Abstract

We present a model based on the implication of an exceptional $E_6$-GUT symmetry for the anomalous magnetic moment of the muon. We follow a particular chain of breakings with Higgses in the $78$ and $351$ representations. We analyse the radiative correction contributions to the muon mass and the effects of the breaking of the so-called Weinberg symmetry. We also estimate the range of values of the parameters of our model.

1 Introduction

Among the known leptons, the muon is potentially interesting for several reasons. First, its relatively long lifetime of 2.2 $\mu$s ($c\tau = 658.65$ m) makes it possible to perform precision measurements. Second, it is sensitive to new sectors of heavy particles and new interactions. In this sense, the muon anomaly has provided a stringent test for new theories of Particle Physics, since any new field or particle which couples to the muon must contribute to $a_\mu$.

The most recent results reported by the Muon ($g-2$) Collaboration \cite{1} have triggered a renewal of interest on the theoretical prediction of the anomalous magnetic moment of the muon (commonly referred to as the muon anomaly), $a_\mu = \frac{g-2}{2}$, in the Standard Model (SM). This experimental value is claimed to show that there remains a discrepancy with the SM theoretical calculations at the confidence level of 2.3$\sigma$ to 3.3$\sigma$ \cite{1}\cite{2}, if the hadronic light-by-light contribution, $a_\mu^{HLO}(LBL) = 80(40) \times 10^{-11}$ \cite{3}, is used instead of $a_\mu^{HLO}(LBL) = 136(25) \times 10^{-11}$ \cite{4}, as a consequence that $e^+e^-$ annihilation data are used to evaluate this contribution against hadronic $\tau$ decays data \cite{5}. Among all contributions that yield corrections to the muon anomaly, the hadronic contributions are less accurate, due to the hadronic vacuum polarization effects in the diagrams which use data inputs coming from the $e^+e^-$ annihilation cross section and the hadronic $\tau-$ decays. Also it is not clear, at present, whether the value from $\tau-$ decay data can be improved much further, due to the difficulty in evaluating more precisely the effect of isospin breaking \cite{5}.

In fact, these measurements have provided the highest accuracy of the validity of the different theories for strong, weak and electromagnetic interactions because they have reached a fabulous relative precision of 0.5 parts per million (ppm) in the determination of $a_\mu$. However, if this confidence level for the muon anomaly remains, it is possible that we are under a window open for a New Physics at a high energy scale, $\Lambda$. The study of the muon anomaly becomes relevant because it is more sensitive to interactions that are not predicted in the SM but will be possibly reached at the CERN Large Hadron Collider (LHC), with $\sqrt{s} = 14$ TeV.

On the theoretical side, if we take into account the effects of virtual massive particles in the diagrams contributing to the lepton anomaly, the ratios between the corrections to the anomalies are of the order $\left(\frac{m_\tau}{m_e}\right)^2 \sim 4 \times 10^4$ for the muon and electron, and of the order $\left(\frac{m_\tau}{m_e}\right)^2 \sim 1.2 \times 10^7$ for the tau and electron. The same huge enhancement factor would also affect the contributions coming from degrees of freedom beyond the SM, so that the measurement of the $\tau-$ anomaly would represent the best opportunity to detect new physics. Unfortunately, the very short lifetime of the $\tau-$ lepton which, precisely because of its high mass, can also decay into hadronic states, makes such a measurement impossible at present; this is the reason why there is an emphasis on the muon anomaly.

In this case, it becomes interesting to estimate the order of the correction of $a_\mu$ in the context of theories beyond the SM. This is done in terms of powers of $\frac{m_\mu}{\Lambda}$. This is related \cite{10} to the validity or the breaking of the chiral symmetry for leptons together with the change of sign for $m_\mu$. If this symmetry, which is referred to as Weinberg Symmetry
(WS), is respected, then $\Delta a_\mu \sim (m_\mu/\Lambda)^2$; on the other hand, if it is broken, $\Delta a_\mu \sim m_\mu/\Lambda$. This is important because in the latter case the explanation of the muon anomaly may be given by a new physics at a relatively high energy, whereas in the former it should appear at a scale close to the electroweak (EW) one.

