Abstract
In this contribution, classes of shear-free cosmological dust models with irrotational fluid flows will be investigated in the context of scalar-tensor theories of gravity. In particular, the integrability conditions describing a consistent evolution of the linearised field equations of quasi-Newtonian universes are presented. We also derive the covariant density and velocity propagation equations of such models and analyse the corresponding solutions to these perturbation equations.

DOI: 10.31526/LHEP1.2018.05

Although general relativity theory (GR) is a generalization of Newtonian Gravity in the presence of strong gravitational fields, it has no properly defined Newtonian limit on cosmological scales. Newtonian cosmologies are an extension of the Newtonian theory of gravity and are usually referred to as quasi-Newtonian, rather than strictly Newtonian formulations [1, 2, 3]. The importance of investigating the Newtonian limit for general relativity on cosmological contexts is that, there is a viewpoint that cosmological studies can be done using Newtonian physics, with the relativistic theory only needed for examination of some observational relations [4]. General relativistic quasi-Newtonian cosmologies have been studied in the context of large-scale structure formation and non-linear gravitational collapse in the late-time universe. This despite the general covariant inconsistency of these cosmological models except in some special cases such as the spatially homogeneous and isotropic, spherically symmetric, expanding (FLRW) spacetimes. Higher-order or modified gravitational theories of gravity such as $f(R)$ theories of gravity have been shown to exhibit more shared properties with Newtonian gravitation than those of general relativity [5, 6]. In [4], a covariant approach to cold matter universes in quasi-Newtonian cosmologies has been developed and it has been applied and extended in [2] in order to derive and solve the equations governing density and velocity perturbations. This approach revealed the existence of integrability conditions in GR. In this work, we derive the evolution of the velocity and density perturbations in the comoving (Lagrangian) and quasi-Newtonian frames. We investigate the existence of integrability conditions of a class of irrotational and shear-free perfect fluid cosmological models in the context of scalar-tensor gravity. Such work has been done in the context of $f(R)$ gravity [6], where some models of $f(R)$ gravity have been shown to exhibit Newtonian behaviour in the shear-free regime.

The so-called $f(R)$ theories of gravity are among the simplest modification of Einstein’s GR. These theories come about by a straightforward generalisation of the Lagrangian in the Einstein-Hilbert action [7, 8] as

$$S_{f(R)} = \frac{1}{2} \int d^4x \sqrt{-g} \left( f(R) + 2 \mathcal{L}_m \right), \tag{1}$$

where $\mathcal{L}_m$ is the matter Lagrangian and $g$ is the determinant of the metric tensor $g_{\mu\nu}$. Another modified theory of gravity is the scalar-tensor theory of gravitation. This is a broad class of gravitational models that tries to explain the gravitational interaction through both a scalar field and a tensor field. A subclass of this theory, known as the action the Brans-Dicke (BD) theory, has an action of the form

$$S_{BD} = \frac{1}{2} \int d^4x \sqrt{-g} \left[ \phi R - \frac{\omega}{\phi} \nabla \phi \nabla \phi + 2 \mathcal{L}_m \right], \tag{2}$$

where $\phi$ is the scalar field and $\omega$ is a coupling constant considered to be independent of the scalar field $\phi$. An interesting aspect of $f(R)$ theories of gravity is their proven equivalence with the BD theory of gravity [8, 9] with $\omega = 0$. If we define the $f(R)$ extra degree of freedom as

$$\phi \equiv f'' - 1, \tag{3}$$

then the actions [1] and [2] become dynamically equivalent. In a FLRW background universe, the resulting non-trivial field equations lead to the following Raychaudhuri and Friedmann equations that govern the expansion history of the Universe [10]:

$$\dot{\phi} + \frac{1}{3} \Theta^2 = -\frac{1}{2(\phi + 1)} \left[ \mu_m + 3 p_m + f - R(\phi + 1) + 3 \alpha \phi \right] \tag{4}$$

$$+ 3 \phi'' \left( \frac{\phi''}{\phi'} \right) + 3 \phi - 3 \phi' \frac{\phi'}{\phi},$$

$$\Theta^2 = \frac{3}{(\phi + 1)} \left[ \mu_m + \frac{R(\phi + 1) - f}{2} + 3 \phi \right], \tag{5}$$

where $\Theta \equiv 3H = \frac{a}{a(t)}$, $H$ being the Hubble parameter, $a(t)$ is the scale factor, $\mu_m$ and $p_m$ are the energy density and isotropic pressure of standard matter, respectively.

