Abstract. This paper is devoted to Fokker-Planck and linear kinetic equations with very weak confinement corresponding to a potential with at most logarithmic growth and no integrable stationary state. Our goal is to understand how to measure the decay rates when the diffusion wins over the confinement although the potential diverges at infinity.

1. Introduction. This paper addresses the large time behavior of the solutions to the macroscopic Fokker-Planck equation and to kinetic equations with Fokker-Planck or scattering collision operators.

The first part of this paper deals with the *macroscopic Fokker-Planck equation*

\[
\frac{\partial u}{\partial t} = \Delta_x u + \nabla_x \cdot (\nabla_x V u) = \nabla_x (e^{-V} \nabla_x (e^V u))
\]  

(1)

where \(x \in \mathbb{R}^d, \ d \geq 3,\) and \(V\) is a potential such that \(e^{-V} \notin L^1(\mathbb{R}^d)\), that is, \(e^{-V} \, dx\) is an *unbounded invariant measure*. We shall investigate the two following examples

\[
V_1(x) = \gamma \log |x| \quad \text{and} \quad V_2(x) = \gamma \log \langle x \rangle
\]

with \(\gamma < d\) and \(\langle x \rangle := \sqrt{1 + |x|^2}\) for any \(x \in \mathbb{R}^d\). These two potentials share the same asymptotic behavior as \(|x| \to \infty\). The potential \(V_1\) is invariant under scalings, whereas \(V_2\) is smooth at the origin. In both cases, the only integrable equilibrium state is 0. Thus, if the initial datum \(u_0\) is such that \(u_0 \in L^1(\mathbb{R}^d)\), we expect that the solution to (1) converges to 0 as \(t \to +\infty\). When \(\gamma > 0\), the potential \(V\) is *very weakly confining* in the sense that, even if it eventually slows down the decay rate, it is not strong enough to produce a stationary state of finite mass: the diffusion wins over the drift. Our goal is to establish the rate of convergence in suitable norms. We

shall use the notation \( \| \cdot \|_p := \| \cdot \|_{L^p(dx)} \) in case of Lebesgue’s measure and specify the measure otherwise.

**Theorem 1.1.** Assume that \( d \geq 3 \), \( \gamma < (d-2)/2 \) and \( V = V_1 \) or \( V = V_2 \). Then any solution \( u \) of (1) with initial datum \( u_0 \in L^1_+ \cap L^2(\mathbb{R}^d) \) satisfies, for all \( t \geq 0 \),

\[
\| \nabla u(t, \cdot) \|_2^2 \leq \frac{\| u_0 \|_2^2}{(1 + ct)^{\frac{d}{4}}} \quad \text{with} \quad c := \frac{4}{d} \min \left\{ 1, 1 - \frac{2\gamma}{d-2} \right\} \left( C_{\text{Nash}} \right)^{-\frac{4}{d-2}} \| u_0 \|_1^{4/d}. \tag{2}
\]

Here \( C_{\text{Nash}} \) denotes the optimal constant in Nash’s inequality \([22, 10]\).

Note that the scale invariance of (1) allows us to identify the leading order term of the solution of (1) as \( t \to +\infty \). It is the strongest of our results on (1) but initial data need to have a sufficient decay as \( |x| \to \infty \).

**Theorem 1.2.** Let \( d \geq 3 \), \( \gamma < d \), \( V = V_1 \) or \( V = V_2 \), and \( u_0 \in L^1_+ \cap L^2(e^V dx) \). If \( \gamma > 0 \), let us assume that \( \| |x|^k u_0 \|_1 < \infty \) for some \( k \geq \max\{2, \gamma/2\} \). Then any solution of (1) with initial datum \( u_0 \) satisfies

\[
\forall t \geq 0, \quad \| u(t, \cdot) \|_{L^2(e^V dx)} \leq \| u_0 \|_{L^2(e^V dx)} \left( 1 + ct \right)^{-\frac{d-\min\{2, \gamma\}}{2}}.
\]

The constant \( c \) depends on \( d, \gamma, k \), \( \| u_0 \|_{L^2(e^V dx)} \), \( \| u_0 \|_1 \), and \( \| |x|^k u_0 \|_1 \).

The proof of Theorem 1.2 is done in Section 2.2. Although this is a side result, let us notice that the case in which the potential contributes to the decay, i.e., when \( \gamma < 0 \), is also covered in Theorem 1.2. The scale invariance of (1) with \( V = V_1 \) can be exploited to obtain intermediate asymptotics in self-similar variables. Let us define

\[
u_*(t, x) = \frac{c_*}{(1 + 2t)^{\frac{d-\min\{2, \gamma\}}{2}}} |x|^{-\gamma} \exp \left( -\frac{|x|^2}{2(1 + 2t)} \right), \tag{4}\]

The following result on intermediate asymptotics allows us to identify the leading order term of the solution of (1) as \( t \to +\infty \). It is the strongest of our results on (1) but initial data need to have a sufficient decay as \( |x| \to \infty \).

**Theorem 1.3.** Let \( d \geq 1 \), \( \gamma \in (0, d) \) and \( V = V_1 \). If for some constant \( K > 1 \), the function \( u_0 \) is such that

\[
\forall x \in \mathbb{R}^d, \quad 0 \leq u_0(x) \leq K u_*(0, x)
\]

where \( c_* \) is chosen such that \( \| u_* \|_1 = \| u_0 \|_1 \) then the solution \( u \) of (1) with initial datum \( u_0 \) satisfies

\[
\forall t \geq 0, \quad \| u(t, \cdot) - u_*(t, \cdot) \|_p \leq K c_* \left( \frac{1}{\gamma_1} \| u_0 \|^{\frac{1}{1-p}}_1 \right)^{\frac{1}{1-p}} (1 + 2t)^{-\zeta_0}\tag{4}\]

for any \( p \in [1, +\infty) \), where \( \zeta_0 := \frac{d}{2} \left( 1 - \frac{1}{p} \right) + \frac{d}{2} \min \left\{ 4, 4 (d - \gamma), d - 1 \right\} \).

More detailed results will be stated in Section 2.3. Let us quote some relevant papers for (1). In the case without potential, the decay rates of the heat equation is known for more than a century and goes back to [15]. Standard techniques use the Fourier transform, Green kernel estimates and integral representations: see for
instance [14]. There are many other parabolic methods which provide decay rates and will not be reviewed here like, for instance, the Maximum Principle, Harnack inequalities and the parabolic regularity theory: see for instance [25].

In his celebrated paper [22], J. Nash was able to reduce the question of the decay rates for the heat equation to (3): see [7] for detailed comments on the optimality of such a method. Entropy methods have raised a considerable interest in the recent years, but the most classical approach based on the so-called carré du champ method applies to (1) only for potentials $V$ with convexity properties and a sufficient growth at infinity: typically, if $V(x) = |x|^{\alpha}$, then $\alpha \geq 1$ is required for obtaining a Poincaré inequality and the rate of convergence to a unique stationary solution is then exponential, when measured in the appropriate norms; see [3] for a general overview. An interesting family of weakly confining potentials is made of functions $V$ with an intermediate growth, such that $e^{-V}$ is integrable but $\lim_{|x| \to \infty} V(x)/|x| = 0$: all solutions of (1) are attracted by a unique stationary solution, but the rate is expected to be algebraic rather than exponential. A typical example is $V(x) = |x|^{\alpha}$ with $\alpha \in (0, 1)$. The underlying functional inequality is a weak Poincaré inequality; see [24, 20], and [2] for related Lyapunov type methods à la Meyn and Tweedie or [5] for recent spectral considerations. We refer to [1] and [27, 28, 29] for further considerations on, respectively, weighted Nash inequalities and spectral properties of the diffusion operator.

The second part of this paper is devoted to kinetic equations involving a degenerate diffusion operator acting only on the velocity variable or scattering operators, for very weak potentials like $V_1$ or $V_2$. Various hypocoercivity methods have been developed over the years in, e.g., [16, 17, 21, 26, 12], in order to prove exponential rates in appropriate norms, in presence of a strongly confining potential. In that case, the growth of the potential at infinity has to be fast enough not only to guarantee the existence of a stationary solution but also to provide macroscopic coercivity properties which typically amount to a Poincaré inequality. A popular simplification is to assume that the position variable is limited to a compact set, for example a torus. Such results are the counterpart in kinetic theory of diffusions covered by the carré du champ method, as emphasized in [4].

Recently, hypocoercivity methods have been extended in [6] to the case without any external potential by replacing the Poincaré inequality by Nash type estimates. The sub-exponential regime or the regime with weak confinement, i.e., of a potential $V$ such that a weak Poincaré inequality holds, has also been studied in [9, 18]. What we will study next is the range of very weak potentials $V$, which have a growth at infinity which is below the range of weak Poincaré inequalities, but are still such that $\lim_{|x| \to \infty} V(x) = +\infty$. This regime is the counterpart at kinetic level of the results of Theorems 1.1, 1.2 and 1.3. As in the case of (1) when $\gamma \geq 0$, the drift is opposed to the diffusion, but it is not strong enough to prevent that the solution locally vanishes.

Let us consider the kinetic equation

$$\partial_t f + v \cdot \nabla_x f - \nabla_x V \cdot \nabla_v f = Lf$$

where $Lf$ is one of the two following collision operators:

(a) a Fokker-Planck operator

$$Lf = \nabla_v \cdot \left( M \nabla_v \left( M^{-1} f \right) \right),$$
(b) a scattering collision operator
\[ Lf = \int_{\mathbb{R}^d} \sigma(\cdot, v') (f(v') - f(\cdot)) M(\cdot) dv'. \]

We consider the case of a global equilibrium of the form
\[ \forall (x, v) \in \mathbb{R}^d \times \mathbb{R}^d, \quad M(x, v) = M(v) e^{-V(x)} \quad \text{where} \quad M(v) = (2\pi)^{-\frac{d}{2}} e^{-\frac{1}{2} |v|^2}. \]

We shall say that the gaussian function \( M(v) \) is the local equilibrium and assume that the scattering rate \( \sigma(v, v') \) satisfies
\[ \begin{align*}
\text{(H1)} & \quad 1 \leq \sigma(v, v') \leq \sigma, \quad \forall v, v' \in \mathbb{R}^d, \text{ for some } \sigma \geq 1, \\
\text{(H2)} & \quad \int_{\mathbb{R}^d} (\sigma(v, v') - \sigma(v', v)) M(v') dv' = 0 \quad \forall v \in \mathbb{R}^d.
\end{align*} \]

Notice that \( \mathcal{M} \not\subset L^1(\mathbb{R}^d \times \mathbb{R}^d) \) if \( V = V_1 \) or \( V = V_2 \), so that the space \( L^2(\mathcal{M}^{-1} dx dv) \) is defined with respect to an unbounded measure. As in the case of (1), the only integrable equilibrium state is 0. Thus, if the initial datum \( f_0 \) is such that \( f_0 \in L^1(dx dv) \), we expect that the solution to (5) converges to 0 locally as \( t \to +\infty \) and look for the rate of convergence in suitable norms.

