Abstract

In this paper, explicit method of constructing approximations (the Triangle Entropy Method) is developed for nonequilibrium problems. This method enables one to treat any complicated nonlinear functionals that fit best the physics of a problem (such as, for example, rates of processes) as new independent variables.

The work of the method was demonstrated on the Boltzmann’s-type kinetics. New macroscopic variables are introduced (moments of the Boltzmann collision integral, or scattering rates). They are treated as independent variables rather than as infinite moment series. This approach gives the complete account of rates of scattering processes. Transport equations for scattering rates are obtained (the second hydrodynamic chain), similar to the usual moment chain (the first hydrodynamic chain). Various examples of the closure of the first, of the second, and of the mixed hydrodynamic chains are considered for the hard spheres model. It is shown, in particular, that the complete account of scattering processes leads to a renormalization of transport coefficients.

The method gives the explicit solution for the closure problem, provides thermodynamic properties of reduced models, and can be applied to any kinetic equation with a thermodynamic Lyapunov function.

Introduction

In this paper, explicit method of constructing approximations (the Triangle Entropy Method [1,2]) is developed for nonequilibrium problems of Boltzmann’s-type kinetics, i.e. when the standard moment variables become insufficient. This method enables one to treat any complicated nonlinear functionals that fit best the physics of a problem (such as, for example, rates of processes) as new independent variables.

The method is applied to the problem of derivation of hydrodynamics from the Boltzmann equation. New macroscopic variables are introduced (moments of the Boltzmann collision integral, or scattering rates). They are treated as independent variables rather than as infinite moment series. This approach gives the complete account of rates of scattering processes. Transport equations for scattering rates are obtained (the second hydrodynamic chain), similar to the usual moment chain (the first hydrodynamic chain).

Using the triangle entropy method, three different types of the macroscopic description are considered. The first type involves only moments of distribution functions, and results coincide with those of the Grad method in the Maximum Entropy version. The second type of description involves only scattering rates. Finally, the third type involves both the moments and the scattering rates (the mixed description).

The second and the mixed hydrodynamics are sensitive to the choice of the collision model. The second hydrodynamics is equivalent to the first hydrodynamics only for Maxwell molecules, and the mixed hydrodynamics exists for all types of collision models excluding Maxwell molecules.

Various examples of the closure of the first, of the second, and of the mixed hydrodynamic chains are considered for the hard spheres model. It is shown, in particular, that the complete account of scattering processes leads to a renormalization of transport coefficients.

The method gives the explicit solution for the closure problem, provides thermodynamic properties of reduced models, and can be applied to any kinetic equation with a thermodynamic Lyapunov function, for example, to the Fokker–Planck Equation.

Reduction of description for dissipative kinetics assumes (explicitly or implicitly) the following picture (Fig. 1a): There exists a manifold of slow motions $\Omega_{\text{slow}}$ in the space of distributions. From the initial conditions the system goes quickly in a small neighborhood of the manifold, and after that moves slowly along it. The manifold of slow motion (slow manifold, for short) must be positively invariant: if a motion starts on the manifold at $t_0$, then it stays on the
manifold at $t > t_0$. In some neighborhood of the slow manifold the directions of fast motion could be defined. Of course, we always deal not with the invariant slow manifold, but with some approximate (ansatz) slow manifold $\Omega$.

There are three basic problems in the model reduction:

1. How to **construct** an approximate slow manifold;
2. How to **project** the initial equation onto the constructed approximate slow manifold, i.e. how to split motions into fast and slow;
3. How to **improve** the constructed manifold and the projector in order to make the manifold more invariant and the motion along it slower.

The first problem is often named “the closure problem”, and its solution is the closure assumption; the second problem is “the projection problem”. Sometimes these problems are discussed and solved simultaneously (for example, for the quasiequilibrium, or, which is the same, for MaxEnt closure assumptions [3,4,5,6,7,9]). Sometimes solution of the projection problem after construction of ansatz takes a long time. The known case of such a problem gives us the Tamm–Mott-Smith approximation in the theory of shock waves (see, for example, [10]). However if one has constructed the closure assumption which is at the same time the invariant manifold [10,12,13], then the projection problem disappears, because the vector field is always tangent to the invariant manifold. In this paper, we would like to add several new tools to the collection of methods for solution the closure problem. The second problem was discussed in Ref. [11]. We do not discuss here the third main problem of model reduction: How to improve the constructed manifold and the projector in order to make the manifold more invariant and the motion along it more slow. This discussion can be found in various works [10,12,13,14,15], and the broad review of the methods for invariant manifolds construction was performed in Refs. [16,17].

Our standard example in this paper is the Boltzmann equation, but most of the methods can be applied to an almost arbitrary kinetic equation with a convex thermodynamic Lyapunov function. Let us discuss the initial kinetic equation as an abstract ordinary differential equation

$$\frac{df}{dt} = J(f),$$

(1)

Many of partial differential kinetic equations or integro-differential kinetic equations with suitable boundary conditions (or conditions at infinity) can be discussed as abstract ordinary differential equation in appropriate space of functions. The corresponding semigroup of shifts in time can be considered too. Sometimes, when an essential theorem of existence and uniqueness of solution is not proven, it is possible to discuss a corresponding shift in time with the support of physical sense: the shift in time for physical system should exist. Benefits from the latter approach are obvious as well as its risk.
Conditional entropy maxima for these fast directions are somewhere here.

where $f = f(q)$ is the distribution function, $q$ is the point in particle phase space (for the Boltzmann equation), or in configuration space (for the Fokker-Planck equation). This equation is defined in some domain $U$ of a vector space of admissible distributions $E$.

The dissipation properties of the system (1) are described by specifying the entropy $S$, the distinguished Lyapunov function which monotonically increases along solutions of equation (1). In a certain sense, this Lyapunov function is more fundamental than the system (1) itself. That is, usually, the entropy is known much better than the right hand side of equation (1).

We assume that a concave functional $S$ is defined in $U$, such that it takes maximum in an inner point $f^* \in U$. This point is termed the equilibrium.

For any dissipative system (1) under consideration in $U$, the derivative of $S$ due to equation (1) must be nonnegative,

$$\frac{dS}{dt}\bigg|_f = (D_fS)(J(f)) \geq 0,$$

where $D_fS$ is the linear functional, the differential of the entropy.

For dissipative systems, we always keep in mind the following picture (Fig. 1b). The vector field $J(f)$ generates the motion on the phase space $U$: $df/dt = J(f)$. An ansatz manifold $\Omega$ is given, it is the current approximation to the invariant manifold.

The projected vector field $PJ(f)$ belongs to the tangent space $T_f$, and the equation $df/dt = PJ(f)$ describes the motion along the ansatz manifold $\Omega$ (if the initial state belongs to $\Omega$).
Fig. 2. Parametrization by macroscopic variables: linear (a), nonlinear (b) and layer-linear (c). Thin arrows illustrate the bijection $M \leftrightarrow f_M$. a) Moment parametrization in fast-slow decomposition. Dashed lines – the plains of constant value of moments $M$. These plains coincide with directions of fast motion in the moment approximation. b) Non-linear macroscopic parametrization in fast-slow decomposition. Dashed curves – the surfaces of constant value of macroscopic variables $M$. Plains of fast motion are tangent to these surfaces. c) Nonlinear, but layer–linear macroscopic parametrization in fast-slow decomposition. The surfaces of constant value of macroscopic variables $M$ (dashed lines) are plain, but the dependence $m(f)$ is nonlinear. Plains of fast motion coincide with these plains.

The choice of the projector $P$ might be very important. There is some “duality” between accuracy of slow invariant manifold approximation and restrictions on the projector choice. If $\Omega$ is an exactly invariant manifold, then the vector field $J(f)$ is tangent to $\Omega$, and all projectors give the same result. If $\Omega$ gives a good smooth approximation for such an invariant manifold, then the set of admissible projectors is rather broad. On the other hand, there is the unique choice of the projector applicable for every (arbitrary) ansatz $\Omega$ [10,11], any other choice leads to violation of the Second Law in projected equations.

In the initial geometry of the fast–slow decomposition (Figs. 1a, 1b) the “slow variables” (or “macroscopic variables”) are internal coordinates on the slow manifold, or on its approximation $\Omega$. It is impossible, in general, to define these macroscopic variables as functionals of $f$ outside these manifolds. Moreover, this definition cannot be unique.

The *moment parametrization* starts not from the manifold, but from the macroscopic variables defined in the whole $U$ (Fig. 2a), and for the given vari-
ables it is necessary to find the corresponding slow manifold. Usually, these slow variables are linear functions (functionals), for example, hydrodynamic fields (density, momentum density, and pressure) are moments of one-particle distribution functions $f(x, v)$. The moment vector $M$ is the value of linear operator $m$: $M = m(f)$. The moments value serve as internal coordinates on the (hypothetic) approximate slow manifold $\Omega$. It means that points of $\Omega$ are parameterized by $M$, $\Omega = \{f_M\}$, and the consistency condition holds:

$$m(f_M) = M.$$  

In the example with one-particle function $f$ and hydrodynamic fields $m(f)$ it means that slow manifold consists of distribution $f(x, v)$ parameterized by their hydrodynamic fields (as in the Chapman–Enskog method [34]). For a given $\Omega = \{f_M\}$, the moment equation has a very simple form:

$$\frac{dM}{dt} = m(J(f_M)), \quad (3)$$

and the correspondent equation for the projected motion on the manifold $\Omega = \{f_M\}$ is

$$\frac{df}{dt} = (D_M f_M) m(J(f_M)), \quad (4)$$

Where $D_M f_M$ is differential of the parametrization $M \mapsto f_M$.

How to find a manifold $\Omega = \{f_M\}$ for a given moment parametrization? A good initial approximation is the quasiequilibrium (or MaxEnt) approximations. The basic idea is: in the fast motion the entropy should increase, hence, the point of entropy maximum on the plane of rapid motion is not far from the slow manifold (Fig. 1a). If our moments $M$ are really slow variables, and don’t change significantly in rapid motion, then the manifold of conditional entropy maxima $f_M$:

$$S(f) \rightarrow \text{max}, \quad m(f) = M \quad (5)$$

could serve as appropriate ansatz for slow manifold.

Most of the works on nonequilibrium thermodynamics deal with quasiequilibrium approximations and corrections to them, or with applications of these approximations (with or without corrections). This viewpoint is not the only possible but it proves very efficient for the construction of a variety of useful models, approximations and equations, as well as methods to solve them. From time to time it is discussed in the literature, who was the first to introduce the quasiequilibrium approximations, and how to interpret them. At least a
part of the discussion is due to a different role the quasiequilibrium plays in the entropy-conserving and the dissipative dynamics. The very first use of the entropy maximization dates back to the classical work of G. W. Gibbs [19], but it was first claimed for a principle of informational statistical thermodynamics by E. T. Jaynes [3]. Probably the first explicit and systematic use of quasiequilibria to derive dissipation from entropy-conserving systems was undertaken by D. N. Zubarev. Recent detailed exposition is given in [4]. For dissipative systems, the use of the quasiequilibrium to reduce description can be traced to the works of H. Grad on the Boltzmann equation [20]. A review of the informational statistical thermodynamics was presented in [21]. The connection between entropy maximization and (nonlinear) Onsager relations was also studied [22,23]. The viewpoint of the present authors was influenced by the papers by L. I. Rozonoer and co-workers, in particular, [5,6,7]. A detailed exposition of the quasiequilibrium approximation for Markov chains is given in the book [18] (Chap. 3, Quasiequilibrium and entropy maximum, pp. 92-122), and for the BBGKY hierarchy in the paper [9]. The maximum entropy principle was applied to the description the universal dependence the three-particle distribution function \( F_3 \) on the two-particle distribution function \( F_2 \) in classical systems with binary interactions [24]. For a discussion the quasiequilibrium moment closure hierarchies for the Boltzmann equation [6] see the papers [1,2,25]. A very general discussion of the maximum entropy principle with applications to dissipative kinetics is given in the review [26]. Recently the quasiequilibrium approximation with some further correction was applied to description of rheology of polymer solutions [27,28] and of ferrofluids [29,30]. Quasiequilibrium approximations for quantum systems in the Wigner representation [31,32] was discussed very recently [33].

Formally, for quasiequilibrium approximation the linearity of the map \( f \mapsto m(f) \) is not necessary, and the optimization problem (5) could be studied for nonlinear conditions \( m(f) = M \) (Fig. 2b). Nevertheless, the problem (5) with nonlinear conditions lose many important properties caused by concavity of \( S \). The technical compromise is the problem with nonlinear map \( m \), but linear restrictions \( m(f) = M \). It is possible when preimages of points for the map \( m \) are plain (Fig. 2c). Such a “layer–linear” approximation for a generic smooth map \( m_0 : f \mapsto M \) could be created as follows. Let \( \Omega_0 \) be a smooth submanifold in \( U \). In some vicinity of \( \Omega_0 \) we define a map \( m \)

\[
m(f) = m_0(f_0) \text{ if } (Dm_0)_{f_0}(f - f_0) = 0,
\]

where \( f_0 \) are points from \( \Omega_0 \) and \((Dm_0)_{f_0}\) is the differential of \( m_0 \) at the point \( f_0 \). This definition means that \( m(f) = m_0(f_0) \) if \( m_0(f) \) coincides with \( m_0(f_0) \) in linear approximation.

The layer–linear parametrization was introduced in Ref. [35] for construction of generalized model equations for the Boltzmann kinetics.
Eq. (6) defines a smooth layer–linear map \( m \) in a vicinity of \( \Omega_0 \) under some general transversality condition.

Let an initial approximation \( \Omega_0 \) for the slow manifold be unsatisfactory. Two basic ways for improvement are: (i) manifold correction and (ii) manifold extension. On the first way we should find a shifted manifold that is better approximate slow invariant manifold. The list of macroscopic variables remains the same. On the second way we extend the list of macroscopic variables, and, hence, extend the manifold \( \Omega \). The Chapman–Enskog method [34] gives the example of manifold correction in the form of Taylor series expansion, the direct Newton method could give better results [10,12,16,17,39]. The second way is the essence of EIT – extended irreversible thermodynamics [44]. This paper is focused on the manifold extensions also.

Usually moments are graduated in a natural order, by degree of polynomials: concentration (zero order of velocity), average momentum density (first order), kinetic energy (second order), stress tensor (second order), heat flux (third order), etc. Normal logic of EIT is extension of the list of variables by addition of the next irreducible moment tensor. But there is another logic. In general, for the set of moments \( M \) that parametrizes \( \Omega_0 \) a time derivative is a known function of \( f \): \( \frac{dM}{dt} = F_M(f) \). We propose to construct new moments from \( F_M(f) \). It allows to achieve a best possible approximation for \( \frac{dM}{dt} \) through extended variables. For this nonlinear variables we use the layer–linear approximation (6), as well, as a layer–quadratic approximation for the entropy. This (layer) linearization of the problem near current approximation follows lessons of the Newton method.

It should be stressed that “layer–linear” does not mean “linear”, and the modified choice of new variables implies no additional restrictions, but it pretends to be just a more direct way to dynamic invariance. Below this approach is demonstrated on the Boltzmann equation.

