Abstract Treatment options for chronic hepatitis C virus (HCV) infection have drastically changed since the development and licensing of new potent direct-acting antivirals (DAAs). The majority of DAAs are extensively metabolized by liver enzymes and have the ability to influence cytochrome P450 (CYP) enzymes. Additionally, these DAAs are both substrates and inhibitors of drug transporters, which makes the DAAs both possible victims or perpetrators of drug–drug interactions (DDIs). There is a high prevalence of mental illnesses such as depression or psychosis in HCV-infected patients; therefore, psychoactive medications are frequently co-administered with DAAs. The majority of these psychoactive medications are also metabolized by CYP enzymes but remarkably little information is available on DDIs between psychoactive medications and DAAs. Hence, the aim of this review is to provide an overview of the interaction mechanisms between DAAs and psychoactive agents. In addition, we describe evidenced-based interactions between DAAs and psychoactive drugs and identify safe options for the simultaneous treatment of mental illnesses and chronic HCV infection.

Key Points

Escitalopram and citalopram have been studied in combination with most direct-acting antivirals (DAAs) and either of these drugs can be safely combined with hepatitis C virus (HCV) treatment.

No formal interaction studies between psychoactive agents and sofosbuvir or ledipasvir have been performed in humans. However, these DAAs are generally neither victims nor perpetrators of drug interactions and can therefore be safely used in combination with psychoactive drugs.

Boceprevir, simeprevir, and the combination paritaprevir/ritonavir plus ombitasvir with dasabuvir are most likely to cause drug interactions via the inhibition of cytochrome P450 (CYP) 3A4. Therefore, caution must be exercised when CYP3A4 substrates such as midazolam and/or quetiapine are co-administered with these DAAs.

1 Introduction

One of the components previously used in the treatment regimen for hepatitis C virus (HCV) is pegylated interferon; however, it has major adverse effects on mental
Little information is available on interactions between DAAs and psychoactive agents. Therefore, the aim of this review is to provide an overview of the interaction mechanisms of DAAs and psychoactive agents. In addition, we describe evidenced-based interactions between DAAs and psychoactive drugs and identify safe options for treatment of the simultaneous treatment of mental illnesses and HCV infection.

2 Methods

We searched PubMed (1946–January 2016) and EMBASE (1947–January 2016) to identify peer-reviewed studies. The search covered all DAAs recommended in European and US guidelines [11, 12] and licensed by the European Medicines Agency (EMA) and US Food and Drug Administration (FDA). The DAAs included protease inhibitors (PIs) (boceprevir, simeprevir, paritaprevir, and grazoprevir), NS5A inhibitors (daclatasvir, ledipasvir, ombitasvir, and elbasvir), and NS5B polymerase inhibitors (sofosbuvir and dasabuvir). Telaprevir (PI) was excluded from the review because it has limited use in current therapy. We also referred to the work published by Kiser and colleagues [13] for more information about telaprevir and DDIs between DAAs and psychoactive drugs.

The psychoactive agents included were SSRIs, TCAs, typical and atypical antipsychotics, benzodiazepines, monoamine oxidase inhibitors, lithium, and St John’s wort.

The Google and Google Scholar search engines, and ClinicalTrials.gov (http://www.clinicaltrials.gov) website and the Liverpool drug interaction database (http://www.hep-druginteractions.org) were used to identify conference papers and abstracts. All searches were performed in English. The search items contained generic and/or brand names of the drugs and included terms such as antidepressant, antipsychotic, sedative, and tranquilizer.

Information about the pharmacokinetics and metabolism of the DAAs and psychoactive agents were obtained from the Summary of Product Characteristics (SmPC) and FDA prescribing information for each drug as well as from the Lexicomp database (available via http://www.uptodate.com). Enzyme inhibitors and inducers were defined as being strong, moderate, or weak if they changed the area under the plasma concentration–time curve (AUC) of a substrate by 5-fold, >2 to <5-fold, and <2-fold, respectively. Substrates were also grouped as being minor and major substrates of enzymes. These groupings were based on the clinical relevance of the potential interaction described by Lexicomp (http://www.uptodate.com) [14, 15].