When \( V = 0 \), the optimal rate of convergence of a solution \( f \) of (5) with initial datum \( f_0 \) is known. In [6], it has been proved that there exists a constant \( C > 0 \) such that
\[ \iint_{\mathbb{R}^d \times \mathbb{R}^d} |f(t, \cdot, \cdot)|^2 \, d\mu \leq C (1 + t)^{-\frac{\gamma}{2}} \iint_{\mathbb{R}^d \times \mathbb{R}^d} |f_0|^2 \, d\mu \quad \forall t \geq 0, \]
where \( d\mu = M^{-1} dx dv \) and by factorization, the result is extended with same rate for an arbitrary \( \ell > d \) to the measure \( \langle v \rangle^\ell dx dv \) if \( f_0 \in L^2(\mathbb{R}^d \times \mathbb{R}^d, \langle v \rangle^\ell dx dv) \cap L^2_+(\mathbb{R}^d, \langle v \rangle^\ell dv; L^1(\mathbb{R}^d, dx)) \). Our main result on (5) is a decay rate in the presence of a very weak potential. It is an extension of the results of Theorem 1.2 to the framework of kinetic equations.

**Theorem 1.4.** Let \( d \geq 3, V = V_2 \) with \( \gamma \in [0, d) \) and \( k > \max \{2, \gamma/2\} \). We assume that (H1)–(H2) hold and consider a solution \( f \) of (5) with initial datum \( f_0 \in L^2(\mathcal{M}^{-1} dx dv) \) such that \( \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^k f_0 dx dv + \iint_{\mathbb{R}^d \times \mathbb{R}^d} |v|^k f_0 dx dv < +\infty \). Then there exists \( C > 0 \) such that
\[ \forall t \geq 0, \quad \|f(t, \cdot, \cdot)\|^2_{L^2(\mathcal{M}^{-1} dx dv)} \leq C (1 + t)^{-\frac{d+\gamma}{2}}. \]

Standard methods of kinetic theory can be used to establish the existence of solutions of (5) when \( V = V_2 \). We will not give details here. At formal level, similar results can be expected when \( V = V_1 \) but the singularity at \( x = 0 \) raises difficulties which are definitely outside of the scope of this paper.

The expression of the constant \( C \) is explicit. However, due to the method, we cannot claim optimality in the estimate of Theorem 1.4, but at least the asymptotic rate is expected to be optimal by consistency with the diffusion limit, as it is the case when \( V = 0 \) studied in [6]. The strategy of the proof and further relevant references will be detailed in Section 3.

2. Decay estimates for the macroscopic Fokker-Planck equation. In this section, we establish decay rates for (1) and discuss the optimal range of the parameters.
2.1. Decay in \( L^2(\mathbb{R}^d) \). We prove Theorem 1.1. By testing (1) with \( u \), we obtain
\[
\frac{d}{dt} \int_{\mathbb{R}^d} u^2 \, dx = -2 \int_{\mathbb{R}^d} |\nabla u|^2 \, dx + \int_{\mathbb{R}^d} \Delta V |u|^2 \, dx,
\]
with
\[
\Delta V_1(x) = \gamma \frac{d-2}{|x|^2} \quad \text{and} \quad \Delta V_2(x) = \gamma \frac{d-2}{1 + |x|^2} + \frac{2\gamma}{(1 + |x|^2)^2}.
\]
For \( \gamma \leq 0 \) we deduce
\[
\frac{d}{dt} \|u\|_2^2 \leq -2 \|\nabla u\|_2^2 - \frac{2}{C_{\text{Nash}}} \|u_0\|_{-4/d} \|u\|_2^{2+4/d},
\]
from Nash’s inequality (3). Integration completes the proof of (2). For the case \( 0 < \gamma < (d-2)/2 \) we use the following Hardy-Nash inequalities.

**Lemma 2.1.** Let \( d \geq 3 \) and \( \delta < (d-2)^2/4 \). Then
\[
\|u\|_2^{2+\frac{4}{d}} \leq C_{\delta} \left( \|\nabla u\|_2^2 - \delta \int_{\mathbb{R}^d} \frac{u^2}{|x|^2} \, dx \right) \|u\|_1^{\frac{4}{d}} \quad \forall u \in L^1 \cap H^1(\mathbb{R}^d),
\]
with
\[
C_{\delta} = C_{\text{Nash}} \left( 1 - \frac{4\delta}{(d-2)^2} \right)^{-1}.
\]
Let additionally \( \eta < (d^2 - 4)/4 \). Then, for any \( u \in L^1 \cap H^1(\mathbb{R}^d) \),
\[
\|u\|_2^{2+\frac{4}{d}} \leq C_{\delta, \eta} \left( \|\nabla u\|_2^2 - \eta \int_{\mathbb{R}^d} \frac{u^2}{\langle x \rangle^2} \, dx - \delta \int_{\mathbb{R}^d} \frac{u^2}{\langle x \rangle^4} \, dx \right) \|u\|_1^{\frac{4}{d}}
\]
with
\[
C_{\delta, \eta} = C_{\text{Nash}} \left( \min \left\{ 1 - \frac{4\delta}{(d-2)^2}, 1 - \frac{4\eta}{d^2} \right\} \right)^{-1}.
\]

The proof of Lemma 2.1 is given in Appendix C. We use Lemma 2.1 with \( \delta = \gamma (d-2)/2 \) and with \( \eta = \gamma \) (for \( V = V_2 \)), and proceed as for \( \gamma \leq 0 \) to complete the proof of Theorem 1.1.

**Remark 1.** The condition \( \delta < (d-2)^2/4 \) in Lemma 2.1 is optimal for (6) and (7). The restriction on \( \gamma \) in Theorem 1.1 is also optimal. Let \( d \geq 3, \gamma > (d-2)/2 \) and \( V = V_1 \) or \( V = V_2 \). Then there exists \( u \in L^1 \cap H^1(\mathbb{R}^d) \) such that \( \|u\|_2 = 1 \) and
\[
-2 \int_{\mathbb{R}^d} |\nabla u|^2 \, dx + \int_{\mathbb{R}^d} \Delta V |u|^2 \, dx > 0.
\]
In the case \( V = V_1 \), it is indeed enough to observe that \( (d-2)^2/4 \) is the optimal constant in Hardy’s inequality (see Appendix C). The case \( V = V_2 \) follows from the case \( V = V_1 \) by an appropriate scaling.

2.2. Decay in \( L^2(e^{\gamma} \, dx) \). We prove Theorem 1.2. By testing (1) with \( u e^{\gamma} \), we obtain
\[
\frac{1}{2} \frac{d}{dt} \int_{\mathbb{R}^d} u^2 e^{\gamma} \, dx = -\int_{\mathbb{R}^d} e^{-\gamma} |\nabla (u e^{\gamma})|^2 \, dx.
\]
In the case \( V = V_1 \), we have \( e^{\gamma} = |x|^\gamma \) and (8) takes the form
\[
\frac{1}{2} \frac{d}{dt} \int_{\mathbb{R}^d} |x|^\gamma u^2 \, dx = -\int_{\mathbb{R}^d} |x|^{-\gamma} |\nabla (|x|^\gamma u)|^2 \, dx.
\]
If \( \gamma \leq 0 \) and \( a = \frac{d-\gamma}{d+2-\gamma} \), the inequality
\[
\int_{\mathbb{R}^d} |x|^\gamma u^2 \, dx \leq C \left( \int_{\mathbb{R}^d} |x|^{-\gamma} |\nabla (|x|^\gamma u)|^2 \, dx \right)^a \left( \int_{\mathbb{R}^d} |u|^2 \, dx \right)^{2(1-a)}
\]
(9)
follows from the Caffarelli-Kohn-Nirenberg inequalities (see Appendix A, Ineq. (26) applied with \( k = 0 \) to \( v = |x|^\gamma u \)). The conservation of the \( L^1 \) norm of \( u \) gives

\[
\frac{d}{dt} \int_{\mathbb{R}^d} |u|^2 \, |x|^\gamma \, dx \leq -2 \mathcal{C}^{-\left(1 + \frac{d-\gamma}{2}\right)} \|u_0\|_1^{\frac{d}{d-\gamma}} \left( \int_{\mathbb{R}^d} |u|^2 \, |x|^\gamma \, dx \right)^{1 + \frac{2}{d-\gamma}}.
\]

The conclusion of Theorem 1.2 follows by integration. An analogous argument based on the inhomogeneous Caffarelli-Kohn-Nirenberg inequality

\[
\int_{\mathbb{R}^d} |u|^2 \, \langle x \rangle^\gamma \, dx \leq \mathcal{K} \left( \int_{\mathbb{R}^d} \langle x \rangle^{-\gamma} \langle \langle x \rangle^\gamma u \rangle^2 \, dx \right)^a \left( \int_{\mathbb{R}^d} |u|^2 \, dx \right)^{2(1-a)}
\]

with \( a = \frac{d-\gamma}{d+2-\gamma} \)

applies to the case \( \gamma \leq 0 \), \( V = V_2 \) (see Appendix B, Ineq. (30) applied with \( k = 0 \) and \( v = \langle x \rangle^\gamma u \)).

Without additional assumptions, it is not possible to expect a similar result for \( \gamma > 0 \). Let us explain why. In the case \( V = V_1 \) and with \( v = |x|^\gamma u \), consider the quotient

\[
\mathcal{Q}[v] := \frac{\left( \int_{\mathbb{R}^d} |x|^{-\gamma} \langle \nabla v \rangle^2 \, dx \right)^a \left( \int_{\mathbb{R}^d} |x|^{-\gamma} |v| \, dx \right)^{2(1-a)}}{\int_{\mathbb{R}^d} |x|^{-\gamma} \, dx}
\]

As a consequence of (9), \( \mathcal{Q}[v] \) is bounded from below by a positive constant if \( \gamma \leq 0 \) and \( a = (d-\gamma)/(d-\gamma+2) \). Let us consider the case \( \gamma > 0 \).

**Lemma 2.2.** Let \( d \geq 1 \), \( \gamma \in (0, d) \) and \( a = (d-\gamma)/(d-\gamma+2) \). Then there exists a sequence \( (v_n)_{n \in \mathbb{N}} \) of smooth, compactly supported functions such that \( \lim_{n \to \infty} \mathcal{Q}[v_n] = 0 \).

**Proof.** Let us take a smooth function \( v \) and consider \( v_n(x) = v(x + n \, \mathbf{e}) \) for some \( \mathbf{e} \in S^{d-1} \). Then \( \mathcal{Q}[v_n] = O \left( n^{-(1-a)} \right) \). With \( \gamma > 0 \), we know that \( a \) is in the range \( 0 < a < 1 \) if and only if \( \gamma \in (0, d) \).

