Abstract

Background: The spread of Neisseria gonorrhoeae (Ng) isolates resistant to the clinically implemented antibiotics is challenging the efficacy of treatments. Unfortunately, phenotypic and molecular data regarding Ng detected in Switzerland are scarce.

Methods: We compared the characteristics of Ng detected during 1998–2001 (n = 26) to those detected during 2009–2012 (n = 34). MICs were obtained with the Etest and interpreted as non-susceptible (non-S) according to EUCAST criteria. Sequence type (ST) was achieved implementing the NG-MAST. BlaTEM, pona, penA, mtrR, penB, tet (M), gyrA, parC, mefA, ermA/B/C/F, rplD, rplV, and 23S rRNA genes were analyzed.

Results: The following susceptibility results were obtained (period: % of non-S, MIC90 in mg/L): penicillin (1998–2001: 42.3%, 3; 2009–2012: 85.3%, 16), cefixime (1998–2001: 0%, ≤0.016; 2009–2012: 8.8%, 0.125), ceftriaxone (1998–2001: 0%, 0.004; 2009–2012: 0%, 0.047), ciprofloxacin (1998–2001: 7.7%, 0.006; 2009–2012: 73.5%, ≥32), azithromycin (1998–2001: 11.5%, 0.25; 2009–2012: 23.6%, 0.38), tetracycline (1998–2001: 65.4%, 12; 2009–2012: 88.2%, 24), spectinomycin (1998–2001: 0%, 12; 2009–2012: 0%, 8). The prevalence of multidrug-resistant (MDR) isolates increased from 7.7% in 1998–2001 to 70.6% in 2009–2012. International STs and genogroups (G) emerged during 2009–2012 (G1407, 29.4%; G2992, 11.7%; G225, 8.8%). These isolates possessed distinctive mechanisms of resistance (e.g., G1407: PBP1 with L421, PBP2 pattern XXXIV, GyrA with S91F and D95G, ParC with S87R, PorB with G120K and A121N, mtrR promoter with A deletion).

Conclusions: The prevalence of penicillin- ciprofloxacin- and tetracycline-resistant Ng has reached dramatic levels, whereas cefixime and ceftriaxone show MICs that tend to increase during time. International MDR clones less susceptible to cephalosporins are rapidly emerging indicating that the era of untreatable gonococcal infections is close.

Keywords: Gonococcus, ST1407, MIC, Ceftriaxone, Cefixime, MDR, NG-MAST, PBP1, PBP2, Mosaic

Background

Neisseria gonorrhoeae (Ng) is the etiologic agent of the second most common sexually transmitted infection (STI) globally [1]. The number of gonococcal infections is rapidly increasing, especially because subjects are often asymptomatic. This condition contributes to the spread of the pathogen, but also to the silent progression of the infection to more serious clinical conditions as the pelvic inflammatory diseases. Therefore, along with the implementation of effective preventive strategies, the administration of adequate antibiotic treatments can contribute to the control of infections [2,3].

Unfortunately, Ng has a remarkable ability to develop resistance to all of the clinically implemented antibiotics [4]. In brief, resistance to ciprofloxacin (CIP) is usually due to amino acid substitutions in GyrA and ParC [5,6]. Azithromycin (AZT) can become inactive due to mutations in the four copies of the 23S rRNA, production of methylase enzymes encoded by acquired genes (e.g.,...
ermB/F), or substitutions in the L4 and L22 ribosomal proteins [5,7]. Tetracycline (TET) is usually ineffective because of tet(M) gene acquisition [3,5]. Resistance to penicillin (PEN) is due to production of acquired TEM-1-like β-lactamases or alterations of the penicillin binding proteins (PBPs; e.g., amino acid substitutions for PBP1 and PBP2) [3,4,8]. Notably, the over-expression of the MtrCDE efflux pump due to substitutions in its repressor MtrR or deletions/insertions in the mtr promoter region may reduce susceptibility to all of the above mentioned drugs [5,9], whereas substitutions in the PorB outer membrane porin may affect PEN and TET [10].

