the cooling fragment (Lemma 4.4)} \\
\frac{\frac{\alpha \nabla Q}{\mathcal{L} \{ \cdot \} \vdash_{\mathcal{L}}}}{\alpha \nabla Q} \quad \text{a left proof (Lemma 4.5)} \\
\end{array}
\]

**Inductive case involving times.** Consider the inductive case where $\vdash (P_0 \nabla P_1) \rightarrow R$, where $P_0$, $P_1$ and $R$ contain no $times$ operator (hence $\mathcal{P}_0$ and $\mathcal{P}_1$ contain no $par$ operator). Firstly apply splitting:
By Lemma 4.7, there are \( Q_0 \) and \( Q_1 \) containing no times operator and killing context \( K^2\{ \cdot \} \) such that there is a derivation \( \frac{K^2\{ Q_0 \# Q_1 \}}{R} \) such that \( \vdash P_0 \rightarrow Q_0 \) and \( \vdash P_1 \rightarrow Q_1 \).

By Lemma 4.4, since \( R \) and \( K^2\{ Q_0 \# Q_1 \} \) contain no times, there exists \( S \) such that there is a derivation in the cooling fragment \( R \), and derivation in the interaction fragment \( \frac{K^2\{ Q_0 \# Q_1 \}}{S} \). Furthermore, by Lemma 4.8, there exists context \( C^2\{ \cdot \} \) and processes \( S_0 \) and \( S_1 \), such that we have two derivations using only the interaction fragment \( \overline{z} \) and \( \overline{z} \), and derivation over contexts \( \frac{C^2\{ S_0 \# S_1 \}}{\overline{z}} \); and also we have in the cooling fragment a derivation \( \frac{C^2\{ S_0 \# S_1 \}}{S} \). By Lemma 4.9, there exists left context \( L^2\{ \cdot \} \) such that there exists a left derivation over contexts \( \overline{z} \), and another derivation over contexts \( \overline{z} \) using only the interaction fragment.

Now, since \( \vdash P_0 \rightarrow Q_0 \) and \( \overline{z} \) we have \( \vdash P_1 \rightarrow S_0 \), and similarly \( \vdash P_1 \rightarrow S_1 \). Therefore, by the induction hypothesis (noting the size of \( P_0 \) and \( P_1 \) are strictly less than the size of \( P_0 \# P_1 \)), we have \( \vdash P_0 \rightarrow S_0 \) and \( \vdash P_1 \rightarrow S_1 \) must have left proofs. Furthermore, since \( \overline{z} \) in the interaction fragment, we can construct a proof of \( L^2\{ \circ \} \) using the interaction fragment only; hence, by Lemma 4.5, there is a left proof of \( L^2\{ \circ \} \).

Using the derivations constructed above, and applying Lemma 4.10, we can construct the following left proof:

\[
\frac{\circ}{L^2\{ P_1 \rightarrow S_1 \}} \quad \text{a left derivation (Lemma 4.5)}
\]

\[
\frac{\circ}{L^2\{ (P_0 \rightarrow S_0) \# (P_1 \rightarrow S_1) \}} \quad \text{a left derivation (by induction hypothesis)}
\]

\[
\frac{\circ}{L^2\{ (P_0 \# P_1) \# S_0 \# S_1 \}} \quad \text{in the cooling fragment (Lemma 4.10)}
\]

\[
\frac{\circ}{L^2\{ S_0 \# S_1 \}} \quad \text{a left derivation (Lemma 4.9)}
\]

\[
\frac{\circ}{S} \quad \text{in the cooling fragment (Lemma 4.8)}
\]

\[
\frac{\circ}{P_0 \# P_1 \rightarrow R} \quad \text{in the cooling fragment (Lemma 4.4)}
\]

Case involving new quantifier. Consider the inductive case where \( \vdash \exists x . P \rightarrow R \), where \( P \) and \( R \) contain no times operator (hence \( \forall x . \overline{P} \) contains no par). Since \( \vdash \exists x . \overline{P} \rightarrow R \), by splitting (Lemma 4.7), there are formulae \( V \) and \( W \) containing no times operator, such that: \( x \# V \) and \( \vdash \overline{P} \rightarrow W \), either \( V = W \) or \( V = \exists x . W \), and also we have derivation \( R \). There are two cases to consider, both resulting in a left proof of \( \exists x . P \rightarrow R \).

In the first case where \( V = W \), since \( R \) and \( \vdash \overline{P} \rightarrow W \), we have \( \vdash \overline{P} \rightarrow R \); hence, by the induction hypothesis (which can be applied since the size of \( P \) is strictly less than the size of \( \exists x . P \)), there must be a left proof of \( \vdash P \rightarrow R \). By \( \alpha \)-conversion, we can assume \( x \# R \), hence we can construct the following left proof:

\[
\frac{\circ}{\exists x . P \rightarrow R} \quad \text{by the tidy rule}
\]

\[
\frac{\circ}{\exists x . (P \rightarrow R)} \quad \text{by the induction hypothesis}
\]

\[
\frac{\circ}{\exists x . \overline{P} \rightarrow R} \quad \text{by the extract new rule}
\]

\[
\frac{\circ}{\overline{P} \rightarrow R} \quad \text{by the fresh rule.}
\]

In the second case where \( V = \exists x . W \), since \( \overline{P} \rightarrow R \), and \( R \) and \( \exists x . W \) contain no times operator, by Lemma 4.4, there exists \( S \) such that \( \overline{z} \in \text{the cooling fragment} \) and \( \overline{z} \in \text{the interaction fragment} \). By Lemma 4.8, since \( \overline{z} \) in the interaction fragment, there exist context \( C^3\{ \cdot \} \) and formula \( U \) such
that we have: 
\[
\frac{C \{ \text{Ix}_x . U \}}{s}
\]
in the cooling fragment, and also 
\[
\frac{w}{C \{ \cdot \}}
\]
using the interaction fragment only. Hence, by Lemma 4.9, there exists left context \( L^3 \{ \cdot \} \) such that we can construct a left derivation over contexts \( C \{ \cdot \} \), and derivation \( C \{ \cdot \} \) using the interaction fragment only. Furthermore, observe, \( C \{ \text{Ix}_x \} \) using the interaction fragment only; hence, by Lemma 4.5, we have a left proof of \( L^3 \{ \text{Ix}_x \} \). Since \( U \), and \( \vdash P \rightarrow U \), we have \( \vdash P \rightarrow U \); hence, by the induction hypothesis, we have a left proof of \( P \rightarrow U \). Thus we can construct the following left proof, as required.

\[
\frac{\circ}{L^3 \{ \text{Ix}_x \}}
\]
a left derivation (by Lemma 4.5)
\[
\frac{L^3 \{ \text{Ix}_x . P \rightarrow \text{Ix}_x . U \}}{\text{L} \{ \cdot \}}
\]
in the cooling fragment (by Lemma 4.10)
\[
\frac{\text{L} \{ \cdot \}}{\text{L} \{ \cdot \}}
\]
by the close rule
\[
\frac{L^3 \{ \text{Ix}_x . P \rightarrow \text{Ix}_x . U \}}{\text{L} \{ \cdot \}}
\]
in the cooling fragment (by Lemma 4.10)
\[
\frac{\text{L} \{ \cdot \}}{\text{L} \{ \cdot \}}
\]
a left derivation (by induction hypothesis)
\[
\frac{\text{L} \{ \cdot \}}{\text{L} \{ \cdot \}}
\]
in the cooling fragment (by Lemma 4.10)
\[
\frac{\text{L} \{ \cdot \}}{\text{L} \{ \cdot \}}
\]
a left derivation (by Lemma 4.9)
\[
\frac{\text{L} \{ \cdot \}}{\text{L} \{ \cdot \}}
\]
in the cooling fragment (by Lemma 4.8)

Notice that the above cases are similar. Remaining inductive cases follow the same pattern. □

In a left proof, we can always identify the bottommost atomic interaction rule, as expressed in the following lemma.

