Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Brief Communication

Sufficient sleep attenuates COVID-19 pandemic-related executive dysfunction in late adolescents and young adults

Abstract

Purpose: To investigate the interaction between (1) sleep and the COVID-19 pandemic; and (2) social cumulative risk and COVID-19 pandemic on executive function (EF).

Methods: Forty late adolescents/young adults (19.25 ± 1.12 y.o.) completed sleep questionnaires and the Behavior Rating Inventory of Executive Function-Adults (BRIEF-A) before and during the COVID-19 pandemic, yielding 80 observations for data analysis. Multilevel random-effects models with interaction terms were used to estimate the associations.

Results: Compared to pre-pandemic sleep, participants slept 24 min longer (t = -2.07, p = 0.03) and also had increased sleep latency (t = 1.83, p = 0.07) during COVID-19. Mid-sleep times shifted 40 min later (t = 3.22, p = 0.003), and BRIEF-A scores increased (indicating greater dysfunction), during the pandemic (p < 0.05). The worsening in EF during the pandemic was attenuated by increasing sleep duration (B = -4.38, p = 0.04) and magnified by social cumulative risk (B = 3.19, p = 0.04). Poor sleep quality was independently associated with increase in EF problems (p < 0.05).

Conclusion: Sufficient sleep may represent a resilience factor against EF decline during this unprecedented crisis.

1. Introduction

Coronavirus pandemic (COVID-19) has increased mental health issues, such as depressive symptoms and suicidal ideation, across age groups [1,2]. Executive function (EF) reflects cognitive processes underlying goal-directed behaviors, emotional responses and social interaction [3], and is essential for building resilience to cope with stressful life events such as COVID-19. The pandemic has also affected sleep patterns [4,5], which is known to influence EF [6,7]. Global investigation shows later self-reported bedtimes and wake-up times, increased sleep disturbances, and poorer sleep quality compared to pre-pandemic baseline, despite longer sleep duration [4,5,8]. Among all age groups, the greatest effect on sleep is observed in adolescents and young adults [4,8]. Given that EF shows continued development into early adulthood [3], poor sleep may have a more profound influence among adolescents/young adults under this unprecedented crisis. However, how sleep interacts with COVID-19 on affecting EF remains unclear.

The primary aim of this study was to track changes to sleep and EF before and during COVID-19, and examine whether sleep moderated the pandemic-related changes to EF, in adolescents/young adults. Additionally, both social disparities and COVID-19 are public health crises. As a second aim, we explored whether changes in EF varied by social risk factors. This study will contribute to a better understanding of the resilience and risk factors of adolescents and young adults during crises.

2. Material and methods

Leveraging an ongoing study on sleep and cardiovascular risk factors, this longitudinal study collected data via Research Electronic Data Capture (REDCap) system on sleep and EF before (baseline) and during COVID-19. Using a convenience sample from a public university, 60 participants completed self-reported assessments between April and December 2019 (baseline). After
remote learning began, 40 of them completed follow-up assessments in April–May 2020 (age 19.25 ± 1.12 y.o., 37F:3M), yielding 80 observations (before and during COVID-19) for data analysis. There were no differences between baseline and follow-up data except gender ($\chi^2 = 9.41, p = 0.002$). The attrition rate of males (8 out of 11 dropped) was higher than females (12/49). All data were collected only during the academic year. Participants provided informed consent per Institutional Review Board-approved guidelines.

2.1. Measurements

2.1.1. Sleep

Participants completed a seven-day sleep diary and the Pittsburgh Sleep Quality Index (PSQI) before and during COVID-19. Diary responses provided variables of sleep duration, sleep latency (amount of time to fall asleep), sleep midpoint times (clock time halfway between sleep onset and offset), and social jetlag (absolute difference between mid-sleep times on weekdays and weekends). The PSQI is composed of 19 items categorized into seven subscales: sleep quality, sleep latency, duration, efficiency, sleep disturbances, sleep medication use and daytime dysfunction. The PSQI total score represents overall sleep quality, with poorer sleeper defined as total scores $\geq 5$ [8]. The PSQI has shown good psychometric properties in adolescents/young adults [9,10].

2.1.2. Executive function

The Behavior Rating Inventory of Executive Function-Adults (BRIEF-A) assessed EF in everyday activities [11]. Seventy-five questions were grouped into behavioral regulation index (BRI) and metacognition index (MI). The BRI reflects regulatory control of behavior/emotional responses, and MI represents the ability to cognitively manage tasks through initiating, planning/organizing, sustaining working memory, and monitoring. The BRI and MI (secondary outcomes) form an overall summary score, the Global Executive Composite (GEC) scores (primary outcome). Age-adjusted T-scores were calculated, with higher scores indicating greater dysfunction. The BRIEF-A has demonstrated good internal consistency (Cronbach's alpha = 0.72–0.96) and construct and convergent validity [11].