For the proof of Theorem 1.2 in the case \( 0 < \gamma < d \), \( V = V_1 \), we start by estimating the growth of the moment

\[
M_k(t) := \int_{\mathbb{R}^d} |x|^k u \, dx,
\]

which evolves according to

\[
M_k' = k \left( d + k - 2 - \gamma \right) \int_{\mathbb{R}^d} u \, |x|^{k-2-\gamma} \, dx \leq k \left( d + k - 2 - \gamma \right) M_0^{\frac{a}{a-1}} M_k^{1-\frac{a}{a-1}}
\]

where we have used Hölder’s inequality and \( M_0(t) = M_0(0) = \|u_0\|_1 \). Integration gives

\[
M_k(t) \leq \left( M_k(0)^{2/k} + 2 \left( d + k - 2 - \gamma \right) M_0^{2/k} t \right)^{k/2}.
\]

If \( \gamma \in (0, d) \) and \( a = \frac{d+2k-\gamma}{d+2k+2-\gamma} \), by inserting the Caffarelli-Kohn-Nirenberg inequality

\[
\int_{\mathbb{R}^d} |x|^\gamma u^2 \, dx \leq \mathcal{C} \left( \int_{\mathbb{R}^d} |x|^{-\gamma} \langle |x|^\gamma u \rangle^2 \, dx \right)^a \left( \int_{\mathbb{R}^d} |x|^k |u| \, dx \right)^{2(1-a)}
\]
(see Appendix A, Ineq. (26) applied to $v = |x|^\gamma u$ in (8), we observe that the function $z = \int_{\mathbb{R}^d} u^2 |x|^\gamma \, dx$ solves
\[
\frac{dz}{dt} \leq -2 \left( C^{-1} z \right)^{1 + \frac{2k}{d+2k-\gamma}} M_k(t)^{-\frac{4}{d+2k-\gamma}},
\]
and, after integration,
\[
z(t) \leq z(0) \left( 1 + a \left( (1 + b t)^{1 - \frac{2k}{d+2k-\gamma}} - 1 \right) \right)^{-k/\theta}
\]
with $a$ and $b$ depend only on the quantities entering into the constant $c$ of Theorem 1.2. Let $\theta = 2k/(d+2k-\gamma)$ and observe that
\[
1 + a \left( (1 + b t)^{1-\theta} - 1 \right) \geq (1 + c t)^{1-\theta} \quad \forall t \geq 0,
\]
if $c = b \min \{a, a^{1/(1-\theta)}\}$. Our estimate becomes
\[
z(t) \leq z(0) \left( 1 + a \left( (1 + b t)^{1-\theta} - 1 \right) \right)^{-k/\theta} \leq z(0) (1 + c t)^{-k(1-\theta)/\theta} = z(0) (1 + c t)^{-\frac{d+2k-\gamma}{d+2k-\gamma}}.
\]
In the case $V = V_2$ we can adopt the same strategy, based on a moment now defined as
\[
M_k(t) := \int_{\mathbb{R}^d} \langle x \rangle^k u \, dx,
\]
and on the inhomogeneous Caffarelli-Kohn-Nirenberg inequality
\[
\int_{\mathbb{R}^d} \langle x \rangle^\gamma u^2 \, dx \leq K \left( \int_{\mathbb{R}^d} \langle x \rangle^{-\gamma} |\nabla(\langle x \rangle^\gamma u)|^2 \, dx \right)^{\frac{a}{2}} M_k^{2(1-a)}
\]
with $a = \frac{d+2k-\gamma}{d+2k-\gamma}$.
(see Appendix B, Ineq. (30) applied to $v = \langle x \rangle^\gamma u$). This completes the proof of Theorem 1.2.

\[\Box\]

2.3. Decay in self-similar variables and intermediate asymptotics.

We prove Theorem 1.3. With the parabolic change of variables
\[
u(t,x) = (1 + 2 t)^{-d/2} v(\tau,\xi), \quad \tau = \frac{1}{2} \log(1 + 2 t), \quad \xi = \frac{x}{\sqrt{1+2t}},
\]
which preserves mass and initial data, (1) is changed into
\[
\frac{\partial \nu}{\partial \tau} = \Delta_\xi \nu + \nabla_\xi \cdot (\nu \nabla_\xi \Phi),
\]
where
\[
\Phi(\tau,\xi) = V(e^\tau \xi) + \frac{1}{2} |\xi|^2.
\]
We investigate the long-time behavior of solutions of (1) by considering quasi-equilibria
\[
v_*(\tau,\xi) := M(\tau) e^{-\Phi(\tau,\xi)},
\]
of (11) with an appropriately chosen $M(\tau)$.

For the scale invariant case $V = V_1$, the potential $\Phi_1(\tau,\xi) = \gamma \left( \log |\xi| + \tau \right) + \frac{1}{2} |\xi|^2$ in (11) can be replaced by the time independent potential $\phi_1(x) = \gamma \log |\xi| + \frac{1}{2} |\xi|^2$.

With $M(\tau) = c_* e^{\gamma \tau}$, time independent equilibria
\[
v_{*,1}(\xi) := c_* |\xi|^{-\gamma} e^{-|\xi|^2/2},
\]
are available. For the second case $V = V_2$ with potential

$$
\Phi_2(\tau, \xi) := \frac{\gamma}{2} \log \left(1 + e^{2\tau |\xi|^2}\right) + \frac{1}{2} |\xi|^2,
$$

we shall use

$$
v_{*,2}(\tau, \xi) := c_{*} \left(e^{-2\tau} + |\xi|^2\right)^{-\gamma/2} e^{-|\xi|^2/2},
$$

so that $v_{*,2}$ is asymptotically equivalent to $v_{*,1}$ as $\tau \to \infty$.

If a quasi-equilibrium of the form (12) satisfies

$$
\frac{\partial v_\tau}{\partial \tau} \geq 0,
$$

which holds for both examples (13) and (14) if $\gamma > 0$, then $v_\tau$ is obviously a supersolution of (11), thus proving the following result on uniform decay estimates.

**Proposition 1.** Let $\gamma \in (0, d)$ and $u(t, x)$ be a solution of (1) with initial datum such that, for some constant $c_{*} > 0$,

$$
0 \leq u(0, x) \leq c_{*} (\sigma + |x|^2)^{-\gamma/2} \exp \left(-\frac{|x|^2}{2}\right) \quad \forall x \in \mathbb{R}^d,
$$

with $\sigma = 0$ if $V = V_1$ and $\sigma = 1$ if $V = V_2$. Then

$$
0 \leq u(t, x) \leq \frac{c_{*}}{(1 + 2t)^{\frac{d-\gamma}{2}}} (\sigma + |x|^2)^{-\gamma/2} \exp \left(-\frac{|x|^2}{2(1 + 2t)}\right) \quad \forall x \in \mathbb{R}^d, \, t \geq 0.
$$

For $0 < \gamma < d$, we obtain a pointwise decay: the attracting potential is too weak for confinement (no stationary state can exist, at least among $L^1(\mathbb{R}^d)$ solutions) but it slows down the decay compared to solutions of the heat equation (that is, solutions corresponding to $V = 0$).

The result of Proposition 1 is also true for $\gamma \leq 0$ if $V = V_1$. In that case, a repulsive potential with $\gamma < 0$ accelerates the pointwise decay, but does not change the uniform decay rate as $t \to +\infty$ because

$$
\forall t > 0, \quad \max_{r > 0} r^{-\gamma} \exp \left(-\frac{r^2}{4t}\right) = \left(\frac{e}{2 \gamma t}\right)^{\gamma/2}.
$$

In order to obtain an estimate in $L^2(e^V dx)$, let us state a result on a Poincaré inequality. We introduce the notations

$$
\Phi_{\gamma, \sigma}(\xi) := \frac{\gamma}{2} |\xi|^2 + \frac{1}{2} \log (\sigma + |\xi|^2),
$$

$$
Z_{\gamma, \sigma} := \int_{\mathbb{R}^d} e^{-\Phi_{\gamma, \sigma}(\xi)} d\xi \quad \text{and} \quad d\mu_{\gamma, \sigma} := Z_{\gamma, \sigma}^{-1} e^{-\Phi_{\gamma, \sigma}} d\xi.
$$

**Lemma 2.3.** Assume that $d \geq 1$, $\gamma \in (0, d)$ and $\sigma \in \mathbb{R}^+$. With the above notations, there is a positive constant $\lambda_{\gamma, \sigma}$ such that

$$
\int_{\mathbb{R}^d} |\nabla w|^2 d\mu_{\gamma, \sigma} \geq \lambda_{\gamma, \sigma} \int_{\mathbb{R}^d} |w - \overline{w}|^2 d\mu_{\gamma, \sigma}
$$

$$
\forall w \in H^1(\mathbb{R}^d, d\mu_{\gamma, \sigma}) \quad \text{such that} \quad \overline{w} = \int_{\mathbb{R}^d} w d\mu_{\gamma, \sigma}.
$$

Moreover, for any $\gamma \in (0, d)$, $\min_{\sigma \in [0, 1]} \lambda_{\gamma, \sigma} > 0$. 

\[\text{(15)}\]
Proof. Let us consider a potential $\psi$ on $\mathbb{R}^d$. We assume that $\psi$ is a measurable function such that
\[
\ell = \lim_{r \to +\infty} \inf_{f \in \mathcal{D}(B_r)} \frac{\int_{\mathbb{R}^d} (|\nabla f|^2 + \psi |f|^2) \, d\xi}{\int_{\mathbb{R}^d} |f|^2 \, d\xi} > 0,
\]
where $B_r := \{ x \in \mathbb{R}^d : |x| > r \}$ and $\mathcal{D}(B_r)$ denotes the space of smooth functions on $\mathbb{R}^d$ with compact support in $B_r$. According to Persson’s result [23, Theorem 2.1], the lower end of the continuous spectrum of the Schrödinger operator $-\Delta + \psi$ is $\ell$.

With $w = f e^{\Phi_{\gamma,\sigma}}/2$ and $\psi = \frac{1}{4} |\nabla \Phi_{\gamma,\sigma}|^2 - \frac{1}{2} \Delta \Phi_{\gamma,\sigma}$, $\lambda_{\gamma,\sigma}$ is either $\ell = 4$ if $-\Delta + \psi$ has no eigenvalue in the interval $(0, 4)$, or the lowest positive eigenvalue of $-\Delta + \psi$ in the interval $(0, 4)$, since the kernel is generated by constant functions. This proves that $0 < \lambda_{\gamma,\sigma} \leq 4$. An elementary computation shows that
\[
4 \psi(\xi) = X - (2 d + \sigma - 2 \gamma) - \gamma (2 d + 2 \sigma - \gamma - 4) X^{-1} - \gamma (\gamma + 4) X^{-2}
\]
with $X = |\xi|^2 + \sigma$, which allows in principle for an explicit computation of $\lambda_{\gamma,\sigma}$ and shows that it is continuous with respect to $\sigma$ on $\mathbb{R}^+$.

In the special case $\sigma = 0$, it is possible to compute $\lambda_{\gamma,0}$ as follows.

**Lemma 2.4.** Assume that $d \geq 1$ and $\gamma \in (0, d)$. With the above notations, we have $\lambda_{\gamma,0} = 4 (1 - \gamma)$ if $d = 1$ and $\lambda_{\gamma,0} = \min \{4, 4 (d - \gamma), d - 1\}$ if $d \geq 2$.

**Proof.** A decomposition in spherical harmonics shows that the lowest eigenvalue associated with a non-radial eigenfunction (in dimension $d \geq 2$) is of the form $f(\xi) = g(r) Y(\omega)$ with $r = |\xi|$, $\omega = \xi/r$ and $-\Delta_{\mathbb{S}^{d-1}} Y = k (k + d - 2) Y$, $k \in \mathbb{N}$. If $k \neq 0$, $g \equiv 1$ is optimal and the eigenvalue is $k (k + d - 2)$ with $k = 1$. Otherwise $k = 0$ and $g$ is the lowest non-trivial Hermite polynomial with zero average on $\mathbb{R}^+ \ni r$ in dimension $n = d - \gamma$, that is $g(r) = r^2 - n$ and the corresponding eigenvalue is $4n$. Notice that $n$ is not necessarily an integer, but can be considered as a real parameter. All other eigenvalues are larger. We conclude by taking the minimum of the two eigenvalues. If $d = 1$, a similar conclusion holds with $f(\xi) = \xi$.

