$B\bar{B}$ mixing with the bulk fields in the Randall-Sundrum model

Jong-Phil Lee*

Abstract

We calculate the $B\bar{B}$ mixing in the Randall-Sundrum bulk model. In this model, all the Standard Model fields except the Higgs can reside in the bulk. Two suggestive models of "mixed" and "relaxed" scenarios are considered. We find that the enhancement of the loop function is 0.51% for the "relaxed" and 1.07% for the "mixed" scenario when the first 4th KK modes are included, for a bulk fermion mass parameter $\nu = -0.3$.

I. INTRODUCTION

The idea of extra dimension provides a very elegant explanation for the gauge hierarchy problem of the standard model (SM). Arkani-Hamed, Dimopoulos, and Dvali (ADD) suggested that there exist $n$ flat extra dimensions with factorizable geometry [1]. In this model, the enormous Planck scale $M_{Pl}$ is induced by the largeness of the extra dimensional volume $V_n$, via $M_{Pl}^2 = M_0^{n+2}V_n$. New fundamental scale $M_0$ in $4 + n$ dimension can be set down around 1 TeV, which resolves the hierarchy problem. An alternative to ADD was soon proposed by Randall and Sundrum (RS) [2] where the gauge hierarchy is explained by an exponential warp factor from a 5-dimensional non-factorizable geometry. In this model, two branes are embedded at the boundaries of the AdS$_5$ slice with a single $S_1/Z_2$ orbifold extra dimension.

In the original model of ADD or RS, only the gravity can propagate in the bulk. Effects of the bulk graviton appear in 4D world as an infinite tower of Kaluza-Klein (KK) modes. Their phenomenological signatures at colliders are widely studied.

A natural extension at the next step is to put the SM fields into the bulk. In the universal extra dimension (UED) model by Appelquist, Cheng, and Dobrescu (ACD), all the SM fields are allowed to live in the extra dimensions [3]. In the RS model, Goldberger and Wise tried to put the scalar fields into the bulk, which has been developed to the bulk-stabilizing modulus field, or radion [4]. They provided an open possibility that the SM matter fields might reside in the extra dimension. Later the gauge bosons are placed in the bulk in [5]. But the electroweak precision data constrain the first KK state of the gauge boson so strongly that the typical scale on the TeV brane goes up to about 100 TeV. Apparently, this is not a good solution to the gauge hierarchy problem. The problem was alleviated by putting fermion fields in the bulk while confining the Higgs to the TeV brane [6]. An attempt of constructing the bulk fermion fields was already done in [7] to explain the neutrino masses and mixings.

Equipped with the RS-bulk SM fields, lots of works have been done to refine the model and accommodate it to the existing data. Here the fermion mass parameter $\nu \equiv m_\psi/k$ plays an important role, where $m_\psi$ is the fermion bulk mass and $R_5 = -20k^2$ is the 5-dimensional curvature [8,9]. When placing the fermion fields in the bulk, there might occur large contributions to the flavor changing neutral current (FCNC) or the SM $\rho$ parameter. Simple assumptions of a universal bulk fermion mass and the minimal flavor violation where the CKM paradigm governs the flavor mixing can be a solution to this potential problems.

However, when the Yukawa interaction is taken into account, non-negligible mixing in the top sector can give a large contribution to the $\rho$ parameter. Even worse is that the shifted mass spectrum in the top quark KK modes does not guarantee the Glashow-Iliopoulos-Maiani (GIM) cancellation, which will cause a disastrous FCNC. Toward a more realistic model, Hewett-Petriello-Rizzo (HPR) proposed the so called ”mixed scenario” where the first two generations of fermions are placed in the bulk while the third is localized on the TeV brane [10]. While the HPR model reproduces the quark mass hierarchies $m_c/m_t$ and $m_s/m_b$ without spoiling the $\rho$ parameter constraints, it seems unnatural to confine only one family into the wall; there still remains a potential danger of FCNC.

As an alternative, a ”relaxed” model was suggested by Kim-Kim-Song (KKS) where the assumption of universal bulk fermion mass is slightly modified, retaining all the fermions in the bulk [11]. In this approach, the $SU(2)$-singlet bottom quark field has a different bulk
mass $m'_\psi$. They showed that introducing another parameter can be accommodated well to the electroweak precision data of $\Delta \rho \equiv \rho - \rho_{SM}$ and $b \to s\gamma$.

In this paper, we analyze $B\bar{B}$ mixing based on the KKS. With the advent of the $B$-factory era, we are now entering the age of precision tests of flavor physics. Current world average of $\Delta M_B$, which parameterizes the $B\bar{B}$ mixing, is $\Delta M_B = 0.502 \pm 0.006$ ps$^{-1}$ [12] where the experimental error is very small. Relevant box diagrams are already studied in ACD-UED model, resulting in a 17% enhancement of the loop function [13,14]. Present work will be a good comparison to the ACD-UED result. It is also interesting to compare the results from KKS and HPR each other. If the fermion mass parameter $\nu = -0.3$ is chosen (which is phenomenologically viable in the literature), especially, mixing in the top sector is rather small; the GIM cancellation is incomplete but we expect some remnant. And the diagonalization of the mass matrix can be done perturbatively. Naive thoughts lead to the idea that HPR will produce larger effects than KKS, yielding to what amount of the excess of FCNC from the HPR would appear.