The linearised thermodynamic quantities for the scalar field are the energy density $\mu_\phi$, the pressure $p_\phi$, the energy flux

$$f', f'', \text{etc. are the first, second, etc. derivatives of } f \text{ w.r.t. the Ricci scalar } R.$$
The covariant linearised evolution equations in the general case
are given by \[ (f - R(f + 1)) \varphi - \varphi \psi' \psi' \psi \varphi \varepsilon^2 \varphi \left( \frac{ \phi' }{ \phi } + \frac{ \phi' }{ \phi } \right), \tag{6} \]
\[ \psi' = \frac{ \phi' }{ \phi + 1 } \left( \varphi \varphi \varepsilon^2 \varphi \right), \tag{7} \]
\[ q^\phi - \frac{ \phi' \psi' }{ \phi + 1 } \left( \varphi \varphi \varepsilon^2 \varphi \right), \tag{8} \]
\[ \pi^a_{ab} = \frac{ \phi' }{ \phi + 1 } \left( \varphi \varphi \varepsilon^2 \varphi \right) \]

The total (effective) energy density, isotropic pressure, anisotropic
depressure and heat flux of standard matter and scalar field
combination are given by
\[ \mu = \frac{ \mu_m }{ \mu + 1 } + \mu \varphi, \quad p = \frac{ \rho_m }{ \rho + 1 } + \rho \varphi, \quad \pi = \frac{ \pi_m }{ \rho + 1 } + \pi \varphi, \quad q_a = \frac{ \pi_m }{ \rho + 1 } + \pi \varphi. \tag{9} \]

Given a choice of 4-velocity field \( u^a \) in the Ehlers-Ellis covariant
approach, the dynamics, kinematics and gravito-electromagnetics of the FLRW background is characterised respectively by the equations \[ \phi, \eta, \gamma, \theta \]
\[ \varphi = 0, \quad \varphi = 0, \quad \varphi = 0, \quad \varphi = 0, \quad \varphi = 0. \tag{10} \]
\[ \varphi = 0, \quad \varphi = 0, \quad \varphi = 0, \quad \varphi = 0, \quad \varphi = 0. \tag{11} \]
\[ E_{ab} = 0 = H_{ab}, \tag{12} \]

where \( \varphi, \varphi, \varphi, \varphi, \varphi \) and \( \varphi \) are the expansion, acceleration, vorticity
and the shear terms. \( E_{ab} \) and \( H_{ab} \) are the "gravito-electric" and "gravito-magnetic" components of the Weyl tensor \( C_{abcd} \)
defined from the Riemann tensor \( R_{abcd} \) as
\[ C_{ab} = R_{ab} - 2 \varphi \varphi - \frac{1}{3} \varphi \varphi - \frac{1}{3} \varphi \varphi, \quad E_{ab} = \frac{1}{2} \eta_{abc} C_{ghbd} u^c u^d. \tag{13} \]

The covariant linearised evolution equations in the general case
are given by \[ \phi, \theta, \gamma, \eta \]
\[ \varphi = 0, \quad \varphi = 0, \quad \varphi = 0, \quad \varphi = 0. \tag{14} \]

and the linearised constraint equations are given by
\[ C_0 = E_{ab} - \varphi \varphi A_{ab} - \frac{1}{2} \pi_{ab} = 0, \tag{22} \]
\[ C_1 = \varphi \varphi - \varphi \varphi \varphi + \varphi \varphi \varphi - \frac{1}{2} \pi_{ab} = 0, \tag{23} \]
\[ C_2 = \varphi \varphi \omega_a = 0, \tag{24} \]
\[ C_3 = \varphi \varphi - \varphi \varphi - \varphi \varphi + \varphi \varphi \varphi - \frac{1}{2} \pi_{ab} = 0, \tag{25} \]
\[ C_4 = \varphi \varphi \varphi - \varphi \varphi + \varphi \varphi \varphi - \frac{1}{2} \pi_{ab} = 0, \tag{26} \]
\[ C_5 = \varphi \varphi \varphi + \varphi \varphi \varphi - \varphi \varphi \varphi - \frac{1}{2} \pi_{ab} = 0. \tag{27} \]