1 Difficulties of classical methods of the Boltzmann equation theory

The Boltzmann equation remains the most inspiring source for the model reduction problems. The first systematic and (at least partially) successful method of constructing invariant manifolds for dissipative systems was the celebrated Chapman–Enskog method [34] for the Boltzmann kinetic equation. The main difficulty of the Chapman–Enskog method [34] are “nonphysical” properties of high-order approximations. This was stated by a number of authors and was discussed in detail in [36]. In particular, as it was noted in [37], the Burnett approximation results in a short-wave instability of the acoustic
spectra. This fact contradicts the $H$-theorem (cf. in [37]). The Hilbert expansion contains secular terms [36]. The latter contradicts the $H$-theorem.

The other difficulties of both of these methods are: the restriction upon the choice of the initial approximation (the local equilibrium approximation), the requirement for a small parameter, and the usage of slowly converging Taylor expansion. These difficulties never allow a direct transfer of these methods on essentially nonequilibrium situations.

The main difficulty of the Grad method [20] is the uncontrollability of the chosen approximation. An extension of the list of moments can result in a certain success, but it can also give nothing. Difficulties of moment expansion in the problems of shock waves and sound propagation are discussed in [36].

Many attempts were made to refine these methods. For the Chapman–Enskog and Hilbert methods these attempts are based in general on some better re-arrangement of expansions (e.g. neglecting high-order derivatives [36], reex-panding [36], Pade approximations and partial summing [1,38,40,41], etc.). This type of work with formal series is wide spread in physics. Sometimes the results are surprisingly good – from the renormalization theory in quantum fields to the Percus-Yevick equation and the ring-operator in statistical mechanics. However, one should realize that success cannot be guaranteed. Moreover, rearrangements never remove the restriction upon the choice of the initial local equilibrium approximation.

Attempts to improve the Grad method are based on quasiequilibrium approxima-tions [5,6]. It was found in [6] that the Grad distributions are linearized versions of appropriate quasiequilibrium approximations (see also [1,2,25]). A method which treats fluxes (e.g. moments with respect to collision integrals) as independent variables in a quasiequilibrium description was introduced in [1,2,42,43], and will be discussed later.

The important feature of quasiequilibrium approximations is that they are always thermodynamic, i.e. they are consistent with the $H$-theorem by con-struction.

2 Triangle Entropy Method

In the present subsection, which is of introductory character, we shall refer, to be specific, to the Boltzmann kinetic equation for a one-component gas whose state (in the microscopic sense) is described by the one-particle distribution function $f(v,x,t)$ depending on the velocity vector $v = \{v_k\}_{k=1}^3$, the spatial position $x = \{x_k\}_{k=1}^3$ and time $t$. The Boltzmann equation describes the
evolution of $f$ and in the absence of external forces is
\[
\partial_t f + v_k \partial_k f = Q(f, f), \tag{7}
\]
where $\partial_t \equiv \partial/\partial t$ is the time partial derivative, $\partial_k \equiv \partial/\partial x_k$ is partial derivative with respect to $k$-th component of $x$, summation in two repeating indices is assumed, and $Q(f, f)$ is the collision integral (its concrete form is of no importance right now, just note that it is functional-integral operator quadratic with respect to $f$).

The Boltzmann equation possesses two properties principal for the subsequent reasoning.

1. There exist five functions $\psi_\alpha (v)$ (additive collision invariants),
\[
1, v, v^2
\]
such that for any their linear combination with coefficients depending on $x, t$ and for arbitrary $f$ the following equality is true:
\[
\int \sum_{\alpha=1}^{5} a_\alpha (x, t) \psi_\alpha (v) Q(f, f) \, dv = 0, \tag{8}
\]
provided the integrals exist.

2. The equation (7) possesses global Lyapunov functional: the $H$-function,
\[
H(t) \equiv H[f] = \int f(v, x, t) \ln f(v, x, t) \, dv \, dx, \tag{9}
\]
the derivative of which by virtue of the equation (7) is non-positive under appropriate boundary conditions:
\[
dH(t)/dt \leq 0. \tag{10}
\]

Grad’s method [20] and its variants construct closed systems of equations for macroscopic variables when the latter are represented by moments (or, more general, linear functionals) of the distribution function $f$ (hence their alternative name is the “moment methods”). The entropy maximum method for the Boltzmann equation is of particular importance for the subsequent reasoning. It consists in the following. A finite set of moments describing the macroscopic state is chosen. The distribution function of the quasiequilibrium state under given values of the chosen moments is determined, i.e. the problem is solved
\[
H[f] \to \min, \text{ for } \hat{M}_i[f] = M_i, \quad i = 1, \ldots, k, \tag{11}
\]
where $\hat{M}_i[f]$ are linear functionals with respect to $f$; $M_i$ are the corresponding values of chosen set of $k$ macroscopic variables. The quasiequilibrium distribution function $f^*(v, M(x, t))$, $M = \{M_1, \ldots, M_k\}$, parametrically depends on $M_i$, its dependence on space $x$ and on time $t$ being represented only by $M(x, t)$. Then the obtained $f^*$ is substituted into the Boltzmann equation (7), and operators $\hat{M}_i$ are applied on the latter formal expression.

In the result we have closed systems of equations with respect to $M_i(x, t)$, $i = 1, \ldots, k$:

$$\partial_t M_i + \hat{M}_i[v_k \partial_k f^*(v, M)] = \hat{M}_i[Q(f^*(v, M), f^*(v, M))].$$  \quad (12)

The following heuristic explanation can be given to the entropy method. A state of the gas can be described by a finite set of moments on some time scale $\theta$ only if all the other moments (“fast”) relax on a shorter time scale time $\tau$, $\tau << \theta$, to their values determined by the chosen set of “slow” moments, while the slow ones almost do not change appreciably on the time scale $\tau$. In the process of the fast relaxation the $H$-function decreases, and in the end of this fast relaxation process a quasiequilibrium state sets in with the distribution function being the solution of the problem (11). Then “slow” moments relax to the equilibrium state by virtue of (12).

The entropy method has a number of advantages in comparison with the classical Grad’s method. First, being not necessarily restricted to any specific system of orthogonal polynomials, and leading to solving an optimization problem, it is more convenient from the technical point of view. Second, and ever more important, the resulting quasiequilibrium $H$-function, $H^*(M) = H[f^*(v, M)]$, decreases due of the moment equations (12).

Let us note one common disadvantage of all the moment methods, and, in particular, of the entropy method. Macroscopic parameters, for which these methods enable to obtain closed systems, must be moments of the distribution function. On the other hand, it is easy to find examples when the interesting macroscopic parameters are nonlinear functionals of the distribution function. In the case of the one-component gas these are the integrals of velocity polynomials with respect to the collision integral $Q(f, f)$ of (7) (scattering rates of moments). For chemically reacting mixtures these are the reaction rates, and so on. If the characteristic relaxation time of such nonlinear macroscopic parameters is comparable with that of the “slow” moments, then they should be also included into the list of “slow” variables on the same footing.

In this paper for constructing closed systems of equations for non-linear (in a general case) macroscopic variables the triangle entropy method is used. Let us outline the scheme of this method.
Let a set of macroscopic variables be chosen: linear functionals $\hat{M}[f]$ and nonlinear functionals (in a general case) $\hat{N}[f]$:  
\[ \hat{M}[f] = \{\hat{M}_1[f], \ldots, \hat{M}_k[f]\}, \quad \hat{N}[f] = \{\hat{N}_1[f], \ldots, \hat{N}_l[f]\}. \]

Then, just as for the problem (11), the first quasiequilibrium approximation is constructed under fixed values of the linear macroscopic parameters $M$:  
\[ H[f] \to \min \text{ for } \hat{M}_i[f] = M_i, \quad i = 1, \ldots, k, \]

and the resulting distribution function is $f^*(v, M)$. After that, we seek the true quasiequilibrium distribution function in the form,  
\[ f = f^*(1 + \varphi), \]

where $\varphi$ is a deviation from the first quasiequilibrium approximation. In order to determine $\varphi$, the second quasiequilibrium approximation is constructed. Let us denote $\Delta H[f^*, \varphi]$ as the quadratic term in the expansion of the $H$-function into powers of $\varphi$ in the neighbourhood of the first quasiequilibrium state $f^*$. The distribution function of the second quasiequilibrium approximation is the solution to the problem,  
\[ \Delta H[f^*, \varphi] \to \min \text{ for } \hat{M}_i[f^* \varphi] = 0, \quad i = 1, \ldots, k, \]
\[ \Delta \hat{N}_j[f^*, \varphi] = \Delta N_j, \quad j = 1, \ldots, l, \]

where $\Delta \hat{N}_j$ are linear operators characterizing the linear with respect to $\varphi$ deviation of (nonlinear) macroscopic parameters $N_j$ from their values, $N_j^* = \hat{N}_j[f^*]$, in the first quasiequilibrium state. Note the importance of the homogeneous constraints $\hat{M}_i[f^* \varphi] = 0$ in the problem (15). Physically, it means that the variables $\Delta N_j$ are “slow” in the same sense, as the variables $M_i$, at least in the small neighborhood of the first quasiequilibrium $f^*$. The obtained distribution function,  
\[ f = f^*(v, M)(1 + \varphi^{**}(v, M, \Delta N)) \]

is used to construct the closed system of equations for the macroparameters $M$, and $\Delta N$. Because the functional in the problem (15) is quadratic, and all constraints in this problem are linear, it is always explicitly solvable.

Further in this section some examples of using the triangle entropy method for the one-component gas are considered. Applications to chemically reacting mixtures were discussed in [42].
3 Linear macroscopic variables

Let us consider the simplest example of using the triangle entropy method, when all the macroscopic variables of the first and of the second quasiequilibrium states are the moments of the distribution function.

3.1 Quasiequilibrium projector

Let \( \mu_1(v), \ldots, \mu_k(v) \) be the microscopic densities of the moments

\[ M_1(x, t), \ldots, M_k(x, t) \]

which determine the first quasiequilibrium state,

\[ M_i(x, t) = \int \mu_i(v) f(v, x, t) \, dv, \quad (17) \]

and let \( \nu_1(v), \ldots, \nu_l(v) \) be the microscopic densities of the moments

\[ N_1(x, t), \ldots, N_l(x, t) \]

determining together with (7) the second quasiequilibrium state,

\[ N_i(x, t) = \int \nu_i(v) f(v, x, t) \, dv. \quad (18) \]

The choice of the set of the moments of the first and second quasiequilibrium approximations depends on a specific problem. Further on we assume that the microscopic density \( \mu \equiv 1 \) corresponding to the normalization condition is always included in the list of microscopic densities of the moments of the first quasiequilibrium state. The distribution function of the first quasiequilibrium state results from solving the optimization problem,

\[ H[f] = \int f(v) \ln f(v) \, dv \rightarrow \min \quad (19) \]

for

\[ \int \mu_i(v) f(v) \, dv = M_i, i = 1, \ldots, k. \]

Let us denote by \( M = \{M_1, \ldots, M_k\} \) the moments of the first quasiequilibrium state, and by \( f^*(v, M) \) let us denote the solution of the problem (19).
The distribution function of the second quasiequilibrium state is sought in the form,
\[ f = f^*(v, M)(1 + \varphi). \] (20)

Expanding the \( H \)-function (9) in the neighbourhood of \( f^*(v, M) \) into powers of \( \varphi \) to second order we obtain,
\[
\Delta H(x, t) \equiv \Delta H[f^*, \varphi] = H^*(M) + \int f^*(v, M) \ln f^*(v, M) \varphi(v) \, dv \\
+ \frac{1}{2} \int f^*(v, M) \varphi^2(v) \, dv,
\] (21)

where \( H^*(M) = H[f^*(v, M)] \) is the value of the \( H \)-function in the first quasiequilibrium state.

When searching for the second quasiequilibrium state, it is necessary that the true values of the moments \( M \) coincide with their values in the first quasiequilibrium state, i.e.,
\[
M_i = \int \mu_i(v) f^*(v, M)(1 + \varphi(v)) \, dv \\
= \int \mu_i(v) f^*(v, M) \, dv = M_i^*, \quad i = 1, \ldots, k.
\] (22)

In other words, the set of the homogeneous conditions on \( \varphi \) in the problem (15),
\[
\int \mu_i(v) f^*(v, M) \varphi(v) \, dv = 0, i = 1, \ldots, k,
\] (23)

ensures a shift (change) of the first quasiequilibrium state only due to the new moments \( N_1, \ldots, N_l \). In order to take this condition into account automatically, let us introduce the following structure of a Hilbert space:

(1) Define the scalar product
\[
(\psi_1, \psi_2) = \int f^*(v, M) \psi_1(v) \psi_2(v) \, dv.
\] (24)

(2) Let \( E_\mu \) be the linear hull of the set of moment densities
\[
\{\mu_1(v), \ldots, \mu_k(v)\}.
\]

Let us construct a basis of \( E_\mu \) \{\( e_1(v), \ldots, e_r(v) \)\} that is orthonormal in the sense of the scalar product (24):
\[
(e_i, e_j) = \delta_{ij},
\] (25)
\(i, j = 1, \ldots, r; \delta_{ij}\) is the Kronecker delta.

(3) Define a projector \(\hat{P}^*\) on the first quasiequilibrium state,

\[
\hat{P}^* \psi = \sum_{i=1}^{r} e_i (e_i, \psi).
\] (26)

The projector \(\hat{P}^*\) is orthogonal: for any pair of functions \(\psi_1, \psi_2\),

\[
(\hat{P}^* \psi_1, (\hat{1} - \hat{P}^*) \psi_2) = 0,
\] (27)

where \(\hat{1}\) is the unit operator. Then the condition (23) amounts to

\[
\hat{P}^* \varphi = 0,
\] (28)

and the expression for the quadratic part of the \(H\)-function (21) takes the form,

\[
\Delta H[f^*, \varphi] = H^*(M) + (\ln f^*, \varphi) + (1/2)(\varphi, \varphi).
\] (29)

Now, let us note that the function \(\ln f^*\) is invariant with respect to the action of the projector \(\hat{P}^*\):

\[
\hat{P}^* \ln f^* = \ln f^*.
\] (30)

This follows directly from the solution of the problem (19) using of the method of Lagrange multipliers:

\[
f^* = \exp \sum_{i=1}^{k} \lambda_i(M) \mu_i(v),
\]

where \(\lambda_i(M)\) are Lagrange multipliers. Thus, if the condition (28) is satisfied, then from (27) and (30) it follows that

\[
(\ln f^*, \varphi) = (\hat{P}^* \ln f^*, (\hat{1} - \hat{P}^*) \varphi) = 0.
\]

Condition (28) is satisfied automatically, if \(\Delta N_i\) are taken as follows:

\[
\Delta N_i = ((\hat{1} - \hat{P}^*) \nu_i, \varphi), i = 1, \ldots, l.
\] (31)

Thus, the problem (15) of finding the second quasiequilibrium state reduces to

\[
\Delta H[f^*, \varphi] - H^*(M) = (1/2)(\varphi, \varphi) \rightarrow \min \text{ for } ((\hat{1} - \hat{P}^*) \nu_i, \varphi) = \Delta N_i, \ i = 1, \ldots, l.
\] (32)
Note that it is not ultimatively necessary to introduce the structure of the Hilbert space. Moreover that may be impossible, since the “distribution function” and the “microscopic moment densities” are, strictly speaking, elements of different (conjugate one to another) spaces, which may be not reflexive. However, in the examples considered below the mentioned difference is not manifested.

In the remainder of this section we demonstrate how the triangle entropy method is related to Grad’s moment method.