The paper is organized as follows. The RS-bulk model is reviewed in the next Section. We simply omit the gravity in the set up. In Sec. III, mixing in the top sector is considered. We follow the description of KKS [11], and do not consider possible gauge boson mixing for simplicity. The box diagrams for the $B\bar{B}$ mixing are calculated in Sec. IV. Section V contains the results and discussions. A summary is given in Sec. VI.

II. SETUP OF THE MODEL

In the RS model, one spatial dimension is compactified on a $S_1/Z_2$ orbifold of radius $r_c$ with a nonfactorizable geometry

$$ds^2 = G_{MN}dx^M dx^N = e^{-2\sigma(\phi)} \eta_{\mu\nu} dx^\mu dx^\nu + r_c^2 d\phi^2,$$

where the four-dimensional metric tensor is $\eta_{\mu\nu} = \text{diag}(1, -1, -1, -1)$, and $\sigma(\phi) = kr_c|\phi|$, $0 \leq |\phi| \leq \pi$. The model parameter $k$ is related to the 5-dimensional curvature $R_5 = -20k^2$.

In the original RS model, only the graviton can propagate through the bulk with its KK modes. We do not consider the graviton KK modes here because they are irrelevant for $B\bar{B}$ mixing. We follow the model setup of KKS [11].

Nonabelian gauge fields $A^a_M(x, \phi)$ can reside in the bulk via the 5D action

$$S_A = -\frac{1}{4} \int d^5x \sqrt{-G} G^{MK} G^{NL} F^a_{KL} F^a_{MN},$$

where $F^a_{MN} = \partial_M A^a_N - \partial_N A^a_M - g_5 \epsilon^{abe} A^b_M A^e_N$ ($a, b, c = 1, 2, 3$). Choosing the gauge of $A_4(x, \phi) = 0$ and assuming the KK expansion of $A_\mu$ to be

$$A^a_\mu(x, \phi) = \sum_{n=0}^{\infty} A^{a(n)}_\mu(x) \frac{X^{(n)}_A(\phi)}{\sqrt{r_c}},$$

we have a 4-dimensional effective action of massive KK gauge bosons as
where

\[ D = \text{obtained by the orthonormality condition} \]

Consider the bulk fermion with arbitrary Dirac bulk mass. A Dirac fermion field \( \Psi \) with bulk mass \( m_\psi \) is described by the 5-dimensional action [7]

\[ S_F = \int d^4x \int d\phi \sqrt{-G} \left\{ E^A_\Lambda \left[ \frac{i}{2} \bar{\Psi} \gamma^A (D_A - \bar{D}_A) \Psi \right] - m_\psi \text{sgn}(\phi) \bar{\Psi} \Psi \right\}, \]

where \( D_A \) is the covariant derivative, \( \gamma^A = (\gamma^\mu, i\gamma_5) \), and the inverse vielbein \( E^A_\Lambda = \text{diag}(e^\sigma, e^\sigma, e^\sigma, e^\sigma, 1/r_c) \). The underlined uppercase Roman indices describe objects in the tangent frame. Possible spin connection \( \omega_{\mu\nu} \) is omitted because it vanishes when the Hermitian conjugate is included.

Integration by parts leads to

\[ S_F = \int d^4x \int d\phi r_c \left\{ e^{-3\sigma} \left( \bar{\Psi}_L i \partial_\phi \Psi_L + \bar{\Psi}_R i \partial_\phi \Psi_R \right) \right. \]

\[ + \frac{1}{2} r_c \left[ \bar{\Psi}_L (e^{-4\sigma} \partial_\phi + \partial_\phi e^{-4\phi}) \Psi_R - \bar{\Psi}_R (e^{-4\sigma} \partial_\phi + \partial_\phi e^{-4\phi}) \Psi_L \right] \]

\[ - e^{-4\sigma} m_\psi \text{sgn}(\phi) (\bar{\Psi}_L \Psi_R + \bar{\Psi}_R \Psi_L) \right\}, \]
where the periodic boundary conditions of $\Psi_{L,R}(x, \pi) = \Psi_{L,R}(x, -\pi)$ are imposed. Expanding $\Psi$ as

$$\Psi_{L,R}(x, \phi) = \sum_{n=0}^{\infty} \psi^{(n)}_{L,R} e^{2\sigma(\phi) \hat{f}^{(n)}_{L,R}(\phi)} ,$$

