Based on ab initio calculations of both the ABC- and AB-stacked graphites, interlayer potentials (i.e., graphene-graphene interaction) are obtained as a function of the interlayer spacing using a modified Möbius inversion method, and are used to calculate basic physical properties of graphite. Excellent consistency is observed between the calculated and experimental phonon dispersions of AB-stacked graphite, showing the validity of the interlayer potentials. More importantly, layer-related properties for nonideal structures (e.g., the exfoliation energy, cleave energy, stacking fault energy, surface energy, etc.) can be easily predicted from the interlayer potentials, which promise to be extremely efficient and helpful in studying van der Waals structures.

The interlayer cohesive properties in graphite have been an attractive issue for more than 50 years⁶⁻⁹, and revive these years due to the observation of graphene and few-layer graphite¹⁰⁻¹². Although there exist AB and ABC stackings of graphite in nature, a stable single crystal specimen can be well prepared only for AB-stacked graphite¹³⁻¹⁵. This fact has greatly hindered the research on layer-related properties of graphite and as a result, the overwhelming majority of theoretical efforts have been devoted only to AB-stacked graphite¹⁶⁻¹⁹. Actually, it is a physical challenge to theoretically describe the van der Waals (vdW) interactions in complex materials, and extensive work is still needed for better understanding the interlayer cohesion in graphite both theoretically and experimentally. However, as will be shown in this work, the interlayer binding energies in graphites with various stackings are closely related. Therefore, instead of focusing on only one type of stackings, the present work combines both AB- and ABC-stacked graphites to study interlayer potentials in graphite or graphene-graphene interactions, which can be extracted by combining ab initio calculations with Chen-Möbius inversion¹⁶⁻¹⁸, and further be employed to study layer-related properties of graphite systems over a wide range.

In this work, we use ab initio calculations to generate binding energies of ABC- and AB-stacked graphite as functions of the layer separation. Afterward, the graphene-graphene interaction potentials are obtained using Möbius inversion procedure. Finally, a few examples are given to show the validity and usefulness of the deduced interlayer potentials. These potentials are expected to be powerful in studying graphites with arbitrary c-axis stacking order¹⁹ or layer spacings, which can be too large for ab initio calculations, and in understanding even predicting the transformation of stacking orders in multi-layer graphene²⁰. Further by including the variance of lattice parameters, this method can be extended to study strain effects on stacking orders²¹.

Results

By evaluating values of the equilibrium interlayer distance, \(d_0\), the binding energy, \(E_b\), and the elastic coefficient, \(C_{33}\), and making comparison with experimental values as listed in Table I, we find that PBE/DFT-D2 is the best exchange-correlation functional among the functionals that we choose for presenting the ab initio binding energies of graphites. As a verification, we check the asymptotic behavior of the interlayer potentials as a function of the interlayer distance, \(d\). Obviously, the interlayer binding energy curve from PBE/DFT-D2 between 4 ~ 8 Å satisfies the rule very well, which agrees with previous finding using random phase approximation in AB-stacked graphite²². What is more, we note that the PBE/DFT-D2 calculated \(E_b\) of AB-stacked graphite is greater than that of ABC-stacked one at equilibrium interlayer distance by 0.25 meV/atom, which qualitatively agrees with the estimation of its natural abundance (80%)²³.

Despite of four different arrangements along hexagonal close packed (hcp) (0001) direction, AB, ABC, ABAC, and AA stackings, there are only two different graphene-graphene interaction potentials due to the three-fold rotation symmetry in individual graphene layers. Herein, we use \(\phi(A)(d)\) to denote the interlayer potentials between A-B, A-C, or B-C layers, and \(\phi(A)(d)\) those between aligned layers, i.e., A-A, B-B, and C-C layers.
Based on the PBE/DFT-D2 results and using a modified Möbius method as will be introduced in the Method section, interlayer potentials $\Phi^{AA}(d)$ can be extracted. In Fig. 2, we plot the interlayer potentials $\Phi^{AB}(d)$ and $\Phi^{AA}(d)$ as functions of $d$. As shown in the figure, $\Phi^{AA}(d)$ takes its minimum value at $d_0$, and $\Phi^{AB}(d)$ monotonically increases from $d > 5 \text{Å}$. (Note that $\Phi^{AA}(d)$ is plotted only for large interlayer distances, since equations (8) and (9) requires that $d \geq 2d_1$, where $d_1$ is the minimum interlayer distance we set for ab initio calculation).