### 3.2 Ten-moment Grad approximation.

Let us take the five additive collision invariants as moment densities of the first quasiequilibrium state:

$$\mu_0 = 1; \mu_k = v_k \ (k = 1, 2, 3); \mu_4 = \frac{mv^2}{2},$$  \hspace{1cm} (33)

where $v_k$ are Cartesian components of the velocity, and $m$ is particle’s mass. Then the solution to the problem (19) is the local Maxwell distribution function $f^{(0)}(v, x, t)$:

$$f^{(0)} = n(x, t) \left(\frac{2\pi k_B T(x, t)}{m}\right)^{-3/2} \exp\left\{-\frac{m(v - u(x, t))^2}{2k_B T(x, t)}\right\},$$  \hspace{1cm} (34)

where

$n(x, t) = \int f(v) \, dv$ is local number density,

$u(x, t) = n^{-1}(x, t) \int f(v)v \, dv$ is the local flow density,

$T(x, t) = \frac{m}{3k_B} n^{-1}(x, t) \int f(v)(v - u(x, t))^2 \, dv$ is the local temperature,

$k_B$ is the Boltzmann constant.

Orthonormalization of the set of moment densities (33) with the weight (34) gives one of the possible orthonormal basis

$$e_0 = \frac{5k_B T - m(v - u)^2}{(10n)^{1/2}k_B T},$$

$$e_k = \frac{m^{1/2}(v_k - u_k)}{(nk_B T)^{1/2}}, \ k = 1, 2, 3,$$  \hspace{1cm} (35)
\[ e_4 = \frac{m(v - u)^2}{(15n)^{1/2}k_B T}. \]

For the moment densities of the second quasiequilibrium state let us take,

\[ \nu_{ik} = mv_i v_k, \quad i, k = 1, 2, 3. \] (36)

Then

\[ (\hat{1} - \hat{P}^{(0)})\nu_{ik} = m(v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} m(v - u)^2, \] (37)

and, since \((\hat{1} - \hat{P}^{(0)})\nu_{ik}, (\hat{1} - \hat{P}^{(0)})\nu_{ls}\) = \((\delta_{il}\delta_{ks} + \delta_{kl}\delta_{is})P k_B T / m\), where \(P = nk_B T\) is the pressure, and \(\sigma_{ik} = (f, (\hat{1} - \hat{P}^{(0)})\nu_{ik})\) is the traceless part of the stress tensor, then from (20), (33), (34), (37) we obtain the distribution function of the second quasiequilibrium state in the form

\[ f = f^{(0)} \left( 1 + \frac{\sigma_{ik} m}{2P k_B T} \left[ (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (v - u)^2 \right] \right) \] (38)

This is precisely the distribution function of the ten-moment Grad approximation (let us recall that here summation in two repeated indices is assumed).

### 3.3 Thirteen-moment Grad approximation

In addition to (33), (36), let us extend the list of moment densities of the second quasiequilibrium state with the functions

\[ \xi_i = \frac{mv_i v^2}{2}, \quad i = 1, 2, 3. \] (39)

The corresponding orthogonal complements to the projection on the first quasiequilibrium state are

\[ (\hat{1} - \hat{P}^{(0)})\xi_i = \frac{m}{2}(v_i - u_i) \left( (v - u)^2 - \frac{5k_B T}{m} \right). \] (40)

The moments corresponding to the densities \((\hat{1} - \hat{P}^{(0)})\xi_i\) are the components of the heat flux vector \(q_i\):

\[ q_i = (\varphi, (\hat{1} - \hat{P}^{(0)})\xi_i). \] (41)
Since
\[((\hat{1} - \hat{P}^{(0)})\xi_i, (\hat{1} - \hat{P}^{(0)})\nu_{lk}) = 0,\]
for any \(i, k, l\), then the constraints
\[((\hat{1} - \hat{P}^{(0)})\nu_{lk}, \varphi) = \sigma_{ik}, ((\hat{1} - \hat{P}^{(0)})\xi_i, \varphi) = q_i\]
in the problem (32) are independent, and Lagrange multipliers corresponding to \(\xi_i\) are
\[\frac{1}{5n} \left( \frac{k_B T}{m} \right)^2 q_i. \tag{42}\]

Finally, taking into account (33), (38), (40), (42), we find the distribution function of the second quasiequilibrium state in the form
\[f = f^{(0)} \left( 1 + \frac{\sigma_{ik} m}{2 P k_B T} \left( (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (v - u)^2 \right) \right. \]
\[+ \frac{q_i m}{P k_B T} (v_i - u_i) \left( \frac{m (v - u)^2}{5 k_B T} - 1 \right) \left. \right) \tag{43},\]
which coincides with the thirteen-moment Grad distribution function [20].

Let us remark on the thirteen-moment approximation. From (43) it follows that for large enough negative values of \((v_i - u_i)\) the thirteen-moment distribution function becomes negative. This peculiarity of the thirteen-moment approximation is due to the fact that the moment density \(\xi_i\) is odd-order polynomial of \(v_i\). In order to eliminate this difficulty, one may consider from the very beginning that in a finite volume the square of velocity of a particle does not exceed a certain value \(v_{\text{max}}^2\), which is finite owing to the finiteness of the total energy, and \(q_i\) is such that when changing to infinite volume \(q_i \to 0, v_{\text{max}}^2 \to \infty\) and \(q_i (v_i - u_i)(v - u)^2\) remains finite.

On the other hand, the solution to the optimization problem (11) does not exist (is not normalizable), if the highest-order velocity polynomial is odd, as it is for the full 13-moment quasiequilibrium.

Approximation (38) yields \(\Delta H\) (29) as follows:
\[\Delta H = H^{(0)} + n \frac{\sigma_{ik} \sigma_{ik}}{4 P^2}. \tag{44}\]
while $\Delta H$ corresponding to (43) is,

$$\Delta H = H^{(0)} + n \frac{\sigma_{ik} \sigma_{ik}}{4P^2} + n \frac{q_k q_k \rho}{5P^3},$$  \hspace{1cm} (45)

where $\rho = mn$, and $H^{(0)}$ is the local equilibrium value of the $H$-function

$$H^{(0)} = \frac{5}{2} n \ln n - \frac{3}{2} n \ln P - \frac{3}{2} n \left(1 + \ln \frac{2\pi}{m}\right).$$  \hspace{1cm} (46)

These expressions coincide with the corresponding expansions of the quasiequilibrium $H$-functions obtained by the entropy method, if microscopic moment densities of the first quasiequilibrium approximation are chosen as $1, v_i$, and $v_i v_j$, or as $1, v_i, v_i v_j$, and $v_i v^2$. As it was noted in [6], they differs from the $H$-functions obtained by the Grad method (without the maximum entropy hypothesis), and in contrast to the latter they give proper entropy balance equations.

The transition to the closed system of equations for the moments of the first and of the second quasiequilibrium approximations is accomplished by proceeding from the chain of the Maxwell moment equations, which is equivalent to the Boltzmann equation. Substituting $f$ in the form of $f^{(0)}(1 + \varphi)$ into equation (7), and multiplying by $\mu_i(v)$, and integrating over $v$, we obtain

$$\partial_t (1, \hat{P}^{(0)}(\mu_i(v))) + \partial_t (\varphi(v), \mu_i(v)) + \partial_k (v_k \varphi(v), \mu_i(v)) + \partial_k (v_k, \mu_i(v)) = M_Q[\mu_i, \varphi].$$  \hspace{1cm} (47)

Here

$$M_Q[\mu_i, \varphi] = \int Q(f^{(0)}(1 + \varphi), f^{(0)}(1 + \varphi)) \mu_i(v) \, dv$$

is a “moment” (corresponding to the microscopic density) $\mu_i(v)$ with respect to the collision integral (further we term $M_Q$ the collision moment or the scattering rate). Now, if one uses $f$ given by equations (38), and (43) as a closure assumption, then the system (47) gives the ten- and thirteen-moment Grad equations, respectively, whereas only linear terms in $\varphi$ should be kept when calculating $M_Q$.

Let us note some limitations of truncating the moment hierarchy (47) by means of the quasiequilibrium distribution functions (38) and (43) (or for any other closure which depends on the moments of the distribution functions only). When such closure is used, it is assumed implicitly that the scattering rates
in the right hand side of (47) “rapidly” relax to their values determined by "slow" (quasiequilibrium) moments. Scattering rates are, generally speaking, independent variables. This peculiarity of the chain (47), resulting from the nonlinear character of the Boltzmann equation, distinct it essentially from the other hierarchy equations of statistical mechanics (for example, from the BBGKY chain which follows from the linear Liouville equation). Thus, equations (47) are not closed twice: into the left hand side of the equation for the $i$-th moment enters the $(i + 1)$-th moment, and the right hand side contains additional variables – scattering rates.

A consequent way of closure of (47) should address both sets of variables (moments and scattering rates) as independent variables. The triangle entropy method enables to do this.

4 Transport equations for scattering rates in the neighbourhood of local equilibrium. Second and mixed hydrodynamic chains

In this section we derive equations of motion for the scattering rates. It proves convenient to use the following form of the collision integral $Q(f, f)$:

$$Q(f, f)(v) = \int w(v', v' | v, v_1)(f(v')f(v'_1) - f(v)f(v_1))\,dv'\,dv'_1\,dv_1. \quad (48)$$

where $v$ and $v_1$ are velocities of the two colliding particles before the collision, $v'$ and $v'_1$ are their velocities after the collision, $w$ is a kernel responsible for the post-collision relations $v'(v, v_1)$ and $v'_1(v, v_1)$, momentum and energy conservation laws are taken into account in $w$ by means of corresponding $\delta$-functions. The kernel $w$ has the following symmetry property with respect to its arguments:

$$w(v'_1, v' | v, v_1) = w(v'_1, v'_1 | v_1, v) = w(v', v'_1 | v_1, v) = w(v, v_1 | v', v'_1). \quad (49)$$

Let $\mu(v)$ be the microscopic density of a moment $M$. The corresponding scattering rate $M_Q[f, \mu]$ is defined as follows:

$$M_Q[f, \mu] = \int Q(f, f)(v)\mu(v)\,dv. \quad (50)$$

First, we should obtain transport equations for scattering rates (50), analogous to the moment’s transport equations. Let us restrict ourselves to the case when $f$ is represented in the form,

$$f = f^{(0)}(1 + \varphi), \quad (51)$$
where \( f^{(0)} \) is local Maxwell distribution function (34), and all the quadratic with respect to \( \varphi \) terms will be neglected below. It is the linear approximation around the local equilibrium.

Since, by detailed balance,

\[
f^{(0)}(v)f^{(0)}(v_1) = f^{(0)}(v')f^{(0)}(v'_1)
\]

(52)

for all such \((v, v_1), (v', v'_1)\) which are related to each other by conservation laws, we have,

\[
M_Q[f^{(0)}, \mu] = 0, \text{ for any } \mu.
\]

(53)

Further, by virtue of conservation laws,

\[
M_Q[f, \hat{P}^{(0)}\mu] = 0, \text{ for any } f.
\]

(54)

From (52)-(54) it follows,

\[
M_Q[f^{(0)}(1 + \varphi), \mu] = M_Q[\varphi, (1 - \hat{P}^{(0)})\mu]
\]

(55)

\[
= -\int w(v', v'_1 | v, v_1)f^{(0)}(v)f^{(0)}(v_1) \{(1 - \hat{P}^{(0)})\mu(v)\} \, dv' \, dv'_1 \, dv_1 \, dv.
\]

We used notation,

\[
\{\psi(v)\} = \psi(v) + \psi(v_1) - \psi(v') - \psi(v'_1).
\]

(56)

Also, it proves convenient to introduce the microscopic density of the scattering rate, \( \mu_Q(v) \):

\[
\mu_Q(v) = \int w(v', v'_1 | v, v_1)f^{(0)}(v_1) \{(1 - \hat{P}^{(0)})\mu(v)\} \, dv' \, dv'_1 \, dv_1.
\]

(57)

Then,

\[
M_Q[\varphi, \mu] = -(\varphi, \mu_Q),
\]

(58)

where \((\cdot, \cdot)\) is the \( L_2 \) scalar product with the weight \( f^{(0)} \) (34). This is a natural scalar product in the space of functions \( \varphi \) (51) (multipliers), and it is obviously related to the entropic scalar product in the space of distribution functions at the local equilibrium \( f^{(0)} \), which is the \( L_2 \) scalar product with the weight \((f^{(0)})^{-1}\).
Now, we obtain transport equations for the scattering rates (58). We write down the time derivative of the collision integral due to the Boltzmann equation,

\[ \partial_t Q(f, f)(v) = \hat{T}Q(f, f)(v) + \hat{R}Q(f, f)(v), \]  

(59)

where

\[
\hat{T}Q(f, f)(v) = \int w(v', v'_1 \mid v, v_1) \left[ f(v') v_{1k} \partial_k f(v_1) + f(v) v_k \partial_k f(v) \right] \, dv' dv'_1 dv_1 dv \\
- f(v') v'_{1k} \partial_k f(v'_1) - f(v') v'_k \partial_k f(v') \, dv' dv'_1 dv_1 dv;
\]

(60)

\[
\hat{R}Q(f, f)(v) = \int w(v', v'_1 \mid v, v_1) \left[ Q(f, f)(v') f(v'_1) + Q(f, f)(v'_1) f(v') \right] \, dv' dv'_1 dv_1 dv.
\]

(61)

Using the representation,

\[ \partial_k f^{(0)}(v) = A_k(v) f^{(0)}(v); \]

(62)

\[ A_k(v) = \partial_k \ln(nT^{-3/2}) + \frac{m}{k_B T} (v_i - u_i) \partial_k u_i + \frac{m(v - u)^2}{2k_B T} \partial_k \ln T, \]

and after some simple transformations using the relation

\[ \{A_k(v)\} = 0, \]

(63)

in linear with respect to \( \varphi \) deviation from \( f^{(0)} \) (51), we obtain in (59):

\[
\hat{T}Q(f, f)(v) = \partial_k \int w(v', v'_1 \mid v, v_1) f^{(0)}(v_1) f^{(0)}(v) \left\{ v_k \varphi(v) \right\} \, dv'_1 dv' dv_1 \\
+ \int w(v', v'_1 \mid v, v_1) f^{(0)}(v_1) f^{(0)}(v) \left\{ v_k A_k(v) \right\} \, dv' dv'_1 dv_1 \\
+ \int w(v', v'_1 \mid v, v_1) f^{(0)}(v) f^{(0)}(v_1) \left\{ v_k A_k(v) \right\} \varphi(v) A_k(v_1) (v_{1k} - v_k) \\
+ \varphi(v_1) A_k(v)(v_k - v_{1k}) + \varphi(v') A_k(v'_1) (v'_k - v'_{1k}) \\
+ \varphi(v'_1) A_k(v')(v'_{1k} - v'_k) \, dv'_1 dv' dv_1;
\]

(64)

\[
\hat{R}Q(f, f)(v) = \int w(v', v'_1 \mid v, v_1) f^{(0)}(v) f^{(0)}(v_1) \left\{ \xi(v) \right\} \, dv'_1 dv' dv_1;
\]

\[ \xi(v) = \int w(v', v'_1 \mid v, v_1) f^{(0)}(v_1) \left\{ \varphi(v) \right\} \, dv'_1 dv' dv_1; \]

(65)

\[
\partial_t Q(f, f)(v) = -\partial_t \int w(v', v'_1 \mid v, v_1) f^{(0)}(v) f^{(0)}(v_1) \left\{ \varphi(v) \right\} \, dv' dv'_1 dv_1.
\]

(66)
Let us use two identities:

1. From the conservation laws it follows
   \[
   \{ \varphi(\mathbf{v}) \} = \left\{ (\hat{\mathbf{1}} - \hat{P}^{(0)}) \varphi(\mathbf{v}) \right\} .
   \] (67)

2. The symmetry property of the kernel \( w \) (49) which follows from (49), (52)
   \[
   \int w(\mathbf{v'}, \mathbf{v}_1' | \mathbf{v}, \mathbf{v}_1) f^{(0)}(\mathbf{v}_1)f^{(0)}(\mathbf{v}) g_1(\mathbf{v}) \{ g_2(\mathbf{v}) \} \, d\mathbf{v'} \, d\mathbf{v}_1' \, d\mathbf{v} \, d\mathbf{v}_1 = \int w(\mathbf{v'}, \mathbf{v}_1' | \mathbf{v}, \mathbf{v}_1) f^{(0)}(\mathbf{v}_1)f^{(0)}(\mathbf{v}) g_2(\mathbf{v}) \{ g_1(\mathbf{v}) \} \, d\mathbf{v'} \, d\mathbf{v}_1' \, d\mathbf{v} \, d\mathbf{v}_1 .
   \] (68)

It is valid for any two functions \( g_1, g_2 \) ensuring existence of the integrals, and also using the first identity.