**Lemma 4.12.** For any left proof of \( P \) in BV1 containing at least one instance of the atomic interaction rule, there exists left context \( L \{ \cdot \} \) and atom \( \alpha \) such that:

- There exists a derivation of the form 
  \[
  \frac{L \{ \text{Ix}_x . P \rightarrow \text{Ix}_x . Q \}}{P}
  \]
in the cooling fragment of BV1.
- There exists a left proof of \( L \{ \circ \} \) in BV1.

The subtlety of the above lemma is that the bottommost rule of the interaction fragment may be a tidy rule. In this scenario, it is always possible to remove such tidy rules from the proof until the bottommost rule of the interaction fragment is an instance of atomic interaction.

### 4.3 Permuting nominal quantifiers to expand their scope

We require two technical lemmas for normalising proofs with name binders. Extrusion of names is when a private name is sent over the network and becomes known by another process that receives the message. A challenge when handling extrusion is that the scope of the binder for the name should be expanded such that the process receiving the name is in the scope of the name binder. In order to handle the expansion of the scope of name binders, we require the following technical devices.

In what follows the quantifier we wish to expand we identify using a box. We require the concept of when quantifiers are connected through a derivation. To identify connected quantifiers, we ensure that if a quantifier is in a box in the conclusion, then it is also in a box in the premiss, where the following rules are treated in a special way.

- The medial new rule duplicates boxed quantifiers: 
  \[
  \frac{C \{ \text{Ix}_x . P . \text{Ix}_x . Q \}}{C \{ \text{Ix}_x . (P . Q) \}}
  \]

In a left proof, we can always identify the bottommost atomic interaction rule, as expressed in the following lemma.
Instances of *suspend* and *close* rules connect two boxed nominal quantifiers in the conclusion, as follows, where $\odot \in \{\forall, \exists\}$.

- $\vdash [\exists_x (P \odot Q)]$ and $\vdash [\exists_x (P \exists x. Q)]$.

Instances of *tidy name* and *fresh* end or begin paths: $c[\exists x.]$ or $c[\exists x. P]$ or $c[\exists x. P]$.

A proof containing boxed nominal quantifiers is *minimally connected*, whenever all boxes are connected in the proof, as described above, and no box can be removed without either violating connectedness or removing all boxes. To understand this concept consider the following example derivation, where boxed quantifiers trace the path of a *new* connective.

We also require the following definition removing boxed quantifiers from formulae, where $\kappa$ is $\odot$ or an atom, $\check{O} \in \{\forall, \Pi, \exists, \Im\}$ and $\odot \in \{\odot, \odot, \odot\}$.

$$\operatorname{rm}(\check{O}_x. P) = \operatorname{rm}(P) \quad \operatorname{rm}(\check{O}_y. P) = \check{O}_y.\operatorname{rm}(P) \quad \operatorname{rm}(P \odot Q) = \operatorname{rm}(P) \odot \operatorname{rm}(Q) \quad \operatorname{rm}(\kappa) = \kappa.$$  

Using the above devices, we can establish the following normalisation lemma.

**Lemma 4.13.** If $\vdash C\{P\}$, where $P$ contains at least one minimally connected boxed new quantifier $\exists x.$, and $x$ only appears bound by boxed quantifiers in $C\{P\}$ (avoiding name confusion), then $\vdash C\{I\!x.\operatorname{rm}(P)\}$.

**Proof.** The proof is established by induction on the structure of the derivation. One case is illustrated. Consider the case where the bottommost rule of a proof is of the following form, where $x \# P, x \# R$ and no boxed quantifier appears in $P$; hence $\operatorname{rm}(P) = P$.

$$C\{P \limp I\!x. (Q \limp R)\} \quad \operatorname{extrude\ new}$$

By the induction hypothesis $C\{I\!x.\operatorname{rm}(P \limp Q \limp R)\}$ is provable, hence $\vdash C\{P \limp I\!x.\operatorname{rm}(Q \limp R)\}$, since $\vdash C\{P \limp I\!x.\operatorname{rm}(Q \limp R)\}$ and $C\{I\!x. (P \limp \operatorname{rm}(Q \limp R))\} = C\{I\!x.\operatorname{rm}(P \limp Q \limp R)\}$. 

Consider again the example provided immediately before Lemma 4.13. The function $\operatorname{rm}$ can be applied to that example derivation to obtain the derivation below. Observe the boxed quantifiers and redundant rules have been deleted; also $I\!x.$ is reinserted with a wider scope.
Note the scope of universal quantifiers in the conclusion of a proof can also be expanded, due to the following implications, where ⊙ ∈ {⊙, ▷, ◁}, ⤧ ∈ {∀, ⌀, ⃝} and x ≠ R.

\[ ∀x.P \circ R \rightarrow ∀x.(P \circ R) \quad \vdash R \circ ∀x.Q \rightarrow ∀x.(R \circ Q) \quad \vdash ⤧x.∀y.P \rightarrow ∀y.⧬x.P. \]

The above implications show that universal quantification distributes over all other operators, as long as name capture is avoided. Thus the process of expanding the scope of universal quantifiers is simpler than for nominal quantifiers.

### 4.4 Permuting exists to the bottom of certain derivations

For certain derivations, it is possible to permute the select1 rule, concerning the instantiation of existential quantifiers, to the bottom of the derivation, as long as the select1 rule does not commute with an extrusion rule binding a variable in the term introduced. To understand this subtlety, consider the following derivation, where x ≠ P.

\[
\text{Ix.(} \bar{ax} \ ^\forall \ ( ax \ ^\exists P \{ x/y \} ))
\]

select1

\[
\text{Ix.(} \bar{ax} \ ^\forall \ y.(ay \ ^\exists P))
\]

extrude new.

The instance of the select1 rule above cannot permute with the instance of the extrude name rule. Fortunately, this situation can be avoided for formulae relevant to embedding processes by first expanding the scope of nominal and universal quantifiers, using Lemma 4.13.

This leads to the following normalisation property.

### Lemma 4.14

Consider a derivation in the cooling fragment of the form \( C \mid \[ axQ \] \), where an existential quantifier is identified by a box. Also, assume t is such that: if there is a quantifier ⤧ ∈ {∀, ⌀} such that a rule of the form \( C \mid \[ by \ ( R \ ^\exists x \ ^\exists s ) \] \) appears in the derivation, then the variable y bound by ⤧ is such that y ≠ t. In such a scenario, a derivation \( C \mid \[ P \{ x/y \} \] \) can be constructed in the cooling fragment.

### 5. Constructing labelled transitions from proofs

This section combines the results from the previous sections to establish the main result of the paper (Theorem 3.8). In order to ensure that all scenarios are covered, we require the following definition and lemma. Observe that process contexts transform to left contexts when used in embeddings.
Definition 5.1. A process context \( \mathcal{P}\{\cdot\} \) is defined according to the following grammar, where \( p \) ranges over \( \pi \)-calculus processes: \( \mathcal{P}\{\cdot\} ::= \{\cdot\} | \mathcal{P}\{\cdot\} \upharpoonright p | \mathcal{P}\{\cdot\} \upharpoonright \nu x.\mathcal{P}\{\cdot\} \).