If a comoving 4-velocity \( \varphi^a \) is chosen such that, in the linearised form
\[ \varphi^a = u^a + \varphi^a, \quad \varphi^a u^a = 0, \quad \varphi^a < 1, \tag{28} \]
the dynamics, kinematics and gravito-electromagnetics quantities
\[ \varphi, \varphi, \varphi, \varphi \]
undergo transformation.

Here \( \varphi^a \) is the relative velocity of the comoving frame with respect
to the observer in the quasi-Newtonian frame, defined such that it vanishes in the background. In other words, it is a non-relativistic peculiar velocity. Quasi-Newtonian cosmological models are irrotational, shear-free dust spacetimes characterised by \[ \varphi, \varphi, \varphi \]
and the gravito-magnetic constraint \[ \varphi, \varphi, \varphi \]
and the shear-free and irrotational condition \[ \varphi, \varphi, \varphi \]
show that the gravito-magnetic component of the Weyl tensor automatically vanishes:
\[ H_{ab} = 0. \tag{30} \]

The vanishing of this quantity implies no gravitational radiation in quasi-Newtonian cosmologies, and Eq. \[ \varphi, \varphi, \varphi \]
together with Eq. \[ \varphi, \varphi, \varphi \]
show that \( \varphi^{ab} \) is irrotational and thus \( \varphi \) is \( \varphi \):
\[ \eta^{abc} \varphi \varphi A_{ab} = 0 = \varphi^{abc} \varphi \varphi A_{ab}. \tag{31} \]
Since the vorticity vanishes, there exists a velocity potential such that
\[ \varphi = \varphi \varphi \varphi. \tag{32} \]

A constraint equation \[ \varphi \varphi \varphi = 0 \]
is said to evolve consistently with the evolution equations \[ \varphi, \varphi, \varphi \]
if
\[ C_0 = F_0^A B_C + G^A B_C \varphi \varphi C_B, \tag{33} \]
where \( F \) and \( G \) are quantities that depend on the kinematics, dynamics and gravito-electromagnetics quantities but not their derivatives. It has been shown \[ \varphi, \varphi, \varphi \]
that the non-linear models are generally inconsistent if the silent constraint \[ \varphi, \varphi, \varphi \] is imposed, but that the linear models are consistent \[ \varphi, \varphi, \varphi \]. Thus, a simple approach to the integrability conditions for quasi-Newtonian
cosmologies follows from showing that these models are in fact a sub-class of the linearised silent models. This can happen by using the transformation between the quasi-Newtonian and comoving frames. The transformed linearised kinematics, dynamics and gravitoelectromagnetic quantities from the quasi-Newtonian frame to the comoving frame are given as follows:

\[ \Theta = \Theta + \nabla^a v_a , \]  

(34) 

\[ A_a = A_a + \omega_a + \frac{1}{3} \Theta v_a , \]  

(35) 

\[ \omega_a = \frac{1}{2} \eta_{abc} \nabla^b v^c , \]  

(36) 

\[ \tilde{\sigma}_{ab} = \sigma_{ab} + \tilde{\nabla} (a v_b) , \]  

(37) 

\[ \tilde{\rho} = \rho , \quad \tilde{p} = p , \quad \tilde{\pi}_{ab} = \pi_{ab} , \quad \tilde{q}_a^m = q_a^m \]  

(38) 

\[ \tilde{q}_a^{m\prime} = q_a^{m\prime} - (\mu_m + p_m) v_a , \]  