We consider the 78 and 351 Higgs representations of THE $E_6$ Grand-Unified Theory (GUT). The representations between square brackets refer to the $E_6$-group, those between brackets refer to $SO(10) \otimes \bar{U}(1)$ and the ones between parentheses correspond to the $SU(5) \otimes \bar{U}(1)$ group. The symmetry breaking pattern $[6, 7, 8, 9]$ is depicted below.

$$E_6$$
$$\left[78\right] \{1, 0\}$$
$$\downarrow$$
$$SO(10) \otimes \bar{U}(1)$$
$$\left[351\right] \{1, -8\}$$
$$\downarrow$$
$$SO(10)$$
$$\left[78\right] \{45, 0\} (1, 0)$$
$$\downarrow$$
$$SU(5) \otimes \bar{U}(1)$$
$$\left[351\right] \{16, -5\} (1, -5)$$
$$\downarrow$$
$$SU(5)$$
$$\left[351\right] \{54, 4\} \{24, 0\}, \{351\} \{144, 1\} \{24, 5\}$$
$$\downarrow$$
$$SU(3)_C \otimes SU(2)_L \otimes U(1)$$
$$\left[351\right] \{10, -2\}$$
$$\downarrow$$
$$SU(3)_C \otimes U(1)_{e,m}$$

The order of magnitude of the contribution is $\Delta a_\mu \sim m_\mu/m_M$, where $m_M$ is the mass of the exotic fermion. This fermion is analogous to the ordinary muon contained in the $[27]$ representation of fermions in $\{10, -2\}$ under $SO(10) \times \bar{U}(1)$. This connection makes sense if the radiative correction to the muon mass is small and if there occurs breaking of WS. On the other hand, if the muon mass is only due to radiative corrections, the right mixing angle between leptons is zero and WS is not broken.

Our paper is organized as follows. In the Section 2, we discuss the WS in the SM in connection with the order of magnitude of the muon anomaly. In the Section 3, we present our model, considering the sequences of breakings of symmetries $[1]$. In Section 4, we analyse the question of the radiative mass of the muon due to the mixings with the
massive fermion that occur in the breaking chain $SU(5) \rightarrow SU(3)_C \otimes SU(2)_L \otimes U(1)$ with \{144, 1\} Higgs; in Section 5, we analyse WS in the context of our model and, finally, in Section 6, we present our General Conclusions.

2 WS and the anomalous magnetic moment in the SM

The WS is a well-known property [10] of the SM of Particle Physics. In this section, we briefly review its main points, since this result is connected with the order of magnitude of the $\Delta a_\mu$ contribution in the $E_6$ model. The mass term $m_\mu \overline{\mu}_\mu$ breaks chiral symmetry; the field redefinition below changes the sign of the mass term:

$$\mu \rightarrow \gamma_5 \mu \ , \quad m_\mu \rightarrow -m_\mu ,$$

where $\mu$ is the field variable associated to the muon.

If the WS Eq. (2) is valid, the corrections to $a_\mu$ must be of even powers of the ratio of $m_\mu$ to a larger scale $\Lambda$:

$$a_\mu = c_0 \left( \frac{m_\mu}{\Lambda} \right)^0 + c_2 \left( \frac{m_\mu}{\Lambda} \right)^2 + \ldots .$$

The effective interaction that gives a non-zero contribution to the muon anomalous magnetic moment is $a_\mu \frac{e}{4m_\mu} \frac{1}{m_\mu} F^{\alpha\beta}$; for the SM version, it may be written as

$$L_{\text{eff}} = a_\mu \frac{e}{4m_\mu} \left( \overline{\Psi}_L \sigma^{\alpha\beta} \mu_R \frac{f_0 \varphi_V}{m_\mu} \right) F^{\alpha\beta} ,$$

with a Higgs field doublet $\varphi = \left( \begin{array}{c} 0 \\ \varphi_1 \end{array} \right) = \varphi_V + \left( \begin{array}{c} 0 \\ h_1/\sqrt{2} \end{array} \right)$, such that

$$\overline{\Psi}_L = \left( \begin{array}{c} \nu \\ \mu \end{array} \right)_L , \quad \varphi_V = \left( \begin{array}{c} 0 \\ \nu_1 \sqrt{2} \end{array} \right) ; \quad f_0 \frac{v_1}{\sqrt{2}} = m_\mu .$$