Now, multiplying (64)-(67) by the microscopic moment density \( \mu(\mathbf{v}) \), performing integration over \( \mathbf{v} \) (and using identities (67), (69)) we obtain the required transport equation for the scattering rate in the linear neighborhood of the local equilibrium:

\[
-\partial_t \Delta M_Q[\varphi, \mu] \equiv -\partial_t (\varphi, \mu_Q) = (v_k A_k(\mathbf{v}), \mu_Q((\hat{\mathbf{1}} - \hat{P}^{(0)}) \mu(\mathbf{v}))) + \partial_k (\varphi(\mathbf{v}) v_k, \mu_Q((\hat{\mathbf{1}} - \hat{P}^{(0)}) \mu(\mathbf{v}))) + \int w(\mathbf{v'}, \mathbf{v}_1' | \mathbf{v}, \mathbf{v}_1) f^{(0)}(\mathbf{v}_1)f^{(0)}(\mathbf{v}) g_1(\mathbf{v}) \{ g_2(\mathbf{v}) \} \, d\mathbf{v'} \, d\mathbf{v}_1' \, d\mathbf{v} \, d\mathbf{v}_1 \times \{ (\hat{\mathbf{1}} - \hat{P}^{(0)}) \mu(\mathbf{v}) \} A_k(\mathbf{v}_1)(v_{1k} - v_k) \varphi(\mathbf{v}) \, d\mathbf{v'} \, d\mathbf{v}_1' \, d\mathbf{v} \, d\mathbf{v}_1 + \left( \xi(\mathbf{v}), \mu_Q \left( (\hat{\mathbf{1}} - \hat{P}^{(0)}) \mu(\mathbf{v}) \right) \right) .
\] (69)

The chain of equations (69) for scattering rates is a counterpart of the hydrodynamic moment chain (47). Below we call (69) the \textit{second chain}, and (47) - the \textit{first chain}. Equations of the second chain are coupled in the same way as the first one: the last term in the right part of (69) \( (\xi, \mu_Q((\hat{\mathbf{1}} - \hat{P}^{(0)}) \mu)) \) depends on the whole totality of moments and scattering rates and may be treated as a new variable. Therefore, generally speaking, we have an infinite sequence of chains of increasingly higher orders. Only in the case of a special choice of the collision model – Maxwell potential \( U = -kT^{-4} \) – this sequence degenerates: the second and the higher-order chains are equivalent to the first (see below).

Let us restrict our consideration to the first and second hydrodynamic chains. Then a deviation from the local equilibrium state and transition to a closed macroscopic description may be performed in three different ways for the microscopic moment density \( \mu(\mathbf{v}) \). First, one can specify the moment \( \bar{M}[\mu] \) and
perform a closure of the chain (47) by the triangle method given in previous subsections. This leads to Grad’s moment method. Second, one can specify scattering rate \( \hat{M}_Q[\mu] \) and perform a closure of the second hydrodynamic chain (69). Finally, one can consider simultaneously both \( \hat{M}[\mu] \) and \( \hat{M}_Q[\mu] \) (mixed chain). Quasiequilibrium distribution functions corresponding to the last two variants will be constructed in the following subsection. The hard spheres model (H.S.) and Maxwell’s molecules (M.M.) will be considered.

5 Distribution functions of the second quasiequilibrium approximation for scattering rates

5.1 First five moments and collision stress tensor

Elsewhere below the local equilibrium \( f^{(0)}(34) \) is chosen as the first quasiequilibrium approximation.

Let us choose \( \nu_{ik} = mv_i v_k(36) \) as the microscopic density \( \mu(v) \) of the second quasiequilibrium state. Let us write down the corresponding scattering rate (collision stress tensor) \( \Delta_{ik} \) in the form,

\[
\Delta_{ik} = - (\varphi, \nu_{Qik}),
\]

where

\[
\nu_{Qik}(v) = m \int w(v', v_1 | v_1, v) f^{(0)}(v_1) \times \left\{ (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (v - u)^2 \right\} dv' dv_1 dv_1
\]

is the microscopic density of the scattering rate \( \Delta_{ik} \).

The quasiequilibrium distribution function of the second quasiequilibrium approximation for fixed scattering rates (70) is determined as the solution to the problem

\[
(\varphi, \varphi) \rightarrow \min \quad \text{for} \quad (\varphi, \nu_{Qik}) = - \Delta_{ik}.
\]

The method of Lagrange multipliers yields
\[ \varphi(v) = \lambda_{ik} \nu_{Qik}(v), \]
\[ \lambda_{ik}(\nu_{Qik}, \nu_{Qls}) = \Delta_{ls}, \quad (73) \]

where \( \lambda_{ik} \) are the Lagrange multipliers.

In the examples of collision models considered below (and in general, for centrally symmetric interactions) \( \nu_{Qik} \) is of the form

\[ \nu_{Qik}(v) = (\hat{1} - \hat{P}^{(0)}) \nu_{ik}(v) \Phi((v - u)^2), \quad (74) \]

where \( (\hat{1} - \hat{P}^{(0)}) \nu_{ik} \) is determined by relationship (37) only, and function \( \Phi \) depends only on the absolute value of the peculiar velocity \( (v - u) \). Then

\[ \lambda_{ik} = r \Delta_{ik}; \]
\[ r^{-1} = (2/15) \left( \Phi^2((v - u)^2), (v - u)^4 \right), \quad (75) \]

and the distribution function of the second quasiequilibrium approximation for scattering rates (70) is given by the expression

\[ f = f^{(0)}(1 + r \Delta_{ik} \mu_{Qik}). \quad (76) \]

The form of the function \( \Phi((v - u)^2) \), and the value of the parameter \( r \) are determined by the model of particle’s interaction. In the Appendix, they are found for hard spheres and Maxwell molecules models (see (148)-(153)). The distribution function (76) is given by the following expressions:

For Maxwell molecules:

\[ f = f^{(0)} \times \left\{ 1 + \mu_0^{M.M.} m (2 \nu^2 k_B T)^{-1} \Delta_{ik} \left( (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (v - u)^2 \right) \right\}, \]
\[ \mu_0^{M.M.} = \frac{k_B T \sqrt{2m}}{3 \pi A_2(5) \sqrt{\kappa}}, \quad (77) \]

where \( \mu_0^{M.M.} \) is viscosity coefficient in the first approximation of the Chapman–Enskog method (it is exact in the case of Maxwell molecules), \( \kappa \) is a force constant, \( A_2(5) \) is a number, \( A_2(5) \approx 0.436 \) (see [34]);

For the hard spheres model:
\[ f = f^{(0)} \]
\[ \times \left\{ 1 + \frac{2\sqrt{2\tilde{r}m\mu_0^{\text{H.S.}}}}{5P^2k_BT} \Delta_{ik} \int_{-1}^{1} \exp \left\{ -\frac{m(v-u)^2}{2k_BT} y^2 \right\} (1-y^2)(1+y^2) \right. \]
\[ \times \left( \frac{m(v-u)^2}{2k_BT} (1-y^2) + 2 \right) dy \left[ (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik}(v-u)^2 \right] \right\}, \]
\[ \mu_0^{\text{H.S.}} = \frac{5\sqrt{k_BTm}}{16\sqrt{\pi\sigma^2}}, \quad \text{(78)} \]

where \( \tilde{r} \) is a number represented as follows:

\[ \tilde{r}^{-1} = \frac{1}{16} \int_{-1}^{1} \int_{-1}^{1} \alpha^{-11/2} \beta(y) \beta(z) \gamma(y) \gamma(z) \]
\[ \times (16\alpha^2 + 28\alpha(\gamma(y) + \gamma(z)) + 63\gamma(y)\gamma(z)) \, dy \, dz, \quad \text{(79)} \]
\[ \alpha = 1 + y^2 + z^2, \quad \beta(y) = 1 + y^2, \quad \gamma(y) = 1 - y^2. \]

Numerical value of \( \tilde{r}^{-1} \) is 5.212, to third decimal point accuracy.

In the mixed description, the distribution function of the second quasiequilibrium approximation under fixed values of the moments and of the scattering rates corresponding to the microscopic density (36) is determined as a solution of the problem

\[ (\varphi, \varphi) \rightarrow \min \quad \text{for} \]
\[ ((1 - \hat{P}^{(0)})(\nu_{ik}, \varphi) = \sigma_{ik}, \]
\[ (\nu_{Qik}, \varphi) = \Delta_{ik}. \quad \text{(80)} \]

Taking into account the relation (74), we obtain the solution of the problem (80) in the form,

\[ \varphi(v) = (\lambda_{ik} \Phi((v-u)^2) + \beta_{ik})((v_i - u_i)(v_k - u_k) - (1/3)\delta_{ik}(v-u)^2) \] \[ \quad (81) \]

Lagrange multipliers \( \lambda_{ik}, \beta_{ik} \) are determined from the system of linear equations,

\[ ms^{-1}\lambda_{ik} + 2PkB^{-1}\beta_{ik} = \sigma_{ik}, \]
\[ mr^{-1}\lambda_{ik} + ms^{-1}\beta_{ik} = \Delta_{ik}, \quad \text{(82)} \]
where

\[ s^{-1} = (2/15)(\Phi((v - u)^2), (v - u)^4). \tag{83} \]

If the solvability condition of the system (82) is satisfied,

\[ D = m^2 s^{-2} - 2P k_B T r^{-1} \neq 0, \tag{84} \]

then the distribution function of the second quasiequilibrium approximation exists and takes the form

\[ f = f^{(0)} \left\{ 1 + (m^2 s^{-2} - 2P k_B T r^{-1})^{-1} \right. \]
\[ \times \left[ (m s^{-1} \sigma_{ik} - 2P k_B T m^{-1} \Delta_{ik}) \Phi((v - u)^2) \right. \]
\[ + (m s^{-1} \Delta_{ik} - m r^{-1} \sigma_{ik}) \left[ (v_i - u_i)(v_k - u_k) - (1/3)\delta_{ik}(v - u)^2 \right] \} \tag{85} \]

The condition (84) means independence of the set of moments $\sigma_{ik}$ from the scattering rates $\Delta_{ik}$. If this condition is not satisfied, then the scattering rates $\Delta_{ik}$ can be represented in the form of linear combinations of $\sigma_{ik}$ (with coefficients depending on the hydrodynamic moments). Then the closed by means of (76) equations of the second chain are equivalent to the ten moment Grad equations, while the mixed chain does not exist. This happens only in the case of Maxwell molecules. Indeed, in this case

\[ s^{-1} = 2P^2 k_B T (m^2 \mu_{0}^{\text{M.M.}})^{-1}; D = 0. \]

The transformation changing $\Delta_{ik}$ to $\sigma_{ik}$ is

\[ \mu_{0}^{\text{M.M.}} \Delta_{ik} P^{-1} = \sigma_{ik}. \tag{86} \]

For hard spheres:

\[ s^{-1} = \frac{5P^2 k_B T}{4\sqrt{2} \mu_0^{\text{H.S.}} m^2} \cdot \tilde{s}^{-1}, \tilde{s}^{-1} = \int_{-1}^{+1} \gamma(y)(\beta(y))^{-7/2} \left( \beta(y) + \frac{7}{4} \gamma(y) \right) \, dy. \tag{87} \]

The numerical value of $\tilde{s}^{-1}$ is 1.115 to third decimal point. The condition (83) takes the form,

\[ D = \frac{25}{32} \left( \frac{P^2 k_B T}{m \mu_0^{\text{H.S.}}} \right)^2 (\tilde{s}^{-2} - \tilde{r}^{-1}) \neq 0. \tag{88} \]
Consequently, for the hard spheres model the distribution function of the second quasiequilibrium approximation of the mixed chain exists and is determined by the expression

\begin{equation}
\begin{aligned}
f = f^{(0)} \left\{ 1 + m(4P_{k_B}T(\tilde{s}^{-2} - \tilde{r}^{-1}))^{-1} \right. \\
\times \left[ \sigma_{ik} \tilde{s}^{-1} - \frac{8\sqrt{2}}{5P} \mu_{0}^{H.S.} \Delta_{ik} \right]^{+1} \exp \left( -\frac{m(v - u)^2}{2k_B T} y^2 \right) \\
\times (1 - y^2)(1 + y^2) \left( \frac{m(v - u)^2}{2k_B T} (1 - y^2) + 2 \right) dy \\
+ 2 \left( \tilde{s}^{-1}. \frac{8\sqrt{2}}{5P} \mu_{0}^{H.S.} \Delta_{ik} - \tilde{r}^{-1} \sigma_{ik} \right) \\
\times (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (v - u)^2 \right\}.
\end{aligned}
\end{equation}

(89)

5.2 First five moments, collision stress tensor, and collision heat flux vector

Distribution function of the second quasiequilibrium approximation which takes into account the collision heat flux vector \( Q \) is constructed in a similar way. The microscopic density \( \xi_{Q_i} \) is

\begin{equation}
\xi_{Q_i}(v) = \int w(v', v'_{1} | v, v_{1}) f^{(0)}(v_{1}) \left\{ (\hat{H}(v_{1}) - \hat{P}^{(0)}_{v_{1}}) \frac{v_{1}^2}{2} \right\} dv' dv'_{1} dv_{1}.
\end{equation}

(90)

The desired distribution functions are the solutions to the following optimization problems: for the second chain it is the solution to the problem (72) with the additional constraints,

\begin{equation}
m(\varphi, \xi_{Q_i}) = Q_i.
\end{equation}

(91)

For the mixed chain, the distribution functions is the solution to the problem (80) with additional conditions,

\begin{equation}
m(\varphi, \xi_{Q_i}) = Q_i,
\end{equation}

(92)

\begin{equation}
m(\varphi, (\hat{H}^{(0)}_{v_{1}}) \xi_{i}) = q_i.
\end{equation}

(93)

Here \( \xi_i = v_i v^2 / 2 \) (see (39)). In the Appendix functions \( \xi_{Q_i} \) are found for Maxwell molecules and hard spheres (see (153)-(158)). Since
\begin{align}
(\xi_{Q_i}, \nu_{Q_{kj}}) &= (\hat{1} - \hat{P}^{(0)})\xi_{i}, \nu_{Q_{kj}}) \\
&= (\xi_{Q_i}, (\hat{1} - \hat{P}^{(0)})\nu_{kj}) = ((\hat{1} - \hat{P}^{(0)})\xi_{i}, (\hat{1} - \hat{P}^{(0)})\nu_{kj}) = 0, \quad (94)
\end{align}

the conditions (91) are linearly independent from the constraints of the problem (72), and the conditions (93) do not depend on the constraints of the problem (80).