We say a process context \( \mathcal{P}\{\cdot\} \) binds variable \( x \), when there appears a \( \nu x \). in scope of the hole of the context. That is, the context is such that \( \mathcal{P}\{\cdot\} = \mathcal{P}^0\{\nu x.\mathcal{P}\{\cdot\}\} \).

Lemma 5.2.

— For \( \pi \)-calculus process \( q \) and process context \( \mathcal{P}\{\cdot\} \) that binds neither \( x \) nor \( z \), the following labelled transition exists: \( \mathcal{P}^0\{\xi x.q\} \xrightarrow{\xi x} \mathcal{P}\{q\} \).

— Assuming \( x \) and \( z \) are not bound by \( \mathcal{P}^1\{\cdot\} \) and \( \mathcal{P}^2\{\cdot\} \), there exists the following transition.\[
\mathcal{P}^0\{\mathcal{P}^1\{\xi x.p\} \upharpoonright \mathcal{P}^2\{\pi(y).q\}\} \xrightarrow{\upharpoonright} \mathcal{P}^0\{\mathcal{P}^1\{p\} \upharpoonright \mathcal{P}^2\{q[z/y]\}\}.
\]

— Where \( x \) and \( z \) are not bound by \( \mathcal{P}^1\{\cdot\} \) and \( \mathcal{P}^2\{\cdot\} \), or \( \mathcal{P}^3\{\cdot\} \) and \( z \) is fresh for all processes appearing in the contexts \( \mathcal{P}^1\{\cdot\} \) and \( \mathcal{P}^3\{\cdot\} \), the following transition exists: \( \mathcal{P}^0\{\mathcal{P}^1\{\nu z.\mathcal{P}^2\{\xi x.p\}\} \upharpoonright \mathcal{P}^3\{\pi(z).q\}\} \xrightarrow{\upharpoonright} \mathcal{P}^0\{\mathcal{P}^1\{q\}\} \).

— Assume that \( q \) is a \( \pi \)-calculus process and \( \mathcal{P}^0\{\cdot\} \) and \( \mathcal{P}^1\{\cdot\} \) are process contexts that do not bind \( x \) and \( z \); and \( z \) is fresh for \( \mathcal{P}^0\{\cdot\} \). Under these conditions, the following labelled transition exists: \( \mathcal{P}^0\{\nu z.\mathcal{P}^1\{\xi x.q\}\} \xrightarrow{\nu x[z]} \mathcal{P}^0\{\mathcal{P}^1\{q\}\} \).

— Assuming that \( x \) and \( y \) are not bound by \( \mathcal{P}\{\cdot\} \) and \( x \) is fresh for \( \mathcal{P}\{\cdot\} \), there is always the following labelled transition: \( \mathcal{P}\{y(x).q\} \xrightarrow{y(x)} \mathcal{P}\{q\} \).

Similar situations where processes composed by parallel composition are swapped also hold.

Proof. The most involved case where a bound output interacts with an input is presented. Consider where \( x \) and \( z \) are not bound by \( \mathcal{P}^1\{\cdot\} \) or \( \mathcal{P}^2\{\cdot\} \) and \( z \) is fresh for all processes appearing in the contexts \( \mathcal{P}^1\{\cdot\} \) and \( \mathcal{P}^3\{\cdot\} \).

Since \( x(z).q \xrightarrow{x(z)} q \) and \( \xi x.p \xrightarrow{\xi x} p \), by induction on the structure of \( \mathcal{P}^3\{\cdot\} \) and \( \mathcal{P}^2\{\cdot\} \), we have \( \mathcal{P}^3\{x(z).q\} \xrightarrow{x(z)} \mathcal{P}^3\{q\} \) and \( \mathcal{P}^2\{\xi x.p\} \xrightarrow{\xi x} \mathcal{P}^2\{p\} \). Thereby \( \nu z.\mathcal{P}^2\{\xi x.p\} \xrightarrow{\nu z} \mathcal{P}^2\{p\} \), so, by induction on the structure of \( \mathcal{P}^1\{\cdot\} \), we have \( \mathcal{P}^1\{\nu z.\mathcal{P}^2\{\xi x.p\}\} \xrightarrow{\nu z} \mathcal{P}^1\{\mathcal{P}^2\{p\}\} \). Thereby, by interaction of labels, \( \mathcal{P}^1\{\nu z.\mathcal{P}^2\{\xi x.p\}\} \upharpoonright \mathcal{P}^3\{x(z).q\}\} \xrightarrow{\upharpoonright} \nu z.(\mathcal{P}^1\{\mathcal{P}^2\{p\}\} \upharpoonright \mathcal{P}^3\{q\}) \). Hence, by structural induction on context \( \mathcal{P}^0\{\cdot\} \), we have constructed the following transition as required: \( \mathcal{P}^0\{\mathcal{P}^1\{\nu z.\mathcal{P}^2\{\xi x.p\}\} \upharpoonright \mathcal{P}^3\{x(z).q\}\} \xrightarrow{\upharpoonright} \mathcal{P}^0\{\nu z.(\mathcal{P}^1\{\mathcal{P}^2\{p\}\} \upharpoonright \mathcal{P}^3\{q\})\} \).

\(\square\)

5.1 Key scenarios for extracting executions

Here we identify key scenarios required for inducing labelled transitions, while preserving provability. In each scenario, consider a proof of the following form, where \( \mathcal{L}\{\cdot\} \) is a left context.

\[\xrightarrow{\circ} \overline{\mathcal{L}\{\cdot\}} \text{ a left proof} \]
\[\overline{\mathcal{L}\{\xi x \upharpoonright xz\}} \text{ using atomic interaction} \]
\[\overline{\mathcal{P}} \text{ using the cooling fragment only} \]

Recall that, by Lemma 4.12, this form can always be achieved for left proofs with at least one atom.

Now, observe, moving upwards in a proof no rule of BV1 introduces atoms or quantifiers. Hence atom \( xz \) and co-atom \( \xi x \) involved in the atomic interaction rule must also appear in the
conclusion, \( P \). Furthermore, since the bottommost interaction rule is always in a left context and cooling rules preserve this property, the atom also appears in a left context in the conclusion of the proof. These observations allow us to identify the following scenarios, all essential for the main result of this paper.

5.1.1 Scenario for inducing free output transitions
The simplest scenario is where, in a left proof, the bottommost atomic interaction rule involves an atom \( xz \) that can be traced to two particular sub-formulae in the conclusion of the proof, each an embedding of a process \( \overline{xz}.p \) and \( \mathcal{P}\{\overline{xz}.q\} \), respectively.

**Lemma 5.3.** Assume that \( \vdash \mathcal{L}\{\circ\} \) holds and \( \overline{\mathcal{K}}(\llbracket [p]_\pi \longrightarrow [\mathcal{P}\{\overline{xz}.q\}]_\tau \rrbracket) \) is a derivation in the cooling fragment of BV1, such that \( p \) and \( q \) are \( \pi \)-calculus processes, \( \mathcal{K}\{\cdot\} \) is a killing context, \( \mathcal{L}\{\cdot\} \) is a left context, \( \mathcal{P}\{\cdot\} \) is a process context, \( x \) and \( z \) are not bound by \( \mathcal{P}\{\cdot\} \) and the instances of \( xz \) in the conclusion and premiss are connected.