An interesting consequence of Lemma 2.4 is a result of intermediate asymptotics, which allows to identify the leading order term of the solution of (1) as $t \to +\infty$.

**Corollary 1.** Assume that $d \geq 1$, $\gamma \in (0, d)$ and $V = V_1$. With the above notations, if $u$ solves (1) with an initial datum $u_0 \in L^1_+(\mathbb{R}^d)$ such that $(u_0(0, x))^{-1} u_0^2 \in L^1_+(\mathbb{R}^d)$, with $u_0$ defined by (4), and if we choose $c_0$ in (4) such that $\|u_0(0, \cdot)\|_1 = \|u_0\|_1$, then
\[
\int_{\mathbb{R}^d} \frac{(u(t, x) - u_*(t, x))^2}{u_*(t, x)} \, dx \leq (1 + 2 t)^{-\lambda_{\gamma,0}} \int_{\mathbb{R}^d} \frac{(u(0, x) - u_*(0, x))^2}{u_*(0, x)} \, dx.
\]

**Proof.** By definition of $u_*$, we have
\[
\int_{\mathbb{R}^d} v_{*, 1} \, d\xi = \int_{\mathbb{R}^d} v(0, \xi) \, d\xi = \int_{\mathbb{R}^d} u_0 \, dx.
\]
Then, using the Poincaré inequality (16) and Lemma 2.4, we know that
\[
\frac{d}{dt} \int_{\mathbb{R}^d} (v - v_{1,*})^2 e^{\phi_1} \, d\xi = -2 \int_{\mathbb{R}^d} \left| \nabla_{\xi} (e^{\phi_1} (v - v_{1,*})) \right|^2 e^{\phi_1} \, d\xi
\]
\[
\leq -2 \lambda_{\gamma,0} \int_{\mathbb{R}^d} (v - v_{1,*})^2 e^{\phi_1} \, d\xi,
\]
from which we deduce that
\[ \int_{\mathbb{R}^d} (v - v_1,*)^2 \, e^{\phi_1} \, dx \leq e^{-2\lambda_{\gamma,0}} \int_{\mathbb{R}^d} (u(0, x) - v_1,*)^2 \, e^{\phi_1} \, dx . \]

This concludes the proof using the parabolic change of variables (10).

\[ \] Proof of Theorem 1.3. A Cauchy-Schwarz inequality shows that
\[
\left( \int_{\mathbb{R}^d} |u(t, x) - u_*(t, x)| \, dx \right)^2 \leq \int_{\mathbb{R}^d} u_*(t, x) \, dx \int_{\mathbb{R}^d} \frac{(u(t, x) - u_*(t, x))^2}{u_*(t, x)} \, dx \\
\leq (1 + 2t)^{-\lambda_{\gamma,0}} \int_{\mathbb{R}^d} u_0 \, dx \int_{\mathbb{R}^d} \frac{(u(0, x) - u_*(0, x))^2}{u_*(0, x)} \, dx .
\]

The Hölder interpolation inequality
\[ \|u(t, \cdot) - u_*(t, \cdot)\|_p \leq \|u(t, \cdot) - u_*(t, \cdot)\|_1^{\frac{1}{p}} \|u(t, \cdot) - u_*(t, \cdot)\|_{\infty}^{1 - \frac{1}{p}} \]
combined with the results of Proposition 1 and Corollary 1 concludes the proof after taking (15) and the expression of \( \lambda_{\gamma,0} \) stated in Lemma 2.4 into account. \( \square \)

3. Decay estimate for the kinetic equation with weak confinement. In this section, we prove Theorem 1.4 by revisiting the \( L^2 \) approach of [12] in the spirit of [6].

3.1. Notations and elementary computations. On the space \( L^2(M^{-1} \, dx \, dv) \), we define the scalar product
\[ \langle f, g \rangle = \int_{\mathbb{R}^d \times \mathbb{R}^d} f \, g \, e^V \, M^{-1} \, dx \, dv \]
and the norm \( \|f\| = \langle f, f \rangle^{1/2} \). Let \( \Pi \) be the orthogonal projection operator on Ker(\( L \)) given by \( \Pi f := M \rho[f] \), where \( \rho[f] := \int_{\mathbb{R}^d} f(v) \, dv \), and \( T \) be the transport operator such that \( Tf = v \cdot \nabla_x f - \nabla_x V \cdot \nabla_v f \). We assume that
\[ M(v) = (2\pi)^{-\frac{d}{2}} \, e^{-\frac{1}{2} |v|^2} \quad \forall \, v \in \mathbb{R}^d . \]

Let us use the notation \( u[v] := e^V \rho[v] \) and observe that
\[ T \Pi f = M e^{-V} v \cdot \nabla_x u[f] , \quad (T \Pi)^* f = -M \nabla_x \cdot \rho[v f] , \]
\[ (T \Pi)^*(T \Pi) f = -M \nabla_x \cdot (e^{-V} \nabla_x u[f]) , \]
where the last identity follows from \( \int_{\mathbb{R}^d} M(v) \, v \otimes v \, dv = \text{Id} \). To build a suitable Lyapunov functional, as in [11, 12, 6] we introduce the operator \( A \) defined by
\[ A := (\text{Id} + (T \Pi)^*(T \Pi))^{-1}(T \Pi)^* . \]

As in [12] we define the Lyapunov functional \( H \) by
\[ H[f] := \frac{1}{2} \|f\|^2 + \varepsilon \, \langle Af, f \rangle \]
and obtain by a direct computation that
\[ \frac{d}{dt} H[f] = -D[f] \]
with
\[
D[f] := -\langle Lf, f \rangle + \varepsilon \langle ATf, f \rangle + \varepsilon \langle AT(\text{Id} - \Pi)f, f \rangle \\
- \varepsilon \langle TA(\text{Id} - \Pi)f, (\text{Id} - \Pi)f \rangle - \varepsilon \langle AL(\text{Id} - \Pi)f, f \rangle ,
\]
where we have used that $\langle Af, Lf \rangle = 0$. For the first term in $D[f]$, we rely on the microscopic coercivity estimate (see \[12\])
\[
-\langle Lf, f \rangle \geq \lambda_m \|(\text{Id} - \Pi)f\|^2 .
\]

The second term $\langle ATf, f \rangle$ is expected to control the macroscopic contribution $\|\Pi f\|$. In Section 3.2 the remaining terms will be estimated to show that for $\varepsilon$ small enough $D[f]$ controls $\|(\text{Id} - \Pi)f\|^2 + \langle ATf, f \rangle$. As in Section 2.2, estimates on moments are needed, which will be proved in Section 3.3 and used in Section 3.4 to show a Nash type estimate and to complete the proof of Theorem 1.4 by relating the entropy dissipation $D[f]$ to $H[f]$ and by solving the resulting differential inequality.

3.2. Proof of the Lyapunov functional property of $H[f]$. Let us define the notations
\[
\langle u_1, u_2 \rangle_V := \int_{\mathbb{R}^d} u_1 u_2 e^{-V} \, dx \quad \text{and} \quad \|u\|_V^2 := \langle u, u \rangle_V
\]
associated with the norm $L_2(e^{-V} \, dx)$. Unless it is specified, $\nabla$ means $\nabla_x$.

Lemma 3.1. With the above notations, we have
\[
\|Af\| \leq \frac{1}{2} \|(\text{Id} - \Pi)f\| , \quad \|TAf\| \leq \|(\text{Id} - \Pi)f\|
\]
and
\[
|\langle TA(\text{Id} - \Pi)f, (\text{Id} - \Pi)f \rangle| \leq \|(\text{Id} - \Pi)f\|^2 .
\]

Proof. We already know from \[12, Lemma 1\] that the operator $TA$ is bounded. Let us give a short proof for completeness. The equation $Af = g$ is equivalent to
\[
(T\Pi)^* f = g + (T\Pi)^* (T\Pi) g . \tag{18}
\]
Multiplying (18) by $g M^{-1} e^V$, we get that
\[
\|g\|^2 + \|T\Pi g\|^2 = \langle f, T\Pi g \rangle = \langle (\text{Id} - \Pi)f, T\Pi g \rangle \leq \|(\text{Id} - \Pi)f\| \|T\Pi g\| \leq \frac{1}{4} \|(\text{Id} - \Pi)f\|^2 + \|T\Pi g\|^2
\]
from which we deduce that $\|Af\| = \|g\| \leq \frac{1}{2} \|(\text{Id} - \Pi)f\|$. Since $A = \Pi A$, because (18) can be rewritten as $g = \Pi T^2 \Pi g - \Pi T f$ using $(T\Pi)^* = - \Pi T$, we also have that $TAF = T\Pi g$ and obtain that $\|TAF\| = \|T\Pi g\| \leq \|(\text{Id} - \Pi)f\|$. The estimate on $|\langle TA(\text{Id} - \Pi)f, (\text{Id} - \Pi)f \rangle|$ follows. \hfill \Box

The term $\langle ATf, f \rangle$ is the one which gives the macroscopic decay rate. Let $w[f]$ be such that $(\text{Id} + (T\Pi)^* (T\Pi))^{-1} \Pi f = w M e^{-V}$. Then $w$ solves
\[
w - Lw = u[f] \quad \text{where} \quad Lw := e^V \nabla \cdot (e^{-V} \nabla w) . \tag{19}
\]

Lemma 3.2. With the above notations, if $u = u[f]$ and $w = w[f]$ solves (19), we have
\[
\langle ATf, f \rangle = \|\nabla w\|_V^2 + \|Lw\|_V^2 \leq \frac{5}{4} \|u\|_V^2 .
\]
Proof. Let $w$ be a solution of (19). Since

$$AT\Pi f = (\text{Id} + (T\Pi)^*(T\Pi))^{-1}(T\Pi)^*(T\Pi)\Pi f$$

$$= (\text{Id} + (T\Pi)^*(T\Pi))^{-1}(\text{Id} + (T\Pi)^*T\Pi - \text{Id})\Pi f$$

$$= \Pi f - (\text{Id} + (T\Pi)^*(T\Pi))^{-1}\Pi f = \Pi f - w Me^{-V} ,$$

we obtain that

$$AT\Pi f = (u - w) Me^{-V} .$$

Using (19) and integrating on $\mathbb{R}^d$ after multiplying by $\Pi f = u Me^{-V}$, we obtain that

$$\langle AT\Pi f, \Pi f \rangle = \langle u, u - w \rangle_V = \langle w - Lw, -Lw \rangle_V = \|\nabla w\|^2_V + \|Lw\|^2_V .$$

On the other hand, we can also write that

$$\langle AT\Pi f, \Pi f \rangle = \langle u, u - w \rangle_V = - \langle u, Lw \rangle_V$$

and obtain that

$$\|\nabla w\|^2_V + \|Lw\|^2_V = - \langle u, Lw \rangle_V \leq \|u\|_V \|Lw\|_V \leq \frac{1}{4} \|u\|^2_V + \|Lw\|^2_V ,$$

using the Cauchy-Schwarz inequality. As a consequence, we obtain that

$$\|\nabla w\|^2_V \leq \frac{1}{4} \|u\|^2_V \quad \text{and} \quad \|Lw\|_V \leq \|u\|_V ,$$

which concludes the proof. \qed

**Lemma 3.3.** With the above notations, if $u = u[f]$ and $w$ solves (19), we have

$$\|\text{Hess}(w)\|^2_V \leq \max\{1, \gamma\} \langle AT\Pi f, \Pi f \rangle .$$