Distribution function of the second quasiequilibrium approximation of the second chain for fixed $\Delta_{ik}, Q_i$ is of the form,

\begin{align}
f &= f^{(0)}(1 + r\Delta_{ik}\nu_{Qik} + \eta Q_i\xi_{Qi}). \quad (95)
\end{align}

The parameter $\eta$ is determined by the relation

\begin{align}
\eta^{-1} = (1/3)(\xi_{Qi}, \xi_{Qi}). \quad (96)
\end{align}

According to (157), for Maxwell molecules

\begin{align}
\eta = \frac{9m^3(\mu_0^{M.M.})^2}{10P^3(k_BT)^2}, \quad (97)
\end{align}

and the distribution function (95) is

\begin{align}
f &= f^{(0)} \times \left\{ 1 + \mu_0^{M.M.}m(2P^2k_BT)^{-1}\Delta_{ik}((v_i - u_i)(v_k - u_k) - (1/3)\delta_{ik}(v - u)^2)
+ \mu_0^{M.M.}m(P^2k_BT)^{-1}(v_i - u_i) \left( m(v - u)^2 \right) \right\}. \quad (98)
\end{align}

For hard spheres (see Appendix)

\begin{align}
\eta = \frac{64m^3(\mu_0^{H.S.})^2}{125P^3(k_BT)^2}, \quad (99)
\end{align}

where $\eta$ is a number equal to 16.077 to third decimal point accuracy.

The distribution function (95) for hard spheres takes the form

\begin{align}
f &= f^{(0)} \left\{ 1 + 2\sqrt{2} m(\mu_0^{H.S.}) \Delta_{ik} \sum_{-1}^{+1} \int \exp\left( -\frac{m(v - u)^2}{2k_BT} y^2 \right) \beta(y)\gamma(y) \right\}.
\end{align}
\[
\times \left( \frac{m(v - u)^2}{2k_BT} \gamma(y) + 2 \right) dy \left( (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik}(v - u)^2 \right) \\
+ \frac{2\sqrt{2}\eta m^3 \mu_{H.S.}}{25P^2(k_BT)^2} Q_i \left[ (v_i - u_i) \left( \frac{(v - u)^2}{m} - \frac{5k_BT}{m} \right) \right] \\
\times \int_{-1}^{+1} \exp \left( -\frac{m(v - u)^2}{2k_BT} y^2 \right) \beta(y) \gamma(y) \left( \frac{m(v - u)^2}{2k_BT} \gamma(y) + 2 \right) dy \\
+ (v_i - u_i)(v - u)^2 \int_{-1}^{+1} \exp \left( -\frac{m(v - u)^2}{2k_BT} y^2 \right) \beta(y) \gamma(y) \\
\times \left( \sigma(y) \frac{m(v - u)^2}{2k_BT} + \delta(y) \right) \right\}. \tag{100}
\]

The functions \( \beta(y), \gamma(y), \sigma(y) \) and \( \delta(y) \) are
\[
\beta(y) = 1 + y^2, \quad \gamma(y) = 1 - y^2, \quad \sigma(y) = y^2(1 - y^2), \quad \delta(y) = 3y^2 - 1. \tag{101}
\]

The condition of existence of the second quasi-equilibrium approximation of the mixed chain \((84)\) should be supplemented with the requirement
\[
R = m^2 \tau^{-2} - \frac{5P(k_BT)^2}{2m} \eta^{-1} \neq 0. \tag{102}
\]

Here
\[
\tau^{-1} = \frac{1}{3} \left( (\hat{I} - \hat{I}^{(0)} v_i^2 v_i, \xi_{Q_i}(v_i) \right). \tag{103}
\]

For Maxwell molecules
\[
\tau^{-1} = (5P^2 k_B^2 T^2) / (3\mu_{H.M.}^0 m^3),
\]
and the solvability condition \((102)\) is not satisfied. Distribution function of the second quasi-equilibrium approximation of mixed chain does not exist for Maxwell molecules. The variables \(Q_i\) are changed to \(q_i\) by the transformation
\[
3\mu_{H.M.}^0 Q_i = 2Pq_i. \tag{104}
\]

For hard spheres,
\[
\tau^{-1} = \tilde{\tau}^{-1} = \frac{25(Pk_BT)^2}{8\sqrt{2m^3 \mu_{H.S.}^0}}, \tag{105}
\]
where
\[
\tau^{-1} = \frac{1}{8} \int_{-1}^{+1} \beta^{-9/2}(y)\gamma(y)\{63(\gamma(y) + \delta(y)) + 7\beta(y)(4 - 10\gamma(y) + 2\delta(y) - 5\sigma(y)) + \beta^2(y)(25\gamma(y) - 10\delta(y) - 40) + 20\beta^3(y)\} dy.
\]

The numerical value of \(\tau^{-1}\) is about 4.322. Then the condition (102) is verified:

\[
R \approx 66m^{-4}(P_{kB}T)^{4}(\mu_0^{H.S.})^2.
\]

Finally, for the fixed values of \(\sigma_{ik}, \Delta_{ik}, q_i\) and \(Q_i\), the distribution function of the second quasiequilibrium approximation of the second chain for hard spheres is of the form,

\[
f = f^{(0)} \left\{1 + \frac{m}{4P_{kB}T}(\tilde{s}^{-2} - \tilde{\eta}^{-1})^{-1}\right.
\]

\[
\times \left[\left(\tilde{s}^{-1}\sigma_{ik} - \frac{8\sqrt{2}}{5P}\mu_0^{H.S.}\Delta_{ik}\right) + \int_{-1}^{+1} \exp\left(-\frac{m(v - u)^2}{2k_B T}y^2\right) \times \beta(y)\gamma(y)\left(\frac{m(v - u)^2}{2k_B T}\gamma(y) + 2\tilde{s}^{-1}\frac{8\sqrt{2}}{5P}\mu_0^{H.S.}\Delta_{ik} - \tilde{\eta}^{-1}\sigma_{ik}\right) \right]
\]

\[
\times \left(\delta_{ik}(v - u)^2 + \frac{1}{3}\delta_{ik}(v - u)^2\right) + \frac{m^2}{10(P_{kB}T)^2}(\tilde{\eta}^{-2} - \tilde{\eta}^{-1})^{-1}\left[\left(\tilde{s}^{-1}q_i - \frac{4\sqrt{2}}{5P}\mu_0^{H.S.}Q_i\right)\times \left(\delta_{ik}(v - u)^2 - \frac{5k_B T}{m}\right) + \int_{-1}^{+1} \exp\left(-\frac{m(v - u)^2}{2k_B T}y^2\right) \times \beta(y)\gamma(y)\left(\frac{m(v - u)^2}{2k_B T}\gamma(y) + 2\tilde{s}^{-1}\frac{8\sqrt{2}}{5P}\mu_0^{H.S.}\Delta_{ik} - \tilde{\eta}^{-1}\sigma_{ik}\right) \right]
\]

\[
\times \left(\delta_{ik}(v - u)^2 + \frac{1}{3}\delta_{ik}(v - u)^2\right) + \int_{-1}^{+1} \exp\left(-\frac{m(v - u)^2}{2k_B T}y^2\right) \times \beta(y)\gamma(y)\left(\frac{m(v - u)^2}{2k_B T}\gamma(y) + 2\tilde{s}^{-1}\frac{8\sqrt{2}}{5P}\mu_0^{H.S.}\Delta_{ik} - \tilde{\eta}^{-1}\sigma_{ik}\right) \right]
\]

\[
+ 2\left(\frac{4\sqrt{2}}{5P}\mu_0^{H.S.}\tilde{s}^{-1}Q_i - \tilde{\eta}^{-1}q_i\right)(v - u_i)\left(\delta_{ik}(v - u)^2 - \frac{5k_B T}{m}\right)\right\}. \quad (107)
\]

Thus, the expressions (77), (78), (89), (98), (100) and (107) give distribution functions of the second quasiequilibrium approximation of the second and mixed hydrodynamic chains for Maxwell molecules and hard spheres. They are analogues of ten- and thirteen-moment Grad approximations (38), (42).

The next step is to close the second and mixed hydrodynamic chains by means of the found distribution functions.
6 Closure of the second and mixed hydrodynamic chains

6.1 Second chain, Maxwell molecules

The distribution function of the second quasiequilibrium approximation under fixed $\Delta_{ik}$ for Maxwell molecules (77) presents the simplest example of the closure of the first (47) and second (69) hydrodynamic chains. With the help of it, we obtain from (47) the following transport equations for the moments of the first (local equilibrium) approximation:

\[
\begin{align*}
\partial_t \rho + \partial_i (u_i \rho) &= 0; \\
\rho (\partial_t u_k + u_i \partial_i u_k) + \partial_k P + \partial_i (P^{-1} \mu^\text{M.M.}_0 \Delta_{ik}) &= 0; \\
\frac{3}{2} (\partial_t P + u_i \partial_i P) + \frac{5}{2} P \partial_i u_i + P^{-1} \mu^\text{M.M.}_0 \Delta_{ik} \partial_i u_k &= 0. \\
\end{align*}
\]  

(108)

Now, let us from the scattering rate transport chain (69) find an equation for $\Delta_{ik}$ which closes the system (70). Substituting (77) into (69), we obtain after some computation:

\[
\begin{align*}
\partial_t \Delta_{ik} + \partial_s (u_s \Delta_{ik}) + \Delta_{ks} \partial_s u_k + \Delta_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \Delta_{ls} \partial_s u_l \\
+ P^2 (\mu^\text{M.M.}_0)^{-1} \left( \partial_t u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s \right) \\
+ P (\mu^\text{M.M.}_0)^{-1} \Delta_{ik} + \Delta_{ik} \partial_s u_s &= 0. \\
\end{align*}
\]  

(109)

For comparison, let us give ten-moment Grad equations obtained when closing the chain (46) by the distribution functions (38):

\[
\begin{align*}
\partial_t \rho + \partial_i (u_i \rho) &= 0; \\
\rho (\partial_t u_k + u_i \partial_i u_k) + \partial_k P + \partial_i \sigma_{ik} &= 0; \\
\frac{3}{2} (\partial_t P + u_i \partial_i P) + \frac{5}{2} P \partial_i u_i + \sigma_{ik} \partial_i u_k &= 0; \\
\partial_t \sigma_{ik} + \partial_s (u_s \sigma_{ik}) + P \left( \partial_t u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s \right) \\
+ \sigma_{is} \partial_s u_s + \sigma_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \sigma_{ls} \partial_s u_l + P (\mu^\text{M.M.}_0)^{-1} \sigma_{ik} &= 0. \\
\end{align*}
\]  

(110)

Using the explicit form of $\mu^\text{M.M.}_0 (77)$, it is easy to verify that the transformation (86) maps the systems (108), (109) and (110) into one another. This is a consequence of the degeneration of the mixed hydrodynamic chain which was already discussed. The systems (108), (109) and (110) are essentially equivalent. These specific properties of Maxwell molecules result from the fact that
for them the microscopic densities \((1 - \hat{P}^{(0)})v_iv_k\) and \((1 - \hat{P}^{(0)})v_iv^2\) are eigen functions of the linearized collision integral.

6.2 Second chain, hard spheres

We now turn our attention to the closure of the second and of the mixed hydrodynamic chains for the hard spheres model. Substituting the distribution function (78) into (46) and (69), we obtain an analogue of the systems (108) and (109) (second chain, hard spheres):

\[
\begin{align*}
\partial_t \rho + \partial_i (u_i \rho) &= 0; \\
\rho (\partial_t u_k + u_i \partial_i u_k) + \partial_k P + \tilde{r}s^{-1} \cdot \frac{8\sqrt{2}}{5} \partial_i (\mu_0^{H.S.} P^{-1} \Delta_{ik}) &= 0; \\
\frac{3}{2} (\partial_t P + u_i \partial_i P) + \frac{5}{2} P \partial_i u_i + \tilde{r}s^{-1} \cdot \frac{8\sqrt{2}}{5} \mu_0^{H.S.} P^{-1} \Delta_{ik} \partial_t u_k &= 0; \\
\partial_t \Delta_{ik} + \partial_s (u_s \Delta_{ik}) + \tilde{r}a_1 (\partial_s u_s) \Delta_{ik} + \frac{5\tilde{s}^{-1} P^2}{8\sqrt{2} \mu_0^{H.S.}} \left( \partial_t u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s \right) \\
&+ \tilde{r}(\tilde{a}_1 + \tilde{a}_2) \left( \Delta_{is} \partial_s u_k + \Delta_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \Delta_{is} \partial_s u_t \right) \\
&+ \tilde{r}(\tilde{a}_1 + \tilde{a}_3) \left( \Delta_{is} \partial_t u_k + \Delta_{ks} \partial_t u_i - \frac{2}{3} \delta_{ik} \Delta_{is} \partial_t u_t \right) + (P\tilde{r} \tilde{a}_0 / \mu_0^{H.S.}) \Delta_{ik} = 0.
\end{align*}
\]

The dimensionless parameters \(\tilde{a}_0, \tilde{a}_1, \tilde{a}_2\) and \(\tilde{a}_3\) are determined by the quadratures

\[
\begin{align*}
\tilde{a}_1 &= \frac{1}{16} \int_{-1}^{1} \int_{-1}^{1} \beta(y) \beta(z) \gamma^2(z) \gamma(y) \alpha^{-13/2}(y, z) \\
&\times \{99\gamma(y)\gamma(z)(\gamma(z) - 1) + 18\alpha(y, z)(2\gamma(z)(\gamma(z) - 1) \\
&+ 4\gamma(y)(4\gamma(z) - 3)) + 8\alpha^2(y, z)(4\gamma(z) - 3) \} dydz; \\
\tilde{a}_2 &= \frac{1}{16} \int_{-1}^{1} \int_{-1}^{1} \beta(y) \beta(z) \gamma^2(y) \gamma^2(z) \alpha^{-11/2}(y, z) \{ 63\gamma(y) \gamma(z) \\
&+ 14\alpha(y, z)(3\gamma(y) + 2\gamma(z)) + 24\alpha^2(y, z) \} dydz; \\
\tilde{a}_3 &= \frac{1}{16} \int_{-1}^{1} \int_{-1}^{1} \alpha^{-11/2}(y, z) \beta(y) \beta(z) \gamma(y) \gamma(z) \\
&\times \{ 63\gamma(y) \gamma(z)(\gamma(z) - 1) + 14(2\gamma(z)(\gamma(z) - 1) \\
&+ \gamma(y)(3\gamma(z) - 2))\alpha(y, z) + 8\alpha^2(y, z)(3\gamma(z) - 2) \} dydz; \\
\tilde{a}_0 &\approx \frac{1}{1536\sqrt{2}} \int_{-1}^{1} \int_{-1}^{1} \int_{-1}^{1} \tilde{\psi}(x, y, z) \alpha^{-13/2}(x) \beta(y) \beta(z)
\end{align*}
\]
\[ \times \gamma(x) \gamma(y) \gamma(z) \{ 10395 \gamma(x) \gamma(y) \gamma(z) + 3780 \psi(x, y, z) \] 
\[ \times (\gamma(x) \gamma(y) + \gamma(x) \gamma(z) + \gamma(y) \gamma(z)) + 1680 \psi^2(x, y, z) \] 
\[ \times (\gamma(x) + \gamma(y) + \gamma(z)) + 960 \psi^3(x, y, z) \} \, dx \, dy \, dz; \]
\[ \psi(x, y, z) = 1 + x^2 + y^2 + z^2. \] (114)

Their numerical values are \( \tilde{a}_1 \approx 0.36, \tilde{a}_2 \approx 5.59, \tilde{a}_3 \approx 0.38, \tilde{a}_0 \approx 2.92 \) to second decimal point.