The use of antipsychotics and antidepressants during DAA therapy increases the risk of drug-drug interactions (DDIs). Both DAAs and psychoactive agents are extensively metabolized in the liver and have the ability to affect the activities of various enzymes (e.g., cytochrome P450 [CYP]) and drug transporters (e.g., P-glycoprotein [P-gp]). This makes DAAs as well as psychoactive agents possible victims (objects of DDIs) and perpetrators (causes of DDIs) of drug interactions, which could negatively affect treatment outcomes as a result of adverse effects (increased plasma concentrations) or treatment failure (decreased plasma concentrations) [8, 9]. In order to interpret the DDIs between DAAs and psychoactive agents, it is important to have sufficient knowledge of their therapeutic ranges. Benzodiazepines, tricyclic antidepressants (TCAs), and antipsychotics have a narrow therapeutic range, while SSRIs have a broad therapeutic range. Generally, drugs with narrow therapeutic ranges are more likely to have clinically relevant DDIs than drugs with large therapeutic ranges [10]. DAAs have a large therapeutic range, which makes them less susceptible to the effects of an increase or decrease in their plasma concentrations caused by, for example, CYP inhibition or induction. However, extremely low plasma concentrations could lead to virologic failure.
3 Drug-Drug Interaction (DDI) Mechanisms: Direct-Acting Antivirals (DAAs)

In this section, we elaborate on the mechanisms by which DAAs can be perpetrators and/or victims of DDIs. We focused on interactions through hepatic drug metabolism and drug transporters because they are the most important pathways underlying interactions between DAAs and psychoactive agents. These mechanisms are illustrated using examples of drug interactions between DAAs and psychoactive agents or non-psychoactive drugs, which were studied in healthy volunteers.

Tables 1 and 2 give an overview of the involvement of enzymes and drug transporters in the metabolism of DAAs and psychoactive agents, respectively. Table 3 shows the results of drug interaction studies performed between DAAs and psychoactive drugs.

3.1 Phase I and II Reactions: DAAs as Perpetrators

Drugs that influence drug-metabolizing enzymes (perpetrators) such as CYP and uridine diphosphate glucuronyltransferase (UGT) have the ability to affect the plasma concentration of substrates of the enzymes (victims). Inhibitors of CYP and UGT generally cause an increased plasma concentration of the victim, while inducers usually lower the plasma concentration of the victim.

Ritonavir is included in the fixed-dose combination with paritaprevir, ombitasvir, and dasabuvir to ‘boost’ the pharmacokinetic characteristics of paritaprevir through the inhibition of CYP3A4; this opens the door for DDIs to occur. For example, the AUC and maximum plasma concentration ($C_{max}$) of orally administered midazolam, a CYP3A4 substrate, increased ~26-fold and ~4-fold, respectively, when midazolam was co-administered with ritonavir (note: the interaction between ritonavir and midazolam is studied in the absence of paritaprevir, ombitasvir, or dasabuvir) [16]. Increases in the plasma concentration of midazolam have also been observed when the drug was administered with boceprevir, simeprevir, and grazoprevir, which are also CYP3A4 inhibitors. Boceprevir is a strong inhibitor of CYP3A4, while simeprevir and grazoprevir are mild CYP3A4 inhibitors (Table 3) [17–19].

UGTs are inhibited by DAAs such as ombitasvir, dasabuvir, and paritaprevir. Lorazepam (benzodiazepine) is a UGT substrate; however, this interaction has not been studied. Interaction studies between furosemide (UGT1A1 substrate) and combination regimen paritaprevir/ritonavir, ombitasvir, and dasabuvir have indicated the importance of UGT inhibition. Results from these studies showed that the AUC and $C_{max}$ of furosemide were increased by 8 and 42 %, respectively. As a result of this, a reduction in the dose of furosemide of up to 50 % might be required if the drugs have to be co-administered [20].