So as to better describe the interlayer potentials, we use the Rahaman-Stillinger-Lemberg (RSL2) function

$$
\Phi(d) = D_0 e^{-\frac{d}{d_0}} + \frac{a_1}{1 + e^{b_1(d - d_0)}} + \frac{a_2}{1 + e^{b_2(d - d_0)}} + \frac{a_3}{1 + e^{b_3(d - d_0)}},
$$

(1)

to fit the deduced interlayer potentials. With the total 12 adjustable parameters, $a_i$, $b_i$, $c_i$ ($i = 1, 2, 3$), this function can well describe pair interactions between layers. The best-fit parameters for the interlayer potentials are listed in Table II.

From the deduced interlayer potentials $\Phi^{AB}(d)$ and $\Phi^{AA}(d)$, we can reproduce the interlayer binding energies of variously stacked graphites as:

$$
E^{AA}_\Phi(d) = \sum_{n=1}^{\infty} \phi^{AA}(nd),
$$

$$
E^{AB}_\Phi(d) = \sum_{n=1}^{\infty} \phi^{AB}((2n - 1)d) + \sum_{n=1}^{\infty} \phi^{AA}(2nd),
$$

$$
E^{ABC}_\Phi(d) = \sum_{n=1}^{\infty} \phi^{AA}(3nd) + \sum_{n=1}^{\infty} \phi^{AB}((3n - 1)d) + \sum_{n=1}^{\infty} \phi^{AB}((3n - 2)d),
$$

(2)

where the subscript $\Phi$ means that the functions are evaluated from $\Phi^{AA/AB}(d)$, instead of directly obtained from ab initio calculations. The reconstructed binding energy curves of AB- and ABC-stacked graphites are plotted and compared in Fig. 3. It is clearly shown in Fig. 3(a) and (b) that the binding energies of AB- and ABC-stacked graphites are well reproduced. Especially, the interlayer binding energy difference between AB- and ABC-stacked graphites is well distinguished in Fig. 3(c). Also, the obtained binding energy curve of AA-stacked graphite shows good consistency with the ab initio

**Table I** | Ab initio equilibrium interlayer distance $d_0$ (in Å), binding energy $E_b$ (in meV/atom), and elastic constant $C_{33}$ (in GPa) obtained using various exchange-correlation functionals for AA-, AB-, and ABC-stacked graphites

results for $d \geq 2d_1$, where $d_1$ is the minimum $d$ used in ab initio calculations (data not shown).

**Discussion**

Besides giving us more insight into weak interlayer interactions, interlayer potentials are powerful in studying layer-related properties, such as $c$-axis phonon dispersion, exfoliation energy, cleave energy, surface energy, and stacking fault energy.

Since interlayer potentials can fully describe the interactions between layers along the hcp $(0001)$ direction, we can use interlayer potentials to calculate interlayer vibrations. We take a graphene layer as a whole and use the interlayer potentials to describe the graphene-graphene interaction. The phonon dispersion results, which are actually the $c$-axis vibration spectra, are illustrated in Fig. 4, where the branches of phonon dispersion for AB-stacked graphite are well consistent with those of the neutron scattering data from Ref. 24.

In unit of meV, the values of frequency are $17$ meV, $1.5$ meV, and $0$ at the $\Gamma$ point from the interlayer potentials, which qualitatively agree with the experimental values: $15$, $6$, and $0$ meV²Å⁻¹.

Exfoliation energy, $E_{\text{exf}}$, is the energy required to remove one graphene plane from the surface of a bulk graphite, and can be used to estimate $E_b$. With the interlayer potentials, we can easily obtain $E_{\text{exf}}$. For instance, the exfoliation energy for AB-stacked graphite is followed as:

$$E_{\text{exf}} = \sum_{n=1}^{\infty} \left\{ \phi^{AB}[(2n-1)d_0] + \phi^{AA}(2nd_0) \right\}.$$  (3)

Compared to equation (2), the $E_{\text{exf}}$ in the above equation is exactly half of the interlayer binding energy. Thereby, the exfoliation energy is about $55.16$ meV/atom. Similarly, we can obtain an exfoliation energy $57.14$ meV/atom when two graphene layers are exfoliated.

