(Dated: February 1, 2008)

The entanglement fidelity provides a measure of how well the entanglement between two subsystems is preserved in a quantum process. By using a simple model we show that in some cases this quantity in its original definition fails in the measurement of the entanglement preserving. On the contrary, the modified entanglement fidelity, obtained by using a proper local unitary transformation on a subsystem, is shown to exhibit the behavior similar to that of the concurrence in the quantum evolution.

PACS numbers: 03.67.Mn, 03.65.Ud

Quantum entanglement is a key element for applications of quantum communications and quantum information. A complete discussion of this has been given in Ref. [1]. Characterizing and quantifying the entanglement is a fundamental issue in quantum information theory. For pure and mixed states of two qubits this problem about the description of the entanglement has been well elucidated [2, 3, 4, 5, 6, 7]. Recently, Jordan et al. [8] considered two entangled qubits, one of which interacts with a third qubit named as a control one that is never entangled with either of the two entangled qubits. They found that the entanglement of these two qubits can be both increased and decreased by the interaction with the control qubit on just one of them. If we regard the control qubit as an environment and the state of the qubit interacting with the control qubit as the information source, this example is just a model for the time evolution of quantum information via a noisy quantum channel originating from the interaction with the control qubit. Schumacher [9] and Barnum et al. [10] have investigated a general situation where R and Q are two quantum systems and the joint system RQ is initially prepared in a pure entangled state |ΨRQ⟩. The system R is dynamically isolated and has a zero internal Hamiltonian, while the system Q undergoes some evolution that possibly involves interaction with the environment. The evolution of Q might represent a transmission process via some quantum channel for the quantum information in Q. They introduced a fidelity \( F_e = \langle \Psi^{RQ} | \rho^{RQ} | \Psi^{RQ} \rangle \), which is the probability that the final state \( \rho^{RQ} \) would pass a test checking whether it agrees with the initial state \( |\Psi^{RQ}\rangle \). This quantity is called as entanglement fidelity (referred hereafter as EF). The EF can be defined entirely in terms of the initial state \( \rho^{Q} \) and the evolution of system Q, so EF is related to a process, specified by a quantum operation \( \varepsilon^{Q} \), which we shall discuss later in more details, acting on some initial state \( \rho^{Q} \). Thus, the EF can be denoted by a function form \( F_e(\rho^{Q}, \varepsilon^{Q}) \). The EF is usually used to measure how well the state \( \rho^{Q} \) is preserved by the operation \( \varepsilon^{Q} \) and to identify how well the entanglement of \( \rho^{Q} \) with other systems is preserved by the operation of \( \varepsilon^{Q} \). The complete discussion of EF can be seen in [9, 11]. In the present work we will investigate the following question: Is EF a good measurement of the entanglement preserving? Using the example of Jordan et al., we find that in some cases EF defined above completely fails for measuring the entanglement preserving though it may be a good measurement of the entanglement preserving in the case of slight noise. We also find that in order to make the EF indeed equivalent to an entanglement measure the modified entanglement fidelity (MEF) should be used. Some detailed discussions about the MEF have been given in [3, 12, 13]. Recently, Surmacz et al. [14] have investigated the evolution of the entanglement in a quantum memory and showed that the MEF can be used to measure how well a quantum memory setup can preserve the entanglement between a qubit undergoing the memory process and an auxiliary qubit. For the example of Jordan et al., we derive an analytic expression of the MEF and the comparison of it with the concurrence is given.