3.2 Phase I and II Reactions: DAAs as Victims

DAAs, e.g., daclatasvir, simeprevir, grazoprevir, and elbasvir, are predominantly metabolized by CYP3A4/5 in the liver and gastrointestinal tract. Thus, caution is needed when DAAs are administered with strong inducers or inhibitors of CYP3A4. A reduced plasma concentration of DAAs creates a potential risk of resistance of the virus to the administered drug and/or virologic failure, while elevated drug concentrations increase the risk of adverse events. Most psychoactive agents do not strongly inhibit or induce CYP3A4 and, thus, we do not expect DAAs to be victims of psychoactive agents. St John’s wort, which is a psychoactive agent, is the exception; it is a strong CYP3A4 inducer. However, co-administration of boceprevir and St John’s wort showed only a slight decrease in the plasma concentration of boceprevir (9 %) [21].

DAAs are not metabolized by UGT or other phase II enzymes; therefore, phase II-mediated DDIs with DAAs as victims are not usually expected.

3.3 Drug Transporters: DAAs as Perpetrators

DAAs inhibit various drug transporters such as the efflux transporters P-gp and breast cancer resistance protein (BCRP) (Table 1), which are, among other located at the blood–brain barrier (BBB). Little information is available on DDIs between psychoactive agents and drug transporters. However, it is known that amitriptyline and risperidone are P-gp substrates (Table 2). Accordingly, inhibition of these transporters increases substrate concentrations in the cerebrospinal fluid [22]. Since the pharmacological action of psychoactive drugs takes place in the brain, inhibition of P-gp can result in an increased pharmacological effect.

No formal interaction studies have been conducted between the P-gp substrates and DAAs. The effect of P-gp inhibition by DAAs has been studied using digoxin, which is a known P-gp substrate. Boceprevir had a minor influence on plasma digoxin concentrations (an increase in AUC and $C_{max}$ by 19 and 18 %, respectively) [17]. Daclatasvir and simeprevir also affected digoxin plasma concentrations; the AUC of digoxin was increased by 27 and 39 %, and $C_{max}$ was increased by 65 and 31 %, respectively [18, 23]. It should be noted that these interactions between the P-gp inhibitors and digoxin were driven by the concentration of digoxin in the intestinal lumen, which is high after oral intake. For psychoactive drugs,

interactions with P-gp inhibitors take place at the BBB. This is affected by the systemic concentration of the P-gp substrate instead of the concentration in the lumen. Therefore, it is difficult to predict possible interactions between DAAs and psychoactive drugs from these results. Additionally, the clinical relevance of P-gp inhibition by DAAs depends on the inhibitory potential of the perpetrator and the therapeutic range of the victim (see Sect. 4). Many DAAs are inhibitors of organic anion-transporting polypeptide (OATP) 1B1 and OATP1B3, which are uptake transporters. No psychoactive drug is a substrate of OATPs; hence, these transporters are not discussed in this review.

3.4 Drug Transporters: DAAs as Victims

Most DAAs are substrates of P-gp and OATPs; therefore, DAAs are possible victims when psychoactive agents inhibit or induce these transporters. However, there are limited data available on psychoactive agents and transporters. An example demonstrating the importance of a transporter-mediated interaction is the contraindication of the co-administration of grazoprevir with OATP1B1/3 inhibitors.

4 DDI Mechanisms: Psychoactive Agents

Table 2 provides an overview of the enzymes and transporters involved in the metabolism of psychoactive agents. In this section, we describe the mechanisms by which psychoactive agents can be victims and perpetrators of DDIs.

4.1 Psychoactive Agents as Perpetrators

In general, psychoactive agents are more often victims of DDIs than perpetrators. For example, benzodiazepines have limited influence on drug-metabolizing enzymes and transporters (Table 2). Various antipsychotics, SSRIs, and TCAs have the potential to inhibit CYP2D6, which makes these drugs perpetrators of drug interactions. However, the currently available DAAs are not metabolized by CYP2D6 and therefore DDIs via this pathway are not expected (Tables 2, 3).