(39) 

\[ \tilde{E}_{ab} = E_{ab} , \quad \tilde{H}_{ab} = H_{ab} . \]  

(40) 

It follows from the above transformation equations that

\[ \tilde{\rho}_m = 0 , \quad \tilde{q}_a^{m\prime} = 0 , \quad \tilde{A}_a = \tilde{\omega}_a , \]  

(41) 

\[ \tilde{\pi}_{ab}^{m\prime} = 0 , \quad \tilde{\nabla}_{ab} = \tilde{\nabla} (a v_b) , \quad \tilde{E}_{ab} = E_{ab} . \]  

These equations describe the linearised silent universe except that the restriction on the shear in Eq. 41 results in the integrability conditions for the quasi-Newtonian models. Due to the vanishing of the shear in the quasi-Newtonian frame, Eq. 19 is turned into a new constraint

\[ E_{ab} - \frac{1}{2} \tau_{ab}^\phi - \tilde{\nabla} (a \tilde{A}_b) = 0 . \]  

(42) 

This can be simplified by using Eq. 18 and the identity for any scalar \( \phi \):

\[ \eta^{abc} \tilde{A}_a A_c = 0 \Rightarrow A_a = \tilde{\nabla} a \phi . \]  

(43) 

In this case \( \phi \) is the covariant relativistic generalisation of the Newtonian potential.

First integrability condition

Since Eq. 42 is a new constraint, we need to ensure its consistent propagation at all epochs and in all spatial hypersurfaces. Differentiating it with respect to cosmic time \( t \) and by using equations 9, 20 and 23 one obtains

\[ \tilde{\nabla} (a \tilde{\nabla} b) \left[ \phi + \frac{1}{3} \Theta + \frac{\phi}{(\phi + 1)} \right] + \left[ \phi + \frac{1}{3} \Theta \right] \nabla a \nabla b \phi = 0 , \]  

(44) 

which is the first integrability condition for quasi-Newtonian cosmologies in scalar-tensor theory of gravitation and it is a generalisation of the one obtained in [2] i.e., Eq. 44 reduces to an identity for the generalised van Elst-Ellis condition [1][2][3].

The evolution equation of the 4-acceleration \( A_a \) can be shown, using Eqs. 45 and 23 to be

\[ \dot{A}_a + \frac{2}{3} \Theta + \frac{\phi}{(\phi + 1)} \Theta A_a = -\frac{1}{2} \left( \frac{\mu_m v_a + \frac{1}{3} \Theta}{(\phi + 1)} \right) \]  

(46) 

\[ + \frac{\phi}{\phi^\prime} \left( \frac{\phi^\prime}{\phi} - \frac{2\phi}{(\phi + 1)} \right) \nabla a \phi \]  

There is a second integrability condition arising by checking for the consistency of the constraint 44 on any spatial hypersurface of constant time \( t \). By taking the divergence of 42 and by using the following identity:

\[ \tilde{\nabla}^a \tilde{\nabla} (a A_b) = \frac{1}{2} \tilde{\nabla}^2 A_a + \frac{1}{6} \tilde{\nabla}_a (\tilde{\nabla}^c A_c) + \frac{1}{3} (\mu - \frac{1}{3} \Theta^2) A_a , \]  

(47) 

which holds for any projected vector \( A_a \), and by using Eq. 43 it follows that

\[ \tilde{\nabla}^a \tilde{\nabla} (a \tilde{\nabla} b) \phi = \frac{2}{3} \tilde{\nabla}_a (\tilde{\nabla}^2 \phi) + \frac{2}{3} (\mu - \frac{1}{3} \Theta^2) \tilde{\nabla}_a \phi . \]  

(48) 

By using Eqs. 48, 23 and 26 one obtains

\[ \tilde{\nabla} a \mu_m \left[ \frac{1}{2} \left( \phi + \frac{3}{2} (\phi + 1) \Theta \right) \tilde{\nabla} a \Theta + \frac{1}{(\phi + 1)} \right] \tilde{\nabla}^2 \tilde{\nabla} a \phi = -\frac{3}{2} \mu_m \tilde{\nabla} a \phi \]  

