Abstract
In this contribution we describe the new model of multiple partonic interactions (MPI) that has been implemented in Herwig++. Tuning its two free parameters is enough to find a good description of CDF underlying event data. We show extrapolations to the LHC and compare them to results from other models.

1 Introduction
With the advent of the Large Hadron Collider (LHC) in the near future it will become increasingly important to gain a detailed understanding of all sources of hadronic activity in a high energy scattering event. An important source of additional soft jets will be the presence of the underlying event. From the experimental point of view, the underlying event contains all activity in a hadronic collision that is not related to the signal particles from the hard process, e.g. leptons or missing transverse energy. The additional particles may result from the initial state radiation of additional gluons or from additional hard (or soft) scatters that occur during the same hadron–hadron collision. Jet measurements are particularly sensitive to the underlying event because, although a jet’s energy is dominated by the primary hard parton that initiated it, jet algorithms inevitably gather together all other energy deposits in its vicinity, giving an important correction to its energy and internal structure.

In this note, based on Ref. [1], we want to focus on the description of the hard component of the underlying event, which stems from additional hard scatters within the same proton. Not only does this model give us a simple unitarization of the hard cross section, it also allows to give a good description of the additional substructure of the underlying events. It turns out that most activity in the underlying event can be understood in terms of hard minijets. We therefore adopt this model, based on the model JIMMY [2], for our new event generator Herwig++ [3].

An extension to this model along the lines of [4], which also includes soft scatters is underway and will most probably be available for the next release of Herwig++. Covering the entire \( p_t \) range will also allow us to describe minimum bias interactions. We have examined the parameter space of such models at Tevatron and LHC energies in Ref. [5]. Existing measurements and the possible range of LHC measurements are used there to identify the maximally allowed parameter space.

2 Tevatron results
We have performed a tune of the model by calculating the total \( \chi^2 \) against the jet data (\( p_t^{\text{jet}} > 20 \text{ GeV} \)) from Ref. [6]. For this analysis each event is partitioned into three parts, the towards, away and transverse regions. These regions are equal in size in \( \eta - \phi \) space and classify where particles are located in this space with respect to the hardest jet in the event. We compare our predictions to data for the average number of charged particles and for the scalar \( p_t \) sum in each of these regions.

The parameter space for this tune is two dimensional and consists of the \( p_t \) cutoff \( p_t^{\text{min}} \) and the inverse hadron radius squared, \( \mu^2 \). In Fig. 2 we show the \( \chi^2 \) contour for describing all six observables and

*to appear in the proceedings of the HERA and the LHC workshop.
especially those from the transverse region, which is particularly sensitive to the underlying event. For these, and all subsequent plots, we have used Herwig++ version 2.2.1 and the built-in MRST 2001 LO [7] PDFs. All parameters, apart from the ones we were tuning, were left at their default values.

The description of the Tevatron data is truly satisfactory for the entire range of considered values of $p_t^{\text{min}}$. For each point on the $x$-axis we can find a point on the $y$-axis to give a reasonable fit. Nevertheless an optimum can be found between 3...4 GeV. The strong and constant correlation between $p_t^{\text{min}}$ and $\mu^2$ is due to the fact that a smaller hadron radius will always balance against a larger $p_t$ cutoff as far as the underlying event activity is concerned. As a default tune we use $p_t^{\text{min}} = 3.4$ GeV and $\mu^2 = 1.5$ GeV$^2$, which results in an overall $\chi^2/N_{\text{dof}}$ of 1.3.

3 LHC extrapolation

We start the discussion of our predictions for the LHC with the plot in Fig. 2. The plot shows the mean charged multiplicity as a function of pseudorapidity, $\eta$. We show Herwig++ with and without MPI. We used QCD jet production with a minimal $p_T$ of 20 GeV as signal process. The MPI parameters were left at their default values, i.e. the fit to Tevatron CDF data. The effect of MPI is clearly visible, growing significantly from the Tevatron to the LHC.

For calculating the LHC extrapolations we left the MPI parameters at their default values, i.e. the fit to Tevatron CDF data. In Ref. [8] a comparison of different predictions for an analysis modelled on the CDF one discussed earlier was presented. As a benchmark observable the charged particle multiplicity in the transverse region was used. We show this comparison in Fig. 3 together with our
Fig. 3: Multiplicity in the transverse region for LHC runs with Herwig++ (left) and the same observable for several other
generators (right), taken from Ref. [8]. The different data sets for the left plot are (from bottom to top): Tevatron with MPI off,
LHC with MPI on, Tevatron with MPI on and LHC with MPI on.

simulation. All expectations reached a plateau in this observable for $p_{t,jet}^l > 10$ GeV. Our prediction for
this observable also reached a roughly constant plateau within this region. The height of this plateau can
be used for comparison. In Ref. [5] PYTHIA 6.214 [9] ATLAS tune reached a height of $\sim 6.5$, PYTHIA
6.214 CDF Tune A of $\sim 5$ and PHOJET 1.12 [10] of $\sim 3$. Our model reaches a height of $\sim 5$ and seems
to be close to the PYTHIA 6.214 CDF tune, although our model parameters were kept constant at their
values extracted from the fit to Tevatron data.

We have seen already in the previous section that our fit results in a flat valley of parameter points, which
all give a very good description of the data. We will briefly estimate the spread of our LHC expectations,
using only parameter sets from this valley. The range of predictions that we deduce will be the range that
can be expected assuming no energy dependence on our main parameters. Therefore, early measurements
could shed light on the potential energy dependence of the input parameters by simply comparing first
data to these predictions. We extracted the average value of the two transverse observables for a given
parameter set in the region $20$ GeV < $p_{t,jet}^l$ < 30 GeV. We did that for the best fit points at three different
values for $p_{t,min}$, namely 2 GeV, 3.4 GeV and 4.5 GeV, and found an uncertainty of about 7 % for the
multiplicity and 10 % for the sum of the transverse momentum.

| LHC predictions | $\langle N_{chg}\rangle_{transv}$ | $\langle p_{t,sum}\rangle_{transv}[GeV]$ |
|-----------------|---------------------------------|-------------------------------------|
| TVT best fit    | 5.1 ± 0.3                       | 5.0 ± 0.5                           |

Table 1: LHC expectations for $\langle N_{chg}\rangle$ and $\langle p_{t,sum}\rangle$ in the transverse region. The uncertainties are obtained from varying $p_{t,min}$
within the range we considered. For $\mu^2$ we have taken the corresponding best fit (Tevatron) values.

Acknowledgements

We would like to thank our collaborators on the Herwig++ project for many useful discussions. We
wish to thank the organisers of the workshop for a very pleasant atmosphere. This work was supported
in part by the European Union Marie Curie Research Training Network MCnet under contract
MRTN-CT-2006-035606 and the Helmholtz–Alliance “Physics at the Terascale”. MB was supported by
the Landesgraduiertenfördерung Baden-Württemberg.