However, the most threatening global concern is represented by the recent emergence of Ng isolates resistant to cefixime (CFX) and, even more importantly, to ceftriaxone (CRO) [11-15]. Reduced susceptibility to these cephalosporins can be due to a mixture of the mechanisms involved in penicillin resistance, but full resistance necessitates specific mosaic structures of the PBP2 that are caused by recombination events occurring between gonococcus and other commensal Neisseria species [4,16,17].

Taking into account these clinical problems, and based on national and international guidelines [2,18], many countries have recently established active surveillance programs to monitor the evolution of antimicrobial susceptibility for Ng isolates [3,19-22], and the spread of international clones (e.g., sequence types ST1407, ST2992, and ST225) whenever possible, as previously done [23].

**Methods**

**Clinical isolates**

We analyzed the Ng isolates collected by the Laboratory of Clinical Microbiology of the University of Bern (Switzerland) during a 15-year period and isolated implementing standard microbiological methodologies [25]. The characteristics of isolates detected during 1998–2001 (n = 26) were compared to those of gonococci detected during 2009–2012 (n = 34). Strains had been stored at −80°C over the time in glycerol stock tubes (Almedica AG). For the present study, isolates were plated on GC agar (bioMérieux) and species identification was confirmed by using the MALDI-TOF MS (Bruker Daltonik).

**Antimicrobial susceptibility tests (ASTs)**

Minimum inhibitory concentrations (MICs) for PEN, CFX, CRO, CIP, AZT, TET, spectinomycin (SPE) and gentamicin (GEN) were obtained using the Etest method on GC agar plates. Results were categorized according to the 2013 European Committee on Antimicrobial Susceptibility Testing (EUCAST) criteria [26]. Production of β-lactamases was evaluated by implementing the cefinase disk (Oxoid) and also mixing 5 μL of β-lactamase(s) extract with 50 μL of nitrocefin [100 μM] for 1 hour. N. gonorrhoeae ATCC 49226 and Staphylococcus aureus ATCC 29213 were used as controls.

**Analysis of clonality**

Sequence type (ST) designation was achieved by analyzing both por and tbpB genes according to the Neisseria gonorrhoeae Multi-Antigen Sequence Typing methodology (NG-MAST; http://www.ng-mast.net/) [27]. STs were clustered in genogroups (e.g., G1407, G2992, and G225) whenever possible, as previously done [23].

**Molecular characterization of drug resistance genes**

Genomic extraction was performed using the QI Amp DNA mini kit (QIAGEN). The following antibiotic resistance genes (and their encoded proteins) were analyzed as previously described [5]: penA (PBP1), penB (PBP2), blaTEM (β-lactamases), gyrA and parC (quinolone resistance determining region), penB (PorB porin), mtrR and mtrR promoter (MtrCDE efflux pump), rplD and rplV (ribosomal protein L4 and L22, respectively), the four 23S rRNA gene copies, mefA (efflux-mediated resistance mechanism), ermA/B/C/F (methylase enzymes), and tet(M) (ribosomal protection protein). DNA sequencing was performed in service by Eurofins (Ebersberg, Germany) and chromatogram traces were analyzed using DNASTar (Lasergene). Results for all of the above genes were analyzed by searching for homologies with BLAST (http://blast.ncbi.nlm.nih.gov/Blast.cgi) or by comparison with the following deposited wild-type alleles: penA, penB, mtrR and mtrR promoter, gyrA, parC, rplD, and rplV (GenBank: AE004969); penA (GenBank: M32091); blaTEM-1 (GenBank: AJPQ01000032); and 23S rRNA (GenBank: CP001050).