Quantum operation \( \varepsilon^{Q} \) is a map for the state of Q

\[
\rho^{Q} = \varepsilon^{Q}(\rho^{Q}).
\]

Here \( \rho^{Q} \) is the initial state of system Q, and after the dynamical process the final state of the system becomes \( \rho^{Q'} \). Then the dynamical process is described by \( \varepsilon^{Q} \). In the most general case, the map \( \varepsilon^{Q} \) must be a trace-preserving and positive linear map [15, 16], so it includes all unitary evolutions. They also include unitary evolving interactions with an environment \( E \). Suppose that the environment is initially in state \( \rho^{E} \). The operator can be written as

\[
\varepsilon^{Q}(\rho^{Q}) = \text{Tr}_{E} U(\rho^{Q} \otimes \rho^{E}) U^\dagger = \text{Tr}_{E} (\rho^{Q} \otimes \sum_{i} p_{i} |i\rangle\langle i|) U^\dagger = \sum_{j} E^{Q}_{j} \rho^{Q} E^{Q}_{j\dagger},
\]

where \( \sum_{i} p_{i} |i\rangle\langle i| \) is the spectral decomposition of \( \rho^{E} \), with \{\langle i|\} \) being a base in the Hilbert space \( \mathcal{H}_{E} \) of
the environment $E$, and $E_j^Q = \sum_i \sqrt{p_i} |j_i\rangle U |i\rangle$. Now we can use Eq. (2) to get the intrinsic expression of $\langle \Psi^{RQ}|\rho^{RQ'}|\Psi^{RQ}\rangle$, i.e., $F_e(\rho^Q, \varepsilon^Q)$. Because

$$\rho^{RQ} = T^R \otimes \varepsilon^Q(\rho^{RQ}) = \sum_j (1^R \otimes E_j^Q)\rho^{RQ} (1^R \otimes E_j^Q)^\dagger,$$

(3)

one has

$$F_e = \langle \Psi^{RQ}|\rho^{RQ'}|\Psi^{RQ}\rangle = \sum_j \langle \Psi^{RQ}|(1^R \otimes E_j^Q)|\Psi^{RQ}\rangle \times \langle \Psi^{RQ'}|(1^R \otimes E_j^Q)^\dagger|\Psi^{RQ}\rangle = \sum_j (\text{Tr}\rho^Q E_j^Q)(\text{Tr}\rho^{Q'} E_j^Q).$$

(4)

If systems $R$ and $Q$ both have zero internal Hamiltonian and there is no interaction between $R$ and $Q$, the operation $\varepsilon^Q$ entirely originates from the interaction between $Q$ and the environment. In this sense the example of Jordan et al. [8] is a special case of this situation.

We consider two entangled qubits, $A$ and $B$, and suppose that qubit $A$ interacts with a control qubit $C$. Then $A$, $B$, and $C$ respectively correspond to systems $Q$, $R$, and environment $E$ that we have just referred. We suppose that the initial states of the three qubits are

$$W = \rho^{AB}_\pm \otimes \frac{1}{2}1_C,$$

(5)

where

$$\rho^{AB}_\pm = \frac{1}{4}(1 \pm \sigma^A_1 \sigma^B_1 \pm \sigma^A_2 \sigma^B_2 - \sigma^A_3 \sigma^B_3),$$

(6)

with $\sigma^{A(B)}_i$, $i = 1, 2, 3$, being Pauli matrices for qubit $A(B)$. $\rho^{AB}_+$ and $\rho^{AB}_-$ are two Bell states, representing the maximally entangled pure states for the combined system of qubits $A$ and $B$. The total spins of states $\rho^{AB}_+$ and $\rho^{AB}_-$ are 0 and 1, respectively.

We suggest an interaction between qubit $A$ and $C$ described by the unitary transformation

$$U = e^{-itH},$$

(7)

where

$$H = \frac{\lambda \sigma^A_3}{2}(|\alpha\rangle \langle \alpha| + |\beta\rangle \langle \beta|).$$

(8)

$\lambda$ is the strength of the interaction, and $|\alpha\rangle$ and $|\beta\rangle$ are two orthonormal vectors for system $C$. Then the changing density matrix for the combined system of qubits $A$ and $B$ can be calculated as

$$\rho^{AB'} = \text{Tr}_c[(U \otimes 1^B)W(U \otimes 1^B)^\dagger] = \frac{1}{4}[1 \pm (\sigma^A_1 \sigma^B_1 + \sigma^A_2 \sigma^B_2) \cos(\lambda t) - \sigma^A_3 \sigma^B_3)]$$

$$= \rho^{AB}_+ \cos^2(\frac{\lambda t}{2}) + \rho^{AB}_- \sin^2(\frac{\lambda t}{2}),$$