(49) 

\[ + \Theta \phi - \Theta^2 \left( \frac{\phi^\prime}{\phi} - \frac{3\phi}{(\phi + 1)} \right) \tilde{\nabla} a \phi = 2(\phi + 1) \tilde{\nabla}^2 \tilde{\nabla} a \phi - 2 \left[ \mu_m \right] \tilde{\nabla} a \phi - 2 \left( \frac{\phi^\prime}{\phi} - \frac{3\phi}{(\phi + 1)} \right) \tilde{\nabla} a \phi = 0 , \]  

which is the second integrability condition and in general it appears to be independent of the first integrability condition 44.

By taking the gradient of Eq. 45 and using Eq. 23 one can obtain the peculiar velocity:

\[ v_a = -\frac{1}{\mu_m} \left( 2(\phi + 1) \tilde{\nabla} a \phi + \left( \frac{\phi^\prime}{\phi} - \frac{3\phi}{(\phi + 1)} \right) \tilde{\nabla} a \phi \right) . \]  

(50) 

By virtue of Eqs. 16 and 17 \( v_a \) evolves according to

\[ v_a + \frac{1}{3} \Theta v_a = -A_a . \]  

(51) 

The coupled evolution Eqs. 46 and 51 decouple to produce the second-order propagation equation of the peculiar velocity \( v_a \). By using Eqs. 4 and 5 in Eq. 51 one obtains

\[ \begin{align*}
\dot{v}_a + \left[ \Theta + \frac{\phi}{(\phi + 1)} \right] v_a + \frac{1}{9} \Theta^2 - \frac{1}{6(\phi + 1)} (5\mu_m - f) \\
- 4(\phi^\prime) \left[ \Theta + \frac{\phi}{(\phi + 1)} \right] v_a + \frac{1}{(\phi + 1)} \left[ \frac{\phi^\prime}{\phi} - \Theta^2 - \frac{\phi^\prime}{2\phi^\prime} \right] + \frac{\phi^\prime}{2\phi^\prime} \tilde{\nabla} a \phi = 0 .
\end{align*} \]  

(52) 

In the previous section, we showed how imposing special restrictions to the linearized perturbations of FLRW universes in
the quasi-Newtonian setting result in the integrability conditions. These integrability conditions imply velocity and acceleration propagation equations resulting from the generalised van Elst-Ellis condition for the acceleration potential in scalar-tensor theories. In this section, we show how one can obtain the velocity and density perturbations via these propagation equations, thus generalizing GR results obtained in [13].

We define the variables that characterise scalar inhomogeneities the matter energy density, expansion, peculiar velocity, acceleration as well as the scalar fluid and scalar field momentum, respectively, as follows:

\[
\Lambda_m = \frac{a^2 \nabla^2 \mu_m}{\mu_m},
\]

(53)

\[
Z = a^2 \nabla^2 \Phi,
\]

(54)

\[
V^m = a^2 \nabla^2 \psi_d,
\]

(55)

\[
A = a^2 \nabla^2 \phi_A,
\]

(56)

\[
\Phi = a^2 \nabla^2 \phi
\]

(57)

\[
\Psi = a^2 \nabla^2 \phi.
\]

(58)

The system of equations governing the evolutions of these scalar fluctuations are given as follows

\[
\dot{\gamma}^m + \left( \frac{\Theta}{3} + \frac{\phi}{(1 + \phi)} \right) \gamma^m - \frac{1}{2(\phi + 1)} \left[ \mu_m \gamma^m ight] + \frac{1}{3} \Theta \phi \left( \phi + 1 \right) \gamma^m \]

(59)

\[
+ \frac{\phi}{(1 + \phi)} \left[ \frac{\phi}{\mu_m} + \frac{2}{(1 + \phi)} \right] \gamma^m = 0,
\]

\[
\dot{D}^m + \left[ \frac{\phi}{(1 + \phi)} \right] D^m - \frac{3 \mu_m}{2(\phi + 1)} \gamma^m - \Theta \gamma^m
\]