**Results**

**Clinical isolates**

Ng isolates collected during 1998–2001 were from 18 males (median age 26.5; range 0–37 years) and 8 females (median age 26.0; range 16–40 years), whereas those collected during 2009–2012 were from 30 males (median age 33.0; range 21–56 years) and 4 females (median age 25.0; range 23–49 years). In 1998–2001, samples from males were urethral (n = 17) and ocular swabs (n = 1), whereas those from females were cervical (n = 4), vaginal (n = 2),
and wound swabs (n = 1), or sterile fluids (n = 1). With regard to 2009–2012, samples from males were urethral (n = 29) and pharyngeal swabs (n = 1), whereas those from females were vaginal (n = 3) and abscess swabs (n = 1).

**Antimicrobial susceptibility**

The MIC distributions for the eight antibiotics tested against *Ng* isolates detected during the two different periods are shown in Figure 1.

![Figure 1 MIC values distribution for the eight antibiotics tested against the *Ng* isolates detected during the two different periods (1998–2001 versus 2009–2012). "S", indicates the cut-off of susceptibility, whereas "R" indicates the isolates intermediate or resistant according to the EUCAST criteria [26]. The results clearly show that the MICs for cephalosporins increased over time (i.e., CRO: from MIC₉₀ of 0.004 mg/L to 0.047 mg/L; CFX: from MIC₉₀ ≤ 0.016 to 0.125 mg/L with also 8.8% of the isolates resistant) and that the prevalence of PEN-, CIP-, and TET-resistant isolates reached dramatic levels.](image-url)
During the 15 years, gonococcal isolates showed a remarkable increase in resistance to PEN (from 42.3% to 85.3%) and CIP (from 7.7% to 73.5%), but also a marked rise in resistance to AZT (from 11.5% to 23.6%) and TET (from 65.4% to 88.2%). With regard to cephalosporins, we noted a rise in the MIC values for both CFX (from MIC90 ≤ 0.016 mg/L to MIC90 of 0.125 mg/L, with 8.8% of resistant isolates) and CRO (from MIC90 of 0.004 mg/L to MIC90 of 0.047 mg/L). Only SPE (all 60 isolates were susceptible) and GEN did not show increased MICs (Figure 1).

As shown in Table 1, the prevalence of multidrug-resistant (MDR) isolates (i.e., those resistant to ≥3 antibiotic classes [4]) increased from 7.7% in 1998–2001 to 70.6% in 2009–2012. We also noted that the isolates simultaneously resistant to four antibiotics augmented from 3.8% in 1998–2001 to 26.5% in 2009–2012, whereas those resistant to five antimicrobials (PEN, CIP, AZT, TET, and CFX) reached 5.9% in 2009–2012.

### Clonality

Sequencing types (STs) of Ng isolates detected during 1998–2001 and 2009–2012 are summarized in Figure 2.

### Table 1 Patterns of antimicrobial and associated resistances of the N. gonorrhoeae isolates detected in Switzerland during the study periodb

| Antibiotics               | No. and (%) of isolates | 1998-2001 (n = 26) | 2009-2012 (n = 34) |
|---------------------------|-------------------------|--------------------|--------------------|
| Resistant to ≥ 2 antibiotics: |                         |                    |                    |
| - PEN and CIP             | 14 (53.8)               | 31 (91.2)          |
| - PEN and AZT             | 2 (7.7)                 | 25 (73.5)          |
| - PEN and TET             | 3 (11.5)                | 8 (23.5)           |
| - CIP and TET             | 14 (53.8)               | 28 (82.4)          |
| - CIP and AZT             | 2 (7.7)                 | 23 (67.6)          |
| - AZT and TET             | 1 (3.8)                 | 7 (20.6)           |
| Resistance to ≥ 3 antibiotics (i.e., MDR isolates): | | |
| - PEN, CIP, and AZT       | 2 (7.7)                 | 24 (70.6)          |
| - PEN, CIP, and TET       | 1 (3.8)                 | 7 (20.6)           |
| - PEN, AZT, and TET       | 2 (7.7)                 | 23 (67.6)          |
| - CIP, AZT, and TET       | 3 (11.5)                | 8 (23.5)           |
| Resistance to ≥ 4 antibiotics: |                         |                    |                    |
| - PEN, AZT, and TET       | 1 (3.8)                 | 7 (20.6)           |
| - PEN, CIP, TET, and CFX  | 0 (0.0)                 | 2 (5.9)            |
| Resistance to ≥ 5 antibiotics (PEN, CIP, AZT, TET, and CFX) | 0 (0.0) | 2 (5.9) |

Note. PEN, penicillin; CIP, ciprofloxacin; AZT, azithromycin; TET, tetracycline; CFX, cefixime.