and requiring that

$$\int_{-\pi}^{\pi} d\phi e^{\sigma(\phi)} \hat{f}^{(m)*}_{L}(\phi) \hat{f}^{(n)}_{L}(\phi) = \int_{-\pi}^{\pi} d\phi e^{\sigma(\phi)} \hat{f}^{(m)*}_{R}(\phi) \hat{f}^{(n)}_{R}(\phi) = \delta_{mn} ,$$

$$\left( \pm \frac{1}{r_c} \partial_{\phi} - m_{\psi} \right) \hat{f}^{(n)}_{L,R}(\phi) = -M^{(n)}_{L} e^{\sigma} \hat{f}^{(n)}_{R,L}(\phi) ,$$

we have the effective action for the massive Dirac fermions

$$S_{F} = \sum_{n=0}^{\infty} \int d^{4}x \left[ \bar{\psi}^{(n)}(x)i\gamma^{\mu} \partial_{\mu} \psi^{(n)}(x) - M^{(n)}_{L} \bar{\psi}^{(n)}(x) \psi^{(n)}(x) \right] .$$

The $Z_{2}$-symmetry of $S_{F}$ in (10) requires that $\bar{\Psi} \Psi = \bar{\Psi}_{L} \Psi_{R} + \bar{\Psi}_{R} \Psi_{L}$ be $Z_{2}$-odd. This requirement is satisfied if we impose the opposite $Z_{2}$-parity on $\hat{f}^{(n)}_{L,R}$. We fix $\hat{f}^{(n)}_{L,R}$ to be $Z_{2}$-even(odd). Introducing $\nu \equiv m_{\psi}/k$ of order 1, the solutions are, for $n \neq 0$,

$$\hat{f}_{L}^{(n)} \equiv \chi^{(n)}(\phi) = \frac{e^{\sigma/2}}{N^{(n)}_{\chi}} \left[ J_{1/2-\nu}(z^{(n)}) + \beta^{(n)}_{\chi} Y_{1/2-\nu}(z^{(n)}) \right] ,$$

$$\hat{f}_{R}^{(n)} \equiv \tau^{(n)}(\phi) = \frac{e^{\sigma/2}}{N^{(n)}_{\tau}} \left[ J_{1/2+\nu}(z^{(n)}) + \beta^{(n)}_{\tau} Y_{1/2+\nu}(z^{(n)}) \right] ,$$

where $z^{(n)}_{f}(\phi) \equiv (M^{(n)}_{f}/k)e^{\sigma(\phi)}$ and for $n = 0$,

$$\chi^{(0)}(\phi) = \frac{e^{\nu\sigma(\phi)}}{N^{(0)}_{\chi}} , \quad \tau^{(0)}(\phi) = 0 .$$

Mass spectrum and the coefficients $\beta^{(n)}_{\chi,\tau}$ as well as the normalization constants $N^{(n)}_{\chi,\tau}$ are determined by the boundary conditions:

$$0 = \left( \frac{d}{d\phi} - m_{\psi} r_{c} \right) \chi^{(n)}|_{\phi=0,\pi} - \tau^{(n)}|_{\phi=0,\pi} .$$

Explicitly,

$$\beta^{(n)}_{\chi} = - \frac{J_{-(1/2+\nu)}(M^{(n)}_{f}/k)}{Y_{-(1/2+\nu)}(M^{(n)}_{f}/k)} ,$$

from the boundary conditions at $\phi = 0$, and
\[ J_{-(1/2+\nu)}(x_f^{(n)}) + \beta^{(n)}_\chi Y_{-(1/2+\nu)}(x_f^{(n)}) = 0 \]  

(20)

at \( \phi = \pi \), where \( x_f^{(n)} \equiv z_f^{(n)}(\phi = \pi) \). Similar expressions can be given for the \( \tau^{(n)}(\phi) \) sector, and the left- and right-handed excitation masses are degenerate to \( M_f^{(n)} \) for a given \( n \). The normalization constants are

\[ N^{(n)}_{\chi,\tau} = \frac{e^{-kr_c\pi}}{x_f^{(n)} \sqrt{kr_c}} \sqrt{z_f^{(n)}^2 \left[ J_{1/2+\nu}(z_f^{(n)}) + \beta^{(n)}_\chi Y_{1/2+\nu}(z_f^{(n)}) \right] \left[ z_f^{(n)}(\phi=\pi) \right] \left[ z_f^{(n)}(\phi=0) \right]} . \]  

(21)

Some difficulties arise when the fermions are included in the bulk because the fermion field contents must be doubled. In our setup of (11), a fermion which belongs to a specific representation of a gauge group should be vector-like, possessing both left- and right-handed chiralities. For each generation, we have an \( SU(2) \)-doublet \( Q = (q_u, q_d)^T \) and two \( SU(2) \)-singlets \( u \) and \( d \) where both chiralities are allowed for all of them. Explicitly,

\[ Q(x, \phi) = Q_L + Q_R = \sum_n \frac{e^{2\sigma(\phi)}}{\sqrt{r_c}} \left[ Q_L^{(n)}(x) \chi^{(n)}(\phi) + Q_R^{(n)}(x) \tau^{(n)}(\phi) \right] , \]  