Now, to have the WS invariance (2) in the SM, one must perform the transformations

$$\Psi_L \rightarrow \gamma_5 \Psi_L = -\Psi_L \ , \quad \mu_R \rightarrow \gamma_5 \mu_R = \mu_R \ , \quad \varphi \rightarrow -\varphi .$$

We can prove that the neutral current Lagrangian density reads as

$$L_{\text{NC}} = -e \overline{\mu} \overline{\Psi}_L \gamma^\alpha \mu A_\alpha - \frac{g}{2 \cos \theta_W} \overline{\mu} \gamma^\alpha \left( v_z - a_z \gamma^5 \right) \mu Z_\alpha ;$$

the charged current Lagrangian density is written as

$$L_{\text{CC}} = \frac{g}{2 \sqrt{2}} \left[ \overline{\nu}_\mu \gamma^\alpha \left( 1 - \gamma^5 \right) \mu W^{(+)\alpha} + \overline{\nu}_\mu \gamma^\alpha \left( 1 - \gamma^5 \right) \mu W^{(-)\alpha} \right] ,$$
and the Yukawa sector

$$\mathcal{L}_{YUK} = - f_0 (\bar{\mu}_R \varphi L + \bar{\mu}_L \varphi R) = - \frac{1}{\sqrt{2}} f_0 (v_1 + h_1) \bar{\mu} \mu,$$

(9)

where \( m_\mu = f_0 \frac{\mu}{\sqrt{2}} \) is the muon mass and the interactions are invariant under the transformations of Eq. (3). Therefore, the corrections to \( a_\mu \) are of the type of Eq. (3) with the EW scale, \( \Lambda \). The first term is the electromagnetic contribution \( c_0 = \frac{\alpha}{2\pi} + ... \), computed recently up to \( (\alpha/\pi)^5 \) [11]; the second term, \( c_2 (\frac{m_\mu}{\Lambda})^2 \sim a_\mu^{QED} \times 1, 7 \times 10^{-6} \approx 2 \times 10^{-9} \), corresponds to the weak contribution.

### 3 An alternative E₆-model for the muon anomaly

The exceptional group \( E_6 \) [12] was proposed as an alternative to \( SU(5) \)—and \( SO(10) \)—models, and it is actually, in many aspects, the preferred gauge group for Grand Unification. In this section, let us discuss the pattern of breakings [11] based on the \([78] \) and \([351] \) representations. The ordinary fermions of the SM are contained in the \( \{16, 1\} \subset 27 \)—dimensional representation:

$$[27] = \{16, 1\} \oplus \{10, -2\} \oplus \{1, 4\}.$$  

(10)

There are 11 additional fermions with respect to the SM fermions. For the first generation, these particles are:

$$\Psi_L = \left( \begin{array}{c|c|c} D^C & N & E \end{array} \right)_L \oplus \left( \begin{array}{c|c|c} D & N^C & E^C \end{array} \right)_L.$$

(11)

The gauge bosons are contained in the adjoint \( 78 \)—dimensional representation, that, with respect to \( SO(10) \otimes U(1) \), is decomposed as below:

$$[78] = \{45, 0\} \oplus \{16, -3\} \oplus \{1, 0\} \oplus \{16, 3\}.$$  

(12)

For the first generation, the exotic fermions of the \( 10 \) representation of \( SO(10) \) can acquire mass from the Higgs \( \{54, 4\} \) of the \([351] \) representation of \( E_6 \), because \( \{10\} \otimes \{10\} = \{54\} \oplus \{45\} \oplus \{1\} \). The mass terms are of the type [13]

$$\varphi_2 (\{54, 24\}) \left( D^c D - \frac{3}{2} E^c E - \frac{3}{2} N^c N \right).$$

(13)

In this same representation, \( \{144, 1\} \), let us mix these fermions with the ordinary ones, because both components contain a \( 24 \) of \( SU(5) \), which has one invariant component.
under $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y : \{16\} \otimes \{10\} = \{144\} \oplus \{16\}$. This mixing term is given by

$$\varphi_3 (144, 24) \left( d^c D - \frac{3}{2} E^c e - \frac{3}{2} N^c \nu \right).$$