Another method to calculate $E_b$ is to get the cleave energy, $E_{\text{cl}}$, which is the interaction energy between two semi-infinite crystals. In AB-stacked graphite, it shows that

$$E_{\text{cl}} = \sum_{n=1}^{\infty} \left\{ (2n-1)\phi^{AB}[(2n-1)d_0] + 2n\phi^{AA}(2nd_0) \right\}.$$  (4)

Apparently, the cleave energy is bigger than the exfoliation energy in AB-stacked graphite. The difference is about $2.3$ meV/atom.

The surface energy is defined as the excess free energy per unit area of a particular crystal facet. It is usually calculated using the supercell method: $E_{\text{surf}} = (E_s - N E_0)/2A$, where $E_s$ is the total energy of the supercell, $E_0$ the bulk energy per layer, $A$ the surface area of the supercell, and the factor $2$ derived from two surfaces in the supercell model. $E_{\text{surf}}$ can also be easily computed by interlayer potentials, which yields that the surface energy is about $351$ ml/m² for AB-stacked graphite. The interlayer potentials may also be used to establish the size of the surface relaxation and the impact on the formation energy. In the present surface relaxation is only between the surface layer and the neighboring layer. The surface relaxation energy from the interlayer potentials is $338$ ml/m², which is $13$ ml/m² smaller than the ideal surface energy. The relaxation interlayer distance is about $3.238$ Å, while the equilibrium interlayer distance is $3.231$ Å. Similarly, we also calculated the surface energy of ABC-stacked graphite along hcp $(0001)$. Its value is $344$ ml/m² which is smaller by $7$ ml/m² than that of AB-stacked graphite. Note that the surface energy calculated with LDA is only $75$ ml/m² for AB-stacked graphite as reported in Ref. 25. The large difference is mainly derived from the interlayer cohesive energy of the different exchange-correlation approximations.

Also, commonly seen stacking faults can be studied. We calculate the intrinsic stacking fault energies of AB-stacked graphite according to the equation $E_{\text{surf}} = (E_{\text{surf}} - E_{\text{ideal}})/A_{\text{sl}}$. Herein $E_{\text{sl}}$ is the energy of the intrinsic stacking fault, $E_{\text{ideal}}$ is the energy of the perfect stacking, and $A_{\text{sl}}$ is the area of the stacking fault plane.

Ideal stackings are ··· ABAB··· for AB-stacked graphite, ··· ABCABC··· for ABC-stacked graphite, ··· ABAC··· for the ABAC-stacked graphite, and ··· AA··· for AA-stacked graphite. Herein, we only consider one stacking fault from AB-stacked to AA-, ABC-, and ABAC-stacked graphites. From AB- to ABAB-stacked graphite, namely ··· ABCABC:ABABC··· to ··· ABCAB: ABCABC·· the stacking fault energy is $-8.0$ ml/m², which also indicates that AB-stacked graphite is more stable than ABC-stacked one. From AB- to AA-stacked graphite, ··· ABAB:ABA··· to ··· ABAB:BABA··· the stacking fault energy is $148$ ml/m². From AB- to ABAC-stacked graphite, ··· ABAC:ABA··· to ··· ABAC:CABA···, the stacking fault energy is $7.9$ ml/m², which implies that the interlayer binding energy of ABC-stacked graphite is very close to that of ABAC-stacked graphite.

In summary, we have obtained interlayer potentials $\phi^{AB/AA}(d)$ combining the Möbius inversion method with ab initio results. The interlayer potentials can well reproduce binding energies of
graphs with AB or ABC stackings, indicating the validity of the interlayer potentials, and can be used to predict many properties such as c-axis phonon dispersion, exfoliation energy, surface energy, surface relaxation, and stacking fault energies of various graphites. We conclude that the interlayer potentials offer an easy and efficient way to investigate layer-related properties of graphites, and the combination of Möbius inversion method and \textit{ab initio} calculation may find wide applications in layered structures.