4.2 Psychoactive Agents as Victims

Most benzodiazepines are substrates of various CYP enzymes, such as CYP3A4, CYP2B6, CYP2C19, and CYP1A2; therefore, benzodiazepines are potential victims of DDIs. Benzodiazepines have a narrow therapeutic range.
Table 2: Overview of the route of metabolism, effects on enzymes, and transporters of psychoactive agents

Note that most of these drugs have older registration files and, therefore, possible involvement of transporters and CYP enzymes may not be studied in sufficient detail per the current standards.

Information in this table was compiled from the following sources: European Medicines Association summary of product characteristics, US Food and Drug Administration prescribing information, and data from Lexicomp, available through [http://www.uptodate.com](http://www.uptodate.com) (October 2015).

Note: assignment of major/minor substrate status based on their clinically relevant drug interaction potential ([http://www.uptodate.com](http://www.uptodate.com))

No information about hepatic metabolism and/or drug transporters were available for: Flunitrazepam, loprazolam, nitrazepam, prazepam, lithium salts, chlorprothixene, fluspirilene, penfluridol, pericyazine, pipamperone, sulphiride, and tiapride.

COMT catechol-O-methyl transferase, CYP cytochrome P450, MAO monoamine oxidase, P-gp P-glycoprotein, UGT uridine diphosphate glucuronosyltransferase.

△ Adis
of CYP enzymes, as shown in Table 2. CYP3A4 and such as boceprevir and ritonavir. Might occur with, for example, strong CYP3A4 inhibitors have been conducted so far. Theoretically, interactions between midazolam and boceprevir is contraindicated [17]. Similarly, an increase in the plasma concentration of midazolam is expected when it is administered with paritaprevir/ritonavir, ombitasvir, and dasabuvir; therefore, this co-administration is also contraindicated [20]. Interactions between midazolam and simprevir or grazoprevir have both been studied and increased midazolam AUC and $C_{\text{max}}$ values were observed; thus, caution is needed with co-administration [18, 19]. On the other hand, daclatasvir has been shown to have little effect on midazolam exposure [23].

SSRIs are hepatically metabolized by various CYP enzymes (e.g., CYP3A4, CYP2D6, CYP2C9, and CYP2C19), particularly CYP3A4. Theoretically, this puts patients at risk when they are also taking DAAs. However, SSRIs have a broad therapeutic range; therefore, increased plasma concentrations of SSRIs are not likely to result in significant toxicities [10]. For instance, the co-administration of escitalopram (CYP3A4 substrate) and DAAs such as boceprevir, simprevir, or the combination of paritaprevir/ritonavir, ombitasvir, and dasabuvir did not result in a clinically relevant increase in the escitalopram plasma concentration [17, 18, 20].

Antipsychotics are metabolized in the liver by a variety of CYP enzymes, as shown in Table 2. CYP3A4 and CYP2D6 are involved in this metabolism; however, they can be inhibited by DAAs. Most antipsychotics have a narrow therapeutic range. Therefore, DDIs involving antipsychotics can result in clinically relevant outcomes, especially with strong CYP3A4 inhibitors such as boceprevir and ritonavir. However, no interaction studies have been conducted so far. Theoretically, interactions might occur with, for example, strong CYP3A4 inhibitors such as boceprevir and ritonavir.

5 Clinical Guidance

In this section, we provide guidance for clinical decision making regarding the use of a combined treatment of DAAs and psychoactive drugs. Most potential drug interactions have not been subjected to rigid pharmacokinetic testing in humans, and recommendations are often based on theoretical interpretations of the pharmacokinetics characteristics of drugs.

We believe that a relevant interaction only occurs when a drug (victim) is metabolized to a ‘major’ or ‘moderate’ extent. Major or moderate substrate status is based on the potential clinically relevant drug interaction as described by Lexicomp [15]. A major status indicates that the regimen should be modified, whereas a moderate status implies that the therapy should be monitored. Consequently, a drug should have strong (>5-fold increase in substrate AUC) or moderate (2- to 5-fold increase in substrate AUC) influence on an enzyme/transporter (perpetrator) in order to cause an interaction (Tables 4, 5, 6, 7, 8, 9, 10).