Under these assumptions, \( \vdash \mathcal{K}\{[p]_\pi \longrightarrow [\mathcal{P}\{q\}]_\pi\} \) holds.

Notice that the former process \( \overline{xz}.p \) is in a form where it has committed to performing a free output, indicating that the process can only perform action \( \overline{xz} \), after which process \( p \) is reached. The latter process \( \mathcal{P}\{\overline{xz}.q\} \) is ready to perform an action \( \overline{xz} \), assuming \( x \) and \( z \) are free variables. In this scenario, the action in each sub-formula can be removed from the proof while preserving provability, as described in what follows.

This scenario is no more complex to prove than established result Theorem 2.1. Simply remove the instances of atoms \( xz \) and \( \overline{xz} \) from the derivation in the cooling fragment to obtain derivation \( \overline{\mathcal{L}\{\cdot\}} \), from which a proof of \( \mathcal{K}\{[p]_\pi \longrightarrow [\mathcal{P}\{q\}]_\pi\} \) can be constructed, as required.

Observe that some rules become redundant, so are removed from the proof in this process. For example, consider a left proof beginning with the following derivation.

\[
\begin{align*}
\circ & \quad \text{a left proof} \\
\overline{\text{Hy}}. (xz \uplus \overline{xz}) & \quad \text{tidy new} \\
\overline{\text{Hy}}. ([q]_\pi \longrightarrow \overline{\text{Hy}}. [p]_\pi) & \quad \text{atomic interaction} \\
\overline{\text{Hy}}. (xz \uplus \overline{xz}) & \quad \text{extrude new} \\
\overline{\text{Hy}}. (xz \uplus [q]_\pi) & \quad \text{sequence} \\
\overline{\text{Hy}}. (xz \uplus [q]_\pi) & \quad \text{medial new.}
\end{align*}
\]

In the above proof, after removing the highlighted atoms \( xz \) and \( \overline{xz} \), instances of the rules sequence, medial new, extrude new and tidy new are deleted, yielding a proof of \([q]_\pi \longrightarrow \overline{\text{Hy}}. [p]_\pi\).

5.1.2 Scenario for inducing an internal interaction involving free output
In the second scenario, the atom \( xz \) involved in the bottommost atomic interaction in a left proof can be traced to a free output and input action prefix in a process that can perform a \( \tau \)-transition of the form \( \mathcal{P}^0\{\mathcal{P}^1\{\overline{xz}.p\} | \mathcal{P}^2\{x(y).q\}\} \). This scenario allows us to induce \( \tau \)-transitions in the process on the right-hand side of a linear implication, which is essential for weak simulations.
Lemma 5.4. Assume that $\vdash L\{ o \}$ holds and $\vdash K\{ s \}, \neg \vdash [P^0, \vdash P^1[z, P] | P^2[z(y)q]]$, is a derivation in the cooling fragment where $s, p$ and $q$ are $\pi$-calculus processes, $P^1\{ \cdot \}$ are process contexts and $L\{ \cdot \}$ is a left context, where atoms $xz$ in the premiss of the derivation can be traced to the head of the subprocesses indicated in the conclusion, and assume that $x$ and $z$ are not bound by $P^1\{ \cdot \}$ and $P^2\{ \cdot \}$.

Under the above assumptions, we have: $\vdash K\{ s \}, \neg \vdash [P^0, \vdash P^1[p] | P^2[q[z/y]]]_{\pi}$.

To establish the above lemma, we require the decomposition result for existential quantifiers in Lemma 4.14, in order to handle the existential quantifier in the embedding of the input. Also, observe that if formula $\exists x.P$ is in a left context, it will never be the case that $\exists x.P$ is nested inside another existential quantifier, where a nested quantifier would be able to influence the term introduced.

By the above observations, the derivation in the cooling fragment must be of the following form, for some left context $L'\{ \cdot \}$ and formula $R$ where the existential quantifier from the input action is underlined and each $L'\{ \cdot \}$ is structurally congruent to an embedding of the respective $P^1\{ \cdot \}$. Thereby, the conclusion of the following derivation is structurally congruent to $K\{ s \}, \neg \vdash [P^0, \vdash P^1 z, p] | P^2 x(y), q]$.

$$\frac{L\{ \overline{x} \overline{y} x z \} \quad \text{using the cooling fragment only}}{L'\{ R[z/y] \} \quad \text{by the selectI rule}}$$

$$\frac{L'\{ \exists y, R \} \quad \text{using the cooling fragment only.}}{K\{ s \}, \neg \vdash L^0 \{ L^1 \{ \overline{x} a = [p]_{\pi} \} \overline{y} L^2 \{ \exists y a [q]_{\pi} \} \}}$$

Since $P^1\{ \cdot \}$ and $P^2\{ \cdot \}$ do not bind $x$ and $z$, we have that $L^1\{ \cdot \}$ and $L^2\{ \cdot \}$ do not bind $x$ and $z$. Thereby, we can appeal to Lemma 4.14 to construct the following derivation in the cooling fragment of BV1.

$$\frac{L\{ \overline{x} \overline{y} x z \} \quad \text{a derivation in the cooling fragment}}{L'\{ R[z/y] \} \quad \text{a derivation in the cooling fragment}}$$

$$\frac{K\{ s \}, \neg \vdash L^0 \{ L^1 \{ \overline{x} a = [p]_{\pi} \} \overline{y} L^2 \{ xz = [q[z/y]]_{\pi} \} \}}$$

We can now, similar to Lemma 5.3, delete the instances of the atoms $\overline{x}$ and $xz$ involved in the bottommost interaction everywhere in the proof, while removing redundant rules. This leads to a left proof of the following formula, as desired: $K\{ s \}, \neg \vdash [P^0, \vdash P^1[p] | P^2[q[z/y]]]$.

5.1.3 Scenario for inducing internal interaction involving bound output

Consider when both atoms of the bottommost atomic interaction rule appear in the embedding of a process of the form $P^0\{ P^1\{ vz, P^2\{ \overline{x} z, p \} \} | P^3\{ x(z), q \} \}$, where $z$ is bound by new. In this scenario, clearly a $\tau$-transition can be induced as formally stated in the following lemma.

Lemma 5.5. Assume that $\vdash L\{ o \}$ holds and $\vdash K\{ s \}, \neg \vdash [P^0, \vdash P^1[vz, P^2[z, P] | P^3[x(z), q]]]_{\pi}$ is a derivation in the cooling fragment, where $x$ and $z$ are not bound by $P^1\{ \cdot \}$, $P^2\{ \cdot \}$ or $P^3\{ \cdot \}$ and $z$ is fresh for $P^1\{ \cdot \}$ and $P^3\{ \cdot \}$.

In this scenario, $\vdash K\{ s \}, \neg \vdash [P^0\{ vz, (P^1\{ P^2[p] \} | P^3\{ q \})]_{\pi}$ holds.

To establish the above lemma, firstly we expand the scope of nominal quantifiers, to obtain a proof of a form similar to that in the previous scenario. By Lemma 4.13, we can expand the scope of quantifiers, to obtain the following derivation in the cooling fragment.
we can construct a derivation in the cooling fragment of the following form.