### 6.3 Mixed chain

The closure of the mixed hydrodynamic chain with the functions (89) gives the following modification of the system of equations (113):

\[ \partial_t \rho + \partial_i (u_i \rho) = 0; \]
\[ \rho (\partial_t u_k + u_i \partial_i u_k) + \partial_k P + \partial_i \sigma_{ik} = 0; \]
\[ \frac{3}{2} (\partial_t P + u_i \partial_i P) + \frac{5}{2} P \partial_i u_i + \sigma_{ik} \partial_i u_k = 0; \]
\[ \partial_t \sigma_{ik} + \partial_s (u_s \sigma_{ik}) + P \left( \partial_t u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s \right) \]
\[ + \sigma_{is} \partial_s u_k + \sigma_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \sigma_{ls} \partial_s u_l + \Delta_{ik} = 0; \]
\[ \partial_t \Delta_{ik} + \partial_s (u_s \Delta_{ik}) + \frac{5 P^2}{8 \sqrt{2} \mu_0} \left( \partial_t u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s \right) \]
\[ + \frac{5 P}{4 \sqrt{2} \mu_0} \left( \tilde{a}_1 \frac{1}{2} (\partial_s u_s) \alpha_{ik} \right) \]
\[ + \frac{1}{2} (\tilde{a}_1 + \tilde{a}_2) \left( \alpha_{is} \partial_s u_k + \alpha_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \alpha_{ls} \partial_s u_l \right) \]
\[ + \frac{1}{2} (\tilde{a}_1 + \tilde{a}_3) \left( \alpha_{is} \partial_k u_s + \alpha_{ks} \partial_i u_s - \frac{2}{3} \delta_{ik} \alpha_{ls} \partial_s u_l \right) \]
\[ + \tilde{b}_1 (\partial_s u_s) \beta_{ik} + (\tilde{b}_1 + \tilde{b}_2) \left( \beta_{is} \partial_s u_k + \beta_{ks} \partial_s u_i - \frac{2}{3} \delta_{ik} \beta_{ls} \partial_s u_l \right) \]
\[ + (\tilde{b}_1 + \tilde{b}_2) \left( \beta_{is} \partial_k u_s + \beta_{ks} \partial_i u_s - \frac{2}{3} \delta_{ik} \beta_{ls} \partial_s u_l \right) \}
\[ + \frac{5 P^2}{8 \sqrt{2} (\mu_0 H.S.)^2 (\tilde{s}^2 - \tilde{r}^{-1})} \left\{ \frac{5}{8 \sqrt{2} \tilde{r}} \beta_{ik} + \tilde{a}_0 \alpha_{ik} \right\} = 0; \] (115)

\[ \alpha_{ik} = s^{-1} \sigma_{ik} - \frac{8 \sqrt{2}}{5P} \cdot \mu_0^{H.S.} \Delta_{ik}; \]

\[ \beta_{ik} = s^{-1} \frac{8 \sqrt{2}}{5P} \cdot \mu_0^{H.S.} \Delta_{ik} - \tilde{r}^{-1} \sigma_{ik}. \] (116)

It is clear from the analysis of distribution functions of the second quasiequilibrium approximations of the second hydrodynamic chain that in the Grad
moment method the function $\Phi(c^2)$ is substituted by a constant. Finally, let us note the simplest consequence of the variability of function $\Phi(c^2)$. If $\mu_0$ is multiplied with a small parameter (Knudsen number $Kn$ equal to the ratio of the main free path to the characteristic spatial scale of variations of hydrodynamic values), then the first with respect to $Kn$ approximation of collision stress tensor $\Delta^{(0)}_{ik}$ has the form,

$$\Delta^{(0)}_{ik} = P \left( \partial_i u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u \right)$$

(117)

for Maxwell molecules, and

$$\Delta^{(0)}_{ik} = \frac{5\tilde{r}}{8\sqrt{2s\tilde{a}_0}} P \left( \partial_i u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u \right)$$

(118)

for hard spheres. Substitution of these expressions into the momentum equations results in the Navier-Stokes equations with effective viscosity coefficients $\mu_{\text{eff}}$:

$$\mu_{\text{eff}} = \mu_{\text{M.M.}}^{0}$$

(119)

for Maxwell molecules and

$$\mu_{\text{eff}} = \tilde{a}_0^{-1} \mu_{\text{H.S.}}^{0}$$

(120)

for hard spheres. When using ten-moment Grad approximation which does not distinguish Maxwell molecules and hard spheres, we obtain $\mu_{\text{eff}} = \mu_{\text{H.S.}}^{0}$. Some consequences of this fact are studied below in Sect. 7.

7 Alternative Grad equations and a “new determination of molecular dimensions” (revisited)

7.1 Nonlinear functionals instead of moments in the closure problem

Here we apply the method developed in the previous sections to a classical problem: determination of molecular dimensions (as diameters of equivalent hard spheres) from experimental viscosity data. Scattering rates (moments of collision integral) are treated as new independent variables, and as an alternative to moments of the distribution function, to describe the rarefied gas near local equilibrium. A version of entropy maximum principle is used
to derive the Grad-like description in terms of a finite number of scattering rates. New equations are compared to the Grad moment system in the heat non-conductive case. Estimations for hard spheres demonstrate, in particular, some 10% excess of the viscosity coefficient resulting from the scattering rate description, as compared to the Grad moment estimation. All necessary details of the second chain formalism that are necessary for this example are explained below.

Here we consider a new system of non-hydrodynamic variables, scattering rates $M_Q(f)$:

$$M_{Q_{i_1i_2i_3}}(f) = \int \mu_{i_1i_2i_3} Q(f, f) \, dv;$$

$$\mu_{i_1i_2i_3} = m v_1 i_1 v_2 i_2 v_3 i_3,$$

which, by definition, are the moments of the Boltzmann collision integral $Q(f, f)$:

$$Q(f, f) = \int w(v', v'_1, v, v_1) \{f(v')f(v'_1) - f(v)f(v_1)\} \, dv' \, dv'_1 \, dv_1.$$

Here $w$ is the probability density of a change of the velocities, $(v, v_1) \rightarrow (v', v'_1)$, of the two particles after their encounter, and $w$ is defined by a model of pair interactions. The description in terms of the scattering rates $M_Q$ (121) is alternative to the usually treated description in terms of the moments $M$:

$$M_{i_1i_2i_3}(f) = \int \mu_{i_1i_2i_3} f \, dv.$$

A reason to consider scattering rates instead of the moments is that $M_Q$ (121) reflect features of the interactions because of the $w$ incorporated in their definition, while the moments do not. For this reason we can expect that, in general, a description with a finite number of scattering rates will be more informative than a description provided by the same number of their moment counterparts.

To come to the Grad-like equations in terms of the scattering rates, we have to complete the following two steps: (i) to derive a hierarchy of transport equations for $\rho$, $u$, $P$, and $M_{Q_{i_1i_2i_3}}$ in a neighborhood of the local Maxwell states $f_0(\rho, u, P)$; (ii) to truncate this hierarchy, and to come to a closed set of equations with respect to $\rho$, $u$, $P$, and a finite number of scattering rates.

In the step (i), we derive a description with infinite number of variables, which is formally equivalent both to the Boltzmann equation near the local equilibrium, and to the description with an infinite number of moments. The approximation comes into play in the step (ii) where we reduce the description
to a finite number of variables. The difference between the moment and the alternative description occurs at this point.

The program of two steps, (i) and (ii), is similar to what is done in the Grad method [20], with the only exception (and this is important) that we should always use scattering rates as independent variables and not to expand them into series in moments. Consequently, we use a method of a closure in the step 2 that does not refer to the moment expansions. Major steps of the computation will be presented below.

7.2 Linearization

To complete the step (i), we represent $f$ as $f_0(1 + \varphi)$, where $f_0$ is the local Maxwellian, and we linearize the scattering rates (121) with respect to $\varphi$:

$$\Delta M_{Q_{i_1i_2i_3}}(\varphi) = \int \Delta \mu_{Q_{i_1i_2i_3}} f_0 \varphi \, dv; \quad (122)$$

$$\Delta \mu_{Q_{i_1i_2i_3}} = L_Q(\mu_{i_1i_2i_3}).$$

Here $L_Q$ is the usual linearized collision integral, divided by $f_0$. Though $\Delta M_Q$ are linear in $\varphi$, they are not moments because their microscopic densities, $\Delta \mu_Q$, are not velocity polynomials for a general case of $w$.

It is not difficult to derive the corresponding hierarchy of transport equations for variables $\Delta M_{Q_{i_1i_2i_3}}, \rho, u,$ and $P$ (we refer further to this hierarchy as to the alternative chain): one has to calculate the time derivative of the scattering rates (121) due to the Boltzmann equation, in the linear approximation (122), and to complete the system with the five known balance equations for the hydrodynamic moments (scattering rates of the hydrodynamic moments are equal to zero due to conservation laws). The structure of the alternative chain is quite similar to that of the usual moment transport chain, and for this reason we do not reproduce it here (details of calculations can be found in [45]). One should only keep in mind that the stress tensor and the heat flux vector in the balance equations for $u$ and $P$ are no more independent variables, and they are expressed in terms of $\Delta M_{Q_{i_1i_2i_3}}, \rho, u,$ and $P$.

7.3 Truncating the chain

To truncate the alternative chain (step (ii)), we have, first, to choose a finite set of "essential" scattering rates (122), and, second, to obtain the distribution functions which depend parametrically only on $\rho, u, P$, and on the chosen
set of scattering rates. We will restrict our consideration to a single non-
hydrodynamic variable, $\sigma_{Qij}$, which is the counterpart of the stress tensor $\sigma_{ij}$. 
This choice corresponds to the polynomial $mv_iv_j$ in the expressions (121) and (122), and the resulting equations will be alternative to the 10 moment Grad 
system \(^\text{2}\). For a spherically symmetric interaction, the expression for $\sigma_{Qij}$ may 
be written:

$$
\sigma_{Qij}(\varphi) = \int \Delta\mu_{Qij}f_0\varphi \, dv; \quad (123)
$$

$$
\Delta\mu_{Qij} = L_Q(mv_iv_j) = \frac{P}{\eta_{Q0}(T)}S_Q(c^2) \left\{ c_i c_j - \frac{1}{3}\delta_{ij}c^2 \right\}.
$$

Here $\eta_{Q0}(T)$ is the first Sonine polynomial approximation of the Chapman-
Enskog viscosity coefficient (VC) \(^{[34]}\), and, as usual, $c = \sqrt{\frac{m}{2kT}}(v - u)$. The 
scalar dimensionless function $S_Q$ depends only on $c^2$, and its form depends on 
the choice of interaction $w$.

### 7.4 Entropy maximization

Next, we find the functions

$$
f^\ast(\rho, u, P, \sigma_{Qij}) = f_0(\rho, u, P)(1 + \varphi^\ast(\rho, u, P, \sigma_{Qij}))
$$

which maximize the Boltzmann entropy $S(f)$ in a neighborhood of $f_0$ (the 
quadratic approximation to the entropy is valid within the accuracy of our 
consideration), for fixed values of $\sigma_{Qij}$. That is, $\varphi^\ast$ is a solution to the following 
conditional variational problem:

$$
\Delta S(\varphi) = -\frac{k_B}{2} \int f_0\varphi^2 \, dv \rightarrow \max, \quad (124)
$$

i) $\int \Delta\mu_{Qij}f_0\varphi \, dv = \sigma_{Qij}; \quad$ ii) $\int \left\{ 1, v, v^2 \right\} f_0\varphi \, dv = 0.$

The second (homogeneous) condition in (124) reflects that a deviation $\varphi$ from 
the state $f_0$ is due only to non-hydrodynamic degrees of freedom, and it is 
straightforwardly satisfied for $\Delta\mu_{Qij}$ (123).

Notice, that if we turn to the usual moment description, then condition (i) 
in (124) would fix the stress tensor $\sigma_{ij}$ instead of its scattering counterpart

\(^{[38]}\) To get the alternative to the 13 moment Grad equations, one should take into 
account the scattering counterpart of the heat flux, $q_{Qi} = m \int v_i \frac{v}{T}Q(f, f) \, dv$. 

38
σ_{Q,ij}. Then the resulting function \( f^*(\rho, u, P, \sigma_{ij}) \) will be exactly the 10 moment Grad approximation. It can be shown that a choice of any finite set of higher moments as the constraint (i) in (124) results in the corresponding Grad approximation. In that sense our method of constructing \( f^* \) is a direct generalization of the Grad method onto the alternative description.

The Lagrange multipliers method gives straightforwardly the solution to the problem (124). After the alternative chain is closed with the functions \( f^*(\rho, u, P, \sigma_{Q,ij}) \), the step (ii) is completed, and we arrive at a set of equations with respect to the variables \( \rho, u, P, \) and \( \sigma_{Q,ij} \). Switching to the variables \( \zeta_{ij} = n^{-1} \sigma_{Q,ij} \), we have:

\[
\frac{\partial_t n + \partial_i (nu_i)}{n} = 0; \quad (125) \\
\rho(\partial_t u_k + u_i \partial_i u_k) + \partial_k P + \rho \left\{ \frac{\eta_{Q_0}(T)n}{2r_Q P} \zeta_{ik} \right\} = 0; \quad (126) \\
\frac{3}{2} (\partial_k P + u_i \partial_i P) + \frac{5}{2} P \partial_i u_i + \left\{ \frac{\eta_{Q_0}(T)n}{2r_Q P} \zeta_{ik} \right\} \partial_i u_k = 0; \quad (127) \\
\partial_i \zeta_{ik} + \partial_s (u_s \zeta_{ik}) + \{ \zeta_{ks} \partial_s u_i + \zeta_{is} \partial_s u_k - \frac{2}{3} \delta_{ik} \zeta_{rs} \partial_s u_r \} \\
+ \left\{ \frac{\gamma - \frac{2\beta_Q}{r_Q}}{r_Q} \right\} \zeta_{ik} \partial_s u_s - \frac{P^2}{\eta_{Q_0}(T)n} (\partial_i u_k + \partial_k u_i - \frac{2}{3} \delta_{ik} \partial_s u_s) \\
- \frac{\alpha_Q P}{r_Q \eta_{Q_0}(T)} \zeta_{ik} = 0. \quad (128)
\]

Here \( \partial_t = \partial/\partial t, \partial_i = \partial/\partial x_i \), summation in two repeated indices is assumed, and the coefficients \( r_Q, \beta_Q, \) and \( \alpha_Q \) are defined with the help of the function \( S_Q \) (123) as follows:

\[
r_Q = \frac{8}{15\sqrt{\pi}} \int_0^{\infty} e^{-c^2} c^6 \left( S_Q(c^2) \right)^2 dc; \\
\beta_Q = \frac{8}{15\sqrt{\pi}} \int_0^{\infty} e^{-c^2} c^6 S_Q(c^2) \frac{dS_Q(c^2)}{dc} dc; \\
\alpha_Q = \frac{8}{15\sqrt{\pi}} \int_0^{\infty} e^{-c^2} c^6 S_Q(c^2) R_Q(c^2) dc. \quad (129)
\]

The function \( R_Q(c^2) \) in the last expression is defined due to the action of the operator \( L_Q \) on the function \( S_Q(c^2)(c_i c_j - \frac{1}{3} \delta_{ij} c^2) \):

\[
\frac{P}{\eta_{Q_0}} R_Q(c^2)(c_i c_j - \frac{1}{3} \delta_{ij} c^2) = L_Q(S_Q(c^2)(c_i c_j - \frac{1}{3} \delta_{ij} c^2)). \quad (130)
\]
Finally, the parameter $\gamma_Q$ in (125-129) reflects the temperature dependence of the VC:

$$\gamma_Q = \frac{2}{3} \left(1 - \frac{T}{\eta_Q(T)} \left(\frac{d\eta_Q(T)}{dT}\right)\right).$$

The set of ten equations (125-129) is alternative to the 10 moment Grad equations.