5.1 Protease Inhibitors

5.1.1 Boceprevir

Table 4 shows benzodiazepines, antidepressants, and antipsychotics that are safe to combine with boceprevir. Of the currently available DAAs, boceprevir is one of the most potent CYP3A4 inhibitors. Therefore, we do not recommend combining boceprevir and drugs primarily metabolized by CYP3A4, especially if they have a narrow therapeutic range (a contraindication).

Co-administration of midazolam and boceprevir (both oral and parenteral) is contraindicated since the midazolam AUC and $C_{\text{max}}$ are both significantly increased [17]. This exceptional increase was not observed with other DAAs, which emphasizes the strong inhibitory potential of boceprevir on CYP3A4.

On the other hand, no dose adjustment is required when escitalopram is administered with boceprevir. This is unexpected as escitalopram is a CYP3A4 substrate. It is possible that there is involvement of other unknown enzymes or transporters; hence, the underlying mechanism cannot be explained [17].

Boceprevir is also a P-gp inhibitor. Theoretically, this inhibition could have an impact on P-gp substrates; however, it seems to have minimal clinical relevance due to the mild inhibition of P-gp by boceprevir [17, 22]. Boceprevir may not be a victim of any DDIs with benzodiazepines, SSRIs, TCAs, or antipsychotics, as studies with midazolam and escitalopram have shown [17]. Additionally, interaction studies between St John’s wort and boceprevir showed no alterations in the plasma concentration of boceprevir; hence, this combination is safe to use [17, 21].

Finally, physicians should take care when prescribing boceprevir in combination with drugs that might prolong the QT interval and are metabolized by CYP3A4 [17]. For instance, SSRIs and TCAs may influence the QT interval and serious pharmacodynamic interactions may occur when they are administered with boceprevir (Table 4).
## Table 3 Overview of studied interactions between direct-acting antivirals and psychoactive agents

| DAA Drug | DAA AUC | DAA C_{max} | DAA C_{min} | Drug Drug | Drug AUC | Drug C_{max} | Drug C_{min} | Recommendation | References |
|----------|---------|-------------|-------------|-----------|----------|-------------|-------------|----------------|------------|
| **Protease inhibitors** | | | | | | | | | | |
| Boceprevir | Escitalopram (10 mg) | 0.91 (0.81–1.02) | 1.02 (0.96–1.08) | | | | | | | [17, 61] |
| Midazolam po (4 mg) | | | | | | | | | | |

When possible, geometric mean ratios (with 90% confidence intervals in parentheses) are presented; otherwise, percentages are shown.

AUC: area under the concentration–time curve, C_{max}: maximum plasma concentration, C_{min}: minimum plasma concentration, DAA: direct-acting antiviral, DDIs: drug–drug interactions, DSV: dasabuvir, iv: intravenous, OBV: ombitasvir, po: oral, PTV: paritaprevir.

† indicates increase

* The interactions with midazolam are studied without elbasvir. No interaction studies with elbasvir/grazoprevir were performed.
Table 4 Overview of safe options for and contraindicated psychoactive agents that have a potential interaction with boceprevir

| Class of psychoactive agent | Safe options | Contraindicated | Potential interaction | Unknown |
|-----------------------------|--------------|-----------------|-----------------------|---------|
| Benzodiazepines             | Bromazepam   | Midazolam (oral and intravenous) | Alprazolam | Loprazolam |
|                             | Clobazam     |                 | Brotizolam            |         |
|                             | Flunitrazepam|                 | Chlordiazepoxide      |         |
|                             | Lorazepam    |                 | Clorazepate           |         |
|                             | Lormetazepam |                 | Diazepam              |         |
|                             | Nitrazepam   |                 | Flurazepam            |         |
|                             | Oxazepam     |                 | Zolpidem              |         |
|                             | Prazepam     |                 | Zopiclone             |         |
|                             | Temazepam    |                 |                       |         |
|                             | Midazolam    |                 |                       |         |
|                             | Alprazolam   |                 |                       |         |
|                             | Brotizolam   |                 |                       |         |
|                             | Chlordiazepoxide|             |                       |         |
|                             | Clorazepate  |                 |                       |         |
|                             | Diazepam     |                 |                       |         |

c Possible risk for prolongation of the QT interval (http://www.crediblemeds.org)
5.1.2 Simeprevir