(22a)

\[ u(x, \phi) = u_L + u_R = \sum_n \frac{e^{2\sigma(\phi)}}{\sqrt{r_c}} \left[ u_L^{(n)}(x) \tau^{(n)}(\phi) + u_R^{(n)}(x) \chi^{(n)}(\phi) \right] , \]  

(22b)

where we have assigned \( \chi^{(n)} \) to the left-handed \( SU(2) \) doublet and the right-handed \( SU(2) \) singlet in order to accommodate the SM fermion fields. The \( SU(2) \) singlet down part \( d(x, \phi) \) has the same KK decomposition as \( u(x, \phi) \).

With these bulk-SM fields, the charged current interactions look like

\[ S_{fW} = \int d^5x \sqrt{-G} e^\sigma \frac{g_5}{\sqrt{2}} [\bar{q}_u W^+ q_d + \text{h.c.}] \]

\[ = \int d^4x \frac{g}{\sqrt{2}} \sum_{l=0}^\infty \left[ \sum_{n,m=0}^\infty \bar{q}_u^{(n)} W^{+l} q_d^{(m)} (\sqrt{2\pi} \int_{-\pi}^\pi d\phi e^\sigma \tau^{(n)}(\phi) \chi^{(m)} A_l(\phi)) \right] + \text{h.c.} \]  

(23)

where \( g = g_5/\sqrt{2\pi r_c} \) and the coupling constant \( C_{nml}^{fW} \) is

\[ C_{nml}^{fW} = \sqrt{2\pi} \int_{-\pi}^\pi d\phi e^\sigma \chi^{(n)}(\phi) \chi^{(m)}(\phi) A_l(\phi) . \]  

(24)

**III. MIXING IN THE TOP SECTOR**

For the bulk fermions, there are two sources of physical fermion mass spectrum. One is the KK mass which is proportional to \( \sim \tilde{q}_u L q_d R \) or \( \sim \tilde{u}_L u_R \). The other is the Yukawa interaction which relates the \( SU(2) \) doublet with the singlet, \( \sim \tilde{q}_u L u_R \), as in the SM. This
difference results in mixing among the fermion KK modes. If the quark masses were sufficiently smaller than the KK mass scale, this mixing effects might be negligible. In this case, all the fermion KK mass spectrum would be almost degenerate assuming that the model is minimal with a single parameter $m_\psi$ for the universal bulk fermion mass. The exact degeneracy between the KK masses for the $T_3 = \pm 1/2$ fermions is responsible for the vanishing contribution to $\Delta \rho$. Furthermore, we can expect the GIM cancellation at each level of KK modes because all the up- (and down-) type quarks are degenerate.

The presence of top quark which is very heavy makes the mixing non-negligible. Consequently, degenerate top and bottom KK masses are shifted. They can cause a large $\Delta \rho$, because the quantum correction is proportional to the squared mass difference between up- and down-type quarks. Adding higher KK modes makes the problem worse.

As mentioned in the Introduction, HRP proposed the "mixed" scenario where the 3rd-generation fermions are confined to the TeV brane while the other two can propagate in the bulk. Instead, we adopt the KKS model of [11] where the $SU(2)$-singlet bottom quark field has a different bulk fermion mass $m'_b$. The model is recapitulated in the 5D action for the 3rd-generation quarks

$$S = \int d^4x \int d\phi \sqrt{-G} \left[ E^A_a(i\bar{Q}\gamma^aD_AQ + i\bar{t}\gamma^aD_At + i\bar{\nu}\gamma^aD_A\nu) \right] - \text{sgn}(\phi)(m_\psi \{\bar{Q}Q + \bar{t}t\} + m'_bbb) .$$

Expanding the fermion fields with the mode functions and integrating over $\phi$ yield the bulk fermion KK masses as

$$\mathcal{L} = -\sum_{n=1}^{\infty} k_{EW} \left[ x_f^{(n)}(\nu) \left( \bar{q}_L^{(n)} q_R^{(n)} + \bar{q}_b^{(n)} q_b^{(n)} + \bar{t}_L^{(n)} t_R^{(n)} \right) + x_f^{(n)}(\nu') \bar{b}_L^{(n)} b_R^{(n)} \right] + \text{h.c} .$$

where $k_{EW} = k\epsilon \equiv k e^{-k\tau_\pi}$, and $\nu' \equiv m'_b/k$.