*aAll isolates were susceptible to ceftriaxone (CRO) and spectinomycin (SPE).

*bResistant* includes intermediate and resistant according to the EUCAST criteria [26].

In 1998–2001, only the international genogroup G25 was identified (one ST25 in 1998 and one ST3369 in 2001). In contrast, during 2009–2012 the international lineages G1407 (29.4%), G2992 (11.7%), and G225 (8.8%) were detected. Most of these hyperepidemic genogroups were MDR (e.g., 9/10 of the isolates of G1407 were resistant to ≥3 antibiotics). Moreover, Ng of G1407 possessed the highest MICs for CFX and CRO, with MIC50/90 of 0.125/0.19 mg/L and MIC50/90 of 0.032/0.047 mg/L, respectively (data not fully shown; see also Table 2).

### Drug resistance genes

The specific phenotypic and molecular characteristics of Ng detected during 2010–2012 (n = 26) are presented in Table 2.

Isolates with reduced susceptibility to antibiotics possessed the following specific antibiotic resistance traits: PBPl (substitution L421P), PBP2 (mosaics II, V, XII, XIX, or XXXIV), TEM-1-like β-lactamases, GyrA (substitutions S91F, D95G, and D95A), ParC (substitutions S87R and E91G), PorB (substitutions G120K and A121D/N/G), MtrR (substitutions A39T, R44H, G45D, L477P), mtrR promoter (A deletion), and the Tet(M) protective protein. RplD, rplV and 23S rRNA genes did not present mutations and *erm* or *mefA* genes were not detected.

Notably, Ng isolates belonging to G1407, G2992, and G225 constantly possessed specific and conserved antibiotic resistance patterns (e.g., all G1407 had PBPl with L421P, PBP2 pattern XXXIV, GyrA with S91F and D95G, ParC with S87R, PorB with G120K and A121N, and the A deletion in the mtrR promoter region).

### Discussion

Programs monitoring the antibiotic susceptibility of Ng are essential to implement adequate empirical treatments [1,3,18,20]. Information about the underlying molecular mechanisms of resistance is equally important to design and evaluate new rapid diagnostic systems [30]. Moreover, the incidence of Ng hyperepidemic clones should be carefully monitored because these isolates have the potential to spread quickly and are showing increasing resistance to most of the clinically used antibiotics [13,19,23].

In 2008, Le Lin et al. described the emergence (2002) of Ng resistant to CIP in Geneva [31]. Very recently, Kovari et al. have analyzed the susceptibility to four antibiotics (CFX, CRO, CIP and PEN) of 320 isolates collected in 1990 and from 2000 to 2012 at the University of Zurich [32]. However, up to now surveys studying the molecular characteristics, especially the clonality, of Ng detected in Switzerland have not yet been performed. Therefore, the aim of the present work was to fill up the lack of contemporary data regarding gonococcus implementing the methodologies suggested by the acknowledged international institutions [19,20].
Trend of antibiotic susceptibility

Consistently with the study of Kovari et al. [32], our phenotypic data indicate that the prevalence of Ng resistant to either PEN or CIP increased considerably during the last decade (>73%). However, in our study we have also observed that the occurrence of isolates simultaneously resistant to PEN, CIP, and TET has reached a dramatic level (68%). These figures clearly show that the use of these three antibiotics for the empirical treatment of gonococcal infections is no longer safe. This phenomenon is not new and has been observed in other countries. The extensive use of antibiotic treatments without performing the ASTs has generated not only an escalation of "treatment failures" [33-36], but also a positive selective pressure for specific international MDR clones (e.g., G1407 and G225) [3,4].