Hence, by following the same strategy as for Lemma 5.4, we have a procedure for constructing a proof of the following formula, as required: $\Gamma \vdash [\{s\}, \pi] \rightarrow [\{p^0 \{ \nu. (p^1 \{ \nu. (s.z.p) \}) | p^3 \{ x(z).q \} \}]$.

5.1.4 Scenario inducing a bound output transition
Consider the scenario where the bottommost atomic interaction rule applies to an atom that can be traced to process embeddings of the form $\nu. x.z.s$ and $p^0 \{ \nu. p^1 \{ x.z.q \} \}$ – two processes ready to output a fresh name on channel $x$.

**Lemma 5.6.** Suppose, $\Gamma \vdash [\{s.z.q\}, \pi] \rightarrow [\{p^0 \{ \nu. (p^1 \{ s.z.q \}) \}]$. is a derivation in the cooling fragment of BV1, where $s$ and $q$ are $\pi$-calculus process, $\Lambda(\nu)$ is a left context, $p^0(\nu)$ and $p^1(\nu)$ are process contexts that do not bind $x$ and $z$; and $z$ is fresh for $p^0(\nu)$. Also, assume that $\Lambda(\nu)$ has a left proof.

In this scenario, $\Gamma \vdash [\{s\}, \pi] \rightarrow [\{p^0 \{ p^1 \{ q \} \}]$. holds.

The proof is similar to the previous scenario where a bound output is involved in an interaction. By applying Lemma 4.13, we can pull the quantifier $\forall z$ to the outermost level, removing corresponding $\text{wen}$ operators to obtain a derivation in the cooling fragment of the following form.

$$\Gamma \vdash \forall z. (\{x.z.s\}, \pi) \rightarrow [\{p^0 \{ p^1 \{ q \} \}]$$

Hence, by deleting the interacting atoms, a proof of $\Gamma \vdash [\{s\}, \pi] \rightarrow [\{p^0 \{ p^1 \{ q \} \}]$ can be constructed as required.

5.1.5 Scenario inducing an input transition
The scenario for inputs is where the bottommost atomic interaction in a left proof involves an atom that can be traced to the prefix in processes embeddings of the following form in the conclusion of a proof: $x(z).s$ and $p\{ x(z).q \}$, each ready to perform an input action.

**Lemma 5.7.** Assume that $\Gamma \vdash \Lambda(\nu)$ holds and $\Gamma \vdash [\{s.z.q\}, \pi] \rightarrow [\{p \{ x(z).q \} \}]$. is a derivation in the cooling fragment, where $x$ and $z$ are not bound by process context $p\{ \nu \}$ and $z$ does not appear free in $p\{ x(z).q \}$ and $\Lambda(\nu)$ is a left context.

In this scenario, $\Gamma \vdash [\forall z. (\{s\}, \pi) \rightarrow [\{p \{ q \} \}]$. holds.

Similar to the scenarios involving bound output actions, the trick to establish the above lemma is to first move the universal quantifier binding the name in the input action out of the way. Since $\Gamma \vdash \forall z. (\{x.z.s\}, \pi) \rightarrow [\{p \{ x(z).q \} \}] \rightarrow [\forall z. (\{x.z.s\}, \pi) \rightarrow [\{p \{ x(z).q \} \}]$ holds, by Theorem 3.2, we can construct a derivation in the cooling fragment of the following form.

$$\Gamma \vdash \forall z. (\{x.z.s\}, \pi) \rightarrow [\{p \{ x(z).q \} \}]$$

a derivation in the cooling fragment
Observe that the above derivation in the cooling fragment must be of the following form, where $\mathcal{L}\{\cdot\}$ is structurally equivalent to the embedding of $\mathcal{P}\{\cdot\}$.

$$\frac{\mathcal{L}\{\overline{xz} \Leftarrow xz\}}{\mathcal{L}'\{R\}}$$

a derivation in the cooling fragment

by the select 1 rule

$$\frac{\mathcal{L}'\{\exists z.\ R\}}{\mathcal{K}\{\forall z.\left(\left(\overline{xz} \Leftarrow \left[s\right]_\pi\right) \Leftarrow \mathcal{L}\{xz \Leftarrow \left[q\right]_\pi\}\right)\}}$$

a derivation in the cooling fragment

Hence by Lemma 4.14, there exists a derivation in the cooling fragment of the following form.

$$\frac{\mathcal{L}\{\overline{xz} \Leftarrow xz\}}{\mathcal{L}'\{R\}}$$

a derivation in the cooling fragment

$$\frac{\mathcal{K}\{\forall z.\left(\left(\overline{xz} \Leftarrow \left[s\right]_\pi\right) \Leftarrow \mathcal{L}\{xz \Leftarrow \left[q\right]_\pi\}\right)\}}{\text{a derivation in the cooling fragment.}}$$

By removing the pair of atoms $\overline{xz}$ and $xz$ from the above derivation, we can construct the derivation $\mathcal{K}\{\forall z.\left(\left[s\right]_\pi \Rightarrow \left[P\{q\}\right]_\pi\}\}$. Thereby, since we assumed $\mathcal{L}\{\circ\}$ has a proof, we can construct a proof of $\mathcal{K}\{\forall z.\left(\left[s\right]_\pi \Rightarrow \left[P\{q\}\right]_\pi\}\}$.

### 5.2 Proof of the soundness of linear implication with respect to weak simulation

We are now ready to prove the main result of this paper. We require the following intermediate definition mapping histories to a list of quantifiers $\forall$ and $\exists$.

**Definition 5.8.** Let the abbreviation $\mathcal{H}h.P$ be the formula defined such that $\mathcal{H}e.P = P$ and, inductively, $\mathcal{H}(h \cdot x^0).P = \mathcal{H}h.\forall x.P$ and $\mathcal{H}(h \cdot x^i).P = \mathcal{H}h.\exists x.P$.

Given a history $h$, we define a trimming function $[h]$ as follows:

- $[\epsilon] = \epsilon$,
- If $h = h'.x^\bullet$, where $\bullet \in \{i, o\}$, and $x \notin n(h')$ then $[h'] = [h'].x^\bullet$. Otherwise, $[h] = [h']$.

The embedding of histories in Definition 5.8 satisfies the following lemma.

**Lemma 5.9.** If $\sigma$ respects $h$ and $h' = [h]$, then $\vdash \mathcal{H}h.P$ holds, then $\vdash \mathcal{H}h'.P\sigma$.

The following proposition combines the intermediate results established throughout this paper: cut elimination (Theorem 3.2); the mapping of labelled transitions to proofs (Lemma 3.11); the normalisation results Proposition 4.11, Lemmas 4.13 and 4.14; the above Lemma 5.9; as well as the observations made in Lemmas 5.3–5.7 in the previous section.

**Proposition 5.10.** Define ternary relation $\mathcal{R}$ such that $p \mathcal{R}^h q$ whenever $\vdash \mathcal{H}h.\left([p]_\pi \Rightarrow [q]_\pi\right)$. The relation $\mathcal{R}$ is a complete weak open simulation.

**Proof.** Assume that $\vdash \mathcal{H}h.\left([p]_\pi \Rightarrow [q]_\pi\right)$ holds, i.e., $p \mathcal{R}^h q$. There are six cases to consider to show $\mathcal{R}$ is closed under the definition of complete weak open simulation.