2.1.3. Covariates

We collected socio-demographic information (eg age, sex, race, parental education) and body mass index at baseline. Social cumulative risk (SCR) was calculated as the total number of risk factors (non-White, parent education ≤ high school, family income below poverty threshold by family size and number of children, and <two parents in primary household). Additionally, we measured health behaviors [smoking, alcohol consumption and exercise from 0 = never to 3 = always (6–7 times/week)] and COVID status (unknown/infected/not infected) at the follow-up.

2.2. Statistical analyses

At the bivariate level, we compared sleep and EF before and during COVID-19 using paired t tests and the Wilcoxon signed-rank tests. Accounting for age, sex, SCR, BMI, COVID status, health behaviors, a series of linear mixed models tested whether GEC and BRI/MI domains were associated with COVID-19 (before/during) and sleep variables, modeling for by-participant random-intercepts. Sleep variables entered models separately due to collinearity. Next, interaction terms between (1) each sleep variable and COVID-19 and (2) SCR and COVID-19 were added into models separately to estimate the moderating effect of sleep/social risk. Goodness-of-fit statistics, including likelihood ratio (LR) test, AIC, BIC, were used to compare model fit. Data analyses were conducted using STATA 16.

3. Results

Thirty-one participants reported at least one social risk factors, such as non-White (40%) and mother/father's education level ≤ high school (25%). Participants slept 24 min longer (7.35 vs.7.76 h, t = -2.07, p = 0.03), but with increased sleep latency during COVID-19 (22.28 ± 14.18 min) compared to baseline (18.65 ± 12.98 min) (t = -1.83, p = 0.07). The PSQI total scores were consistently high ($6.10 ± 2.04$ vs.$5.95 ± 2.97$, p < 0.05), however worsened in 48% of participants during COVID-19. Midpoint sleep time shifted 40 min later (04:36 vs. 05:11, t = -3.22, p = 0.003) and the trend remained significant after adjusting for covariates. There were no significant changes in PSQI subscale scores and social jetlag (p > 0.05).

Regarding executive function, participants scored worse during the pandemic on GEC ($49.95 ± 9.11$ vs. $53.10 ± 11.47$) and MI ($50.38 ± 9.17$ vs. $54.10 ± 12.19$) compared with pre-COVID assessment. In multilevel models (Table 1), the differences in GEC scores (B = -3.15, p = 0.03) and MI (B = 3.73, p = 0.01) between times remained significant. There were interactions between sleep duration and COVID-19, and SCR and COVID-19, but no main effects of sleep duration or SCR. Specifically, increased sleep duration attenuated the worsening of GEC (B = -4.38, p = 0.04) and MI (B = -5.18, p = 0.02) during COVID-19, whereas SCR (B = 3.19, p = 0.04) intensified the deleterious impact of the COVID-19 on MI (Fig. 1). Adding interaction terms significantly improved model fit (LR test, p < 0.05). Poor sleep (PSQI$\geq 5$) was associated with worse GEC (B = 4.69, p = 0.02) and MI (B = 4.20, p = 0.04) independent of COVID-19. We repeated analyses using PSQI total scores and found similar trends with GEC (B = 0.86, p = 0.03) and BRI (B = 1.07, p = 0.01). Sleep latency, midsleep times and social jetlag were not associated with EF nor moderated the association between pandemic and EF (p > 0.05).

4. Discussion

Compared to baseline, late adolescents and young adults reported longer sleep duration, later midsleep times, increased sleep latency, and worse EF during the pandemic. The pandemic-related changes in EF varied by sleep duration and SCR, such that increasing sleep duration attenuated, and SCR intensified, declines in EF. In general, poor sleep quality was associated with worse EF.

These findings are consistent with earlier evidence from the pandemic, showing that shifted sleep phase and increased sleep latency were pronounced in adolescents/young adults [4,8]. Remote learning and pandemic measures (ie social distancing) may increase sleep opportunities. However, increased screen time and decreased light exposure and physical activity may disrupt sleep quality and chronobiological rhythm. Interestingly, composite sleep quality score in the PSQI did not change compared with the baseline level. Since sleep duration is one aspect of PSQI, increased sleep duration may have masked the decline in other PSQI domains.

Overall EF and metacognition subdomain decreased during COVID-19; this may relate to the reported changes in sleep patterns. Short sleep duration and poor sleep quality have been associated with impaired EF in adolescents and young adults [6,7], supporting our findings of sleep quality and EF. In the current study, sleep duration was not an independent factor for EF, but a moderator. Increasing sleep hours attenuated or even reversed the negative impact of the pandemic on EF. Thus, sufficient sleep may protect against EF decline during stressful events. This is particularly important for late adolescents and emerging young adults who...
investigate the role of sleep and social determinants in pandemic-related changes in EF. Our findings may inform sleep-related interventions, in conjunction with social support programs, to mitigating the negative impact of crises such as COVID-19 for adolescents and young adults.

5. Conclusions

Late adolescents and young adults report longer sleep, yet poorer sleep quality and declined executive function during the pandemic versus pre-COVID baseline. Sufficient sleep duration attenuates, but social risk factors exacerbate, EF declines during COVID-19. Our findings suggest the importance of promoting sleep health and eliminating social disparity to youth health during COVID-19, and shed light on public health strategies in coping with future crises.