Now consider the Yukawa interactions associating the Higgs boson. Ordinary Higgs mechanism works here so that the SM particles acquire masses. It has been argued, however, that if there were bulk Higgs fields, the hierarchy problem remains unsolved [6] or the observed $W$ and $Z$ mass relations cannot be reproduced [9]. We assume here that the Higgs field is confined to the TeV brane. Then the 5D action for Yukawa interactions is

$$S_{fIH} = -\int d^5x \sqrt{-G} \left[ \frac{\lambda^b_{bt}}{k} \bar{Q}(x,\phi) \cdot H(x)b(x,\phi) + \frac{\lambda^t_{t\nu}}{k} \bar{t}(x,\phi) \cdot H(x)t(x,\phi) + \text{h.c} \right] \delta(\phi - \pi) ,$$

where $\lambda^b_{bt}$ is the 5D Yukawa coupling. After the spontaneous symmetry breaking, the Higgs field shifts $H^0 \rightarrow v_5 + H^0$, and the 4D effective Lagrangian becomes

$$\mathcal{L}_{\text{eff}} = \frac{\lambda_{t\nu} v}{\sqrt{2}} (\tilde{q}_{L}^{(0)} + \tilde{\chi}_1 \tilde{q}_{L}^{(1)} + \cdots)(t_{R}^{(0)} + \tilde{\chi}_1 t_{R}^{(1)} + \cdots) + \frac{\lambda_{t\nu} v}{\sqrt{2}} (\tilde{q}_{bL}^{(0)} + \tilde{\chi}_1 \tilde{q}_{bL}^{(1)} + \cdots)(b_{R}^{(0)} + \tilde{\chi}_1 b_{R}^{(1)} + \cdots) ,$$

where $\lambda_{t\nu} = \lambda^b_{bt}(1 + 2\nu)/2(1 - \epsilon^{1+2\nu})$, $v = \epsilon v_5$, $\tilde{\chi}_n \equiv \chi^{(n)}(\pi,\nu)/\chi^{(0)}(\pi,\nu)$, and $\tilde{\chi}_n$ are with $\nu'$. 

7
From Eqs. (26) and (28), the physical mass term for the top sector is

$$\mathcal{L}_{\text{mass}}^t = - \left( \tilde{t}_R^{(0)} \tilde{t}_R^{(1)} \ldots | \tilde{q}_t^{(1)} \ldots \right) \mathcal{M}_t \left( \begin{array}{c} q_{tL}^{(0)} \\ q_{tL}^{(1)} \\ \vdots \\ q_{tL}^{(1)} \\ \vdots \\ q_{tL}^{(1)} \end{array} \right).$$

(29)

The bottom sector shows very similar mass terms. Let the number of the KK states be $n_\infty$ which is, in principle, infinite. Then the $(2n_\infty + 1) \times (2n_\infty + 1)$ matrix $\mathcal{M}_t$ has the form of

$$\mathcal{M}_t = \left( \begin{array}{cc} \mathcal{M}_Y^t & \mathcal{M}_{KK}^t \\ \mathcal{M}_{KK}^q & 0 \end{array} \right),$$

(30)

where the $(n_\infty + 1) \times (n_\infty + 1)$ matrix $\mathcal{M}_Y^t$ is from Yukawa mass term and the $(n_\infty + 1) \times n_\infty$ matrix $\mathcal{M}_{KK}^q$ from KK masses. They are given by

$$\mathcal{M}_Y^t = m_{t,0} \begin{pmatrix} 1 & \hat{\chi}_1 & \hat{\chi}_2 & \cdots \\ \hat{\chi}_1 & \hat{\chi}_2^2 & \hat{\chi}_1 \hat{\chi}_2 & \cdots \\ \hat{\chi}_2 & \hat{\chi}_2 \hat{\chi}_1 & \hat{\chi}_2^2 & \cdots \\ \vdots & \vdots & \vdots & \vdots \end{pmatrix},$$

(31a)

$$\mathcal{M}_{KK}^q = k_{EW} \begin{pmatrix} 0 & x_f^{(1)} & 0 & \cdots \\ 0 & 0 & x_f^{(2)} & \cdots \\ 0 & 0 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots \end{pmatrix} = \mathcal{M}_{KK}^t,$$

(31b)

where $m_{t,0} = \lambda_{t} v / \sqrt{2}$.

Now the physical mass eigenstates $u_L^{(n)}$ are obtained by diagonalizing (30) through an orthogonal matrix $\mathcal{N}$:

$$\begin{pmatrix} u_L^{(0)} \\ u_L^{(1)} \\ u_L^{(2)} \\ \vdots \end{pmatrix} = \mathcal{N} \begin{pmatrix} q_{uL}^{(0)} \\ q_{uL}^{(1)} \\ \vdots \\ q_{uL}^{(1)} \\ \vdots \end{pmatrix}.$$ 

(32)

For example, $q_{uL}$ can be written in terms of KK mass eigenstates $u_L^{(j)}$:

$$q_{uL}^{(n)} = \sum_{j=0}^{2n_\infty} \mathcal{N}_{(j,n)} u_L^{(j)}.$$ 

(33)
Hereafter, the underlined index runs from zero to $2n_{\infty}$. In terms of mass eigenstates, the $Wtb$-vertex in 4D becomes

$$\mathcal{L} = \frac{g}{\sqrt{2}} V_{tb} \left( \sum_{m=0}^{n_{\infty}} C_{9m}^{\text{Wtb}} N_{(2,m)}^{(0)} \right) \bar{b}_{L}^{(0)} \gamma_{\mu} l_{L}^{(f)} W^{(\mu)} + \text{h.c.} \quad (34)$$