(14)

Observe that both Higgs, $\varphi_2 (54, 24)$ and $\varphi_3 (144, 24)$, being singlets $(1, 1, 0)$ under $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$, we shall assume that they take different values of expectation around his quantum fields $h_2$ and $h_3$:

$$\varphi_2 (54, 24) = \frac{1}{\sqrt{2}} (v_2 + h_2)$$  \hspace{1cm}  (15)

$$\varphi_3 (144, 24) = \frac{1}{\sqrt{2}} (v_3 + h_3),$$

(16)

where the v.e.v’s $v_3$ and $v_2$ we will assume them to satisfy the relation $v_3 \leq v_2$.

On the other hand, the ordinary fermions of the SM get masses from the Higgs $\{10\} \otimes \{-2\}$, because the Yukawa term that conserves the $U(1)$ charge is

$$\{16\} \otimes \{16\} = \{10\} \oplus \{126\} \oplus \{120\},$$

(17)

and this Higgs is in the $[351]$. This mass term is

$$H (10, \overline{5}) \left( d^c d + e^c e + N^c L \right).$$

(18)

In order to explain the notation, here $\varphi'(a, 24)$ stands for the component of the Higgs representation, $\varphi'$, where the label $a$ indicates the transformation under $SO(10)$ and the label 24-component refers to $SU(5)$; similarly, for $H (10, \overline{5})$. In fact, this Higgs $H (10, \overline{5})$ is indeed that one of the SM $\varphi_1 (1, 2, 1/2)$ under $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$ which is, as we already said before, written as

$$\varphi_1 (1, 2, 1/2) = \frac{1}{\sqrt{2}} (v_1 + h_1).$$

(19)

Now, let us extend this for the second generation of fermions, and call $M$ the supermassive fermion in analogy to the ordinary muon of the SM.

If the breakings of symmetry are due to a $[351]$, when the GUT symmetry is broken, the mass eigenstates $\mu_o$ and $\hat{M}$ are determined by the expectation values of the ($SO(10), SU(5)$) multiplets $\varphi_2 (54, 24)$ and $\varphi_3 (144, 24)$, through the mixture of left and right components 

$$\left( \begin{array}{c} \mu_{L,R} \\ M_{L,R} \end{array} \right) = \left( \begin{array}{cc} \cos \theta_{L,R} & \sin \theta_{L,R} \\ -\sin \theta_{L,R} & \cos \theta_{L,R} \end{array} \right) \left( \begin{array}{c} \mu_{L,R}^0 \\ M_{L,R}^0 \end{array} \right),$$

(20)

where $\theta_{L,R}$ are the left and right mixing angles, respectively. It is possible that the mixing angle $\theta_R$ is small, of the order $\sim m_{\mu}/m_M$, where $m_M$ is the mass of the heavy muon, $M$, however, due to the weak universality, the angle $\theta_L$ between $\mu_L$ and $M_L$ is expected to be the same mixing angle for $\nu^\mu$ and the neutral exotic lepton $N$; but $\theta_L$ can still be large
The fermion-Higgs interaction Lagrangian is given by:

\[ L = \frac{f_0}{\sqrt{2}} \overline{\mu_L} \mu_R (h_1 + v_1) + \frac{f_1}{\sqrt{2}} \overline{M_L} M_R (h_2 + v_2) + \frac{f_2}{\sqrt{2}} \overline{M_L} M_R (h_3 + v_3) + \frac{f_3}{\sqrt{2}} \overline{M_L} \mu_R (h_1 + v_1) + h.c., \]

where some of the \( f_i \)'s could be vanishing. The previous expression can be written as below:

\[ L = \begin{pmatrix} \overline{\mu_L} & \overline{M_L} \end{pmatrix} \begin{pmatrix} f_0 v_1 & f_2 v_3 \\ f_3 v_1 & f_1 v_2 \end{pmatrix} \begin{pmatrix} \mu_R \\ M_R \end{pmatrix}. \]

The mass matrix reads as:

\[ M = \frac{1}{\sqrt{2}} \begin{pmatrix} f_0 v_1 & f_2 v_3 \\ f_3 v_1 & f_1 v_2 \end{pmatrix}. \]