To show preservation under respectful substitutions, assume $\sigma$ respects $h$, by Lemma 5.9, $\vdash \mathcal{H}[h\sigma].\left([p]_\pi \Rightarrow [q]_\pi\right)$; hence, by Lemma 3.10, $\vdash \mathcal{H}[h\sigma].\left([p\sigma]_\pi \Rightarrow [q\sigma]_\pi\right)$, as required.
To show preservation under $\tau$-transitions, assume $p \xrightarrow{\tau} p'$, and observe $\vdash [p']_{H} \rightarrow [p]_{H}$, by Lemma 3.11. Therefore, by Theorem 3.2, $\vdash x_{1}, \ldots, x_{n}([p']_{H} \rightarrow [q]_{H})$ holds, as required.

Check termination potential is preserved. Assume, in this case, $p \nvdash$ holds. Now, consider, more generally, $r$ such that, $\mathcal{H}h.([p]_{H} \rightarrow [q]_{H})$. By Proposition 4.11, $\mathcal{H}h.([p]_{H} \rightarrow [q]_{H})$ has a left proof, and, whenever there is at least one atom, by Lemma 4.12, the bottommost rule of the interaction fragment can be arranged to be an instance of the atomic interaction rule. Since there are no atoms in $p$, three possible scenarios can occur:

- There are no atoms in $[q]_{H}$ and hence process $r$ is also such that $r \nvdash$.
- Process $q$ is of the form $P_{1}^{1}\{ P_{2}^{2}\{ \bar{x}y.r_{1} \} | P_{3}^{3}\{ x(z).r_{2} \} \}$, where $x, y$ and $z$ are not bound by $P_{2}^{2}\{ \cdot \}$ and $P_{3}^{3}\{ \cdot \}$, and, furthermore, the atoms in the bottommost atomic interaction can be traced to the atoms in the output and input prefixes identified. In this case, by Lemma 5.4, we can construct a proof of $\vdash \mathcal{H}h.([p]_{H} \rightarrow [q]_{H})$. Furthermore, by Lemma 5.2, $P_{1}^{1}\{ P_{2}^{2}\{ \bar{x}y.r_{1} \} | P_{3}^{3}\{ x(z).r_{2} \} \}$ can be traced to the atoms in the output and input prefixes identified. In this case, by Lemma 5.5, we can construct a proof of the following: $\mathcal{H}h.([p]_{H} \rightarrow [q]_{H})$. So, by Lemma 5.2, we have the following: $P_{0}^{0}\{ P_{1}^{1}\{ v.z.P_{2}^{2}\{ \bar{x}z.r_{1} \} | P_{3}^{3}\{ x.z.r_{2} \} \}$ can be applied. Furthermore, $\vdash \mathcal{H}h.([p]_{H} \rightarrow [q]_{H})$ holds hence, since no further $\tau$-transition can be enabled, by the above case analysis, $q_{n} \nvdash$ holds. Hence, we can construct $q_{n}$ such that $q \xrightarrow{\tau} q_{n}$ and $q_{n} \nvdash$ holds, as required.

Check preservation under free outputs. Assume, in this case, $p \xrightarrow{\tau} p'$. Firstly consider, more generally, judgements of the form $\vdash \mathcal{H}h.([\bar{z}z.p']_{H} \rightarrow [r]_{H})$. By Proposition 4.11, we can construct a left proof such that, by Lemma 4.12, the bottommost rule in the interaction fragment is an atomic interaction rule. There are two possibilities:

- As described in detail in the previous case, atoms in the bottommost atomic interaction rule correspond to an input and output prefix in $r$; hence, by Lemma 5.4 or Lemma 5.5 and also appealing to Lemma 5.2, we can construct $r'$ such that $r \xrightarrow{\tau} r'$ and $\vdash \mathcal{H}h.([\bar{z}z.p']_{H} \rightarrow [r']_{H})$.
- Following Lemma 5.3, the atoms in the bottommost atomic interaction rule correspond to $xz$ and an output prefix in $r$, where $r = P\{ \bar{x}z.s \}$ such that $x$ and $z$ are not bound by $P\{ \cdot \}$, and we can construct a proof of $\vdash \mathcal{H}h.([p']_{H} \rightarrow [s]_{H})$. Also, by Lemma 5.2, $r \xrightarrow{\tau} P\{ s \}$.

By Lemma 3.11, $\vdash [\bar{x}z.p']_{H} \rightarrow [p]_{H}$; hence, by Theorem 3.2, $\vdash \mathcal{H}h.([\bar{x}z.p']_{H} \rightarrow [q]_{H})$. Since $\tau$-transitions strictly decrease the size of the processes, $\vdash \mathcal{H}h.([p']_{H} \rightarrow [q]_{H})$. Since $\sigma$-transitions cannot be applied $q = q_{1} \xrightarrow{\tau} q_{2} \xrightarrow{\tau} \cdots \xrightarrow{\tau} q_{n}$. Since no further $\tau$-transition is possible, output transition $p \xrightarrow{\bar{z}} q_{n}$ must be enabled and furthermore we have $\vdash \mathcal{H}h.([p']_{H} \rightarrow [q]_{H})$. Thereby, we can construct $q_{n}$ such that $q \xrightarrow{\bar{z}} q_{n}$ and $p' \xrightarrow{R} q_{n}$ as required.
Check preservation under bound outputs. Consider the cases where $p \xrightarrow{xz} p'$ such that $z$ is fresh for $p$, $q$, and $h$. Consider judgements of the form $\vdash \mathcal{H}h.([vz.xz.p']_\pi \circ [r']_\pi)$, by Proposition 4.11, we can construct a left proof such that the bottommost rule in the interaction fragment is an atomic interaction rule. There are two possibilities:

- As previously, Lemma 5.4 or Lemma 5.5 applies; thereby, appealing also to Lemma 5.2 there exists $r'$ such that $r \xrightarrow{\tau} r'$ and $\vdash \mathcal{H}h.([vz.xz.p']_\pi \circ [r']_\pi)$.
- The atoms in the bottommost atomic interaction rule correspond to the atom $xz$ and an output in $r$, where $r = \mathcal{P}^1\{vz.\mathcal{P}^2(\overline{xz.s})\}$ such that $x$ and $z$ are not bound by $\mathcal{P}^1\{\cdot\}$ or $\mathcal{P}^2\{\cdot\}$ and $z$ is fresh for $\mathcal{P}^1\{\cdot\}$. In this case, following Lemma 5.6, we can construct a proof of $\vdash \mathcal{H}h.(\Pi z.([p']_\pi \circ [p^2\{s\}]_\pi))$ and furthermore, by Lemma 5.2, $r \xrightarrow{xz} \mathcal{P}^1\{[p^2\{s\}]_\pi\}$.

By Lemma 3.11, $\vdash [vz.xz.p']_\pi \circ [q]_\pi$; hence, by Theorem 3.2, $\vdash \mathcal{H}h.([vz.xz.p']_\pi \circ [q]_\pi)$. Now, since $\tau$-transitions strictly decrease the size of the process, only finitely many $\tau$-transitions can be induced; after which, for some $q'$ and $r$ the output transition $r \xrightarrow{\tau} q'$ must be enabled such that $\vdash \mathcal{H}h.((\Pi z.([p']_\pi \circ [q']_\pi))$; hence, by definition of the embedding of histories, $\vdash \mathcal{H}.(h \cdot z^\tau).([p']_\pi \circ [q]_\pi)$. Thereby we have $q'$ such that $q \xrightarrow{\tau} q'$ and $p' \mathcal{R}^{h \cdot z^\tau} q'$, as required.