For light quarks ($m_{q,0} = 0$), $M_{q}$ can be analytically diagonalized to $M_{q} \to \text{diag}(m_{q}^{(0)}, M_{1}^{(0)}, M_{2}^{(0)}, \ldots)$ where

$$m_{q}^{(0)} = 0 \; , \; M_{n}^{(0)} = M_{n_{\infty}+n} = x_{f}^{(n)} k_{EW} \; . \quad (35)$$

The corresponding orthonormal matrix $\mathcal{N}^{(0)}$ is

$$\mathcal{N}_{(0,0)}^{(0)} = 1 \; , \; \mathcal{N}_{(2,0)}^{(0)} = \mathcal{N}_{(2,2)}^{(0)} = 0 \; , \; \mathcal{N}_{(n,m)}^{(0)} = -\mathcal{N}_{(n_{\infty}+n,m)}^{(0)} = \frac{\delta_{nm}}{\sqrt{2}} \; . \quad (36)$$

On the other hand, the diagonalization of $M_{t}$ of the top sector is nontrivial since $m_{t,0}$ is heavy. However, an approximate calculation is possible unless $\hat{\chi}_{n}^{2}$’s are much larger than unity, with a small parameter $m_{t,0}/k_{EW}$. It is shown in [11] that a perturbative diagonalization can be done for $\nu \gtrsim -0.3$. Up to the leading order of the expanding parameter $\delta \equiv m_{t,0}/k_{EW}$, the mass eigenvalues are

$$m_{q} = m_{0} \; , \; M_{n} = k_{EW} \left( x_{f}^{(n)} + \frac{\hat{\chi}_{n}^{2}}{2} \delta \right) \; ,$$

$$M_{n_{\infty}+n} = k_{EW} \left( x_{f}^{(n)} - \frac{\hat{\chi}_{n}^{2}}{2} \delta \right) \; , \quad (37)$$

and the orthonormal matrix $\mathcal{N}$ are

$$\mathcal{N}_{(2,2)}^{(0)} \equiv \mathcal{N}_{(2,2)}^{(1)} + \mathcal{N}_{(2,2)}^{(1)} \frac{\delta}{\sqrt{2}} \; , \quad (38)$$

where

$$\mathcal{N}_{(0,0)}^{(1)} \simeq 0 \; , \; \mathcal{N}_{(0,n)}^{(1)} \simeq 0 \; , \; \mathcal{N}_{(n,0)}^{(1)} \simeq \mathcal{N}_{(n_{\infty}+n,0)}^{(1)} \simeq \frac{\hat{\chi}_{n}^{2}}{x_{f}^{(n)}} \; ,$$

$$\mathcal{N}_{(n,n)}^{(1)} \simeq \mathcal{N}_{(n_{\infty}+n,n)}^{(1)} \simeq \frac{\hat{\chi}_{n}^{2}}{4x_{f}^{(n)}} \; ,$$

$$\mathcal{N}_{(n,m)}^{(1)} \simeq \mathcal{N}_{(n_{\infty}+n,m)}^{(1)} \simeq \frac{x_{f}^{(n)}\hat{\chi}_{n}\hat{\chi}_{m}}{\sqrt{2}(x_{f}^{(n)^{2}} - x_{f}^{(m)^{2}})} \quad \text{(for } n \neq m \text{)} \; . \quad (39)$$
The $B\bar{B}$ mixing is parametrized by the physical mass difference

$$\Delta M_B = \frac{1}{M_B} |\langle \bar{B}^0 | \mathcal{H}_{\text{eff}}(\Delta B = 2) | B^0 \rangle|$$

$$= \frac{G_F M_W^2}{6\pi^2} |V_{tb} V_{td}|^2 \hat{B}_B f_B^2 M_B \eta_B S_0(x_t). \quad (40)$$

where $M_B$ ($M_W$) is the $B$ ($W$) mass, $\eta_B$ the QCD corrections, and $\hat{B}_B$ and $f_B$ are the bag parameter and decay constant, respectively. The loop function $S_0(x_t)$ which recapitulates the box diagrams is

$$S_0(x_t) = \frac{4x_t - 11x_t + x_t^3}{4(1 - x_t)^2} - \frac{3x_t^3 \ln x_t}{2(1 - x_t)^3}; \quad (41)$$

in the SM, with $x_t \equiv (m_t/M_W)^2$.

In the RS-bulk model, bulk fermions and gauge bosons contribute to the box diagrams, as shown in Fig. 1. Since the external fermions are the zero modes, relevant vertex factor is $C_{m0n}^{f_W}$ multiplied by the mass-diagonalizing orthonormal matrix $\mathcal{N}$.