As usually, the previous matrix mass is diagonalized by a bi-unitary transformation \[ U \]
\[ U_L^T M U_R = M_{diag}, \]
where \( U_{L,R} \) is given in \[ (20). \] From \[ U_L^T M U_R = M_{diag}^2, \] it is possible to find

\[ \tan (2\theta_L) = \frac{2 (f_0 f_3 v_2^2 + f_1 f_2 v_1 v_3)}{(f_2^2 - f_0^2) v_2^2 + f_1^2 v_1^2 - f_2^2 v_2^2}; \]

on the other hand, from \[ U_R^T M U_R = M_{diag}^2, \] we obtain

\[ \tan (2\theta_R) = \frac{2 (f_0 f_2 v_1 v_3 + f_1 f_3 v_1 v_2)}{f_1^2 v_2^2 + f_2^2 v_3^2 - (f_2^2 + f_0^2) v_2^2}. \]

In the limit for which all the couplings \( f_i \) are equal and \( v_3 \approx v_2 \gg v_1 \), we have to find \( \tan (2\theta_L) \to \infty, \)

\[ \tan (2\theta_R) \simeq \frac{2 v_1 v_2}{v_2^2 - v_1^2} \]

or to the alges \( \theta_L \) and \( \theta_R \) the values \( \theta_L = \frac{\pi}{4}, \theta_R \sim \frac{\pi}{v_2}. \) As it can be seen, in this case \( \theta_R \) is small.

The part of the interaction Lagrangian for the quantum fluctuations can be written as:

\[ L = \frac{f_0}{\sqrt{2}} \overline{\mu_L} \mu_R h_1 + \frac{f_1}{\sqrt{2}} \overline{M_L} M_R h_2 + \frac{f_2}{\sqrt{2}} \overline{M_L} M_R h_3 + \frac{f_3}{\sqrt{2}} \overline{M_L} \mu_R h_1 + h.c.; \]

after the mixing equations \[ (20), \] we obtain the changing-flavor Lagrangian:

\[ L_{FC} = \frac{f_0}{\sqrt{2}} (c_L s_R \overline{\mu_L} \overline{M_R} + c_R s_L \overline{M_L} \mu_R^0) h_1 + \frac{f_1}{\sqrt{2}} (-s_L c_R \overline{\mu_L} \overline{M_R} - c_L c_R \overline{M_L} \mu_R^0) h_2 + \]

\[ \frac{f_2}{\sqrt{2}} (c_R c_L \overline{\mu_L} \overline{M_R} - s_L s_R \overline{M_L} \mu_R^0) h_3 + \frac{f_3}{\sqrt{2}} (-s_L s_R \overline{\mu_L} \overline{M_R} + c_L c_R \overline{M_L} \mu_R^0) h_1 + h.c. \]
where \( c_{L,R} = \cos \theta_{L,R} \) and \( s_{L,R} = \sin \theta_{L,R} \). We label the neutral mass eigenstates of the Higgses by \( H_1, H_2, H_3 \) whose masses are \( M_1, M_2, M_3 \) respectively. Then, suitable rotations between of fields \( h_1, h_2, h_3 \) must diagonalize the mass matrix in the potential \( V(h_1, h_2, h_3) \). We suppose (from now in ahead) that \( M_1 \ll M_3 \sim M_2 \), assuming conservation of CP, the matrix of rotations will be real. In the limit \( v_1 \ll v_3 \leq v_2 \), the state \( h_1 \rightarrow H_1 \) is weak and any appreciable mixing between scalars will only appear between \( h_2 \) and \( h_3 \):

\[
\begin{pmatrix}
    h_2 \\
    h_3
\end{pmatrix} =
\begin{pmatrix}
    \cos \vartheta & -\sin \vartheta \\
    \sin \vartheta & \cos \vartheta
\end{pmatrix}
\begin{pmatrix}
    H_2 \\
    H_3
\end{pmatrix},
\]

with \( \vartheta \) being the angle of rotation that allows the diagonalization of the matrix. With these mixings of neutral scalars fields, the flavor-changing Lagrangian \( (28) \) now takes the form:

\[
L_{FC}^{\text{eff}} = \frac{1}{2 \sqrt{2}} \sum_{i=1}^{3} \mu^0 \left[ \tilde{\beta}_i + \tilde{\alpha}_i - \gamma_5 (\tilde{\beta}_i - \tilde{\alpha}_i) \right] \hat{M} H_i + \text{h.c.},
\]

where

\[
\begin{align*}
\tilde{\alpha}_1 &= f_0 c_{L} s_{R} - f_3 s_{L} s_{R}, \\
\tilde{\beta}_1 &= f_0 c_{R} s_{L} + f_3 c_{L} c_{R}, \\
\tilde{\alpha}_2 &= - f_1 c_{R} s_{L} \cos \vartheta + f_2 c_{L} c_{R} \sin \vartheta, \\
\tilde{\beta}_2 &= - f_1 c_{L} s_{R} \cos \vartheta - f_2 s_{L} s_{R} \sin \vartheta, \\
\tilde{\alpha}_3 &= f_1 c_{R} s_{L} \sin \vartheta + f_2 c_{L} c_{R} \cos \vartheta, \\
\tilde{\beta}_3 &= f_1 c_{L} s_{R} \sin \vartheta - f_2 s_{L} s_{R} \cos \vartheta.
\end{align*}
\]

The generic diagram with Higgs interchange contributing to the anomaly of the muon is shown in Fig.1. In fact, the explicit calculation \([17]\) of the one-loop contribution yielded by Eq. \((29)\) gives the results (in the limit \( m_M/m_\mu \gg 1 \)):

\[
\Delta a_{\mu}^{\text{FCh}} = \frac{1}{128\pi^2} m_\mu^2 \sum_{i=1}^{3} \xi_i^2 \int_{0}^{1} \frac{dx}{m_\mu^2 x^2 + \left( m_M^2 - m_\mu^2 \right) x + M_i^2 (1-x)} =
\]

8
Figure 2: Plot of $G(z_i)$ as function of $z_i$, where $z_i = M_i^2 / m_M^2$.

\[ G(z_i) = \frac{1}{128\pi^2} \frac{m_\mu}{m_M} \sum_{i=1}^{3} \xi_i^2 G(z_i), \quad (32) \]

denoting $z_i = \frac{M_i^2}{m_M^2}$ where $\xi_i^2 = \alpha_i^2 - \beta_i^2$ with $\alpha_i = \bar{\beta}_i + \bar{\alpha}_i$, $\beta_i = \bar{\beta}_i - \bar{\alpha}_i$ the function $G(z_i) = \frac{(1-z_i)^2 - 2z_i(1-z_i) - 2z_i \ln z_i}{2(1-z_i)^3}$ is plotted in Fig. (2). Let us see two cases of interest:

a) $m_M \simeq M_2 \simeq M_3 \gg M_1$. If we consider the rough case in that $f_1 = f_2$, we have $\xi_3^2 = \xi_2^2$ with the reasonable value $G(z_{2,3}) \simeq 0.3$ and $G(z_1) \simeq 0.5$ In this case the total contribution is

\[ \Delta a_{\mu}^{FCh} = \frac{1}{128\pi^2} \frac{m_\mu}{m_M} (0.5 \times \xi_1^2 + 0.6 \times \xi_2^2), \quad (33) \]

then, for to complete the anomaly value \cite{2} $\Delta a_\mu = 25.2 \times 10^{-10}$, we have

\[ 7.4 \times 10^{-3} \leq \xi_1^2 + 1.2 \times \xi_2^2 \leq 0.64 \quad (34) \]

where we consider $115\, GeV \leq m_M \leq 10\, TeV$.

b) $M_2 \simeq M_3 \gg M_1 \simeq m_M$. The principal contribution come from $H_1$

\[ \Delta a_{\mu}^{FCh} (H_1) \simeq \frac{1}{128\pi^2} \frac{m_\mu}{m_M} \xi_1^2 \, G(z_1), \quad (35) \]

and this case $G(z_{2,3}) \rightarrow 0$. We can find the limits of $\xi_1^2$ over the range masses indicated $7 \times 10^{-3} \leq \xi_1^2 \leq 0.61$, as illustred in Fig. 3.

