Sutured Manifolds and Polynomial Invariants from Higher Rank Bundles

ALIAKBAR DAEMI, YI XIE

Abstract

For each integer number $N \geq 2$, Mariño and Moore defined a generalized Donaldson invariant by the methods of quantum field theory, and made predictions about the values of these invariants. Subsequently, Kronheimer gave a rigorous definition of generalized Donaldson invariants using the moduli space of anti-self-dual connections on hermitian vector bundles of rank $N$. In this paper, Mariño and Moore’s predictions are confirmed for simply connected elliptic surfaces without multiple fibers, and certain surfaces of general type in the case that $N = 3$. The primary motivation is to study 3-manifold instanton Floer homologies which are defined by higher rank bundles. In particular, the computation of the generalized Donaldson invariants are exploited to define a Floer homology theory for sutured 3-manifolds.

1 Introduction

Sutured manifolds were introduced by Gabai [35] to study foliations and the Thurston norm of 3-manifolds [81]. A sutured manifold is a pair of a 3-manifold $M$ and an oriented 1-manifold $\alpha \subset M$ which decomposes the boundary of $M$ in an appropriate way. In [35], Gabai also defines an operation on sutured manifolds, which is called surface decomposition. Surface decompositions can be used to simplify sutured manifolds. Foliations of sutured manifolds are also well-behaved with respect to surface decompositions. As a result, Gabai was able to construct taut foliations for certain families of 3-manifolds in an inductive way.

Floer homological invariants serve as another set of tools for studying topology and geometry of 3-dimensional manifolds. Such invariants were initially constructed for closed and oriented 3-manifolds: $U(N)$-instanton Floer homology [28, 29, 60], Heegaard Floer homology [74], monopole Floer homology [57], and embedded contact homology [45, 46]. Later, Juhász defined sutured Floer homology, a generalization of Heegaard Floer homology to balanced sutured 3-manifolds [47]. Subsequently, sutured version of $U(N)$-instanton Floer homology [58], monopole Floer homology [58], and embedded contact homology were constructed [12, 11, 61]. In particular, Kronheimer and Mrowka used sutured $U(N)$-instanton homology as the main ingredient to establish that Khovanov homology detects the unknot [59]. This invariant was also used to reprove Property P for knots [58], and it lies in the core of a program in the hope of finding a computer-free proof of the famous four color theorem [55]. The primary motivation for this article is to extend $U(N)$-instanton Floer homology to sutured manifolds for higher values of $N$.

1.1 Motivation

Fix an integer number $N \geq 2$, and let $K$ be a knot in $S^3$. Let also $\mu$ denote an element of the knot group, $\pi_1(S^3\backslash K)$, represented by a meridian of $K$:

**Question 1.1.** Does there exist a representation $\varphi : \pi_1(S^3\backslash K) \to SU(N)$ with non-abelian image such that:

$$
\varphi(\mu) = e^{2\pi i/N} \begin{bmatrix} 1 & 0 & \ldots & 0 \\ 0 & \zeta & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & \zeta^{N-1} \end{bmatrix}
$$

(1.2)

where $\zeta = e^{2\pi i/N}$, and $e = e^{\pi i/N}$ or 1 depending on whether $N$ is even or odd?

Suppose the answer to the above question for a knot $K$ is positive. Obviously, $K$ cannot be the unknot. A non-abelian representation $\varphi$ satisfying (1.2) determines a non-trivial representation of $\pi_1(\Sigma_N(K))$ with $\Sigma_N(K)$ being the $N$-fold cyclic branched cover of $S^3$, branched along $K$. This verifies the Covering Conjecture, which asserts that $\Sigma_N(K)$, for a non-trivial knot $K$, is not homeomorphic to $S^3$ [49, Problem 3.38]. Modulo an application of the Poincaré Conjecture, the Covering Conjecture also implies the Smith Conjecture, stating that a non-trivial knot is not the fixed point set of a homeomorphism $f : S^3 \to S^3$ of

---

For the definition of balanced sutured 3-manifolds, see Definition 5.16.
order $N$ [49, Problem 3.38]. The Covering Conjecture and the Smith Conjecture are both theorems now, proved by geometrization techniques [1].