**Proof.** The operator $L = \Delta - \nabla V \cdot \nabla$ is such that

$$[L, \nabla] w = L(\nabla w) - \nabla(L w) = \left( L \left( \frac{\partial w}{\partial x_i} \right) - \frac{\partial}{\partial x_i} (L w) \right)_{i=1}^d = - \text{Hess}(V) : \nabla w$$

and it is self-adjoint on $L^2(e^V dx)$ so that

$$\langle Lw_1, w_2 \rangle_V = - \langle \nabla w_1, \nabla w_2 \rangle_V = \langle w_1, Lw_2 \rangle_V$$

for any $w_1$ and $w_2$. Applied first with $w_1 = w$ and $w_2 = Lw$ and then with $w_1 = w_2 = \nabla w$, this shows that

$$\|Lw\|^2_V = - \langle \nabla w, \nabla Lw \rangle_V = - \langle \nabla w, L\nabla w \rangle_V - \int_{\mathbb{R}^d} \nabla w \cdot [L, \nabla] w e^{-V} dx$$

$$= \|\text{Hess}(w)\|^2_V + \int_{\mathbb{R}^d} \text{Hess}(V) : (\nabla w \otimes \nabla w) e^{-V} dx$$

where $\|\text{Hess}(w)\|^2_V = \int_{\mathbb{R}^d} |\text{Hess}(w)|^2 e^{-V} dx = \sum_{i,j=1}^d \int_{\mathbb{R}^d} \left( \frac{\partial^2 w}{\partial x_i \partial x_j} \right)^2 e^{-V} dx$. In the case $V = V_2$, we deduce from

$$\frac{\partial^2 V}{\partial x_i \partial x_j} = \frac{\gamma}{\langle x \rangle^2} \left( \delta_{ij} - 2 \frac{x_i x_j}{\langle x \rangle^2} \right)$$

that

$$\text{Hess}(V) \geq -\gamma \text{Id} .$$
Hence
\[ \max\{1, \gamma\} \langle \mathcal{A} \mathcal{T} \mathcal{P} f, \Pi f \rangle \geq \|\mathcal{L} w\|^2_V + \max\{1, \gamma\} \|\nabla w\|^2_V, \]
\[ \geq \|\text{Hess}(w)\|^2_V - \gamma \|\nabla w\|^2_V + \max\{1, \gamma\} \|\nabla w\|^2_V, \]
which concludes the proof. \qed

**Lemma 3.4.** With the above notations and with \( m_\gamma := 3 \max\{1, \gamma\} \), we have
\[ \| \langle \mathcal{A} \mathcal{T} (\text{Id} - \Pi) f, \Pi f \rangle \| \leq m_\gamma \langle \mathcal{A} \mathcal{T} \mathcal{P} f, \Pi f \rangle^{1/2} \| (\text{Id} - \Pi) f \|. \]

**Proof.** Assume that \( u = u[f] \) and \( w \) solves (19). Using \( g = (\text{Id} + (\mathcal{T} \mathcal{P})^*(\mathcal{T} \mathcal{P}))^{-1} f \) so that \((\text{Id} + (\mathcal{T} \mathcal{P})^*(\mathcal{T} \mathcal{P})) g = f\) means \( g = (\mathcal{L} w) M^{-1} e^{-V} = f \), let us compute
\[ \langle \mathcal{A} \mathcal{T} (\text{Id} - \Pi) f, \Pi f \rangle = \langle \mathcal{T} (\text{Id} - \Pi) f, \mathcal{P}^* \Pi f \rangle = \langle \mathcal{T} (\text{Id} - \Pi) f, \mathcal{T} \Pi g \rangle \]
\[ = \int \int_{\mathbb{R}^d \times \mathbb{R}^d} \sqrt{M} v \otimes v \frac{(\text{Id} - \Pi)f}{\sqrt{M}} : \text{Hess} w \, dx \, dv \]
\[ = \int \int_{\mathbb{R}^d \times \mathbb{R}^d} \sqrt{M} (v \otimes v - \frac{1}{2} \text{Id}) \frac{(\text{Id} - \Pi)f}{\sqrt{M}} : \text{Hess} w \, dx \, dv \]
We conclude using a Cauchy-Schwarz inequality, Lemma 3.2 and Lemma 3.3. \qed

In order to have unified notations, we adopt the convention that \( \overline{\sigma} = 1/\sqrt{2} \) if \( L \) is the Fokker-Planck operator.

**Lemma 3.5.** With the above notations, we have
\[ \langle \mathcal{A} \mathcal{T} \mathcal{P} \mathcal{L} (\text{Id} - \Pi) f, \Pi f \rangle \leq \sqrt{2} \overline{\sigma} \langle \mathcal{A} \mathcal{T} \mathcal{P} f, \Pi f \rangle^{1/2} \| (\text{Id} - \Pi) f \|. \]

**Proof.** We use duality to write
\[ \langle \mathcal{A} \mathcal{T} \mathcal{P} \mathcal{L} (\text{Id} - \Pi) f, \Pi f \rangle = \langle \mathcal{L} (\text{Id} - \Pi) f, h \rangle \]
where \( h = \mathcal{P}^* f = (\mathcal{T} \mathcal{P}) g \) and \( g = (\text{Id} + (\mathcal{T} \mathcal{P})^*(\mathcal{T} \mathcal{P}))^{-1} f \) so that \((\text{Id} + (\mathcal{T} \mathcal{P})^*(\mathcal{T} \mathcal{P})) g = f \)
and \( h = v \cdot \nabla w M^2 e^{-V} \). Here \( w \) solves (19) with \( u = u[f] \).
• If \( L \) is the Fokker-Planck operator, then \( \int_{\mathbb{R}^d} v L f \, dv = -j \) and
\[ |\langle \mathcal{A} \mathcal{T} \mathcal{P} \mathcal{L} (\text{Id} - \Pi) f, f \rangle| = |\langle j, \nabla w \rangle| \leq \|j\|_V \|\nabla w\|_V \leq \| (\text{Id} - \Pi) f \| \| \nabla w \|_V. \]
We conclude using Lemma 3.2 and an estimate on \( j = |j| e \) where \( e \in S^{d-1} \), that goes as follows: by computing
\[ |j| = \left| \int_{\mathbb{R}^d} v f \, dv \right| = \left| \int_{\mathbb{R}^d} (v \cdot \Pi f) dv \right| \]
\[ \leq \int_{\mathbb{R}^d} \left( (\text{Id} - \Pi)f M^{-1/2} \right) \left( |v \cdot e| M^{1/2} \right) \, dv \]
\[ \leq \left( \int_{\mathbb{R}^d} |(\text{Id} - \Pi)f|^2 M^{-1} \, dv \int_{\mathbb{R}^d} |v \cdot e|^2 M \, dv \right)^{1/2} \]
\[ = \left( \int_{\mathbb{R}^d} |(\text{Id} - \Pi)f|^2 M^{-1} \, dv \right)^{1/2}, \]
we know that
\[ \|j e^V\|_V^2 = \int_{\mathbb{R}^d} |j|^2 e^V \, dx \leq \int \int_{\mathbb{R}^d \times \mathbb{R}^d} |(\text{Id} - \Pi)f|^2 M^{-1} e^V \, dx \, dv = \| (\text{Id} - \Pi) f \|^2. \]
• If \( L \) is the scattering operator, then
\[
\|L(Id - \Pi)f\|^2 \leq \sigma^2 \int_{\mathbb{R}^d} \frac{1}{M} \left| \int_{\mathbb{R}^d} M M' \left| \frac{f'}{M'} - \frac{f}{M} \right|^2 \right| dv \leq \sigma^2 \int_{\mathbb{R}^d} M \left| \sqrt{M'} \sqrt{M'} \left| \frac{f'}{M'} - \frac{f}{M} \right|^2 \right| dv.
\]
and \( \|h\| = \|v \cdot \nabla w \| = \|\nabla w\|_2 \) so that
\[
\langle AL(Id - \Pi)f, f \rangle \leq \sqrt{2} \sigma \langle AT\Pi f, \Pi f \rangle^{1/2} \|f - \Pi f\|.
\]
Notice that for a nonnegative function \( f \), we have the improved bounds \( \|L(Id - \Pi)f\| \leq \sigma \|f\| \) and \( \langle AL(Id - \Pi)f, \Pi f \rangle \leq \sigma \langle AT\Pi f, \Pi f \rangle^{1/2} \|f - \Pi f\| \).

Finally, we apply the results of Lemmas 3.1, 3.4, 3.5 to the right hand side of (17):

**Lemma 3.6.** With the above notations, we have
\[
D[f] \geq \lambda_\varepsilon \left( \|f\| + \langle AT\Pi f, \Pi f \rangle \right)
\]
with
\[
\lambda_\varepsilon := \frac{1}{2} \left( \lambda_m - \sqrt{(\lambda_m - 2\varepsilon)^2 + \varepsilon^2 (m_\gamma + \sqrt{2}\sigma)^2} \right)
\]
and \( \lambda_\varepsilon > 0 \), if \( \varepsilon > 0 \) is small enough.

The functional \( H[f] \) is a Lyapunov function in the sense that \( D[f] \geq 0 \) and the equation \( D[f] = 0 \) has a unique solution \( f = 0 \).

**Proof.** The above mentioned Lemmas imply
\[
D[f] \geq (\lambda_m - \varepsilon) \|f\|^2 + \varepsilon \langle AT\Pi f, \Pi f \rangle - \varepsilon \left( m_\gamma + \sqrt{2}\sigma \right) \|f - \Pi f\| \langle AT\Pi f, \Pi f \rangle^{1/2}.
\]
The Lyapunov function property is a consequence of (19) and Lemma 3.2.

### 3.3. Moment estimates.
Let us consider the case \( V = V_2 \) and define the \( k^{th} \) order moments in \( x \) and \( v \) by
\[
J_k(t) := \|\langle x \rangle^k f(t, \cdot, \cdot)\|_1 \quad \text{and} \quad K_k(t) := \|v^k f(t, \cdot, \cdot)\|_1.
\]
Our goal is to prove estimates on \( J_k \) and \( K_k \). Notice that \( J_0 = K_0 = \|f_0\|_{L^1(\mathbb{R}^d \times \mathbb{R}^d)} \) is constant if \( f \) solves (5).