Introducing the effective couplings

$$T^{ij} \equiv \left( \mathcal{N} \cdot C^{b(i)dW} \right)^{ij}, \quad (42a)$$

$$Q^{ij} \equiv \left( \mathcal{N} \cdot C^{b(i)dW} \right)^{ij}, \quad (42b)$$

the loop function has the form of

$$S(m, n; i, j) = M_W^2 \sum \left[ \left( 1 + \frac{m_{t(i)}^2 m_{t(j)}^2}{4M_A^2 M_B^2} \right) T^{im} T^{jn} T^{jm} I(W^{(m)} W^{(n)} q^{(i)} q^{(j)}) \right. \right.$$

$$+ \left. \left( 1 + \frac{m_{q(i)}^2 m_{q(j)}^2}{4M_A^2 M_B^2} \right) Q^{im} Q^{jn} Q^{jm} I(W^{(m)} W^{(n)} q^{(i)} q^{(j)}) \right. \right.$$

$$- \left. \left( 2 + \frac{m_{q(i)}^2 m_{t(j)}^2 + m_{t(i)}^2 m_{q(j)}^2}{4M_A^2 M_B^2} \right) Q^{im} Q^{jn} Q^{jm} I(W^{(m)} W^{(n)} q^{(i)} q^{(j)}) \right. \right.$$

$$+ \left. \left( \frac{1}{M_A^2} + \frac{1}{M_B^2} \right) \left\{ - m_{t(i)}^2 m_{t(j)}^2 T^{im} T^{jn} T^{jm} I(W^{(m)} \phi^{(m)} q^{(i)} q^{(j)}) \right. \right.$$

$$- m_{q(i)}^2 m_{q(j)}^2 Q^{im} Q^{jn} Q^{jm} I(W^{(m)} \phi^{(m)} q^{(i)} q^{(j)}) \left. \right. \right.$$

$$\left. \left. + (m_{q(i)}^2 m_{t(j)}^2 + m_{t(i)}^2 m_{q(j)}^2) Q^{im} Q^{jn} T^{jm} I(W^{(m)} \phi^{(m)} q^{(i)} q^{(j)}) \right\} \right]. \quad (43)$$

Here we separate the longitudinal part of $W^{(n)}$, denoted by $\phi^{(n)}$, for the calculational convenience, and
\[ I(W^{(m)}W^{(n)}q^{(i)}q^{(j)}) = \int_0^1 dx dy \left[ \frac{M_{mn}^2 + m_q^2}{(M_{mn}^2 - m_q^2)^2} + \frac{2m_q^2 M_{mn}^2}{(M_{mn}^2 - m_q^2)^3} \ln \left( \frac{m_q^2}{M_{mn}^2} \right) \right] , \quad (44a) \]

\[ I(W^{(n)}\phi^{(m)}q^{(i)}q^{(j)}) = \int_0^1 dx dy \left[ \frac{2}{(M_{mn}^2 - m_q^2)^2} + \frac{M_{mn}^2 + m_q^2 m_{\phi q}^2}{(M_{mn}^2 - m_q^2)^3} \ln \left( \frac{m_q^2}{M_{mn}^2} \right) \right] , \quad (44b) \]

where

\[ m_{q q}^2 \equiv x m_q^2 + (1 - x) m_{\phi q}^2 , \quad M_{mn}^2 \equiv y M_A^{(m)} + (1 - y) M_A^{(n)}^2 . \quad (45) \]

V. RESULTS AND DISCUSSIONS

For the numerical results, we used \( kr_c = 11.5, k_{EW} = 1 \text{ TeV} \), and \( \nu = -0.3 \). The choice of \( \nu = -0.3 \) allows us to use Eqs. (38) and (39); for \( \nu \leq -0.4 \), only the numerical diagonalization of the mass matrix is reliable. One question may arise whether this choice would spoil the \( \Delta \rho \) accommodation. This, however, would not be the case because we have another adjustable parameter \( \nu' \) for the \( b \)-sector in KKS model. Even in the case of \( (\nu, \nu') = (-0.3, -0.6) \) the mass differences between top and bottom KK modes are much smaller than 1 TeV [15]. We also give the results for \( \nu = -0.2, -0.1 \) for comparisons.

In this analysis, we include the KK modes only up to \( n = 4 \) gauge boson (which corresponds to \( n = 2 \) fermion because bulk fermion has double field contents) for simplicity. As a comparison, the HPR contribution to the box diagrams is also given. Numerical results are summarized in Table I and Figs. 2, 3. Main results of the analysis are as follows.