(60)

\[
+ \frac{1}{3} \phi \frac{\phi}{(1 + \phi)} \gamma^m - \frac{2}{(1 + \phi)} \gamma^m + \nabla^2 \phi
\]

\[
+ \frac{2}{3} \phi \frac{\phi}{(1 + \phi)} \gamma^m + \frac{\Theta}{(1 + \phi)} \gamma^m
\]

\[
+ \frac{1}{2(\phi + 1)} \left[ \frac{2}{(1 + \phi)} \gamma^m - \phi \frac{\phi}{(1 + \phi)} \gamma^m + \frac{\Theta}{(1 + \phi)} \gamma^m
\]

\[
+ \frac{4 \Theta \phi}{(1 + \phi)} - \frac{\nabla^2 \phi}{(1 + \phi)} - 7 \Theta \phi \gamma^m \right] \gamma^m = 0,
\]

\[
- \frac{\phi}{\phi} \frac{\phi}{\phi} - \frac{\phi}{\phi} \frac{(\phi + 1)}{(\phi + 1)} \gamma^m
\]

(61)

\[
+ \frac{\phi \mu_m}{2(\phi + 1)} \gamma^m = 0.
\]

Since the evolution equations obtained so far are too complicated to be solved, the harmonic decomposition approach is applied to these equations using the eigenfunctions and the corresponding wave number for these equations, therefore we write

\[
X = \sum_k X_k(\vec{x})\quad \text{and} \quad Y = \sum_k Y_k(t)Q_L(\vec{x}),
\]

(62)

where \(Q_L(x)\) are the eigenfunctions of the covariantly defined spatial Laplace-Beltrami operator [6][44], such that

\[
\nabla^2 Q = -k^2 \frac{a^2}{a^2} Q. \tag{63}
\]

The order of the harmonic (wave number) is given by

\[
k = \frac{2\pi a}{\lambda}, \tag{64}
\]

where \(\lambda\) is the physical wavelength of the mode. The eigenfunctions \(Q\) are covariantly constant, i.e.

\[
\dot{Q}(x) = 0. \tag{65}
\]

Applying the harmonic decomposition, the second-order evolution equations [59][68] can be rewritten as

\[
\dot{v}_m^k + \left( \frac{\Theta}{3} + \frac{\phi}{(1 + \phi)} \right) v_m^k - \frac{1}{2(\phi + 1)} \left[ \mu_m v_m^k ight] + \frac{1}{3} \Theta \phi \left( \phi + 1 \right) v_m^k
\]

(66)

\[
+ \frac{1}{2(\phi + 1)} \left[ \frac{2}{(1 + \phi)} v_m^k - \phi \frac{\phi}{(1 + \phi)} v_m^k + \frac{\Theta}{(1 + \phi)} v_m^k
\]

\[
+ \frac{4 \Theta \phi}{(1 + \phi)} - \frac{\nabla^2 \phi}{(1 + \phi)} - 7 \Theta \phi \gamma_m \right] v_m^k
\]

\[
= \frac{\phi}{\phi} \frac{(\phi + 1)}{(\phi + 1)} \gamma_m^k
\]

(67)

\[
+ \frac{\phi}{\phi} \frac{\phi}{\phi} - \frac{\phi}{\phi} \frac{(\phi + 1)}{(\phi + 1)} \gamma_m^k
\]

\[
+ \frac{\phi \mu_m}{(\phi + 1)} \gamma_m^k = 0.
\]

In this section, we consider \(R^n\) model, one of the \(f(R)\) toy models that are considered to be the simplest and widely studied form of higher order \(f(R)\) gravitational theories. The Lagrangian density of such models is given as

\[
f(R) = \beta R^n, \tag{69}
\]

where \(\beta\) represents the coupling parameter and an arbitrary constant \(n \neq 1\) is considered for exploring cosmological models. In [15], it has been shown, using the cosmological dynamical systems approach, that the scale factor \(a(t)\) admits an exact solution of the form

\[
a = a_0 t^{\frac{2}{\nu + 1}}, \tag{70}
\]

with \(w = 0\) and normalized coefficients \(\beta\) and \(a_0\). One can obtain the following expressions for the expansion, the Ricci
scalar and the effective matter energy density respectively:

$$\Theta = \frac{2n}{t}, \quad R = \frac{4n(4n-3)}{3t^2},$$  \hspace{1cm} (71)

$$\mu_m = n \left( \frac{3}{4} \right)^{1-n} \left( \frac{4n^2 - 3nt}{t^2} \right)^{n-1} \left( \frac{-16n^2 + 26nt - 6}{3t^2} \right).$$  \hspace{1cm} (72)