**Lemma 3.7.** Let \( \gamma \in (0, d) \), \( k \in \mathbb{N} \) with \( k \geq 2 \), \( V = V_2 \) and assume that \( f \in C(\mathbb{R}^+, L^2(\mathbb{M}^{-1}dx dv)) \) is a nonnegative solution of (5) with initial datum \( f_0 \) such that \( \int_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^k f_0 dx dv < +\infty \) and \( \int_{\mathbb{R}^d \times \mathbb{R}^d} |v|^k f_0 dx dv < +\infty \). There exist constants \( C_2, \ldots, C_k \) such that
\[
J_k(t) \leq C_\ell (1 + t)^{\ell/2} \quad \text{and} \quad K_k(t) \leq C_\ell \quad \forall t \geq 0, \quad \ell = 2, \ldots, k.
\]

**Proof.** We present the proof for a Fokker-Planck operator, the case of a scattering operator follows the same steps. A direct computation shows that
\[
\frac{dK_\ell}{dt} \leq \ell \gamma \int_{\mathbb{R}^d \times \mathbb{R}^d} \frac{|x \cdot v|}{\langle x \rangle^2} |v|^\ell f(t, x, v) dx dv + \ell (\ell + d - 2) K_{\ell-2} - \ell K_\ell.
\]
A bound $C_{\ell}$ for $K_{\ell}$, $\ell \in \mathbb{N}$, follows after observing that
\[
\iint_{\mathbb{R}^d \times \mathbb{R}^d} \frac{|x \cdot v|}{(x)^2} |v|^{\ell-2} f(t, x, v) \, dx \, dv \leq K_{\ell-1} \leq K_0^{1/\ell} K_{\ell}^{1-1/\ell}
\]
and $K_{\ell-2} \leq K_0^{2/k} K_{\ell}^{1-2/k}$ using Hölder’s inequality twice.

Next, let us compute
\[
\frac{dJ_{\ell}}{dt} = \ell \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^{\ell-2} x \cdot v f(t, x, v) \, dx \, dv =: \ell L_{\ell},
\]
and
\[
\frac{dL_{\ell}}{dt} = \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^{\ell-2} |v|^2 f \, dx \, dv + (\ell - 2) \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^{\ell-4} (x \cdot v)^2 f \, dx \, dv
\]
\[
- \gamma \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^{\ell-4} |x|^2 f \, dx \, dv - L_{\ell}
\]
\[
\leq (\ell - 1) \iint_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^{\ell-2} |v|^2 f \, dx \, dv - L_{\ell}. 
\tag{21}
\]

Note that, again by Hölder’s inequality, $|L_{\ell}| \leq J_{\ell}^{1-1/\ell} K_{\ell}^{1/\ell}$, $\ell = 2, \ldots, k$.

We prove the bound on $J_{\ell}(t)$ by induction. If $\ell = 2$, (21) implies $L_{2}(t) \leq \max \{L_2(0), C_2\} \, \forall t$, and thus, $J_{2}(t) \leq C_2(1 + t)$, up to a redefinition of $C_2$.

Now let $\ell > 2$ and assume that
\[
J_{\ell-1}(t) \leq C_{\ell-1} (1 + t)^{\frac{\ell-1}{\ell-2}}.
\]
We use Hölder’s inequality once more for the right hand side of (21):
\[
\frac{dL_{\ell}}{dt} \leq (\ell - 1) J_{\ell-1}^{\frac{\ell-2}{\ell-1}} K_{2(\ell-1)}^{\frac{1}{\ell-1}} - L_{\ell} \leq (\ell - 1) C_{\ell-1}^{\frac{\ell-2}{\ell-1}} C_{2(\ell-1)}^{\frac{1}{\ell-1}} (1 + t)^{\frac{\ell-1}{\ell-2}} - L_{\ell},
\]
which implies
\[
L_{\ell} \leq C (1 + t)^{\frac{\ell-1}{\ell}},
\]
and one more integration with respect to $t$ establishes the estimate for $J_{\ell}$ in (20), up to an eventual redefinition of $C_{\ell}$.

**Lemma 3.8.** Let $\gamma \in (0, d)$, $k \in \mathbb{N}$ with $k > 2$, $V = V_2$ and assume that $f \in C(\mathbb{R}^+, L^2(\mathcal{M}^{-1} \, dx \, dv))$ is a nonnegative solution of (5) with initial datum $f_0$ such that $\int_{\mathbb{R}^d \times \mathbb{R}^d} \langle x \rangle^k f_0 \, dx \, dv < +\infty$ and $\int_{\mathbb{R}^d \times \mathbb{R}^d} |v|^k f_0 \, dx \, dv < +\infty$. Let $w = w[f]$ be determined by (19) in terms of $u = u[f]$. Then there exists a positive constant $C_k$ such that
\[
0 \leq M_k(t) := \int_{\mathbb{R}^d} w \langle x \rangle^{k-\gamma} \, dx \leq C_k (1 + t)^{k/2} \, \forall t \geq 0.
\]

**Proof.** The solution $w$ of (19) is positive by the maximum principle. In what follows we use the definition of $M_{t}$ for arbitrary integers $\ell$ and note that for $\ell \leq 0$,
\[
M_{t} \leq M_0 = \int_{\mathbb{R}^d} w e^{-V} \, dx = \int_{\mathbb{R}^d} u e^{-V} \, dx = \|f_0\|_1. 
\tag{22}
\]
Multiplication of (19) by $\langle x \rangle^{\ell-\gamma}$ and integration over $\mathbb{R}^d$ gives
\[
M_\ell = \ell (\ell - 2 + d - \gamma) M_{\ell-2} - (\ell - 2 - \gamma) M_{\ell-4} + J_{\ell},
\tag{23}
\]
where $J_{\ell}$ has been estimated in Lemma 3.7. Then, with $\ell = 2$ and (22), we obtain $M_2(t) \leq C_2(1 + t)$. This implies by the Hölder inequality that $M_\ell(t) \leq \sqrt{M_0 M_2(t)} \leq C_1 (1 + t)^{1/2}$. For $2 < \ell \leq k$ the estimate $M_\ell(t) \leq C_\ell (1 + t)^{1/2}$ follows recursively from (23). □
3.4. Decay estimate for the kinetic equation (proof of Theorem 1.4).

Lemma 3.9. Let \( \gamma \in (0, d) \), \( k \geq \max\{2, \gamma/2\} \), \( V = V_2 \) and assume that \( f \in C(\mathbb{R}^+, L^2(\mathcal{M}^{-1}dx \, dv)) \) is a nonnegative solution of (5) with initial datum \( f_0 \) such that \( \int_{\mathbb{R}^d \times \mathbb{R}^d} (x)^k f_0 \, dx \, dv < +\infty \) and \( \int_{\mathbb{R}^d \times \mathbb{R}^d} |v|^k f_0 \, dx \, dv < +\infty \). Assume the above notations, in particular with \( M_k \) defined as in Lemma 3.8, with the constant \( K \) from (30), and with \( a = \frac{d + 2k - 2}{d + 2k - 4} \). Then

\[
\|\Pi f\|^2 \leq 2\langle AT\Pi f, \Pi f \rangle + K M_k^{2(1-a)} \langle AT\Pi f, \Pi f \rangle^a =: \Phi (\langle AT\Pi f, \Pi f \rangle ; M_k) \quad \forall t \geq 0.
\]

Proof. If \( u = u[f] \) and \( w \) solves (19), we recall that

\[
\langle AT\Pi f, \Pi f \rangle = \|\nabla w\|_{V, k}^2 + \|D w\|_{V, k}^2
\]

by Lemma 3.2. From (19), we also deduce that

\[
\|u\|_{V, k}^2 = \langle u, w - L w \rangle_{V, k} \leq \|u\|_{V, k} \left( \|w\|_{V, k}^2 + 2\|\nabla w\|_{V, k}^2 + \|D w\|_{V, k}^2 \right)^{1/2}.
\]

By inequality (30), we have that

\[
\|w\|_{V, k}^2 \leq K \|\nabla w\|_{V, k}^{2a} M_k^{2(1-a)}.
\]

Combining these inequalities gives

\[
\|u\|_{V, k}^2 \leq K \|\nabla w\|_{V, k}^{2a} M_k^{2(1-a)} + \|\nabla w\|_{V, k}^2 + \langle AT\Pi f, \Pi f \rangle,
\]

which, noting that \( \|\Pi f\| = \|u\|_{V, k} \), implies the result. \( \square \)

As a consequence of Lemmas 3.1, 3.6, 3.9 and of the properties of \( \Phi \) we have

\[
H[f] = \frac{1}{2} \|f\|^2 + \varepsilon \langle Af, f \rangle
\leq \frac{1 + \varepsilon}{2} \|f\|^2 \leq \frac{1 + \varepsilon}{2} \left( \| (Id - \Pi) f \|^2 + \Phi (\langle AT\Pi f, \Pi f \rangle ; M_k) \right)
\leq \frac{1 + \varepsilon}{2} \Phi (\| (Id - \Pi) f \|^2 + \langle AT\Pi f, \Pi f \rangle ; M_k) \leq \frac{1 + \varepsilon}{2} \Phi \left( \frac{D[f]}{\lambda_\varepsilon} ; M_k \right),
\]

implying, with Lemma 3.8,

\[
\frac{dH[f]}{dt} = -D[f] \leq -\lambda_\varepsilon \Phi^{-1} \left( \frac{2}{1 + \varepsilon} H[f] ; C_k (1 + t)^{k/2} \right).
\]

The decay of \( H[f] \) can be estimated by the solution \( z \) of the corresponding ODE problem

\[
\frac{dz}{dt} = -\lambda_\varepsilon \Phi^{-1} \left( \frac{2}{1 + \varepsilon} z ; C_k (1 + t)^{k/2} \right), \quad z(0) = H[f_0].
\]

By the properties of \( \Phi \) it is obvious that \( z(t) \to 0 \) monotonically as \( t \to +\infty \), which implies that the same is true for \( \frac{dz}{dt} \). Therefore, there exists \( t_0 > 0 \) such that, in the rewritten ODE

\[
-\frac{2}{\lambda_\varepsilon} \frac{dz}{dt} + K C_k^{2(1-a)} (1 + t)^{k(1-a)} \left( \frac{1}{\lambda_\varepsilon} \frac{dz}{dt} \right)^a = \frac{2z}{1 + \varepsilon},
\]

the first term is smaller than the second for \( t \geq t_0 \), implying the differential inequality

\[
\frac{dz}{dt} \leq -\kappa z^{1/a} (1 + t)^{k(1-1/a)} \quad \text{for } t \geq t_0,
\]
with an appropriately defined positive constant $\kappa$. Integration and estimation as in Section 2.2 gives

$$z(t) \leq C (1 + t)^{\frac{\gamma - d}{1 - a} + 1} = C (1 + t)^{\frac{\gamma - d}{1 - a}}$$

thus completing the proof of Theorem 1.4.

---

**Appendix A. Homogeneous Caffarelli-Kohn-Nirenberg inequalities of Nash type.**

**A.1. The general Caffarelli-Kohn-Nirenberg inequalities.** The main result of [8] goes as follows. Assume that $p \geq 1$, $q \geq 1$, $r > 0$, $0 \leq a \leq 1$ and

$$\frac{1}{p} + \frac{\alpha_*}{d} > 0, \quad \frac{1}{q} + \frac{\beta_*}{d} > 0, \quad \frac{1}{r} + \frac{\gamma_*}{d} > 0,$$

$$\frac{1}{r} + \frac{\gamma_*}{d} = a \left( \frac{1}{p} + \frac{\alpha_* - 1}{d} \right) + (1 - a) \left( \frac{1}{q} + \frac{\beta_*}{d} \right)$$

and, with $\sigma$ such that $\gamma_* = a \sigma + (1 - a) \beta_*,$

$$0 \leq \alpha_* - \sigma \quad \text{if} \quad a > 0.$$ 

Assume moreover that

$$\alpha_* - \sigma \leq 1 \quad \text{if} \quad a > 0 \quad \text{and} \quad \frac{1}{p} + \frac{\alpha_* - 1}{d} = \frac{1}{q} + \frac{\beta_*}{d}.$$

Then there exists a positive constant $C$ such that the inequality

$$\| |x|^{\gamma_*} v \|_r \leq C \| |x|^{\alpha_*} \nabla v \|_p \| |x|^{\beta_*} v \|_q^{1-a}$$

holds for any $v \in C^\infty_0(\mathbb{R}^d)$.