Kronheimer and Mrowka’s sutured $U(2)$-instanton homology group, $\text{SHI}_2^\ast$, can be employed to answer Question 1.1 affirmatively for $N = 2$ and any non-trivial knot $K$ [58]. Associated to any knot $K$, there is a sutured manifold $(M(K), \alpha(K))$ where $M(K)$ is the knot complement and $\alpha(K)$ is the union of two oppositely oriented meridional curves. Kronheimer and Mrowka proved that if the dimension of $\text{SHI}_2^\ast(M(K), \alpha(K))$ is greater than 1, then there is a non-abelian representation of the knot group of $K$ that satisfies (1.2). Similar to foliations, $\text{SHI}_2^\ast$ also behaves well with respect to surface decomposition, and one can inductively construct non-trivial elements of $\text{SHI}_2^\ast(M(K), \alpha(K))$ after simplifying $(M(K), \alpha(K))$ by a series of sutured decomposition. In particular, the dimension of $\text{SHI}_2^\ast(M(K), \alpha(K))$ is at least two for a non-trivial knot $K$. It is also known that if $K$ is a knot with non-trivial Alexander polynomial, then the answer to Question 1.1 is positive for infinitely many values of $N$ [30, 7]. In the light of the success of $\text{SHI}_2^\ast$ in addressing Question 1.1, it is natural to look for the generalization of $\text{SHI}_2^\ast$ for higher values of $N$.

The essential device in the definition of sutured Floer homology group $\text{SHI}_2^\ast$ is an excision theorem for $U(2)$-instanton Floer homology [29, 9, 58]. The proof of the excision theorem is in turn based on Muñoz’s characterization of the structure of a $U(2)$-instanton Floer homology group associated to the 3-manifold $S^1 \times \Sigma$ where $\Sigma$ is a Riemann surface [73]. Muñoz’s work borrows some results about the cohomology ring of the moduli space of rank 2 stable bundles [84, 48, 77, 5], which are not available for higher values of the rank.

In the present paper, we establish an excision theorem for $N = 3$ using the relationship between instanton Floer homology and generalizations of Donaldson invariants from [56]. Roughly speaking, there is a $(3 + 1)$-dimensional topological quantum field theory which associates $U(N)$-instanton Floer homology to 3-manifolds, and its values for closed 4-manifolds is given by $U(N)$ analogues of Donaldson’s polynomial invariants. This relationship between $U(2)$-instanton Floer homology and polynomial invariants have been extensively used to compute the invariants of 4-manifolds. In this paper, we firstly use the TQFT structure to compute the $U(3)$-polynomial invariants of some families of smooth 4-manifolds. Next, we work in the other direction, and use our knowledge of $U(3)$-polynomial invariants to obtain a better understanding of certain $U(3)$-Floer homologies. This allows us to prove the excision theorem and define a Floer homology group $\text{SHI}_3^\ast$ for sutured manifolds in the case that $N = 3$. Computations of generalized polynomial invariants in the physics literature [66] suggest that our approach can be also exploited for higher values of $N$.

1.2 Statement of Results

In his groundbreaking work [18], Donaldson defined polynomial invariants for a smooth manifold $X$ using the moduli space of Anti-Self-Dual connections on $X$. In his work, $X$ is simply connected, $b^+(X)$ is an integer number greater than 1, and the ASD connections are assumed to be defined on an $SU(2)$-bundle $E$ over $X$. Although the assumption on $b^+(X)$ is essential, the definition of polynomial invariants was

---

2The original notation for sutured $U(2)$-instanton homology is $\text{SHI}_\ast$. Here we use the superscript 2 to indicate that this invariant is the sutured version of $U(2)$-instanton homology.
Moreover, if $\phi_1$ and $\phi_2$ are two elements of $A(X)$, then:

$$\phi_1 \cdot \phi_2 = \phi_{1,2} = \phi_{2,1}.$$  

e.g., the generator of $A(X)$ is denoted by $a_1$. We also define a grading on $A(X)$ such that the degree of $a_1$ is equal to $2r - i$. A Hermitian vector bundle $E$ of rank $N$ on $X$ is determined by its first and second Chern classes. Suppose $c_1(E)$ is represented by an embedded surface $w$ in $X$ and $c_2(E)[X] = k$. Then the $U(N)$-polynomial invariants associated to the bundle $E$ is a linear map:

$$D_{X,w,k}^N : A(X)^{\otimes (N-1)} \to \mathbb{C}.$$  

For $z \in A(X)^{\otimes (N-1)}$, the complex number $D_{X,w,k}^N(z)$ is non-zero only if:

$$\deg(z) = 4Nk - 2(N - 1)w \cdot w - (N^2 - 1)\chi(X) + \sigma(X) \quad (1.3)$$  

Therefore, we will not lose any information, if we combine these invariants as:

$$D_{X,w}^N := \sum_k D_{X,w,k}^N.$$  

A substantial part of the present paper is devoted to computing $U(3)$-polynomial invariants of some families of of algebraic surfaces. Our first result in this direction is the following:

**Theorem 1.** Suppose $X$ is a $K3$ surface. Then for any embedded oriented surface $w$ in $X$ and any element $z \in A(X)^{\otimes 2}$:

$$D_{X,w}^3(a_3^2z) = 27D_{X,w}^3(z) \quad D_{X,w}^3(a_3z) = 0. \quad (1.4)$$  

Moreover, if $\Gamma$ and $\Lambda$ are two elements of $H_2(X)$, then:

$$D_{X,w}^3((1 + \frac{a_2}{3} + \frac{a_2^2}{9}) \cdot e^{\Gamma(2)+\Lambda(3)}) = e^{Q(\Gamma)/2-Q(\Lambda)} \quad (1.5)$$  

In order to clarify the statement of the above theorem, the following remarks are in order. The left hand side of (1.5) is defined as:

$$D_{X,w}^3((1 + \frac{a_2}{3} + \frac{a_2^2}{9}) \cdot e^{\Gamma(2)+\Lambda(3)}) := \sum_{i=0}^{\infty} \sum_{j=0}^{\infty} \frac{D_{X,w}^3((1 + \frac{a_2}{3} + \frac{a_2^2}{9})\Gamma_i^{(2)}\Lambda_j^{(3)})}{i!j!}.$$  

Theorem 1 asserts that the above series for a $K3$ surface is convergent, and the resulting number is equal to $e^{Q(\Gamma)/2-Q(\Lambda)}$. Here $Q$ denotes the intersection form of $X$. That is to say, $Q(\Gamma)$ is the algebraic
intersection number of $\Gamma$ with itself. In general, the intersection number of two homology classes $\Gamma$ and $\Gamma'$ is denoted by $\Gamma \cdot \Gamma'$. Since (1.5) holds for all choices of $\Gamma$ and $\Lambda$, Formula (1.3) allows us to compute the following polynomial invariants for all choices of non-negative integer numbers $i$, $j$, the integer number $k \in \{0, 1, 2\}$, and homology classes $\Gamma$ and $\Lambda$:

$$D^3_{X,w}(a^2k\Gamma^2\Lambda^j_3)$$

These invariants determine $D^3_{X,w}(z)$ for all $z \in \mathbb{A}(X)^{\otimes 2}$, because the $K3$ surface satisfies (1.4) and $b_1(X) = 0$.

Our computation of the invariants of $K3$ surfaces motivates the following definition: a smooth 4-manifold $X$ with $b^+ (X) \geq 2$ and $b^1 (X) = 0$ has $w$-simple type with respect to an embedded surface $w$, if:

$$D^3_{X,w}(a^2_3z) = 27D^3_{X,w}(z) \quad D^3_{X,w}(a^3z) = 0 \quad (1.6)$$

for all $z \in \mathbb{A}(X)^{\otimes 2}$. The 4-manifold $X$ has simple type if it has $w$-simple type with respect to any $w$ in $X$. As in the case of the $K3$ surfaces, if $X$ has simple type and the series:

$$\tilde{D}_{X,w}(e^{\Gamma_2}+\Lambda_3) := D^3_{X,w}((1 + \frac{a^2_2}{3} + \frac{a^2_2}{9}) \cdot e^{\Gamma_2}+\Lambda_3)$$

is convergent for all choices of $w$ and $\Gamma, \Lambda \in H_2(X)$, then these series determine all polynomial invariants of $X$.

We can extend our calculation for the $K3$ surfaces to a larger family of complex surfaces. Suppose $W(m, n)$ is the blowup of $\mathbb{CP}^1 \times \mathbb{CP}^1$ at the $4mn$ singular points of the following (complex) curve:

$$B := \{p_1, \ldots, p_{2m}\} \times \mathbb{CP}^1 \cup \mathbb{CP}^1 \times \{q_1, \ldots, q_{2n}\}.$$ 

Let $\tilde{B}$ be the proper transform of $B$, and define $X(m, n)$ to be the branched double cover of $W(m, n)$, branched along the smooth curve $\tilde{B}$. The horizontal and vertical fibrations of $W(m, n)$ by projective lines lift to two fibrations of $X(m, n)$ whose generic fibers are denoted by $f_{m-1}$ and $f_{n-1}$. The Riemann surface $f_i$, for $i \in \{m-1, n-1\}$, has genus $i$. The complex surface $X(2, 2)$ is a $K3$ surface. More generally, $X(m, 2)$ is an elliptic surface without multiple fibers, which is usually denoted by $E(m)$ [41].