Table 4 shows psychoactive medications that can be safely combined with simeprevir. Simeprevir inhibits intestinal CYP3A4 and therefore only interactions with orally administered medications are relevant. Thus, intravenous midazolam can be used safely with simeprevir but oral midazolam should be used with caution, as the AUC and \( C_{\text{max}} \) of midazolam are increased by 45 and 31 %, respectively, when the two are co-administered [18]. Studies have been conducted of escitalopram and it can be safely used in combination with simeprevir [18]. Simeprevir inhibits P-gp and OATP1B1. Simeprevir has a higher impact than boceprevir on the transport activity of

Table 5 Overview of safe options for and contraindicated psychoactive agents that have a potential interaction with simeprevir

| Mianserin                   |              | N/A             |                       |         |
| Mirtazapine                 |              | N/A             |                       |         |
| Moclobemide                 |              | N/A             |                       |         |
P-gp, as indicated in Sect. 3.3. Therefore, inhibition of P-gp by simeprevir may lead to a small increase in concentrations of P-gp substrates (e.g., risperidone and nortriptyline) in the brain. However, the clinical relevance seems limited [18].

Simeprevir is a possible victim of DDIs as it is primarily metabolized by CYP3A4 [18]. St John’s wort may therefore cause a decrease in the plasma concentration of simeprevir as it is a CYP3A4 inducer. Nevertheless, this change might not be clinically relevance since simeprevir exhibits high inter-individual variability in its plasma concentrations [25].

5.2 NS5A Inhibitor

5.2.1 Daclatasvir

Daclatasvir has a negligible influence on the activities of CYP3A4 and other CYP enzymes and no dose adjustments were required when it was studied with midazolam [23]. Based on this information, it is expected that most benzodiazepines, antidepressants, and antipsychotics can be used safely in combination with daclatasvir, as shown in Table 6. Daclatasvir is metabolized by CYP3A4 and thus inducers and inhibitors of CYP3A4 have the ability to affect the plasma concentrations of daclatasvir [23]. Most psychoactive drugs do not influence CYP3A4, with the exception of St John’s wort; therefore, co-administration of St John’s wort and daclatasvir is contraindicated [23].

5.3 NS5B Polymerase Inhibitor

5.3.1 Sofosbuvir

Sofosbuvir is an NS5B inhibitor and not a perpetrator of DDIs as it has no influence on CYP enzymes or drug transporters; therefore, it has no impact on the plasma concentrations of psychoactive drugs [26]. However, an unexpected interaction has occurred involving sofosbuvir and the antiarrhythmic agent amiodarone. This indicates that not every DDI can be predicted based on the activities of CYP, UGT, or drug transporters. The mechanism and the specific role of sofosbuvir in the interaction was uncertain because other DAAs (daclatasvir, simeprevir, and ledipasvir) were simultaneously administered and could have been involved in causing the interaction [27, 28]. Additionally, it could also be caused by a pharmacodynamic interaction.