These interpolation inequalities are known in the literature as the Caffarelli-Kohn-Nirenberg inequalities according to [8] but were introduced earlier by V.P. I’lin in [19]. Next we specialize Ineq. (24) to various cases of Nash type corresponding to $q = 1$.

**A.2. Weighted Nash type inequalities.** We consider special cases corresponding to $r = p = 2$ and $q = 1$.

- Ineq. (24) with $\alpha_* = \beta/2$, $\beta_* = \beta/2$, and $\gamma_* = \beta/2$ can be written under the condition $\beta > -d$ as

$$\int_{\mathbb{R}^d} |x|^\beta v^2 \, dx \leq C \left( \int_{\mathbb{R}^d} |x|^\beta \nabla v^2 \, dx \right)^{\frac{a}{2}} \left( \int_{\mathbb{R}^d} |x|^{\beta/2} |v| \, dx \right)^{2(1-a)}$$

with $a = \frac{d}{d+2}$. (25)

We can indeed check that $\alpha_* - \sigma = 0$ for any $\beta \leq 0$ and $\frac{1}{p} + \frac{\alpha_*}{d} > 0, \frac{1}{q} + \frac{\beta_*}{d} > 0,$ and $\frac{1}{r} + \frac{\gamma_*}{d} > 0$ if and only if $\beta > -d$.

- Ineq. (24) with $\alpha_* = -\gamma/2$, $\beta_* = k - \gamma$ and $\gamma_* = -\gamma/2$ can be written as

$$\int_{\mathbb{R}^d} |x|^{-\gamma} v^2 \, dx \leq C \left( \int_{\mathbb{R}^d} |x|^{-\gamma} \nabla v^2 \, dx \right)^{\frac{a}{2}} \left( \int_{\mathbb{R}^d} |x|^{k-\gamma} |v| \, dx \right)^{2(1-a)}$$

with $a = \frac{d + 2k - \gamma}{d+2+2k-\gamma}$. (26)
under the condition $\gamma < d$ and $k \geq \gamma/2$. We can indeed check that $\alpha_* - \sigma = \frac{2k-\gamma}{2k-\gamma+d} \geq 0$. In that case, we have $\alpha_* - \sigma < 1$ for any $\gamma \leq 0$ and the conditions $\frac{1}{p} + \frac{\gamma}{d} > 0$, $\frac{1}{q} + \frac{\gamma}{d} > 0$, and $\frac{1}{p} + \frac{\gamma}{d} > 0$ are all satisfied.

A.3. A weighted Nash inequality on balls. We adapt the proof of E. Carlen and M. Loss in [10] to the case of homogeneous weights. With $g = |x|^{-\gamma/2}v$, (26) is equivalent to

$$\int_{\mathbb{R}^d} g^2 \, dx \leq C \left( \int_{\mathbb{R}^d} |\nabla g|^2 \, dx \right)^{\frac{\gamma}{4}} \left( 2d - \gamma - 4 \right)^{\frac{\gamma}{4}} \int_{\mathbb{R}^d} \frac{g^2}{|x|^2} \, dx \cdot \left( \int_{\mathbb{R}^d} |x|^{k-\gamma} |g| \, dx \right)^{2(1-a)}.$$

Without loss of generality, we can assume that the function $g$ is nonnegative and radial, by spherically non-increasing rearrangements. From now on, we will only consider nonnegative, radial, non-increasing functions $g$ and the corresponding functions $v(x) = |x|^{\gamma/2}g(x)$. For any $R > 0$, let

$$g_R := g 1_{B_R} \quad \text{and} \quad v_R(x) = |x|^{\gamma/2}g_R(x).$$

We observe that $g - g_R$ is supported in $\mathbb{R}^d \setminus B_R$ and

$$g - g_R \leq g(R) \leq g_R := \frac{\int_{B_R} |x|^{-\gamma/2} \, dx}{\int_{B_R} |x|^{-\gamma/2} \, dx} = \frac{\int_{\mathbb{R}^d} v_R |x|^{-\gamma} \, dx}{\int_{\mathbb{R}^d} |x|^{-\gamma/2} \, dx}$$

because $g$ is radial non-increasing, so that

$$\int_{\mathbb{R}^d} |v - v_R|^2 |x|^{-\gamma} \, dx = \|g - g_R\|^2_2$$

$$\leq g_R \int_{\mathbb{R}^d} |g - g_R| \, dx = g_R \int_{\mathbb{R}^d} |v - v_R| |x|^{-\gamma} \, dx,$$

i.e.,

$$\int_{\mathbb{R}^d} |v - v_R|^2 |x|^{-\gamma} \, dx \leq \frac{\int_{\mathbb{R}^d} v_R |x|^{-\gamma} \, dx}{\int_{\mathbb{R}^d} |x|^{-\gamma/2} \, dx} R^{\gamma-k} \int_{\mathbb{R}^d} |v - v_R| |x|^{-\gamma} \, dx. \quad (27)$$

On the other hand, let us define $\overline{v}_R := \frac{\int_{\mathbb{R}^d} v_R |x|^{-\gamma} \, dx}{\int_{\mathbb{R}^d} |x|^{-\gamma/2} \, dx}$ and observe that

$$\int_{\mathbb{R}^d} |v_R|^2 |x|^{-\gamma} \, dx = \int_{\mathbb{R}^d} |v_R - \overline{v}_R| |x|^{-\gamma} \, dx + \overline{v}_R^2 \int_{\mathbb{R}^d} |x|^{2k-\gamma} \, dx.$$

Let us consider the weighted inequality

$$\int_{B_R} |w|^2 |x|^{-\gamma} \, dx \leq \frac{1}{\lambda^R} \int_{B_R} |\nabla w|^2 |x|^{-\gamma} \, dx \quad \forall w \in H^1(B_R, |x|^{-\gamma} \, dx)$$

such that $\int_{B_R} w |x|^{-\gamma} \, dx = 0. \quad (28)$

The existence of a positive, finite constant $\lambda^R$ can be deduced from elementary variational techniques as in [13]. We infer from the definition of $\overline{v}_R$ that this inequality is equivalent to

$$\int_{\mathbb{R}^d} |v_R|^2 |x|^{-\gamma} \, dx \leq \frac{1}{\lambda^R} \int_{B_R} |\nabla v_R|^2 |x|^{-\gamma} \, dx + \left( \frac{\int_{\mathbb{R}^d} v_R |x|^{-\gamma} \, dx}{\int_{\mathbb{R}^d} |x|^{-\gamma/2} \, dx} \right)^2. \quad (29)$$
With $\lambda_1 := \lambda_1^1$, a simple scaling shows that $\lambda_1^R = \lambda_1 R^{-2}$.

Let us come back to the estimation of $\int_{\mathbb{R}^d} v^2 |x|^{-\gamma} \, dx$. By definition of $v_R$, we know that

$$
\int_{\mathbb{R}^d} v^2 |x|^{-\gamma} \, dx \leq \int_{\mathbb{R}^d} |v_R|^2 |x|^{-\gamma} \, dx + \int_{\mathbb{R}^d} |v - v_R|^2 |x|^{-\gamma} \, dx.
$$

After summing (27) and (29), we arrive at

$$
\int_{\mathbb{R}^d} v^2 |x|^{-\gamma} \, dx \leq \frac{R^2}{\lambda_1} \int_{B_R} |\nabla v|^2 |x|^{-\gamma} \, dx + \frac{\left(\int_{\mathbb{R}^d} v_R |x|^{k-\gamma} \, dx\right)^2}{\int_{B_R} |x|^{2k-\gamma} \, dx} \int_{\mathbb{R}^d} v_R |x|^{k-\gamma} \, dx \int_{\mathbb{R}^d} |v - v_R| |x|^{k-\gamma} \, dx
$$

and notice that

$$
\left(\int_{\mathbb{R}^d} v_R |x|^{k-\gamma} \, dx\right)^2 \leq \int_{\mathbb{R}^d} |v_R| |x|^{k-\gamma} \, dx \int_{\mathbb{R}^d} |v - v_R| |x|^{k-\gamma} \, dx
$$

$$
\leq \left(\int_{\mathbb{R}^d} v |x|^{k-\gamma} \, dx\right)^2 \max \left\{ \frac{1}{\int_{B_R} |x|^{2k-\gamma} \, dx}, \frac{R^{2-k}}{\int_{B_R} |x|^{k-\gamma/2} \, dx} \right\}
$$

$$
= \left(\int_{\mathbb{R}^d} v |x|^{k-\gamma} \, dx\right)^2 c R^{\gamma-d-2k}
$$

using $k > 0$ and $v_R \leq v$, for some numerical constant $c$ which depends only on $d$ and $\gamma$. Collecting terms, we have found that

$$
\int_{\mathbb{R}^d} v^2 |x|^{-\gamma} \, dx \leq \frac{R^2}{\lambda_1} \int_{B_R} |\nabla v|^2 |x|^{-\gamma} \, dx + c R^{\gamma-d-2k} \left(\int_{\mathbb{R}^d} v |x|^{k-\gamma} \, dx\right)^2.
$$

We can summarize our observations as follows.

**Proposition 2.** Let $d \geq 3$, $\gamma \in (0, d)$, $k \geq \gamma/2$ and $a = \frac{d+2k-\gamma}{d+2+2k-\gamma}$. If $C$ denotes the optimal constant in (26), then (28) holds with a constant $\lambda_1^R = \lambda_1 R^{-2}$ for any $R > 0$, where $\lambda_1$ is a positive constant such that $\lambda_1 \leq \kappa C^{-1/a}$ for some explicit positive constant $\kappa$ depending only on $\gamma$ and $d$.

The numerical value of $\kappa$ can be deduced from the expression of $c$ and from the coefficients that arise from the optimization with respect to $R > 0$.

---

**Appendix B. Inhomogeneous Caffarelli-Kohn-Nirenberg inequalities of Nash type.** Our goal is to establish an extension of (26) adapted to the inhomogeneous case.

**Theorem B.1.** If $d \geq 3$, $\gamma \in (0, d)$ and $k \geq \gamma/2$, then

$$
\int_{\mathbb{R}^d} (x)^{-\gamma} v^2 \, dx \leq K \left(\int_{\mathbb{R}^d} (x)^{-\gamma} |\nabla v|^2 \, dx\right)^a \left(\int_{\mathbb{R}^d} (x)^{k-\gamma} |v| \, dx\right)^{2(1-a)}
$$

with $a = \frac{d+2k-\gamma}{d+2+2k-\gamma}$ holds for some optimal constant $K > 0$. 