**Theorem 2.** The elliptic surface $E(n)$ has simple type. Moreover, there are rational numbers $h_1$ and $h_2$ independent of $n$ such that for any embedded surfaces $w$ in $E(n)$ and $\Gamma, \Lambda \in H_2(E(n))$, the series $\tilde{D}_{E(n),w}(e^{\Gamma_2}+\Lambda_3)$ is equal to:

$$e^{-\frac{Q(1)}{2} - Q(\Lambda)}[h_1 \cosh(\sqrt{3}f \cdot \Gamma) - 2h_2 \cos(-\frac{2\pi}{3}w \cdot f + \sqrt{3}f \cdot \Lambda)]^{n-2}.$$ 

where $f = f_1$ represents an elliptic fiber of $E(n)$. Furthermore, $h_1 + h_2 = \pm 1$ for an appropriate choice of the sign.

The set of surfaces $X(m, n)$, as smooth 4-manifolds, are closed with respect to taking fiber sums$^3$. For example, we can take the fiber sum of $X(m, n_1)$ and $X(m, n_2)$ along the fiber $f_{m-1}$, and the

$^3$See section 3.3 for a review of the definition of fiber sum.
resulting 4-manifold is diffeomorphic to \( X(m, n_1 + n_2) \). Given two embedded surfaces \( \Sigma_1 \subset X(m, n_1) \) and \( \Sigma_2 \subset X(m, n_2) \) which intersect a fiber in the same number of points, we can form a surface \( \Sigma_1 \# \Sigma_2 \subset X(m, n_1 + n_2) \). Suppose \( \mathcal{H}(m, n_1, n_2) \subset H_2(X(m, n_1 + n_2)) \) is the space of homology classes generated by homology classes of the surfaces of the form \( \Sigma \#. \Sigma' \). The following theorem about \( X(m, 4) \) is a consequence of Theorem 4.89 about the polynomial invariants of fiber sums. In fact, Theorem 4.89 can be used to obtain similar results about other surfaces in the family \( X(m, n) \).

**Theorem 3.** For \( m \geq 3 \), let \( w \subset X(m, 4) \) be an embedded surface which has the form \( w_1 \# w_2 \) for \( w_1 \subset X(m, 2) \) and \( w \cdot f_{m-1} \not\equiv 0 \text{ mod } 3 \). Let \( K \) denote the canonical class of \( X(m, 4) \). Then there are rational numbers \( h_3 \) and \( h_4 \), independent of \( m \), such that for \( \Gamma, \Lambda \in \mathcal{H}(m, 2, 2) \) the series \( \tilde{D}_{X(m, 4), w}(e^{\Gamma(2) + \Lambda(2)}) \) is convergent and is equal to:

\[
e^{-\frac{Q(\Gamma)}{2} - Q(\Lambda)} \left[ \frac{1}{2} h_3^2 h_4^{m-2} \cosh(\sqrt{3}K \cdot \Gamma) + 2h_3^2 h_4^{m-2} \cos\left( -\frac{2\pi}{3} w \cdot K + \sqrt{3}K \cdot \Lambda \right) \right]
\]

where \( h_1, h_2 \) are the constants of Theorem 2.

We do not attempt to find the undetermined constants \( h_1, h_2, h_3 \) and \( h_4 \) here and leave this task for elsewhere [14]. We also believe that \( X(m, 4) \) has simple type, and the above theorem holds for any choice of \( w \subset X(m, 4) \) and homology classes \( \Gamma \) and \( \Lambda \). But the current version of the theorem is sufficient for our 3-dimensional applications.

The algebraic surfaces in Theorems 1, 2 and 3 are representatives of surfaces with different possible finite Kodaira dimensions. \( K3 \) surfaces, elliptic surface \( E(n) \) with \( n \geq 2 \) and \( X(m, 4) \) for \( m \geq 3 \) have Kodaira dimensions 0, 1 and 2, respectively. Theorem 1 shows that the \( U(3) \)-polynomial invariants of these surfaces associated to homology classes \( \Gamma \) and \( \Lambda \) are determined by the self-intersection of these homology classes. On the other hand, for the \( U(3) \)-polynomial invariants of \( E(n) \) and \( X(m, 4) \) we also need the pairing of \( \Gamma \) and \( \Lambda \) with the fundamental class. Recall that the the first Chern class of the fundamental classes of \( E(n) \) and \( X(m, 4) \) are represented by \( (n - 2)f \) and \( (m - 2)f_3 + 2f_{m-1} \), respectively.