Sofosbuvir is metabolized in the liver and intestine; the drug is not a victim of enzymatic DDIs because it is not metabolized by, for example, CYPs or UGTs [26]. Sofosbuvir is a substrate for P-gp and BCRP; hence, interactions may occur with inducers and inhibitors of P-gp. P-gp inducers, e.g., St John’s wort, could potentially decrease...
Table 7 Overview of safe options for and contraindicated psychoactive agents that have a potential interaction with ledipasvir

| Class of psychoactive agent | Safe options | Contraindicated | Potential interaction | Unknown |
|-----------------------------|--------------|-----------------|-----------------------|---------|
| Benzodiazepine              | Alprazolam   | N/A             | Clobazam              | Loprazolam |
|                             | Bromazepam   |                 |                       |         |
|                             | Brotizolam   |                 |                       |         |
|                             | Chlordiazepoxide |           |                       |         |
|                             | Clorazepate  |                 |                       |         |
|                             | Diazepam     |                 |                       |         |
|                             | Flunitrazepam|                 |                       |         |
|                             | Flurazepam   |                 |                       |         |

|                             | Doxepin      |                 |                       |         |
|                             | Imipramine   |                 |                       |         |
|                             | Maprotiline  |                 |                       |         |
|                             | Others       |                 |                       |         |
|                             | Agomelatine  |                 |                       |         |
|                             | Bupropion    |                 |                       |         |
|                             | Lithium salts|                 |                       |         |
|                             | Mianserin    |                 |                       |         |
|                             | Mirtazapine  |                 |                       |         |
|                             | Moclobemide  |                 |                       |         |
plasma concentrations of sofosbuvir and result in a decrease in the pharmacological effects of sofosbuvir. Therefore, co-administration of the two drugs is contraindicated. Trazodone is also a possible P-gp inducer and may affect the plasma concentration of sofosbuvir (Table 8). Inhibition of P-gp could increase the plasma concentration of sofosbuvir; however, the interaction studies have not been performed in humans [26]. Lastly, the main (inactive) metabolite of sofosbuvir (GS-331007) is not a P-gp substrate [26].

5.4 Fixed-Dose Combinations

5.4.1 Ledipasvir and Sofosbuvir

Ledipasvir inhibits P-gp and BCRP and may cause interactions with P-gp and BCRP substrates (e.g., risperidone, and nortriptyline) [29]. P-gp inhibition at the BBB could potentially increase the exposure of these P-gp substrates in the brain. No interaction studies have been performed between ledipasvir and psychoactive agents. Table 7 shows the psychoactive agents that can be safely used with or potentially interact with ledipasvir.

The metabolism of ledipasvir is unknown but it is mainly excreted unchanged through bile. Thus, ledipasvir is not expected to be a victim of DDIs [29].

Sofosbuvir is discussed in Sect. 5.3.1.

5.4.2 Paritaprevir/Ritonavir, Ombitasvir, and Dasabuvir

Ritonavir is a strong CYP3A4 inhibitor but it also influences other CYP enzymes and drug transporters. Consequently, caution is needed if combining drugs metabolized by CYP3A4 with this fixed-dose regimen (paritaprevir/ritonavir, ombitasvir, and dasabuvir). Psychoactive agents such as duloxetine, escitalopram, zolpidem, alprazolam, and diazepam can be safely administered with this regimen as previous studies have not shown any clinically relevant interactions (Table 9) [20, 30–32].

The plasma concentrations of duloxetine did not alter when it was co-administered with the combination regimen [20]. Duloxetine is a substrate for CYP2D6 and CYP1A2, and ritonavir inhibits CYP2D6 and induces CYP1A2. As no effect was observed when combined with paritaprevir/ritonavir, ombitasvir, and dasabuvir, it was suggested that the inhibition of CYP2D6 and induction of CYP1A2 occurred to similar extents. We recommend that this combination regimen be used with care in patients receiving medications that are metabolized by CYP2D6 and/or CYP1A2, especially as a previous interaction study on the co-administration of olanzapine (CYP1A2 and CYP2D6 substrate) and ritonavir resulted in decreased olanzapine concentrations [33].