(9)

The changing density matrix $\rho^{AB'}$ usually represents a mixed state. In order to quantify the entanglement of it we use the Wootters concurrence $C$ defined as

$$C(\rho) = \max[0, \sqrt{\lambda_1} - \sqrt{\lambda_2} - \sqrt{\lambda_3} - \sqrt{\lambda_4}],$$

(10)

where $\rho$ is the density matrix representing the investigated state of the combined system of $A$ and $B$, $\lambda_1$, $\lambda_2$, $\lambda_3$, and $\lambda_4$ are the eigenvalues of $\rho \sigma^A_3 \sigma^B_3 \rho^* \sigma^A_3 \sigma^B_3$ in the decreasing order, and $\rho^*$ is the complex conjugation of $\rho$. From Eq. (9) we can obtain

$$C(\rho^{AB'}) = |\cos \lambda t|.$$  

(11)

It is found that at time $\lambda t = \frac{\pi}{4}$, the state $\rho^{AB'}$ is changed from a maximally entangled state at $t = 0$ to a separable state and at time $\lambda t = \pi$ the state $\rho^{AB'}$ returns to the maximally entangled state. The explicit calculation about $\rho^{AB'}$ and $C(\rho^{AB'})$ can be seen in [8].

Now we adopt the EF to investigate this example. Using Eqs. (2), (5), (7), and (8), we obtain the quantum operation on qubit $A$,

$$\varepsilon^A(\rho^A) = \text{Tr}_C U (\rho^A \otimes \rho^2) U^\dagger$$

$$= \text{Tr}_C U \left( \rho^A \otimes (\frac{1}{2}(|\alpha\rangle \langle \alpha| + |\beta\rangle \langle \beta|)) \right) U^\dagger$$

$$= \frac{1}{2}e^{-i\sigma^A_3(\frac{\lambda t}{2})} \rho^A e^{i\sigma^A_3(\frac{\lambda t}{2})}$$

$$+ \frac{1}{2}e^{i\sigma^A_3(\frac{\lambda t}{2})} \rho^A e^{-i\sigma^A_3(\frac{\lambda t}{2})}.$$  

(12)

So $E^A_\alpha = \frac{1}{\sqrt{2}}e^{-i\sigma^A_3(\frac{\lambda t}{2})}$ and $E^A_\beta = \frac{1}{\sqrt{2}}e^{i\sigma^A_3(\frac{\lambda t}{2})}$. Substituting them into Eq. (8) and noting that $\rho^A \equiv \text{Tr}_B(\rho^{AB}_\pm) = \frac{1}{4}1$, we can get the EF as

$$F_e = \sum_j (\text{Tr}\rho^A E^A_j)(\text{Tr}\rho^A E^A_j^\dagger)$$

$$= \left( \frac{1}{\sqrt{2}} \text{Tr} \left[ \left( e^{-i\frac{\lambda t}{2}} 0 \right) \frac{1}{2} \left( 1 0 0 1 \right) \right] \right)^2$$

$$+ \left( \frac{1}{\sqrt{2}} \text{Tr} \left[ \left( e^{i\frac{\lambda t}{2}} 0 \right) e^{-i\frac{\lambda t}{2}} \frac{1}{2} \left( 1 0 0 1 \right) \right] \right)^2$$

$$= \left( \frac{\lambda t}{2} \right)^2.$$  

(13)

We can easily find the disagreement between the evolutions of $F_e$ and $C(\rho^{AB'})$. At $\lambda t = \pi$, state $\rho^{AB'}_\pm$ returns to the maximally entangled state as can be seen from the concurrence, but its entanglement fidelity is zero ($F_e = 0$). On the contrary, the initial maximally entangled state have been changed to a separable state at $\lambda t = \frac{\pi}{4}$, but the EF at this time is not zero. The evolutions of EF $F_e$ and concurrence $C(\rho^{AB'})$ are depicted in Fig. 1.