7.5 A new determination of molecular dimensions (revisited)

The observation already made is that for Maxwell molecules we have: $S_{M.M.} \equiv 1$, and $\eta_{0M.M.} \propto T$; thus $\gamma_{M.M.} = \beta_{M.M.} = 0$, $r_{M.M.} = \alpha_{M.M.} = \frac{1}{2}$, and (125-129) becomes the 10 moment Grad system under a simple change of variables $\lambda \zeta_{ij} = \sigma_{ij}$, where $\lambda$ is the proportionality coefficient in the temperature dependence of $\eta_{0M.M.}$.

These properties (the function $S_Q$ is a constant, and the VC is proportional to $T$) are true only for Maxwell molecules. For all other interactions, the function $S_Q$ is not identical to one, and the VC $\eta_Q(T)$ is not proportional to $T$. Thus, the shortened alternative description is not equivalent indeed to the Grad moment description. In particular, for hard spheres, the exact expression for the function $S^{H.S.}$ (123) reads:

$$S^{H.S.} = \frac{5\sqrt{2}}{16} \int_0^1 \exp\left(-c^2t^2\right)(1-t^4)\left(c^2(1-t^2) + 2\right) dt; \quad (131)$$

$$\tilde{\eta}_0^{H.S.} \propto \sqrt{T}.$$  

Thus, $\gamma^{H.S.} = \frac{1}{2}$, and $\beta^{H.S.} \approx 0.07$, and the equation for the function $\zeta_{ik}$ (129) contains a nonlinear term,

$$\theta^{H.S.}\zeta_{ik}\partial_s u_s; \quad (132)$$

where $\theta^{H.S.} \approx 0.19$. This term is missing in the Grad 10 moment equation.

Finally, let us evaluate the VC which results from the alternative description (125-129). Following Grad’s arguments [20], we see that, if the relaxation of $\zeta_{ik}$ is fast compared to the hydrodynamic variables, then the two last terms in the equation for $\zeta_{ik}$ (125-129) become dominant, and the equation for $u$ casts...
Fig. 3. Approximations for hard spheres: bold line – function $S^{H.S.}$, solid line – approximation $S_a^{H.S.}$, dotted line – Grad moment approximation.

into the standard Navier-Stokes form with an effective VC $\eta_{Q eff}$:

$$\eta_{Q eff} = \frac{1}{2\alpha_Q} \eta_{Q0}. \quad (133)$$

For Maxwell molecules, we easily derive that the coefficient $\alpha_Q$ in (133) is equal to $\frac{1}{2}$. Thus, as one expects, the effective VC (133) is equal to the Grad value, which, in turn, is equal to the exact value in the frames of the Chapman–Enskog method for this model.

For all interactions different from the Maxwell molecules, the VC $\eta_{Q eff}$ (133) is not equal to $\eta_{Q0}$. For hard spheres, in particular, a computation of the VC (133) requires information about the function $R^{H.S.}$ (130). This is achieved upon a substitution of the function $S^{H.S.}$ (131) into (130). Further, we have to compute the action of the operator $L^{H.S.}$ on the function $S^{H.S.}(c_i c_j - \frac{1}{3} \delta_{ij} c^2)$, which is rather complicated. However, the VC $\eta_{H.S.}^{Q eff}$ can be relatively easily estimated by using a function $S_a^{H.S.} = \frac{1}{\sqrt{2}}(1 + \frac{1}{3} c^2)$, instead of the function $S^{H.S.}$, in (130). Indeed, the function $S_a^{H.S.}$ is tangent to the function $S^{H.S.}$ at $c^2 = 0$, and is its majorant (see Fig. 3). Substituting $S_a^{H.S.}$ into (130), and computing the action of the collision integral, we find the approximation $R_a^{H.S.}$; thereafter we evaluate the integral $\alpha^{H.S.}$ (129), and finally come to the following expression:

$$\eta_{H.S.}^{Q eff} \geq \frac{75264}{67237} \eta_0^{H.S.} \approx 1.12 \eta_0^{H.S.}. \quad (134)$$

Thus, for hard spheres, the description in terms of scattering rates results in the VC of more than 10% higher than in the Grad moment description.

A discussion of the results concerns the following two items.
Table 1
Three virial coefficients: experimental $B_{\text{exp}}$, classical $B_0$ [46], and reduced $B_{\text{eff}}$ for three gases at $T = 500K$

|       | $B_{\text{exp}}$ | $B_0$  | $B_{\text{eff}}$ |
|-------|------------------|--------|------------------|
| Argon | 8.4              | 60.9   | 50.5             |
| Helium| 10.8             | 21.9   | 18.2             |
| Nitrogen | 168             | 66.5   | 55.2             |

1. Having two not equivalent descriptions which were obtained within one method, we may ask: which is more relevant? A simple test is to compare characteristic times of an approach to hydrodynamic regime. We have $\tau_G \sim \eta_0^{\text{H.S.}}/P$ for 10-moment description, and $\tau_a \sim \eta_{\text{eff}}^{\text{H.S.}}/P$ for alternative description. As $\tau_a > \tau_G$, we see that scattering rate decay slower than corresponding moment, hence, at least for rigid spheres, the alternative description is more relevant. For Maxwell molecules both the descriptions are, of course, equivalent.

2. The VC $\eta_{\text{eff}}^{\text{H.S.}}$ (134) has the same temperature dependence as $\eta_0^{\text{H.S.}}$, and also the same dependence on a scaling parameter (a diameter of the sphere). In the classical book [34] (pp. 228-229), “sizes” of molecules are presented, assuming that a molecule is represented with an equivalent sphere and VC is estimated as $\eta_0^{\text{H.S.}}$. Since our estimation of VC differs only by a dimensionless factor from $\eta_0^{\text{H.S.}}$, it is straightforward to conclude that effective sizes of molecules will be reduced by the factor $b$, where

$$b = \sqrt{\eta_0^{\text{H.S.}}/\eta_{\text{eff}}^{\text{H.S.}}} \approx 0.94.$$ 

Further, it is well known that sizes of molecules estimated via viscosity in [34] disagree with the estimation via the virial expansion of the equation of state. In particular, in book [46], p. 5, the measured second virial coefficient $B_{\text{exp}}$ was compared with the calculated $B_0$, in which the diameter of the sphere was taken from the viscosity data. The reduction of the diameter by factor $b$ gives $B_{\text{eff}} = b^3 B_0$. The values $B_{\text{exp}}$ and $B_0$ [46] are compared with $B_{\text{eff}}$ in the Table 1 for three gases at $T = 500K$. The results for argon and helium are better for $B_{\text{eff}}$, while for nitrogen $B_{\text{eff}}$ is worth than $B_0$. However, both $B_0$ and $B_{\text{eff}}$ are far from the experimental values.

Hard spheres is, of course, an oversimplified model of interaction, and the comparison presented does not allow for a decision between $\eta_0^{\text{H.S.}}$ and $\eta_{\text{eff}}^{\text{H.S.}}$. However, this simple example illustrates to what extend the correction to the VC can affect a comparison with experiment. Indeed, as it is well known, the first-order Sonine polynomial computation for the Lennard-Jones (LJ) potential gives a very good fit of the temperature dependence of the VC for all noble gases [47], subject to a proper choice of the two unknown scaling pa-
rameters of the LJ potential. We may expect that a dimensionless correction of the VC for the LJ potential might be of the same order as above for rigid spheres. However, the functional character of the temperature dependence will not be affected, and a fit will be obtained subject to a different choice of the molecular parameters of the LJ potential. The five-parametric family of pair potentials was discussed in Ref. [48]. These five constants for each pair potential have been determined by a fit to experimental data with some additional input from theory. After that, the Chapman–Enskog formulas for the second virial coefficient and main transport coefficients give satisfactory description of experimental data [48]. Such a semiempirical approach that combines fitting with kinetic theory might be very successful in experimental data description, but does not allow us to make a choice between hierarchies. This choice requires less flexibility in the potential construction. The best solution here is independent determination of the interaction potential without references to transport coefficients or thermodynamic data.

Appendix: Formulas of the second quasiequilibrium approximation of the second and mixed hydrodynamic chains for Maxwell molecules and hard spheres

Let us write \( \nu_{Qik} \) (71) in the standard form:

\[
\nu_{Qik} = \int f^{(0)} |v_1 - v| \left((v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik}(v - u)^2\right) b \, db \, d\epsilon \, dv_1,
\]

(135)

where \( b \) is the impact parameter, \( \epsilon \) is the angle between the plane containing the trajectory of the particle being scattered in the system of the center of mass and the plane containing the entering asymptote, the trajectory, and a certain fixed direction. It is convenient to switch to the dimensionless velocity \( c \):

\[
c_i = \left(\frac{m}{2k_B T}\right)^{1/2} (v_i - u_i)
\]

(136)

and to the dimensionless relative velocity \( g \):

\[
g_i = \frac{1}{2} \left(\frac{m}{k_B T}\right)^{1/2} (v_{1i} - u_i)
\]

(137)

\[^{3}\text{A comparison of molecular parameters of the LJ potential, as derived from the viscosity data, to those obtained from independent sources, can be found elsewhere, e.g. in [34], p. 237.}\]
After standard transformations and integration with respect to \( \epsilon \) (see [34]) we obtain in (136)

\[
\nu_{Qik} = \frac{3P}{m \pi^{1/2}} \times \int \exp(-c_1^2) \varphi_1^{(2)}(g) \left( (c_{1i} - c_i)(c_{1k} - c_k) - \frac{1}{3} \delta_{ik}(c_1 - c)^2 \right) \, dc_1.
\]  

Here

\[
\varphi_1^{(2)} = \int (1 - \cos^2 \chi) \left| v_1 - v \right| b(\chi) \left| \frac{db}{d\chi} \right| d\chi,
\]  

and \( \chi \) is an angle between the vectors \( g \) and \( g' \).

The dependence of \( \varphi_1^{(2)} \) on the vector \( g \) is determined by the choice of the model of particle’s interaction.

For Maxwell molecules,

\[
\varphi_1^{(2)} = \left( \frac{2\kappa}{m} \right)^{1/2} A_2(5),
\]  

where \( \kappa \) is a force constant, \( A_2(5) \) is a number, \( A_2(5) \approx 0.436 \).

For the model of hard spheres

\[
\varphi_1^{(2)} = \frac{\sqrt{2}\sigma^2}{3} \left( \frac{k_B T}{m} \right)^{1/2} \left| c_1 - c \right|,
\]  

where \( \sigma \) is diameter of the sphere modelling the particle.

Substituting (140) and (141) into (139), we transform the latter to the form:

for Maxwell molecules

\[
\nu_{Qik} = \frac{3P}{4m} \left( \frac{2\kappa}{\pi m} \right)^{1/2} A_2(5) \exp(-c^2) \left( \frac{\partial}{\partial c_i} \frac{\partial}{\partial c_k} - \frac{1}{3} \delta_{ik} \frac{\partial}{\partial c_s} \frac{\partial}{\partial c_s} \right) T^{M.M.}(c^2);
\]

\[
T^{M.M.}(c^2) = \int \exp(-x^2 - 2x_k c_k) \, dx;
\]  

for hard spheres

44
\[ \nu_{Qik} = \frac{P \sigma^2}{2\sqrt{\pi m}} \left( \frac{k_B T}{\pi m} \right)^{1/2} \exp(-c^2) \left( \frac{\partial}{\partial c_i} \frac{\partial}{\partial c_k} - \frac{1}{3} \delta_{ik} \frac{\partial}{\partial s} \frac{\partial}{\partial c_s} \right) T^{\text{H.S.}}(c^2); \]

\[ T^{\text{H.S.}}(c^2) = \int |\mathbf{x}| \exp(-x^2 - 2x_k c_k) \, d\mathbf{x}. \quad (143) \]

It is an easy matter to perform integration in (142), the integral is equal to \( \pi^{3/2} e^{-c^2} \).

Therefore for Maxwell molecules,

\[ \nu_{Qik} = \frac{3}{2} \pi \left( \frac{2 \kappa}{m} \right)^{1/2} A_2(5) \left( (v_i - u_i)(v_k - u_k) - \frac{1}{3} \delta_{ik} (\mathbf{v} - \mathbf{u})^2 \right). \quad (144) \]

The integral \( T^{\text{H.S.}} \) in (143) can be transformed as follows:

\[ T^{\text{H.S.}}(c^2) = 2\pi + \pi \int_{-1}^{+1} \exp(c^2(1 - y^2)) c^2(1 + y^2) \, dy. \quad (145) \]

Then for the model of hard spheres,

\[ \nu_{Qik} = \sqrt{2\pi n} \sigma^2 \left( \frac{k_B T}{m} \right)^{3/2} \left( c_i c_k - \frac{1}{3} \delta_{ik} c^2 \right) \times \int_{-1}^{+1} \exp(-c^2 y^2)(1 + y^2)(1 - y^2)(c^2(1 - y^2) + 2) \, dy. \quad (146) \]

Let us note a useful relationship:

\[ d^n T^{\text{H.S.}}/d(c^2)^n = \pi \int_{-1}^{+1} \exp(c^2(1 - y^2)) \times (1 + y^2)(1 - y^2)^n - (c^2(1 - y^2) + n) \, dy, n \geq 1. \quad (147) \]

Use the expressions for the viscosity coefficient \( \mu_0 \) which are obtained in the first approximation of the Chapman–Enskog method:

for Maxwell molecules,

\[ \mu_0^{\text{M.M.}} = \left( \frac{2m}{\kappa} \right)^{1/2} \frac{k_B T}{3\pi A_2(5)}, \quad (148) \]
for hard spheres,
\[ \mu_{0}^{\text{H.S.}} = \frac{5(k_{B}Tm)^{1/2}}{16\pi^{1/2}\sigma^{2}}. \] (149)

Transformation of (144), (146) to the form of (74) gives the following functions \( \Phi((v - u)^2) \):

for Maxwell molecules,
\[ \Phi = \frac{P}{\mu_{0}^{\text{M.M.}}}; \] (150)

for hard spheres
\[ \Phi = \frac{5P}{16\sqrt{2}\mu_{0}^{\text{H.S.}}} \int_{-1}^{1} \exp \left( \frac{-m(v - u)^2}{2k_{B}T}y^2 \right) \times (1 + y^2)(1 - y^2) \left( \frac{m(v - u)^2}{2k_{B}T}(1 - y^2) + 2 \right) dy. \] (151)

The parameter \( r \) from (75) is:

for Maxwell molecules:
\[ r = \left( m\mu_{0}^{\text{M.M.}} \right)^2 / (2P^3k_{B}T); \] (152)

for hard spheres:
\[ r = \tilde{r} \frac{64 \left( m\mu_{0}^{\text{M.M.}} \right)^2}{25P^3k_{B}T}. \] (153)

The dimensionless parameter \( \tilde{r} \) is represented as follows:
\[ \tilde{r}^{-1} = \frac{1}{16} \int \int_{-1}^{1} \alpha^{-11/2}\beta(y)\beta(z)\gamma(y)\gamma(z) \times (16\alpha^2 + 28\alpha(\gamma(y) + \gamma(z)) + 63\gamma(y)\gamma(z)) dy \, dz. \] (154)

Here and below the following notations are used:
\[ \beta(y) = 1 + y^2, \quad \gamma(y) = 1 - y^2, \quad \alpha = 1 + y^2 + z^2. \] (155)
Numerical value of $\tilde{r}^{-1}$ is 5.212 to third decimal point.