Proof. Again we rely on the method of E. Carlen and M. Loss in [10]. The computations are similar to the ones of Proposition 2 except that \(|x|\) has to be replaced by \(\langle x \rangle\). With \(g = \langle x \rangle^{-\gamma/2} v\), (30) is equivalent to
\[
\int_{\mathbb{R}^d} g^2 \, dx \leq K \left( \int_{\mathbb{R}^d} |\nabla g|^2 \, dx - \frac{\gamma}{4} (2d - \gamma - 4) \int_{\mathbb{R}^d} g^2 \langle x \rangle^{-2} \, dx 
- \frac{\gamma}{4} (\gamma - 4) \int_{\mathbb{R}^d} g^2 \langle x \rangle^{-4} \, dx \right)^{\frac{1}{2}} \left( \int_{\mathbb{R}^d} \langle x \rangle^{k-4} |g| \, dx \right)^{2(1-\alpha)}.
\]
Without loss of generality, we assume that the function \(g\) is nonnegative, radial by spherically non-increasing rearrangements, and nonnegative. Let \(v(x) = \langle x \rangle^{\gamma/2} g(x)\) and
\[g_R := g \mathbb{1}_{B_R} \quad \text{and} \quad v_R(x) = \langle x \rangle^{\gamma/2} g_R(x)\]
for any \(R > 0\). We observe that \(g - g_R\) is supported in \(\mathbb{R}^d \setminus B_R\) and
\[g - g_R \leq g(R) \leq \mathcal{F}_R := \frac{\int_{\mathbb{R}^d} g_R \langle x \rangle^{k-\gamma/2} \, dx}{\int_{B_R} \langle x \rangle^{k-\gamma/2} \, dx} = \frac{\int_{\mathbb{R}^d} v_R \langle x \rangle^{k-\gamma} \, dx}{\int_{B_R} \langle x \rangle^{k-\gamma/2} \, dx}\]
because \(g\) is radial non-increasing, so that
\[
\int_{\mathbb{R}^d} |v - v_R|^2 \langle x \rangle^{-\gamma} \, dx = \|g - g_R\|^2_2
\leq \mathcal{F}_R \int_{\mathbb{R}^d} |g - g_R| \, dx = \mathcal{F}_R \langle R \rangle^{\frac{k}{2}-k} \int_{\mathbb{R}^d} |v - v_R| \langle x \rangle^{k-\gamma} \, dx,
\]
that is,
\[
\int_{\mathbb{R}^d} |v - v_R|^2 \langle x \rangle^{-\gamma} \, dx \leq \mathcal{F}_R \int_{B_R} \langle x \rangle^{k-\gamma/2} \, dx \langle R \rangle^{\frac{k}{2}-k} \int_{\mathbb{R}^d} |v - v_R| \langle x \rangle^{k-\gamma} \, dx. \tag{31}
\]
On the other hand, using
\[
\int_{\mathbb{R}^d} |v_R|^2 \langle x \rangle^{-\gamma} \, dx = \int_{\mathbb{R}^d} |v_R - \mathcal{V}_R \langle x \rangle^k|^2 \, dx + \mathcal{V}_R^2 \int_{B_R} \langle x \rangle^{2k-\gamma} \, dx
\]
where \(\mathcal{V}_R := \int_{\mathbb{R}^d} v_R \langle x \rangle^{k-\gamma} \, dx \int_{B_R} \langle x \rangle^{2k-\gamma} \, dx\),
we deduce from the weighted Poincaré inequality
\[
\int_{B_R} |w|^2 \langle x \rangle^{-\gamma} \, dx \leq \frac{1}{\lambda R} \int_{B_R} |\nabla w|^2 \langle x \rangle^{-\gamma} \, dx
\forall w \in H^1(B_R) \text{ such that } \int_{B_R} w \langle x \rangle^{2k-\gamma} \, dx = 0
\]
and from the definition of \(\mathcal{V}_R\) that
\[
\int_{\mathbb{R}^d} |v_R|^2 \langle x \rangle^{-\gamma} \, dx \leq \frac{1}{\lambda R} \int_{B_R} |\nabla v|^2 \langle x \rangle^{-\gamma} \, dx + \frac{\left( \int_{\mathbb{R}^d} v_R \langle x \rangle^{k-\gamma} \, dx \right)^2}{\int_{B_R} \langle x \rangle^{2k-\gamma} \, dx}. \tag{32}
\]
By definition of \(v_R\), we also know that
\[
\int_{\mathbb{R}^d} v^2 \langle x \rangle^{-\gamma} \, dx \leq \int_{\mathbb{R}^d} |v_R|^2 \langle x \rangle^{-\gamma} \, dx + \int_{\mathbb{R}^d} |v - v_R|^2 \langle x \rangle^{-\gamma} \, dx.
\]
After summing (31) and (32), we arrive at

\[ \int_{\mathbb{R}^d} v^2 (x)^{-\gamma} \, dx \leq \frac{1}{\lambda R} \int_{B_R} |\nabla v|^2 (x)^{-\gamma} \, dx + \frac{\langle R \rangle^{\frac{\gamma}{2k}}}{\int_{B_R} \langle x \rangle^{k-\gamma/2} \, dx} \int_{\mathbb{R}^d} v_R \langle x \rangle^{k-\gamma} \, dx \int_{\mathbb{R}^d} |v - v_R| \langle x \rangle^{k-\gamma} \, dx \]

\[ \leq a(R) \int_{B_R} |\nabla v|^2 (x)^{-\gamma} \, dx + b(R) \left( \int_{\mathbb{R}^d} v \langle x \rangle^{k-\gamma} \, dx \right)^2 \]

where \( a \) and \( b \) are two positive continuous functions on \((0, +\infty)\) defined by

\[ a(R) := \frac{1}{\lambda R^d} \quad \text{and} \quad b(R) := \max \left\{ \frac{1}{\int_{B_R} \langle x \rangle^{2k-\gamma} \, dx}, \frac{\langle R \rangle^{\frac{\gamma}{2k}}}{\int_{B_R} \langle x \rangle^{k-\gamma/2} \, dx} \right\} \]

and such that \( \lim_{R \to 0^+} R^d b(R) \in (0, +\infty), \lim_{R \to +\infty} R^{d+2k-\gamma} b(R) \in (0, +\infty), \)

\( \lim_{R \to +\infty} R^{-2} a(R) = 1/\lambda \) where \( \lambda \) is the optimal constant in Proposition 2 while \( \lim_{R \to 0^+} R^{-2} a(R) = 1/\lambda \) is related with Nash’s inequality as in [10] and such that

\[ \int_{B_1} |w|^2 \, dx \leq \frac{1}{\lambda} \int_{B_1} |\nabla w|^2 \, dx \quad \forall w \in H^1(B_1) \quad \text{such that} \quad \int_{B_1} w \, dx = 0. \]

In order to prove (30), we can use the homogeneity of the inequality and assume that \( \int_{\mathbb{R}^d} (x)^{-\gamma} v^2 \, dx = 1 \). What we shown so far is that

\[ \forall R > 0, \quad 1 \leq \left( \int_{\mathbb{R}^d} \langle x \rangle^{k-\gamma} |v| \, dx \right)^2 (a(R) X + b(R)) \]

where \( X = \int_{\mathbb{R}^d} (x)^{-\gamma} |\nabla v|^2 \, dx / \left( \int_{\mathbb{R}^d} \langle x \rangle^{k-\gamma} |v| \, dx \right)^2 \). With the choice \( R = X^{-\frac{1}{d-\alpha}} \), we get that there exists a constant \( K > 0 \) such that \( a(R) X + b(R) < K X^a \). This proves (30) with \( K \leq K \).

Appendix C. Hardy-Nash inequalities.

C.1. Proof of Lemma 2.1. We start with the proof of (7) by first showing a Hardy type inequality. For some \( \alpha \in \mathbb{R} \) to be fixed later we compute

\[ 0 \leq \int_{\mathbb{R}^d} \left| \nabla u + \frac{\alpha x}{1 + |x|^2} u \right|^2 \, dx \]

\[ = \int_{\mathbb{R}^d} |\nabla u|^2 \, dx + \alpha^2 \int_{\mathbb{R}^d} \frac{|x|^2 u^2}{1 + |x|^2} \, dx + \alpha \int_{\mathbb{R}^d} \nabla \left( u^2 \right) \cdot \frac{x}{1 + |x|^2} \, dx. \]

We deduce that

\[ \int_{\mathbb{R}^d} |\nabla u|^2 \, dx + \alpha \int_{\mathbb{R}^d} \frac{|x|^2 u^2}{1 + |x|^2} \, dx - \alpha d \int_{\mathbb{R}^d} \frac{u^2}{1 + |x|^2} \, dx + 2 \alpha \int_{\mathbb{R}^d} \frac{|x|^2 u^2}{(1 + |x|^2)^2} \, dx \geq 0, \]

so that, by writing \( |x|^2 = \langle x \rangle^2 - 1 \), we obtain

\[ \|\nabla u\|_2^2 + \alpha (\alpha - d + 2) \int_{\mathbb{R}^d} \frac{u^2}{1 + |x|^2} \, dx - \alpha (\alpha + 2) \int_{\mathbb{R}^d} \frac{u^2}{(1 + |x|^2)^2} \, dx \geq 0. \]
Concerning the second term, we choose the optimal value \( \alpha = (d - 2)/2 \) in (33), producing the optimal upper bound for \( \delta \). It is now straightforward to show

\[
\| \nabla u \|_{L^2}^2 - \delta \int_{\mathbb{R}^d} \frac{u^2}{1 + |x|^2} \, dx - \eta \int_{\mathbb{R}^d} \frac{u^2}{(1 + |x|^2)^2} \, dx \\
\geq \min \left\{ 1 - \frac{4 \delta}{(d-2)^2}, 1 - \frac{4 \eta}{d^2} \right\} \| \nabla u \|_{L^2}^2 ,
\]

whence the proof of (7) is completed by an application of Nash’s inequality (3).

The result (6) is shown analogously by using the standard Hardy inequality

\[
\| \nabla u \|_{L^2}^2 - \frac{1}{4} (d - 2)^2 \int_{\mathbb{R}^d} \frac{u^2}{|x|^2} \, dx \geq 0
\]

instead of (33). This completes the proof of Lemma 2.1.

C.2. Hardy-Nash vs. Caffarelli-Kohn-Nirenberg inequalities. The values for \( C_\delta \) and \( C_{\delta, \eta} \) given in Lemma 2.1 cannot be expected to be optimal, since the Hardy and Nash inequalities used in the proof have different optimizing functions. Here we shall present an alternative proof of (6), showing that the optimal value for \( C_\delta \) can be given in terms of the optimal constant of an appropriately chosen Caffarelli-Kohn-Nirenberg inequality of Nash type.

We start by rewriting (25) with optimal constant \( C = C_{\text{CKN}} \) as

\[
\left( \int_{\mathbb{R}^d} |v|^2 |x|^\beta \, dx \right)^{1+\frac{2}{d}} \leq C_{\text{CKN}}^{1+\frac{2}{d}} \int_{\mathbb{R}^d} |\nabla v|^2 |x|^\beta \, dx \left( \int_{\mathbb{R}^d} |v| |x|^{\beta/2} \, dx \right)^{\frac{4}{d}} ,
\]

which holds for \( \beta > -d \). A straightforward computation shows that with the change of variables \( v(x) = |x|^{-\beta/2} u(x) \), this is equivalent to (6) with \( \delta = -\beta^2/4 - \beta (d-2)/2 \). Thus, the choice \( \beta = 2 - d + \sqrt{(d-2)^2 - 4 \delta} > -d \) amounts to (6) with optimal constant \( C_\delta = C_{\text{CKN}}^{1+2/d} \).