Check preservation under inputs. Assume in this case $p \xrightarrow{xz} p'$ such that $z$ is fresh for $p$, $q$, and $h$. For a judgement of the form $\vdash \mathcal{H}h.([x(z).p']_\pi \circ [r]_\pi)$, by Proposition 4.11, we can construct a left proof such that, Lemma 4.12, the bottommost rule in the interaction fragment is an atomic interaction rule; thereby identifying the following two possibilities:

- As in other cases, Lemma 5.4 or Lemma 5.5 applies, along with Lemma 5.2 so there exists $r'$ such that $r \xrightarrow{\tau} r'$ and $\vdash \mathcal{H}h.([x(z).p']_\pi \circ [r']_\pi)$.
- The atoms in the bottommost atomic interaction rule correspond to the atom $xz$ and an input in $r$ such that $r = \mathcal{P}\{x(z).s\}$, where $x$ and $z$ are not bound by $\mathcal{P}\{\cdot\}$ and $z$ is fresh for $\mathcal{P}\{\cdot\}$. In this case, Lemma 5.7 applies and hence $\vdash \mathcal{H}h.(\forall z.([p']_\pi \circ [\mathcal{P}\{s\}]_\pi))$. Furthermore, by Lemma 5.2, $r \xrightarrow{xz} \mathcal{P}\{s\}$.

By Lemma 3.11, $\vdash [x(z).p']_\pi \circ [q]_\pi$; hence, by Theorem 3.2, $\vdash \mathcal{H}h.([x(z).p']_\pi \circ [q]_\pi)$. Since $\tau$-transitions strictly decrease the size of a process, finitely many $\tau$-transitions can be applied reaching $s$ such that, for some $q'$, $s \xrightarrow{xz} q'$ such that $\vdash \mathcal{H}h.((\forall z.([p']_\pi \circ [q']_\pi))$, thereby by the definition of embeddings of histories $\vdash \mathcal{H}.(h \cdot z^\tau).([p']_\pi \circ [q']_\pi)$. Thereby we can construct $q'$ such that $q \xrightarrow{xz} q'$ and $p' \mathcal{R}^{h \cdot z^\tau} q'$, as required.

Thus $\mathcal{R}$ is closed under the definition of a complete weak open simulation. 

Theorem 3.8 follows immediately from the above proposition as follows.

Proof of Theorem 3.8. Observe that if $\vdash [p]_\pi \circ [q]_\pi$ and $\text{fv}(p) \cup \text{fv}(q) \subseteq \{x_0, \ldots, x_n\}$, then $\vdash \forall x_0. \ldots. \forall x_n. ([p]_\pi \circ [q]_\pi)$; hence, by definition, $\vdash \mathcal{H}x_0^i \cdot \ldots \cdot x_n^i.([p]_\pi \circ [q]_\pi)$. Therefore, by Proposition 5.10, $p \mathcal{R}^{x_0^i \cdot \ldots \cdot x_n^i} q$ for a complete weak open simulation $\mathcal{R}$; hence $p \preceq q$.

5.3 Example of constructing a weak simulation from the proof of a linear implication

All proofs in this paper are constructive; hence Theorem 3.8 provides a procedure for extracting a complete weak open simulation from a proof of an implication. We illustrate this procedure in the following example of a left proof.
In the above proof, the bottommost interacting atoms and corresponding existential quantifier
are highlighted by boxes. Following Scenario of Lemma 5.4: firstly, we apply Lemma 4.14 to apply
a substitution in place of the highlighted
select1 rule; and, secondly, we remove the highlighted
atoms from the proof. Thereby we construct the following left proof.
Figure 6. Syntax and labelled transitions for the $\pi_I$-calculus (plus symmetric rules for $p \parr q$). Function $n(.)$ is such that $n(\overline{x[z]}) = n(\overline{x[z]}) = \{x, z\}$ and $n(\tau) = \emptyset$.

Again, in the above proof, the bottommost interacting atoms and corresponding quantifiers appear in boxes. Following Scenario of Lemma 5.5: firstly, we apply Lemma 4.13 to expand the scope of the new quantifier in the process embedding on the right of the implication; secondly, we apply Lemma 4.14 to replace the highlighted existential quantifier with a substitution; and, thirdly, we remove the highlighted atoms from the proof. This results in the following left proof.

Following Scenario of Lemma 5.6, using Lemma 4.13, the above proof can be transformed to a left proof of $\mathcal{H}a^i \cdot b^i \cdot k^e(\llbracket 1 \rrbracket_{\pi} \rightarrow \llbracket 1 \rrbracket_{\pi})$, employing tidy rules only. Notice that the scope of the nominal quantifiers in both process embeddings has been enlarged such that they become part of the history. Thereby on the left of the implication in the conclusion of each proof we have constructed transition $\nu k.\overline{a}k \xrightarrow{\pi[k]} 1$, and on the right the following series of transitions.

Notice that $(1 \mid 1) \checkmark$, so termination potential is preserved. Hence relation $\mathcal{S}$, consisting of triples $\nu k.\overline{a}k \mathcal{S}^a^i \cdot b^i \cdot k^e a(x).\nu k.\overline{x}k \mid b(y).\overline{a}y \mid \overline{a}b$ and $1 \mathcal{S}^a^i \cdot b^i \cdot k^e 1 \mid 1$, is a complete weak open simulation.

6. The versatility of the processes-as-formulae approach

We highlight that the versatility of our approach by showing variants of the $\pi$-calculus can also be embedded as processes in $\mathcal{BV}$ such that implication defines a sound preorder over processes. We also discuss a surprising strict inequality in $\mathcal{BV}$ and how it arises naturally when both unrestricted input and private input coexist in a process calculus.

6.1 Extending results to the internal $\pi$-calculus

We briefly outline how the techniques in this paper can be extended to the internal $\pi$-calculus (Sangiorgi 1996a), called the $\pi I$-calculus, where inputs are guaranteed to be private. The syntax and semantics for a fragment of the $\pi I$-calculus are presented in Figure 6. The private restriction on input names is enforced by using $\exists$ in place of $\exists$ in the embedding of private inputs. We are able to obtain that for our embedding of $\pi I$-calculus processes as formulae in $\mathcal{BV}$, linear implication is sound with respect to complete weak simulation, and hence also completed trace inclusion.
The embedding of $\pi I$-calculus processes as $BV1$ formulae is defined as follows:

$$[1]_{\pi I} = \circ \quad [p \mid q]_{\pi I} = [p]_{\pi I} \circ [q]_{\pi I} \quad [\nu x.p]_{\pi I} = \Pi x.[p]_{\pi I}$$

$$[x[z].p]_{\pi I} = \exists z.(xz \circ [p]_{\pi I}) \quad [\exists z.p]_{\pi I} = \Pi z.(\exists z \circ [p]_{\pi I}).$$

Recall from the discussion in Section 3.2 that we use the syntax $x[z]$ to represent private input in the $\pi I$-calculus to syntactically disambiguate from the semantically distinct input $x(z)$ in the $\pi$-calculus. The output process $\exists z.[p].p$ behaves much like the output $\nu z.\exists z.p$ in the $\pi$-calculus, where the private name binder $\nu z$ appears immediately before the action that outputs the name $z$.

For every labelled transition there is a corresponding implication. As with the $\pi$-calculus, Lemma 3.11, the proof follows from cut elimination for $BV1$ (Theorem 3.2), by induction over the structure of the transition system.