It is important to note that CYP2D6 inhibition by ritonavir is dose dependent [34]. Low-dose ritonavir (100 mg twice daily) had only a mild effect on CYP2D6, as shown with the CYP2D6 substrate desipramine (26 % AUC increase), but the therapeutic dose of ritonavir (600 mg twice daily) had a stronger effect (desipramine AUC increase of 145 %) [34–36]. However, this fixed-dose HCV regimen contains only 100 mg of ritonavir. Therefore, we expect DDIs only with co-administered drugs that are primarily metabolized by CYP2D6 and that have a narrow therapeutic range. Such drugs are not

|                            | Moclobemide  |                 |                       |         |
contraindicated with this combination regimen; however, plasma drug concentrations and adverse events should be monitored after co-administration [34].

Ritonavir also inhibits P-gp; therefore, ritonavir may modify plasma concentrations of P-gp substrates such as risperidone and amitriptyline.

Paritaprevir, ombitasvir, and dasabuvir are inhibitors of UGT and thus benzodiazepines (e.g., lorazepam, lormetazepam, and oxazepam) conjugated by UGT could be victims of interactions (Table 6) [20].

5.4.3 Grazoprevir and Elbasvir

Table 10 shows safe options for psychoactive drugs that can be administered with grazoprevir and elbasvir. Grazoprevir is a mild CYP3A inhibitor as it was observed to increase the plasma concentration of midazolam by only 30 % [19]. Therefore, CYP3A4 substrates are not contraindicated for co-administration with grazoprevir. However, we recommend that prescribers be aware of possible interactions with drugs that are primarily metabolized by CYP3A4 and have a narrow therapeutic range. There are no reported studies on drug interactions between the grazoprevir/elbasvir combination and psychoactive agents [19]. Grazoprevir and elbasvir are mainly metabolized by CYP3A4; thus, they should not be administered with St John’s wort and other CYP3A4 inducers or inhibitors [19] (Table 10).

6 Conclusion

In this review we have shown that there is a paucity of experimental data on drug interactions between psychoactive agents and DAAs. Many mechanisms are involved in the metabolism and transport of both classes of drugs, making it difficult to predict which drugs can be safely co-administered to patients.

In our opinion, safe options for concomitant administration should be combinations that have actually been studied in humans, or combinations that are not based on theoretical pharmacokinetic interactions. In addition, all medications used at the start of and during HCV treatment should be inventoried, so that possible DDIs can be evaluated before clinically relevant effects arise. Physicians should also be aware of possible interactions and their consequences. These may include adverse effects caused by increased plasma drug concentrations or reduced efficacy due to decreases in drug exposure. These are of great importance as such issues may also affect adherence to both

| Class of psychoactive agent | Safe options | Contraindicated | Potential interaction | Unknown |

Our final recommendation is that physicians contact pharmacists or clinical pharmacologists for support in managing these interactions.

This review provides an overview of the mechanisms of interactions between DAAs and psychoactive agents. Based on interaction studies, we give recommendations for

| Class of psychoactive agent | Safe options | Contraindicated | Potential interaction | Unknown |
|----------------------------|--------------|-----------------|----------------------|---------|
| Benzodiazepine             | Alprazolam   | Midazolam       | Brotizolam           | Loprazolam |

the co-administration of DAAs and psychoactive agents. The administration of various combinations of drugs results in different potential interactions. It is therefore necessary that theoretical predictions of DDIs be backed with actual drug interaction studies, in order to obtain more conclusive and useful data for clinical applications.

**Compliance with Ethical Standards**

**Funding** No funding was used in the preparation of this review.

**Conflict of interest** E.J. Smolders and C.T.M.M. de Kanter declare that they have no conflicts of interest that are directly relevant to the content of this review. R.J. de Knegt received sponsorship/research grants from BMS and Janssen; is a consultant for AbbVie, BMS, Gilead, Roche, and Janssen; and has delivered lectures for AbbVie, Janssen, Gilead, and Roche. J.P.H. Drenth is on the advisory boards for AbbVie, BMS, Gilead, Janssen, and Merck and received sponsorship/research grants from AbbVie and Janssen. D.M. Burger is on the advisory boards for AbbVie, BMS, Gilead, Janssen, and Merck and received sponsorship/research grants from BMS, Janssen, Merck, and Viiv. However, these conflicts of interests did not influence the preparation of this review.