In Section 3, we introduce various Floer homology groups associated to the 3-manifold \( S^1 \times \Sigma \), and explain how these vector spaces admit ring structure. We also characterize the vector space structure on these Floer homology groups. Theorems 2 and 3 allow us to obtain further information about the ring structure of these rings. We use this information to obtain an excision theorem for \( U(3) \)-instanton Floer homology. With the aid of this excision theorem, we construct the promised sutured Floer homology \( SHI^3 \) by following Kronheimer and Mrowka’s approach in [58]. This sutured Floer homology group has the following property:

**Theorem 4.** For a knot \( K \), suppose the dimension of \( SHI^3(\Sigma(K), \alpha(K)) \) is greater than 1. Then there is a non-abelian representation of \( \pi_1(S^3 \setminus K) \) into \( SU(3) \) that satisfies the holonomy condition (1.2).

We conjecture that \( \dim(\text{SHI}^3(\Sigma(K), \alpha(K)) > 1 \) for any non-trivial knot \( K \). This addresses Question 1.1 for \( N = 3 \). We hope to come back to this conjecture elsewhere.
1.3 Outline of Contents

Section 2 gives a review of the moduli spaces of anti-self-dual connections on 4-manifolds (possibly with boundary) and $U(N)$-polynomial invariants. This section also contains a non-vanishing theorem for $U(N)$-polynomial invariants of algebraic surfaces. The second half of Section 2 discusses how the $U(3)$-polynomial invariants behave in the presence of negative embedded spheres. In particular, we recall the results of Culler’s thesis [13] about the blowup formula for $U(3)$-polynomial invariants and discuss how this formula can be simplified for smooth 4-manifolds with simple type. Section 3 deals with various Floer homology groups, which appear in this paper. After giving an exposition of $U(N)$-instanton Floer homology, we study various Floer homologies of $\Sigma \times S^1$ where $\Sigma$ is an oriented surface. We also discuss a generalization of $U(N)$-instanton Floer homology, which is known as Fukaya-Floer homology in the case that $N = 2$.

The Floer homology groups of Section 3 are our main tools in computing $U(3)$-polynomial invariants of elliptic surfaces in Section 4. The proof of Theorem 4.89 about $U(3)$-polynomial invariants of fibered sums is also given in Section 4. In Section 5, we prove our excision theorem and define the sutured Floer homology group $SHI_3$. To make the exposition of the paper more comprehensible, we omit the proofs of some of the results in Sections 2 and 3. These results are proved by gluing theory of the moduli spaces of anti-self-dual connections in Section 6. Section 7 concerns various questions and conjectures which naturally arise from our work on this paper.

All manifolds in this paper, are smooth and oriented. Given such a manifold $X$, we will write $H_i(X)$ and $H^i(X)$ for the homology and cohomology groups of $X$ with complex coefficients. If we need to work with another coefficient ring $R$, then we use the notations $H_i(X, R)$ and $H^i(X, R)$. Our main results for this paper concern $U(3)$-polynomial invariants and $U(3)$-instanton Floer homologies. However, we believe that our method for the construction of $SHI_3$ should work for arbitrary $N$. Therefore, we try to state our results for general $N$, when it is possible.

Acknowledgements. We thank Lucas Culler, Simon Donaldson, Peter Kronheimer, Claude LeBrun and Tomasz Mrowka for helpful conversations. We also thank Victor Mikhaylov for verifying that our definition of the simple type condition matches the predictions from the physics literature. We are very grateful to the Simons Center for Geometry and Physics for providing a stimulating environment while we were working on this project.

2 Higher Rank Bundles and Polynomial Invariants

2.1 $U(N)$-polynomial Invariants

In this section, we review the definition of $U(N)$-polynomial invariants of 4-manifolds based on [56, 13]. For $N = 2$, there is a substantial literature on the subject (see, for example, [18, 21, 54]). For higher values of $N$, these invariants were firstly defined in [66] by the methods of quantum field theory. A rigorous definition of polynomial invariants for higher rank bundles are given in [56]. As we mentioned earlier, the polynomial invariants of a 4-manifold $X$ are homomorphisms defined on the algebra $\mathbb{A}(X)^{(N-1)}$. In
[56], the polynomial invariants are defined only on the sub-algebra:

\[ A(X) \otimes 1 \otimes \cdots \otimes 1 \]

Kronheimer’s definition was subsequently generalized to the algebra \( A(X)^{\otimes (N-1)} \) in [13]. The construction of Fukaya-Floer homology in subsection 6.3 is based on Culler’s modification of \( U(N) \)-polynomial invariants in [13]. Therefore, we attempt to give enough background on his treatment to motivate the construction of \( U(N) \)-Fukaya-Floer homology.