**Proposition 6.1.** The following hold for $\pi I$-calculus processes.

- If $p \not\triangleright q$, then $[x[z].p]_{\pi I} \not\triangleright [p]_{\pi I}$ holds.
- If $p \not\triangleright q$, then $[x[z].p]_{\pi I} \not\triangleright [p]_{\pi I}$ holds.
- If $p \not\triangleright q$, then $[q]_{\pi I} \not\triangleright [p]_{\pi I}$.

We can define a fine notion of weak simulation for the $\pi I$-calculus (note the ‘open’ constraint is irrelevant for the $\pi I$-calculus, since no distinct free variable can be unified in any context).

**Definition 6.2.** A complete weak simulation is a relation, such that if $p \not\succ q$, the following hold:

- If $p \not\triangleright q$, then there exists $q'$ such that $q \not\triangleright q'$ and $q' \not\triangleright q$.
- If $p \not\triangleright q$, then there exists $q'$ such that $q \not\triangleright q'$ and $q' \not\succ q$.
- If $p \not\triangleright q'$, where $z$ fresh for $p$ and $q$, then there exists $q'$ such that $q \not\triangleright q'$ and $p' \not\succ q'$.
- If $p \not\triangleright q'$, where $z$ fresh for $p$ and $q$, then there exists $q'$ such that $q \not\triangleright q'$ and $p' \not\succ q'$.

Whenever there exists a complete weak simulation $\mathcal{R}$ such that $p \not\prec q$, we write $p \leq q$ and say $p$ is simulated by $q$.

As for the $\pi$-calculus, we can establish the soundness of linear implication with respect to complete weak simulation for the $\pi I$-calculus.

**Theorem 6.3.** For $\pi I$-calculus processes, if $\vdash [p]_{\pi I} \not\triangleright [q]_{\pi I}$, then $p \leq q$.

The proof follows a similar strategy to Proposition 5.10. The proof appeals to Proposition 6.1, Theorem 3.2, Proposition 4.11 and Lemma 4.13, as well as a similar argument to Scenarios of Lemmas 5.5 and 5.6, involving actions with bound names.

### 6.2 Explaining curiosities regarding name extrusion

A curiosity of $BV1$ is that in general the scope of names can only be extruded and not contracted. By this, we mean that when $x \neq Q$, there is not a proof of $\Pi x.P \not\triangleright Q \longrightarrow \Pi x.(P \not\triangleright Q)$ in general. A logical reason for this restriction is that attempts to include an equivalence equating the formulæ $\Pi x.P \not\triangleright Q$ and $\Pi x.(P \not\triangleright Q)$, where $x \neq Q$, presented difficulties when proving cut elimination. Instead we only have the rule *extrude new* in Fig. 4. Most likely, the unidirectional nature of *extrude new* is for deeper reasons. To see this, observe that, with *extrude new* as an equality,
instead of a unidirectional rule, the implication \([v_z a_z. v_z a_z]_\pi \rightarrow [v_z a_z a_z]_\pi\) would wrongly be provable. Such an implication would be unsound with respect to weak simulation. The former process outputs two distinct names, but the latter cannot.

The curiosity regarding scope extrusion, mentioned above, can also be explained in terms of the ability of BV1 to express both the \(\pi\)-calculus and the \(\pi I\)-calculus. To see this, suppose that we provide semantics that combines the \(\pi\)-calculus and the \(\pi I\)-calculus. Such a semantics should give a meaning to process \(a[x], a[y] \mid v_z a_z a_z\), where \(a[x], a[y]\) here represents private inputs of the \(\pi I\)-calculus and \(v_z a_z a_z\) is a \(\pi\)-calculus term that outputs the same fresh name twice. Naïvely, we may wrongly think that the following two transitions form a completed trace.

\[
\begin{array}{c}
\frac{a[x], a[y]}{a[x]} \quad \frac{\rightarrow}{\pi[z]} \quad \frac{\rightarrow}{a_z} \\
\frac{a[x], a[y] \mid v_z a_z a_z}{a[x], a[y] \mid v_z (a[y] \mid a_z)} \\
\end{array}
\]

Suppose, in this hybrid \(\pi/\pi I\)-calculus setting, we wrongly assume that \(v_z (a[y] \mid a_z)\) and \(a[y] \mid v_z a_z\) are equivalent, thereby allowing the above \(\tau\)-transitions to be applied one after another. By making this flawed design decision, we would break the contract on the first private input. In particular, the fresh name \(z\) unified with \(x\) must be guaranteed freshness in the scope of \(x\).

Fortunately, \(v_z (a[y] \mid a_z)\) is not equivalent to \(a[y] \mid v_z a_z\), since the labelled transitions system naturally only pushes fresh names outward. Therefore, \(v_z (a[y] \mid a_z)\) is deadlocked, since \(a_z\) cannot guarantee that the output is private in the relevant scope. Thus process \(v_z (a[y] \mid a_z)\) is not mutually similar to \(a[y] \mid v_z a_z\). However, we do have that \(v_z (a[y] \mid a_z) \leq a[y] \mid v_z a_z\) holds, established by extending the results of this paper to a combined \(\pi/\pi I\)-calculus.

7. Conclusion

This work presents a purely logical embedding of \(\pi\)-calculus and \(\pi I\)-calculus processes as formulae in a proof system. The main result is the soundness of linear implication in the logical system with respect to a notion of weak simulation called complete weak open simulation (Theorem 3.8). The proof is constructive, so such weak simulations can be constructed from linear implications. This result sharpened evidence that linear implication objectively defines a preorder over processes, preserved in all contexts, in the sense that the semantics of linear implication are determined by the fundamental proof theoretic principal of cut elimination, rather than human design. The result is as a critical step in the roadmap towards situating properly this natural preorder in the spectrum of preorders over processes. In particular, linear implication is a branching-time preorder preserved in all contexts.

The paper also casts light on proof search in the calculus of structures. In Proposition 4.11, we show, for a significant fragment of BV and BV1 (larger than previously considered), ‘left proofs’ can always be constructed, where interaction rules are applied only in certain ‘left contexts’. This normalisation procedure ensures that the leftmost atom in a formula is involved in the bottommost instance of an interaction rule. This suggests that, as for other proof systems (Andreoli 1992; Miller et al. 1991), there are significant useful fragments of the calculus of structures for which we can achieve finer control of proof search.

Future work is to pursue the roadmap laid out at the beginning of Section 2. We aim to tighten relationships between linear implication and established preorders over processes, pursuing the hypothesis that (complete weak) variants of ST-simulation (van Glabbeek and Vaandrager 1987; van Glabbeek and Goltz 2001) provide the tightest match for linear implication in the literature. Also, we are in the process of further extending BV such that more expressive process calculi can be embedded, e.g., featuring probabilistic choice. Indeed, one of the advantages of having
established that linear implication is a branching-time preorder is that we know linear implication also respects probabilistic testing (Deng et al. 2007).

Acknowledgements. The authors receive support from MOE, Singapore, Tier 2 grant MOE2014-T2-2-076 and the National Research Foundation Singapore under its National Cybersecurity R&D Program (Award No. NRF2014NCR-NCR001-30). The authors are grateful to Alessio Guglielmi, who suggested trying a de Morgan dual pair of nominal quantifiers.

Notes
1 Details of cut elimination for MAV1 appear in a supporting technical report (Horne et al. 2018).
2 An extensive discussion on this implication appears in a companion paper (Horne et al. 2018).