The parameter (83) is:

for Maxwell molecules

$$s^{-1} = \left(2P^2k_BT\right)/\left(m^2\mu_0^{\text{M.M.}}\right); \quad (156)$$

for hard spheres

$$s^{-1} = \tilde{s}^{-1}5\sqrt{2}P^2k_BT \quad \frac{8m^2\mu_0^{\text{H.S.}}}{.} \quad (157)$$

The dimensionless parameter $\tilde{s}^{-1}$ is of the form

$$\tilde{s}^{-1} = \int_{-1}^{+1} \gamma(y)\beta^{-7/2}(y)\left(\beta(y) + \frac{7}{4}\gamma(y)\right) \, dy. \quad (158)$$

Numerical value of $\tilde{s}^{-1}$ is 1.115 to third decimal point.

The scattering rate density (90) is of the form,

$$\xi_{Qi} = \sqrt{2}\left(\frac{k_BT}{m}\right)^{3/2} \int f^{(0)}(v_1) \mid v_1 - v \mid \left\{c_i\left(c^2 - \frac{5}{2}\right)\right\} b \, db \, d\epsilon \, d\epsilon v_1. \quad (159)$$

Standard transformation of the expression $\{c_i(c^2 - 5/2)\}$ and integration with respect to $\epsilon$ change (159) to the form,

$$\xi_{Qi} = \frac{P}{\sqrt{2\pi m}} \int \exp(-c_1^2)\varphi_1^{(2)}(3c_1^2 - c^2)(c_{1i} - c_i) - (c_1 - c)^2(c_{1i} + c_i) \, dc_1. \quad (160)$$

Further, using the expressions (140) and (141) for $\varphi_1^{(2)}$, we obtain:

for Maxwell molecules:

$$\xi_{Qi} = \frac{P}{m^2} \left(\frac{nk_BT}{\pi}\right)^{1/2} A_2(5) \exp(-c^2) \dot{D}_i T^{\text{M.M.}}(c^2); \quad (161)$$
for hard spheres:

$$\xi_{Qi} = \frac{P k_B T \sigma^2}{\sqrt{\pi} m^2} \exp(-c^2) \hat{D}_i T^{H.S.}(c^2).$$ (162)

The operator $\hat{D}_i$ is of the form

$$\frac{1}{4} \frac{\partial}{\partial c_i} \frac{\partial}{\partial c_s} \frac{\partial}{\partial c_s} + \frac{3}{2} c_i \frac{\partial}{\partial c_s} \frac{\partial}{\partial c_i} - \frac{1}{2} c_i \frac{\partial}{\partial c_s} \frac{\partial}{\partial c_s}. \quad (163)$$

The operator $\hat{D}_i$ acts on the function $\psi(c^2)$ as follows:

$$\frac{d^2 \psi}{d(c^2)^2} 2c_i \left( c^2 - \frac{5}{2} \right) + c_i c^2 \left( \frac{d^2 \psi}{d(c^2)^2} - \frac{d^3 \psi}{d(c^2)^3} \right). \quad (164)$$

From (161), (162) we obtain:

for Maxwell molecules:

$$\xi_{Qi} = \frac{P}{3 \mu^0_{\text{M.M.}}} (v_i - u_i) \left( (v - u)^2 - \frac{5k_B T}{m} \right); \quad (165)$$

for hard spheres:

$$\xi_{Qi} = \frac{5P}{16 \sqrt{2} \mu^0_{\text{H.S.}}} \left\{ (v_i - u_i) \left( (v - u)^2 - \frac{5k_B T}{m} \right) \right. \quad (166)$$

$$\left. \times \int_{-1}^{+1} \exp \left( - \frac{m(v - u)^2}{2k_B T} y^2 \right) \beta(y) \gamma(y) \left( \frac{m(v - u)^2}{2k_B T} \gamma(y) + 2 \right) dy \right. \left. + (v_i - u_i)(v - u)^2 \right. \quad$$

$$\left. \times \int_{-1}^{+1} \exp \left( - \frac{m(v - u)^2}{2k_B T} y^2 \right) \beta(y) \gamma(y) \left( \sigma(y) \frac{m(v - u)^2}{2k_B T} + \delta(y) \right) dy \right\}. \quad$$

The functions $\sigma(y), \delta(y)$ are of the form

$$\sigma(y) = y^2(1 - y^2), \quad \delta(y) = 3y^2 - 1. \quad (167)$$

The parameter $\eta$ from (96) is:
for Maxwell molecules:
\[ \eta = \frac{9m^3 (\mu_{0\text{M.M.}})^2}{10P^3(k_B T)^2}; \]  
(168)

for hard spheres:
\[ \eta = \tilde{\eta} \frac{64m^3 (\mu_{0\text{H.S.}})^2}{125P^3(k_B T)^2}. \]  
(169)

The dimensionless parameter \( \tilde{\eta} \) is of the form

\[
\tilde{\eta}^{-1} = \int_{-1}^{+1} \int_{-1}^{+1} \beta(y) \beta(z) \gamma(y) \gamma(z) \alpha^{-13/2} \left\{ \frac{639}{32} (\gamma(y) \gamma(z) + \sigma(y) \sigma(z) \\
+ \sigma(y) \gamma(z) + \sigma(z) \gamma(y) + \frac{63}{16} \alpha (2\gamma(y) + 2\gamma(z) - 5\gamma(y) \gamma(z) \\
+ 2(\sigma(y) + \sigma(z)) + \gamma(z) \delta(y) + \gamma(y) \delta(z) + \sigma(y) \delta(z) + \sigma(z) \delta(y) \\
+ \frac{7}{8} \alpha^2 (4 - 10\gamma(y) - 10\gamma(z)) + \frac{25}{4} \gamma(y) \gamma(z) + 2\delta(y) \\
+ 2\delta(z) - 5\sigma(y) - 5\sigma(z) - \frac{5}{2} (\gamma(z) \delta(y) + \gamma(y) \delta(z) + \delta(y) \delta(z)) \\
+ \frac{1}{4} \alpha^3 ( -20 + \frac{25}{4} (\gamma(y) + \gamma(z)) - 5(\delta(y) + \delta(z))) + \frac{5}{2} \alpha^4 \right\} dy \, dz.
\]  
(170)

Numerical value of \( \tilde{\eta}^{-1} \) is 0.622 to second decimal point.

Finally, from (165), (167) we obtain \( \tau^{-1}(103) \):

for Maxwell molecules
\[ \tau^{-1} = \frac{5(Pk_B T)^2}{3\mu_0^{\text{M.M.}} m^4}; \]  
(171)

for hard spheres
\[
\tau^{-1} = \tilde{\tau}^{-1} \frac{25P^2(k_B T)^2}{8\sqrt{2}m^3 \mu_0^{\text{H.S.}}};
\]
\[
\tilde{\tau}^{-1} = \frac{1}{8} \int_{-1}^{+1} \beta^{-9/2}(y) \gamma(y) \left\{ 63(\gamma(y) + \sigma(y)) \\
+ 7\beta(y)(4 - 10\gamma(y) + 2\delta(y) - 5\sigma(y)) + 20\beta^3(y) \right\} dy.
\]
\[ + \beta^2(y)(25\gamma(y) - 10\delta(y) - 40) \} \, dy \approx 4.322. \]  

(172)

8 Conclusion and outlook

We developed the Triangle Entropy Method (TEM) for model reduction and demonstrated how it works for the Boltzmann equation. Moments of the Boltzmann collision integral, or scattering rates are treated as independent variables rather than as infinite moment series. Three classes of reduced models are constructed. The models of the first class involve only moments of distribution functions, and coincide with those of the Grad method in the Maximum Entropy version. The models of the second type involves only scattering rates. Finally, the mixed description models involve both the moments and the scattering rates. TEM allows us to obtain all the closure formulas in explicit form, not only for the Maxwell molecules (as it is usual), but for hard spheres also. We found the new Boltzmann–kinetics estimations for the equivalent hard spheres radius for gases.

The main benefits from TEM are:

1. It constructs the closure as a solution of linear equations, and, therefore, often gives it in an explicit form;
2. It provides the thermodynamic properties of reduced models, at least, locally;
3. It admits nonlinear functionals as macroscopic variables, this possibility is important for creation of non-equilibrium thermodynamics of non-linear fluxes, reaction rates, scattering rates, etc.

The following fields for future TEM applications are important:

- Modelling of nonequilibrium processes in gases (Boltzmann kinetics and its generalisations);
- Chemical kinetics models with reaction rates as independent variables;
- Kinetics of complex media (non-Newtonian liquids, polymers, etc.) with the Fokker–Planck equation as the basic kinetic description.

Of course, TEM is a new computational version of the entropy maximum method (MaxEnt) that is in wide use in the Extended irreversible thermodynamics (EIT) [44] after works of Jaynes [3], Kogan and Rosonoer [5,6,7] and Lewis [8].

MaxEnt methods obtain the second wind because the high interest to non-classical nonextensive entropies [49,50]. In this sense, the Fokker–Plank equation seems to be a very attractive example for MaxEnt method application,
and, in particular, for the application of TEM. This classical equation admits a broad class of Lyapunov functions, including nonextensive entropies.

The Fokker–Planck equation (FPE) is a familiar model in various problems of nonequilibrium statistical physics. We consider the FPE of the form

$$\frac{\partial W(x,t)}{\partial t} = \frac{\partial}{\partial x} \left\{ D \left[ W \frac{\partial}{\partial x} U + \frac{\partial}{\partial x} W \right] \right\}. \tag{173}$$

Here, $W(x,t)$ is the probability density over the configuration space $x$ at time $t$, while $U(x)$ and $D(x)$ are the potential and the positively semi-definite ($\langle y, D y \rangle \geq 0$) diffusion matrix.

It is known that for the Boltzmann equation there exists only one universal Lyapunov functional: the entropy (we do not distinguish functionals which are related to each other by monotonic transformations). For the FPE there exists a whole family of universal Lyapunov functionals. Let $h(a)$ be a convex function of one variable $a \geq 0$, $h''(a) > 0$,

$$S_h[W] = -\int W_{eq}(x) h \left[ \frac{W(x,t)}{W_{eq}(x)} \right] dx. \tag{174}$$

The density of production of the generalized entropy $S_h$, $\sigma_h$, is nonnegative:

$$\sigma_h(x) = W_{eq}(x) h'' \left[ \frac{W(x,t)}{W_{eq}(x)} \right] \left( \frac{\partial}{\partial x} \frac{W(x,t)}{W_{eq}(x)}, D \frac{\partial}{\partial x} \frac{W(x,t)}{W_{eq}(x)} \right) \geq 0. \tag{175}$$

The most important variants for the choice of $h$ are:

- $h(a) = a \ln a$, and $S_h$ is the Boltzmann–Gibbs–Shannon entropy (in the Kullback form [51,52]),
- $h(a) = a \ln a - \epsilon \ln a$, $\epsilon > 0$, and $S^\epsilon_h$ is the maximal family of additive entropies [53,54,55] (these entropies are additive for the composition of independent subsystems).
- $h(a) = \frac{1-a^q}{1-a}$, and $S^q_h$ is the family of Tsallis entropies [49,50]. These entropies are not additive, but become additive after a nonlinear monotonous transformation. This property can serve as a definition of the Tsallis entropies in the class of generalized entropies (174) [55].

The MaxEnt closure approximations for the Fokker–Planck equation are developed for the classical Boltzmann–Gibbs–Shannon entropy in the Kullback form and standard linear functionals (moments) as macroscopic variables [52,27,28]. Now we are in position to develop the whole family of approximation in explicit form (due to TEM), for classical and non-classical entropies, for linear and non-linear macroscopic variables.
The crucial question is: where to stop? Is it possible to decide, is this particular model from the hierarchy sufficiently accurate, or we need to go ahead? Without criteria for such a decision we have infinite number of theories.

The residual estimates are possible: we can estimate the defect of invariance (see Fig. 1). If it is too big (in comparison with the full right hand side $J$), then we should switch to the next system of hierarchy. If it vanishes, we could try the previous system. Normally, it is impossible to find one reduced model for all regimes, but it is possible to change the model during simulation.

There exists one more benefit from the hierarchy. For each model we have a correspondent approximate slow invariant manifold $\Omega_i$, and a vector field of reduced dynamics $J_i$ which is defined at points from $\Omega_i$ and is tangent to this manifold. This structure gives a possibility to estimate not the whole defect of invariance, but a “partial defect” $\Delta_i = J_{i+1} - J_i$. Usually it is sufficient to estimate this partial defect of invariance, that is, to check whether the current model is the approximate slow invariant manifold for the next model up to desired accuracy. Examples of these estimates and applications are presented in Refs. [16,17,30,39]. We propose to use the flexible technology of modeling with adaptive choice of the model from hierarchy. This approach could be discussed as intermediate one between the classical one–model calculations and the equation–free approach [57], for example.

We construct the quasiequilibrium hierarchy of models for a system with entropy growth. These systems relax to equilibrium points. But most interesting application is modeling of open systems. It is possible to use obtained hierarchy of models for open systems just by adding flows under the assumption that the fast motion and slow manifold do not change due to the system opening. For example, we usually use the Navier–Stokes equation for systems with external flows that do not relax to equilibrium. If the external flows are fast and the perturbation of slow manifold is significant, then the correspondent perturbation theory [16,17] modifies the model for open system.

The inertial manifold [14,58,59] is the manifold where the limit behaviour of the system is located; it exponentially attracts motions when $t \to \infty$. For a closed system the equilibrium (one point) is already the inertial manifold. In the theory of inertial manifolds the estimates of inertial manifolds dimension for several classes of (open) systems are created and finiteness of this dimension is proved. Inertial manifolds could be considered as the lowest level of any hierarchy of slow manifolds. They belong to all the slow invariant manifolds of the hierarchy. In our construction we build the hierarchy of infinite–dimensional approximate slow manifolds for the Boltzmann equation and do not try to find the smallest invariant manifolds for open systems.

And, finally, we should ask the question: what chain is better, could we prove
that the second hierarchy with scattering rates instead of usual moments is better than the standard Grad hierarchy? We cannot prove this exactly, but can only argue plausibly that the second hierarchy should lead to dynamic invariance faster, than the first one, and support this point of view by examples.