Fortunately, current Ng isolates spreading in Switzerland seem to remain susceptible to the standard therapeutic option CRO [32,37]. However, its MICs are increasing over time ("MIC creep") as observed worldwide [3,4,20], and one should be aware that CRO-resistant isolates can emerge and spread [4,7,11,12,14,17]. This possible development could also be favored by the observed decreased susceptibility to AZT, an antibiotic used together with CRO to cover Chlamydia trachomatis co-infections and more recently also implemented to prevent treatment failures of gonococcal infections [33,37]. In this overall scenario, we noted that all Ng tested were susceptible to SPE, probably because the use of this antibiotic has been abandoned after observing outbreaks of resistant isolates in the 1980s [3,4]. SPE-resistant Ng are now rarely reported [20,21], and this antibiotic could be reconsidered - along with gentamicin - for the treatment of infections due to MDR isolates showing co-associated reduced susceptibility to CRO and AZT [4].

Emergence of successful international STs and genogroups

The NG-MAST analysis pointed out that in the last few years the G1407, G2992, and G225 international genogroups have also reached Switzerland, now representing ~50% of the overall isolates. Most likely, these lineages were initially imported by infected people who had sexual intercourse abroad, but it is difficult to
Table 2 Phenotypic and molecular characteristics (clonality and drug resistance genes) of 26 \textit{N. gonorrhoeae} isolates detected during the period 2010–2012 in Switzerland

Note. WT, wild-type; +, positive; −, negative.

*a* Penicillinase producers according to the cefinase disk test (Oxoid) and nitrocefin test.

*b* Abbreviations and MIC interpretation according to the EUCAST criteria [26]: penicillin (PEN; sensible, $S \leq 0.06$ mg/L); ceftriaxone (CRO; $S \leq 0.125$ mg/L); cefixime (CFX; $S \leq 0.125$ mg/L); ciprofloxacin (CIP; $S \leq 0.03$ mg/L); azithromycin (AZT; $S \leq 0.25$ mg/L); tetracycline (TET; $S \leq 0.25$ mg/L); spectinomycin (SPE; $S \leq 64$ mg/L); gentamicin (GEN; criteria not available).

*c* The characteristics of the PBP2 patterns II, V, XII, and XIX were described by Whiley DM et al. [16], those of pattern XXXIV by Hess D et al. [28], and pattern IIg by Takahashi et al. [29]. Pattern XXI-like does not have -574N and A575V as in the XXI [16].

*d* The L4 of these Ng isolates possessed three substitutions (i.e., V125A, A147G, R157Q) that have no recognized impact on the macrolides resistance.
hypothesize which countries were most responsible for this phenomenon. In fact, G1407 is currently the most frequently detected genogroup worldwide (e.g., 23% of the isolates in Europe), whereas G225 and G2992 are second and third (e.g., 10% and 8% in Europe, respectively) [23]. For instance, ST1407 is first in rank in countries like Austria, Italy, the Netherlands, Portugal, Spain, Romania, Slovenia, United Kingdom, Japan and Canada; ST2992 is very frequent in Ireland and Norway; and ST225 is predominant in Malta and Denmark [19,21,24,38].

As also observed in this work, G1407 and G225 are constantly characterized by fully resistance to CIP and reduced susceptibility (at intermediate level) to PEN, AZT, and TET, whereas G2992 is usually pan-susceptible [3]. G1407 has also decreased susceptibility to CFX and, to a lesser extent, to CRO [4,21,28]. In this context, we note that most of the previously reported CFX or CRO treatment failures were due to Ng isolates of G1407 [4,11,12,39].

**Drug resistance genes**

Due to the number and complexity of the mechanisms [5], we decided to analyze only the main molecular traits of resistance possessed by the Ng isolates found during 2010–2012 (Table 2).