Therefore we have the perturbation equations \(66, 67\) and \(68\) as:

$$\tilde{V}_{\mu}^k = \left( \frac{6-4n}{3t} \right) \tilde{V}_{\mu}^n - \left( \frac{8n^2 - 13nt + 3}{3t^2} \right) \tilde{V}_{\mu}^k - \left[ \frac{n}{4n(4n-3)} \right]^{n-1} \tilde{V}_{\mu}^k.$$

$$\Delta_{\mu}^m = \frac{2(1-n)}{t} \Delta_{\mu}^n + \left( \frac{3 + 13n - 8nt}{t^2} \right) \Delta_{\mu}^k,$$

$$= \left( \frac{62n^2 - 127n + 27}{3t^2} + \frac{n}{4n(4n-3)} \right)^{n-1} \tilde{V}_{\mu}^k + \left[ \frac{2(2n-3)}{3t} \right] \Phi_k.$$

The second-order evolution equation of the density perturbation in the comoving frame admits a general solution of the form \(10\)

$$\Delta_{\mu}^k = C_1 t^{-1} + C_2 t^{2\rho_1} + C_3 t^{2\rho_2} - C_4 C_0 t^{\frac{4n}{3}}.$$

where \(C_1, C_2, C_3\) and \(C_4\) are constants, \(\rho_1\) is given as

$$\rho_1 = \frac{1}{2} \pm \sqrt{(n-1)(256n^6 - 680n^4 + 417n - 81)},$$

and \(C_0\) is the conserved value for the gradient variable \(C_0\), where

$$C_0 = a^3 \Phi_a \tilde{R},$$

where \(\tilde{R}\) is the three dimension Ricci scalar, is defined as

$$\tilde{R} = 2\mu - \frac{2}{3} \Theta^2.$$

Therefore, by using Eqs. \(67\) and \(68\) the general solution of the density perturbation Eq. \(67\) in the quasi-Newtonian frame can be written as

$$\Delta_{\mu}^k = C_1 t^{-1} + C_2 t^{2\rho_1} + C_3 t^{2\rho_2} - C_4 C_0 t^{\frac{4n}{3}} + 2n^2 V_m^k.$$

The gradient variable \(\Phi_a\) is equivalent to \(\mathcal{R}_a\) defined in \(f(R)\) theory \(6\), such that

$$\Phi_a = \Phi \mathcal{R}_a.$$

The solution of \(\mathcal{R}\) has been obtained in the comoving frame \(10\) and it has the form

$$\mathcal{R} = C_5 t^{-3} + C_6 t^{2\beta_{1}} + C_{7} t^{2\beta_{2}} - C_{8} C_0 t^{-\frac{4n}{3}}.$$

Therefore, the solution of the second-order perturbation Eq. \(75\) in the comoving frame can be written as

$$\Phi_k = n(n-1) \left( \frac{4n(4n-3)}{3t^2} \right)^{n-2} \left[ C_5 t^{-3} + C_6 t^{2\beta_{1}} + C_{7} t^{2\beta_{2}} - C_{8} C_0 t^{-\frac{4n}{3}} \right].$$

Therefore, by using Eq. \(83\) the general solution of the perturbation Eq. \(78\) in the quasi-Newtonian frame is given as

$$\Phi_k = n(n-1) \left( \frac{4n(4n-3)}{3t^2} \right)^{n-2} \left[ C_5 t^{-3} + C_6 t^{2\beta_{1}} + C_{7} t^{2\beta_{2}} - C_{8} C_0 t^{-\frac{4n}{3}} \right].$$