In fact, $F_e(\rho^Q, \varepsilon^Q) = F^2(\rho^{RQ}, \rho^{RQ'})$, where $F_e(\rho^{RQ}, \rho^{RQ'})$ is the static fidelity [11]. The static fidelity satisfies $0 \leq F_e(\rho^{RQ}, \rho^{RQ'}) \leq 1$, where the first
symbol of "≤" becomes equality if and only if ρ^{RQ} and ρ^{RQ'} have orthogonal support, and the second symbol becomes equality if and only if ρ^{RQ} = ρ^{RQ'}. When λ = π, from Eq. (9) we can see that ρ^{A}_{AB} = ρ^{A}_{2B}. The ρ^{A}_{2AB} are two different Bell states and correspond respectively to eigenstates of total spin one and total spin zero of the combined system of qubits A and B. So they have orthogonal support in the Hilbert space \( \mathcal{H}^A \otimes \mathcal{H}^B \). This is the reason for the fact that \( F_e(\rho^A, \varepsilon^Q) = F_e^2(\rho^{A}_{AB}, \rho^{A}_{2B}) = 0 \) at \( \lambda = \pi \).

The concept of the EF arises from the mathematical description for the purification of mixed states. Any mixed state can be represented as a subsystem of a pure state in a larger Hilbert space. The entanglement of a pure state may cause the states of subsystems to be mixed. The EF is usually used to measure how faithfully a channel maintains the purification, or, equivalently, how well the channel preserves the entanglement. In the above simple example, however, we have found that, except for some special cases, only in the case of slight noise, i.e., \( \lambda t \longrightarrow 0 \), the EF approximately agrees with the concurrence. This means that this quantity may not be a good measurement for the evolution of the entanglement in the processes of interaction with the environment.

In fact, Schumacher has noted that the EF can be lowered by a local unitary operation but the entanglement cannot be so. From this consideration he defined the MEF

\[
F_e' = \max_{U^{Q'}} \left< \Psi^{RQ} \right| (1^R \otimes U^{Q'}) \rho^{RQ'} (1^R \otimes U^{Q'})^\dagger \left| \Psi^{RQ} \right>
\]

where \( U^{Q} \) is any unitary transformation acting on \( Q \). It is clear that \( F_e' \geq F_e \). Since by using a proper local unitary operation we can make the Bell state \( \rho^{A}_{AB} \) become the Bell state \( \rho^{2AB}_{A} \), we can find that in the above example \( F_e' = 1 \) at time \( \lambda t = \pi \) whereas \( F_e = 0 \) at this time. So at \( \lambda t = \pi \), the MEF equals the concurrence. By using the quantum operation which we discussed above, we can get the intrinsic expression of the MEF

\[
\begin{align*}
F_e' &= \max_{U^{Q}} \left< \Psi^{RQ} \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
\times \left< \Psi^{RQ} \right| (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
= \max_{U^{Q}} \left< \left< \left. \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right> \right. \left| \Psi^{RQ} \right> \right>
\end{align*}
\]

For this example we can derive an analytic expression of \( F_e' \). Suppose U is an arbitrary unitary operation on a single qubit. Then it can be written as \( R_{\gamma(z)} \)

\[
U = e^{-i\alpha} R_{\gamma(z)} R_{\beta(y)}(\gamma) R_{\delta(z)}
\]

where \( \alpha, \beta, \gamma \) and \( \delta \) are real numbers, and \( R_{\gamma(z)} \) is the rotation operator about the \( y(z) \) axis. We have