Isolates of G1407 were slightly resistant to PEN because of L421P in PBP1, overexpression of MtrCDE efflux by one A deletion in the promoter, and reduced permeability of PorB (substitutions G120K and A121N). However, they also showed augmented MICs to CFX and CRO due to the presence of the mosaic XXXIV [4,8,21,28,36,38]. This PBP2 variant may predispose the clone to become highly-resistant to CRO [11,12]. Similarly, G2992 and G225 tested intermediate to PEN, but were fully susceptible to cephalosporins because of the presence of PBP2 mosaics (i.e., II, V, XII, and XIX) that have little effects against CFX and CRO [16]. These commonly reported PBP2 mosaics were also present in the fully cephalosporin-susceptible Ng belonging to sporadic STs.

Non-hyperepidemic isolates were frequently TEM-1 producers but two of them expressed the TEM-135, a TEM-1 variant (substitution M182T) previously reported only in Japan, Thailand, and China [8,40,41]. TEM-135 is a plasmid-mediated enzyme that does not hydrolyze CFX and CRO, but its emergence might represent an intermediate stage of the traditional TEM-1 penicillinase into an extended-spectrum β-lactamase (ESBL) that is able to confer high-level resistance to all β-lactams with the exception of carbapenems [4]. Since this was not a prospective clinical study, we are unable to provide information about the travel history of the two patients infected by TEM-135 producers.

None of the Ng tested possessed acquired genes (*erm*, *mefA*) or chromosomal mutations (23S rRNA, *rplD*, *rplV*) conferring high-level resistance to macrolides [5,7]. However, several isolates (including some of G1407 and G225) were non-susceptible to AZT (MICs of 0.38-0.75 mg/L). This phenomenon may be due to a feeble overexpression of the MtrCDE efflux induced by the A deletion in the *mtrR* promoter [5,9,42]. Finally, almost all CIP-resistant Ng possessed well-known substitutions in GyrA (amino acids 91 and 95) and ParC (amino acid 87). In particular, we highlight that the S91F replacement in GyrA was constantly observed, making it a good single target candidate for the molecular tests functional to categorize Ng as resistant or susceptible to quinolones [6]. The implementation of a rapid bedside molecular test for CIP resistance would allow treatment of infections due to susceptible isolates with this drug and could reduce the selective pressure on CRO in about 25% of gonorrhea in our country while still maintaining good clinical efficacy.

**Conclusions**

This is the first study describing clonality and molecular mechanisms of resistance of gonococcal isolates detected in Switzerland. In this survey, we also analyzed the changes in characteristics of Ng strains detected in the same geographic area and during the last 15 years. We note that studies focusing on these epidemiological temporal trends are still limited but extremely important to comprehend the spread and the evolution of antibiotic resistance in Ng [3,20,22,32].

Overall, our data clearly indicate that the antibiotic susceptibility of contemporary Ng isolates is dramatically decreasing, mainly due to the spread of international MDR clones that also show reduced susceptibility to the standard therapeutic options CRO and AZT [37]. These specific clones (e.g., ST1407 and its genogroups) are predisposed to become more resistant representing the last evolutionary step of the pathogen before the era of extensively and pandrug-resistant isolates [4]. In this context, we emphasize the urgent need of: i) rapid molecular tests able to provide adequate information to select the most appropriate direct antibiotic treatment [30]; ii) novel antimicrobial families against molecular targets not yet affected by resistance mechanisms [4]; iii) increasing numbers of cultures to study and monitor clonality and resistance mechanisms of gonococcus [4].

One limitation of the present study is that the survey was performed in a single institution, was not prospective, and included a relative small number of Ng isolates. However, we believe that our results may be representative for the whole country because distances in Switzerland are very short and our institution is located in the middle of the territory. In support of this speculation, we note that our phenotypic data are consistent with those recently provided by the larger analysis performed in Zurich [32].

To provide more robust and systematic data that are essential for controlling the rapidly increasing number of
gonococcal STI, we strongly believe that an adequate national surveillance monitoring program - supported by the state public institutions - should be established rapidly and before our health care systems dramatically face the attack of untreated gonococcal isolates [4,17].