First, we have the loop function enhancement 0.51\% (1.07\%) for \( \nu = -0.3 \) in KKS (HPR) up to \( n = 4 \), as shown in Table I and Fig. 2. The numbers can be compared to the ACD-UED result where the increase amounts to 17 \% [14]. Increase of the loop function implies the smaller value of \( |V_{td}| \), because \( \Delta M_B = 0.502 \pm 0.006 \text{ ps}^{-1} \sim |V_{td}|^2 \sum S(m, n; i, j) \) is now well measured [12]. Figure 3 shows our results for \( |V_{td}| \). We used \( \sqrt{B_B f_B} = 235 \text{ MeV}, \eta_B = 0.55 \). The QCD correction factor \( \eta_B \) has a small error \( \pm 0.01 \) compared to the hadronic uncertainty [14,16]:

\[ \sqrt{B_B f_B} = (235^{+53}_{-41}) \text{ MeV} . \quad (46) \]

Since the \( B_s \bar{B}_s \) mixing shares the same loop function with \( B \bar{B} \) mixing, increase in \( \sum S(m, n; i, j) \) predicts the equal amount of larger \( \Delta M_{Bs} \). Current bound of it is \( \Delta M_{Bs} > 15 \text{ ps}^{-1} \) [12].

In order to strongly constrain the model parameters, or even rule out, measurements of \( \sin 2 \beta \), e.g., would not be crucial. Rather, determining the CKM angle \( \gamma \) as well as reducing the hadronic uncertainty significantly will severely restrict the parameter space. For example, in the ACD-UED model, Ref. [13] argued that larger value of \( \sqrt{B_B f_B} \) above 222 MeV with one-third reduced error will rule out the the UED model or push up the compactification scale up to multi-TeV region. An analytic study is much easier in the ACD-UED model compared to the RS-type one because the mass spectrum and mode functions have simpler structure in the UED model [3]. In the RS-bulk models, on the other hand, the \( n \)-dependence of the mass spectrums, e.g., is not explicit.
Second, the HPR gives larger values than KKS for each \( n \). The reason is as follows. If all the fermions were in the bulk and no mixing happened, there would be GIM cancellation at every \( n \)-th excitations. In case of KKS, the cancellation is incomplete because there is a small mixing (when \( \nu \gtrsim -0.3 \)) in the top sector. In HPR, however, the third generation resides in the 3-brane; only the first and second generations have their KK excitations in the bulk. There is no compensating contribution from the third generation KK modes, which results in larger loop function. This feature was already pointed out in [11].

The GIM cancellation is advantageous in viewpoint of the convergence. There is, of course, no way to warrant the finiteness of adding up infinite KK tower by checking just a few excitations. In the ACD-UED, it is argued that the GIM mechanism improves the convergence of the loop function in \( B\bar{B} \) mixing [14]. And it is quite encouraging that the RS-bulk SM effects of KKS on \( b \to s\gamma \) are satisfactorily converging as we add higher KK modes [11].

Third, the \( \nu \)-dependence is shown in Fig. 2 and Table I. The KK mode contributions to the box diagrams get larger as \( \nu \) grows. The reason is that both the coupling and the bulk fermion mass become larger when \( \nu \) goes from \(-3\) to \(-1\). This pattern is already studied in previous works; see Fig. 1 of [9] and [10]. We have, for example, the bulk fermion masses \( x_f^{(1)} k_{EW} = 2.71, 2.85, 3.00 \) (TeV) for \( \nu = -0.3, -0.2, -0.1 \), respectively. It is already suggested that the plausible range of \( \nu \) is \(-0.8 \lesssim \nu \lesssim -0.3 \) in the literature [9,10]. If \( \nu \gtrsim -0.3 \), constraints from the electroweak precision data make the first KK mode of gauge boson heavier. In our case, since the loop function grows abruptly for large \( \nu \), present analysis of \( B\bar{B} \) mixing can provide another hint for the upper bound of \( \nu \) when the uncertainties of the parameters for \( \Delta M_B \) are reduced, just as in [13].

One thing to be noticed is that \( B\bar{B} \) mixing involves only the up-type quark’s mass parameter \( \nu \). The main motivations of KKS are i) all the fermions can reside in the bulk, ii) different mass parameters for the top- and bottom-sector can accommodate the electroweak precision data. In this point of view, \( D\bar{D} \) is a good testing ground for the bottom sector. A preliminary result of our approach to \( D\bar{D} \) mixing is that the contribution of the first few KK modes is extremely small. This is mainly due to the smallness of the \( b \) quark mass. Consequently, mixing with the KK masses is quite weak and the GIM cancellation is more complete. Unfortunately, current experimental results are rather poor [17]. More reliable check on the model can be implemented by simultaneous analysis on \( B\bar{B} \) and \( D\bar{D} \) with improved measurements, as well as on the electroweak precision tests.

VI. SUMMARY

In this paper, we have calculated the \( B\bar{B} \) mixing in the RS-bulk model. Contributions from the newly introduced KK modes are positive to increase the loop function. We found that KKS predicts smaller contribution than HPR due to the remnant of the GIM cancellation. More precise determination of the CKM unitarity triangle will test the validity of the model. Also, further developments of the present work, such as including much more KK modes or simultaneous application to various observables, remain challenging.