Using Eq. \(72\), the general solution of the perturbation Eq. \(66\) in the quasi-Newtonian frame is given as

$$V_m^k = (K_2 + K_3 (B_1 - B_2)) t^{\frac{2n}{3} + \gamma_{1}} + (K_1 + K_3 (B_3 + B_4)) t^{\frac{2n}{3} + \gamma_{2}},$$

where \(k_1, k_2\) are two arbitrary constants and

$$K_3 = \frac{3(n-1)}{2} \left( \frac{16n^2 - 4n}{n(4n-3)} \right)^n \sqrt{8n^2 - 48n(2n+2) + 132n - 27},$$

$$\gamma_{1} = -\frac{1}{2} \pm \sqrt{8n^2 - 48n(2n+2) + 132n - 27},$$

$$B_1 = C_1 \int \left( \int \frac{3}{2} \frac{d\gamma_{1}}{dt} \right) dt,$$

$$B_3 = C_1 \int \frac{dn}{\int \left( \frac{2n}{3} + \frac{3}{2} \right)^{n-1} \frac{d\gamma_{1}}{dt} \right) dt.$$
where $B_2$ and $B_3$ are all functions of time and their expressions are rather complicated. Thus, we get the full set of exact solutions for the density and velocity perturbation equations in the quasi-Newtonian frame.

In this subsection, we apply a quasi-static approximation to the evolution equations. In this approximation, terms involving time derivatives for gravitational potential are neglected and only those terms involving density perturbation are kept. A quasi-static approximation was taken such that the time evolutions of $R_a$ are neglected, $R_a \simeq 0$ and $R'_a \simeq 0$.

According to Eq. 77, the time variations in $\Phi_a$ are neglected, i.e., $\Phi_a \simeq 0$ and $\Phi'_a \simeq 0$.

Hence, one can get

$$
\dddot{V}^k_m + \left( \frac{48n^2 - 108n + 7n}{(36 - 18n)t} \right) \dot{V}^k_m + \left( \frac{(8n^2 - 13n + 3)}{32t^2} \right) V^k_m = 0. 
$$

(98)

This second-order equation admits a general solution of the form

$$
V^k_m(t) = C_{10}D^k_{+}E_{+} + C_{10}D^k_{-}E_{-},
$$

(99)

where

$$
D = \sqrt{-32n^2 + 300n^3 - 723n^2 + 588n - 108} \over 6(n - 2)
$$

and

$$
E_{\pm} = \pm \left( \frac{8n^2 - 15n + 6}{6(n - 2)} \right).
$$

Based on this solution in Eq. 77 and its first and second time derivative, the general solution of Eq. 77 is

$$
\Delta(t) = C_{11}t^2 \frac{1}{2} \frac{\dot{\Phi}''}{\dot{\Phi}'} + C_{12}t^2 \frac{\dot{\Phi}'}{\dot{\Phi}'}
$$

(100)

where $C_{11}$ and $C_{12}$ are arbitrary constants and

$$
L_{e+} = \pm \sqrt{36n^2 - 36n - 11}.
$$

There are some other solutions to Eq. 77 which are rather too complicated to be presented here.

**Conclusion:**

Our main goal has been the study of the cosmological perturbation in the context of one of the modified theories of gravity. We reviewed two of these alternative theories of gravity, namely $f(R)$ and scalar-tensor theories. We investigated classes of shear-free cosmological dust models with irrotational fluid flows in the context of scalar-tensor theories. We presented the integrability conditions that describe a consistent evolution of the linearised field equations of quasi-Newtonian universes. We defined the gradient variables that characterize the cosmological perturbations and derived the second-order evolution equations of these variables. The harmonic decomposition approach is applied to these equations in order to solve this complicated system of differential equations. After getting a complete set of the perturbation equations, we solved these equations by considering $R^2$ models to get the exact solutions for the density and velocity perturbations. We introduced the so-called quasi-static approximation to admit the approximated solutions on small scales. Solving the whole system numerically has been left for future work.