4 Radiative corrections to the muon mass

Other interesting possibility is to suppose a situation in which the muon mass comes only from radiative corrections. There are models of this type \cite{19} \cite{20} in the literature.
Figure 3: Space of values of $\xi_2^2$ in the range of masses $115 \text{ GeV} \leq m_M \leq 10 \text{ TeV}$, $115 \text{ GeV} \leq M_1 \leq 700 \text{ GeV}$ for to complete the anomaly value, where $y = \frac{m_M}{m_\mu}$.

In the Ref. [20], the authors, working out an $SU(3) \otimes SU(3) \otimes U(1)$ model, introduce some symmetries to avoid the light fermions from acquiring their masses at tree-level through their couplings to the SM Higgs boson with non-zero vacuum expectation value; as a consequence, the muon gets its mass from the radiative corrections induced by other particles.

The one-loop correction to the muon mass is obtained by removing the photon line from the diagram Fig.(1). The amplitude for this diagram is:

$$\Sigma(p) = -i\kappa^2 \left[ \int \frac{d^4q}{(2\pi)^4} \frac{m_M(|\alpha_i|^2-|\beta_i|^2)+(|\alpha_i|^2+|\beta_i|^2)\gamma^\mu q_\mu}{(q^2-m_{3,i}^2)((p-q)^2-M_i^2)} + \int \frac{d^4q}{(2\pi)^4} \frac{+i(\alpha_i\beta_i^\dagger+\beta_i\alpha_i^\dagger)q_\mu \gamma^\mu \gamma_5}{(q^2-m_{3,i}^2)((p-q)^2-M_i^2)} \right],$$

(36)

where $\kappa = \frac{1}{2\sqrt{2}}$ and $i = 1, 2, 3$. Let us suppose that $M_2$ is the maximal energy scale for our model, then, as $m_\mu \ll m_M, M_2$, we obtain the following expression for the radiatively induced muon mass:

$$m_\mu^{1\text{-loop}} = \frac{(\alpha_2^2-\beta_2^2)}{8(4\pi)^2} m_M F(z_2),$$

(37)

$$F(z_2) = 1 - \frac{1}{z_2-1} \ln z_2,$$

(38)

where $z_2 = \frac{M_2^2}{m_M^2}$. Notice that, for $M_2 \simeq M_3 \gg m_M, M_1$ (or $z_2,3 \gg 1$), the function $F(z_2)$ takes its asymptotic value equal to 1, then

$$m_\mu^{\text{loop}}(H_2,H_3) \simeq \frac{\xi_2^2}{128\pi^2} m_M,$$

(39)
and for the case $M_2 \simeq M_3 \simeq m_M \gg M_1$ the function $F(z_2) \simeq 1 - m_M^2/M_2^2$. To assure small radiative mass for the muon, for example of $0.1\ MeV - 10\ MeV$ with $115 GeV \leq m_M \leq 10\ TeV$, it is necessary that $1.0 \times 10^{-3} \leq \xi_2^2 \leq 1.3 \times 10^{-3}$.

There is another diagram that can contribute to the radiative mass of the muon, as it is shown in Fig. 4. The result was estimated [18] [20] as

$$m_\mu^{1\text{-loop}} \simeq \frac{\varepsilon}{16\pi^2 m_M} \left[ \frac{M_2^2}{m_M^2 - M_2^2} \ln \left( \frac{m_M^2}{M_2^2} \right) - \frac{M_3^2}{m_M^2 - M_3^2} \ln \left( \frac{m_M^2}{M_3^2} \right) \right],$$  

(40)

where $\varepsilon$ is an parameter function of Yukawa couplings that can read from (29) and (30) and of the mixing angle $\theta$. However, $\tilde{M}$, $H_2$ and $H_3$ for the limit natural $m_M \ll M_2 \simeq M_3$, $m_\mu^{1\text{-loop}}$ is essentially zero.