\section*{Methods}

There exist numerous \textit{ab initio} calculation methods with different exchange-correlation approximations to deal with the vdW interaction. However, it is still difficult to exactly include the nonlocal long-range vdW interaction. In the present work, we have tested seven different exchange-correlation functionals (see Table 1)\textsuperscript{33,34}. Considering only the interaction between layers, we fix the interatomic distance within each layer and obtain the corresponding total energy at different interlayer distances by changing the interlayer distance. After extracting the sum of energies of individual layers from the total energy, we get the interlayer binding energy as a function of interlayer distance. All \textit{ab initio} calculations have been performed within the Vienna \textit{Ab initio} Simulation Package (VASP)\textsuperscript{30,31}. To take into account the small energy change caused by the weak vdW interaction, the cutoff energy is taken as 900 eV, the k mesh in the first Brillouin zone is set to be 16 × 16 × 12, and the convergence of total energy is 2 × 10\textsuperscript{-7} eV. In order to better describe the graphene-graphene interaction in graphene, we need to select the best exchange-correlation functional for the system for further analysis. As usually done in literature, we use the consistency of calculated results to the experimental values of equilibrium interlayer distance \(d_{0}\), the binding energy \(E_{b}\), and the elastic coefficient \(C_{11}\), as the criteria. The Morse function\textsuperscript{32} is chosen as the state function to fit the binding energy values near \(d_{0}\). Given the

\begin{equation}
\phi^{AB}_{n} = \frac{1}{\sqrt{S}} \sum_{n=1}^{N} \psi_{n}^{AB},
\end{equation}

we obtain the following formula:

\begin{equation}
\Delta^{AB}(d) = E_{AB}^{ij}(d) - E_{AB}^{ij}\left(\frac{3}{2}d_{0}\right).
\end{equation}

This equation can be written in a simple form:

\begin{equation}
\Delta^{AB}(d) = \sum_{n=1}^{\infty} r(n)\phi^{AB}[b(n)],
\end{equation}

by introducing \((n=1,2,\cdots)\)

\begin{equation}
r(n) = \begin{cases} 1, & \text{if } n=3k-1, \\ 1, & \text{otherwise,} \\ 3k-2, & \text{if } n=3k-2, \\ 3k-3/2, & \text{if } n=3k-1, \\ 3k-1, & \text{otherwise.} \end{cases}
\end{equation}

The idea of solution is simply to work with the multiplicative closure \(B = \{B(n)\}_{n=1}^{\infty}\) of the original set \(b = \{b(n)\}_{n=1}^{\infty}\), i.e., \(B\) is a multiplicative semi-group containing the elements of \(b\) and all products of them\textsuperscript{35}. Correspondingly, the set \(\{r(n)\}_{n=1}^{\infty}\) is extended to another set \(\{R(n)\}_{n=1}^{\infty}\) as

\begin{equation}
\Delta^{AB}(d) = \sum_{n=1}^{\infty} R(n)\phi^{AB}[B(n)],
\end{equation}

where \(R(n)\) satisfies

\begin{equation}
R(n) = \begin{cases} r\{b^{-1}[b(n)]\}, & \text{if } B(n) \in b(n), \\ 0, & \text{otherwise.} \end{cases}
\end{equation}

In the above notation, \(b^{-1}\) refers to the inverse of the arithmetic function \(b(n)\), i.e., a mapping from the set \(\{b(n)\}_{n=1}^{\infty}\) back to the natural numbers. Similarly to the traditional Möbius inversion method, we can write down a symmetric form as a solution of \(\phi^{AA}(d)\):

\begin{equation}
\phi^{AA}(d) = \sum_{n=1}^{\infty} f(n)\phi^{AB}[B(n)],
\end{equation}

and substitute it into equation (14) to determine \(f(n)\):

\begin{equation}
\sum_{n=1}^{\infty} f(n)R\{b^{-1}[B(n)]\} = \delta_{AA},
\end{equation}

from which \(f(n)\) can be obtained recursively. In order to solve \(\phi^{AA}(d)\), we define

\begin{equation}
\Delta^{AA}(d) = E_{AA}(d/2) - \sum_{n=1}^{\infty} \phi^{AA}\left(\frac{n-1}{2}\right),
\end{equation}

and then from equation (8), we have

\begin{equation}
\Delta^{AA}(d) = \sum_{n=1}^{\infty} \phi^{AA}(nd).
\end{equation}

Then, by virtue of Möbius theorem, \(\phi^{AA}(d)\) can be obtained as:

\begin{equation}
\phi^{AA}(d) = \sum_{n=1}^{\infty} \mu(n)\Delta^{AA}(nd),
\end{equation}

where \(\mu(n)\) is the Möbius function.

\begin{table}[h]