\[
\begin{align*}
\sum_{j} \left( \text{Tr} \rho^A U E^A_j \right) \left( \text{Tr} \rho^A (U E^A_j)^\dagger \right) &= \frac{1}{2} \left( 1^2 \text{Tr} \left( e^{i(-\beta/2-\gamma/2) \cos \frac{\gamma}{2}} \right) \right)^2 \\
&= \frac{1}{2} \left( \text{Tr} \left( e^{i(-\beta/2-\gamma/2) \cos \frac{\gamma}{2}} \right) \right)^2 \\
&= \frac{1}{2} \text{Tr} \left( e^{i(-\beta/2-\gamma/2) \cos \frac{\gamma}{2}} \right)^2 \\
&= \frac{1}{2} \cos^2 \left( \gamma \right) \cos^2 \left( \beta/2 + \delta/2 + \lambda t/2 \right) \\
&+ \frac{1}{2} \cos^2 \left( \gamma \right) \cos^2 \left( \beta/2 + \delta/2 - \lambda t/2 \right).
\end{align*}
\]

We should find a unitary operator \( U \) which make

\[
\begin{align*}
F_e' &= \max_{U^{Q}} \left< \Psi^{RQ} \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
\times \left< \Psi^{RQ} \right| (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
= \max_{U^{Q}} \left< \left< \left. \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right> \right. \left| \Psi^{RQ} \right> \right>
\end{align*}
\]

where \( U^{Q} \) is any unitary transformation acting on \( Q \). It is clear that \( F_e' \geq F_e \). Since by using a proper local unitary operation we can make the Bell state \( \rho^{A}_{AB} \) become the Bell state \( \rho^{2AB}_{A} \), we can find that in the above example \( F_e' = 1 \) at time \( \lambda t = \pi \) whereas \( F_e = 0 \) at this time. So at \( \lambda t = \pi \), the MEF equals the concurrence. By using the quantum operation which we discussed above, we can get the intrinsic expression of the MEF

\[
\begin{align*}
F_e' &= \max_{U^{Q}} \left< \Psi^{RQ} \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
\times \left< \Psi^{RQ} \right| (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right>
= \max_{U^{Q}} \left< \left< \left. \right| (1^R \otimes U^{Q}) \rho^{RQ} (1^R \otimes U^{Q})^\dagger \left| \Psi^{RQ} \right> \right. \left| \Psi^{RQ} \right> \right>
\end{align*}
\]
\[ 1 + \cos^2(\beta/2 + \delta/2)(2\cos^2(\lambda t/2) - 1) \]
\[ - \cos^2(\lambda t/2). \]  
(17)

When \(2\cos^2(\lambda t/2) - 1 \geq 0\) we take \(\cos^2(\beta/2 + \delta/2) = 1\) and get \(F'_c = \cos^2(\lambda t/2)\); when \(2\cos^2(\lambda t/2) - 1 < 0\) we take \(\cos^2(\beta/2 + \delta/2) = 0\) and get \(F'_c = 1 - \cos^2(\lambda t/2)\).

The evolutions of the MEF \(F'_c\) and the concurrence \(C(\rho^A B'\rho^A B')\) are depicted in Fig. 2. We can find that the MEF and the concurrence exhibit a similar behavior, although their values do not exactly agree with each other at all moments. When the state \(\rho^A B'\rho^A B'\) returns to the maximally entangled state, the MEF is equal to 1. The maximal difference between them comes at the separable states where the MEF is equal to 1/2 while the concurrence is zero.

We have mentioned that the EF equals 1 if and only if \(\rho^{RQ} = \rho^{RQ'}\). This means that the EF can be used to measure the difference between a quantum channel and the identity channel. If the concern is on the entanglement preserving in an evolution process, however, one has to use the MEF because the EF can be lowered by a local unitary operation in this process but the entanglement cannot be so. If a quantum channel is just a unitary operator, the entanglement is certainly invariant and the MEF always equals to 1 in the quantum process. In this sense the MEF can be used to measure the difference between a quantum channel and an arbitrary unitary operator.

In summary, for the example of Jordan et al., we have derived the analytic expressions of both the EF and the MEF, and show the comparisons of them with the concurrence. From these we find that the MEF may admirably reflects the entanglement preserving in a quantum process.

Acknowledgments We wish to thank K. Surmacz for his stimulating discussion which leads us to notice the MEF.