In our model, the ordinary fermions are massless at the tree level in the GUT scale (i.e. no bare $m_\mu^0$ is possible due to symmetry), but it couples to the heavy fermion $\tilde{M}$ through the mixing with scalars, according to the breaking $SU(5) \otimes \tilde{U}(1) \rightarrow SU(5)$. If we suppose this, then the only diagrams that contribute to the anomaly are those with the interchange of $H_2$ and $H_3$ in the Fig. (1). To simplify, let us suppose the case $M_2 \simeq M_3$ and $f_1 = f_2$ from which $\xi_2^2 = \xi_3^2$; then, the contribution with the $H_2$-interchange is

$$\Delta a_{\mu}^{FCh} = \frac{\xi_2^2}{128\pi^2} \frac{m_\mu}{m_M} G(z_2);$$  

(41)

but, from (36) and (37), we can write for $M_2 \gg m_M$

$$m_\mu^{1\text{-loop}} \simeq \frac{\xi_2^2}{128\pi^2} m_M F(z_2);$$  

(42)

combining these equations, we obtain

$$\Delta a_{\mu}^{FCh} \simeq \frac{m_\mu^2}{M_2^2} \frac{z_2[(1 - z_2)^2 - 2z_2(1 - z_2) + 2z_2^2 \ln z_2]}{2(1 - z_2)^3},$$  

(43)

where the function $P(z_2) = \frac{z_2[(1 - z_2)^2 - 2z_2(1 - z_2) + 2z_2^2 \ln z_2]}{2(1 - z_2)^3}$ is plotted in the Fig.5. In this way, if the mass of the muon is of radiative origin we obtain $\Delta a_{\mu}^{FCh} \sim m_\mu^2/M_2^2$. An analogous result was obtained by Marciano using a toy model [21].
Figure 5: Plot of $P(z_2)$. Note that $P(z_2)$ is roughly $O(1)$ on the values range considered.

5 Weinberg symmetry invariance

In terms of the mixing angles $\theta_{L,R}$, from the bi-unitary diagonalization $U_L^\dagger M U_R = M_{\text{diag}}$, we find for the masses

\begin{align}
    m_\mu &= \frac{1}{\sqrt{2}}[(c_L f_0 - s_L f_3)v_1 c_R - (c_L f_2 v_3 - s_L f_1 v_2)s_R], \\
    m_M &= \frac{1}{\sqrt{2}}[(s_L f_0 + c_L f_3)v_1 s_R + (s_L f_2 v_3 + c_L f_1 v_2)c_R],
\end{align}

where $\theta_{L,R}$ are given in (24) and (25), respectively. Under the WS in (6): $\varphi \rightarrow -\varphi$, (equivalently $v_1 \rightarrow -v_1$), $\theta_L$ is invariant, but $\theta_R \rightarrow -\theta_R$, then $m_\mu \rightarrow -m_\mu$ and $m_M$ is invariant $m_M \rightarrow m_M$. Now, let us remember that $\mu$ and $M$ are in the same fundamental representation $[27]$ of $E_6$. This entails that under WS invariance, we will have $M_L \rightarrow -M_L$, $M_R \rightarrow M_R$. Then, the mass eigenstates transform as:

\begin{align}
    \mu_0^L &= c_L \mu_L - s_L M_L \rightarrow -\mu_0^L, \\
    \mu_0^R &= c_R \mu_R - s_R M_R \rightarrow \mu^L_0, \\
    \tilde{M}_L &= s_L \mu_L + c_L M_L \rightarrow -\tilde{M}_L, \\
    \tilde{M}_R &= s_R \mu_R + c_R M_R \rightarrow \tilde{M}_R.
\end{align}

Thus, the WS invariance is ensured only when $\theta_R \rightarrow 0$ or when $v_2 \gg v_1$. Consequently, the last transformations imply $m_\mu \rightarrow -m_\mu$, but not $m_M \rightarrow -m_M$ and then one may expect a linear correction to the muon magnetic moment as (31). This analysis do not apply if the muon gets its mass by radiative corrections from other particles.

6 General Conclusions

To conclude, it is possible to explain the muon anomaly in our model based on $E_6$ through the breaking chain $[\Pi]$, using only Higgses in $[78]$ and $[351]$ representations with a minimal
set of Higgses to be singlets and doublet under the SM symmetry. We find a linear relation between masses for the muon anomaly, if the radiative correction to muon mass, due to mixing with heavy fermion, is small and WS is broken. On the other hand, we find a quadratic relation between masses whenever we suppose that the muon has its mass generated only by radiative corrections in the GUT scale, since, in this case, WS is conserved.