Suppose \( X \) is a smooth, oriented and connected 4-manifold, \( w \) is an oriented embedded surface in \( X \), and \( k \) is an integer number. Then there is a \( U(N) \)-bundle \( P \), unique up to isomorphism, over \( X \) such that \( c_1(P) = \text{P.D.}[w] \) and \( c_2(P)[X] = k \). An explicit construction of this \( U(N) \)-bundle can be given as follows. Suppose \( D(w) \) is a regular neighborhood of \( w \) in \( X \) whose boundary is denoted by \( S(w) \). Then we can consider a Hermitian line bundle on \( D(w) \) which is trivialized on \( S(W) \) and its relative first Chern class is given by the Thom class of the disc bundle \( D(w) \). By extending the trivialization to the complement of \( D(w) \), we obtain a Hermitian line bundle \( L_w \) where \( c_1(L_w) = \text{P.D.}[w] \). The direct sum of \( L_w \) and the trivial bundle \( \mathbb{C}^{N-1} \) defines a \( U(N) \)-bundle \( P_0 \) on \( X \) with \( c_2(E_0)[X] = 0 \) and \( c_1(E_0) = c_1(L_w) \). Next, fix a \( U(N) \)-bundle on the 4-dimensional ball \( D^4 \) which is trivialized on the boundary and its relative second Chern class is given by \( k\text{P.D.}[pt] \). Removing a ball from \( X \setminus D(w) \) and gluing the above ball gives rise to the same 4-manifold. We can also use the trivializations to glue the \( U(N) \)-bundle on \( D^4 \) to \( P_0 \) and produce a \( U(N) \)-bundle \( P \) with \( c_1(P) = \text{P.D.}[w] \) and \( c_2(P)[X] = k \). The determinant bundle of \( P \) is equal to \( L_w \).

A 2-cycle \( w \) in a closed 4-manifold is a union of embedded closed surfaces in \( X \). We can apply the above construction of the previous paragraph to obtain a Hermitian line bundle \( L_{w_i} \) for each connected component \( w_i \) of \( w \). Then we can replace \( L_{w_i} \) in the previous paragraph with the tensor product of the line bundles \( L_{w_i} \) and produce a \( U(N) \)-bundle \( P \) with \( c_1(P) = \text{P.D.}[w] \) and \( c_2(P)[X] = k \). The topological energy of \( P \) is defined to be:

\[
\kappa := k - \frac{N-1}{2N} w \cdot w
\]

Thus the bundle \( P \) is determined by the pair \((\kappa, w)\). A closed 2-cycle \( w \) in \( X \) is coprime to \( N \), if there is an embedded oriented surface \( \Sigma \subset X \) such that the intersection number \( w \cdot \Sigma \) is coprime to \( N \).

Suppose \( P \) is a \( U(N) \)-bundle on a closed 4-manifold determined by a pair \((\kappa, w)\). Fix an integer number \( l \geq 3 \) and an arbitrary smooth connection \( B_0 \) on \( L_w \). Let \( \mathcal{A}_\kappa(X, w) \) be the space of \( L^2_0 \) connections on \( P \) whose induced connections on \( \text{det}(P) = L_w \) is equal to \( B_0 \). If \( \text{su}(P) \) is the bundle associated to the conjugation action of \( U(N) \) on the Lie algebra \( \text{su}(N) \) of \( SU(N) \), then \( \mathcal{A}_\kappa(X, w) \) is an affine space modeled on the Banach space \( L^2_0(X, \text{su}(P) \otimes \Lambda^1) \). We will also write \( \mathcal{G}_\kappa(X, w) \) for the space of \( L^2_{\Gamma+1} \) automorphisms of \( P \) whose fiber-wise determinant is equal to 1. Then \( \mathcal{G}_\kappa(X, w) \) forms a Banach Lie group with Lie algebra \( L^2_{\Gamma+1}(X, \text{su}(P)) \). This Lie group acts on \( \mathcal{A}_\kappa(X, w) \), and the quotient space is denoted by \( B_\kappa(X, w) \). We will write \([A]\) for an element of \( B_\kappa(X, w) \), represented by a connection \( A \). The center of the Lie group \( U(N) \) induces a finite subgroup of \( \mathcal{G}_\kappa(X, w) \). If this subgroup is the stabilizer of a connection \( A \), then \( A \) is an irreducible connection. Otherwise, the connection \( A \) is called reducible. The space of reducible connections on \( P \) are denoted by \( \mathcal{A}^*_\kappa(X, w) \), and we will write \( B^*_\kappa(X, w) \) for the quotient space.
Fix a Riemannian metric on $X$ and let $\ast$ denote the associated Hodge operator on differential forms of $X$. Then $\ast$ defines an involution on the space of 2-forms on $X$, and 2-forms in the 1-eigenspace (respectively, $-1$-eigenspace) are called self-dual (respectively, anti-self-dual). A connection $A \in \mathcal{A}_\kappa(X, w)$ is anti-self-dual if it satisfies the following equation:

$$F_0^+(A) = 0$$

where $F_0(A)$ denotes the projection of the curvature of $A$ to the space $\mathfrak{su}(P)$, and $F_0^+(A)$ is the self-dual part of $F_0(A)$. In another word, the connection induced by $A$ on the associated PU($N$)-bundle to $P$ has anti-self-dual curvature. The equation (2.1) is invariant with respect to the action of $\mathcal{G}_\kappa(X, w)$ and the quotient space of ASD connections is denoted by $\mathcal{M}_\kappa(X, w)$.

The local behavior of the moduli space $\mathcal{M}_\kappa(X, w)$ around an element $[A]$ is governed by the following elliptic complex, denoted by $\mathcal{D}_A$:

$$L^2_{l+1}(X, \mathfrak{su}(P)) \xrightarrow{d_A} L^2_l(X, \mathfrak{su}(P) \otimes \Lambda^1) \xrightarrow{d_A^+} L^2_{l-1}(X, \mathfrak{su}(P) \otimes \Lambda^1)$$

where $\Lambda^1$ denotes the bundle of self-dual forms on $X$. The $k$th cohomology group of this complex is denoted by $H^k_A$. The connection $A$ is irreducible if and only if $H^0_A$ is trivial. We say $A$ is regular, if $H^2(A)$ is trivial. If $A$ is an irreducible and regular ASD connection, then in a neighborhood of $[A]$, the moduli space is a smooth manifold of dimension $H^1_A$. In this case, the dimension of $H^1_A$ is given explicitly by the following formula:

$$4N \kappa - (N^2 - 1) \frac{X(X) + \sigma(X)}{2}$$

(2.3)

In general, the index of the elliptic complex $\mathcal{D}_A$ is given by (2.3).

The ASD equation (2.1) can be perturbed by changing the metric on $X$. Holonomy perturbations determine another useful family of perturbations of the ASD equations [17, 79, 28, 20, 56, 60]. By abuse of notation, a solution of the perturbation of the ASD equation by a holonomy perturbation is still called an ASD connection, and the moduli space of the solutions of the perturbed equation is still denoted by $\mathcal{M}_\kappa(X, w)$. Suppose $w$ is coprime to $N$ and $b^+(X) \geq 1$. Then for a generic choice of the metric on $X$ and a small holonomy perturbation the moduli space $\mathcal{M}_\kappa(X, w)$ consists of only irreducible and regular connections [56]. Therefore, the moduli space is a smooth manifold whose dimension given in (2.3). This manifold is also orientable and in the case that $N$ is odd [56], a canonical choice of an orientation can be fixed. If $N$ is even, to fix an orientation of the moduli space, we need an orientation of the determinant line of the following elliptic operator:

$$d^+ \oplus d^* : L^2_l(X, \Lambda^1) \rightarrow L^2_{l-1}(X, \Lambda^1) \oplus L^2_{l-1}(X)$$

Such an orientation of the determinant line is called a homology orientation of $X$. The $U(N)$-polynomial invariants of $X$ are given by integrating appropriate cohomology classes on $\mathcal{M}_\kappa(X, w)$.

The pull-back of $P$ to the product space $\mathcal{A}_\kappa(X, w) \times X$ admits an action of $\mathcal{G}_\kappa(X, w)$ which lifts the obvious action on the base. The quotient space defines a PU($N$)-bundle $\mathbb{P}$ over $\mathcal{B}_\kappa^\ast(X, w) \times X$, called the universal bundle associated to $P$. In general, $\mathbb{P}$ cannot be lifted to an SU($N$)-bundle. However, we can define Chern classes of $\mathbb{P}$ as rational cohomology classes of $\mathcal{B}_\kappa^\ast(X, w) \times X$, because the rational
The slant product of the Chern classes of the universal bundle and the homology classes of $X$ gives rise to cohomology classes of $B^*_k(X, w)$. This construction can be used to define an algebra homomorphism:

$$\mu : \mathbb{A}(X)^{(N-1)} \rightarrow H^*(B^*_k(X, w)).$$

(4.4)

where $\mu$ is the unique algebra homomorphism that satisfies the following property:

$$\mu(\alpha_i) = c_r(\mathbb{P})/\alpha.$$

Let the 2-cycle $w$ be coprime to $N$, and arrange a metric and a small holonomy perturbation such that the resulting moduli space consists of irreducible and regular points. We will temporarily write $M_\kappa(X, w, \pi_0)$ for the moduli space to emphasize the dependence on $\pi_0$, denoting the metric and the holonomy perturbation. If $N$ is even, fix a homology orientation for $X$. Then $M_\kappa(X, w, \pi_0)$ can be canonically oriented. Let $d = \dim(M_\kappa(X, w, \pi_0))$, and fix $z \in \mathbb{A}(X)^{(N-1)}$ such that $\deg(z) = d$. If the moduli space $M_\kappa(X, w, \pi_0)$ is compact, then we can evaluate $\mu(z)$ with respect to the fundamental class of $M_\kappa(X, w, \pi_0)$ and obtain a number $D^N_{X, w, k}(z)$. (Recall that $k$ is the second Chern number of $P$.) We wish to show that this number does not depend on $\pi_0$, the metric and the holonomy perturbation. Suppose $\pi_1$ is another choice of a metric and a small holonomy perturbation avoiding reducible and irregular points. If $b^+(X) \geq 2$, then we can find a path $\{\pi_t\}_{0 \leq t \leq 1}$ of metrics and small holonomy perturbations such that the 1-parameter family of moduli spaces:

$$\bigcup_t M_\kappa(X, w, \pi_t)$$

(2.5)

is a smooth manifold of dimension $d + 1$. Since the class $\mu(z)$ can be pulled back to (2.5), Stokes theorem implies that $\pi_0$ and $\pi_1$ give rise to the same number $D^N_{X, w, k}(z)$, assuming (2.5) is also compact. However, $M_\kappa(X, w, \pi_0)$ and the 1-parameter family of moduli spaces are not compact in general and we need to pursue a geometric approach to define the evaluation of $\mu(z)$ on $M_\kappa(X, w, \pi_0)$.

Uhlenbeck compactification of the moduli space $M_\kappa(X, w)$ compensates for the non-compactness of this space. Suppose $\{[A_n]\}$ is a sequence of the elements of $M_\kappa(X, w)$. Then there is a multi-set $x$ of $m$ points in $X$, and a connection $A_\infty \in M_{k-m}(X, w)$ such that, after passing to a subsequence, $(h_n)_*(A_n)$ is $L^1$-convergent to $A_\infty$ on $X \setminus x$ for any given real number $p$ [56, Proposition 11]. Here $h_n$ is an isomorphism from the $U(N)$-bundle carrying $A_n$ to the $U(N)$-bundle carrying $A_\infty$ which is defined only on $X \setminus x$ and its determinant does not depend on $n$.

Another key input is that $\mathbb{P}$ can be replaced with a Hermitian vector bundle [13]. Consider the standard representation of $SU(N)$ on $\mathbb{C}^N$. The tensor product $SU(N)$-space $(\mathbb{C}^N)^{\otimes N}$ induces a representation of the group $PU(N)$. Therefore, we can associate a vector bundle $E$ of rank $N^N$ to $\mathbb{P}$. We call $E$ the universal complex vector bundle. The Chern class $c_i(\mathbb{P})$ can be written as a polynomial in terms of Chern classes $c_j(E)$ for $2 \leq j \leq i$. For example, $c_2(\mathbb{P})$ is equal to $\frac{1}{N^2} c_2(E)$. Therefore, it suffices to define $D^N_{X, w, k}(z)$ for the elements $z \in \mathbb{A}(X)^{(N-1)}$ that:

$$\mu(z) = c_{i_1}(E)/\alpha_1 \cdot \ldots \cdot c_{i_m}(E)/\alpha_m \quad 2 \leq i \leq N.$$  

(2.6)
In order to define this polynomial invariant, let $\Sigma_i$ be a submanifold of codimension at least 2 which represents the homology class $\alpha_i$.

The Chern classes of a vector bundle $V$ of rank $r$ over a manifold $M$ can be represented by stratified subspaces of $M$. The vector bundle $\text{Hom}(\mathbb{C}^{r-i+1}, V)$ is stratified by rank. If $s$ is a generic section of $V$, then:

$$N_i := \{ x \in M \mid \text{rank}(s(x)) \leq r - i \}$$

(2.7)

is a stratified subspace of $M$ with strata of even codimension. Therefore, the fundamental class of $N_i$ determines a well-defined homology class, which is the Poincaré dual of $c_i(V)$.

In order to define $D_{X,w,k}^N(z)$ for $z$ in (2.6), fix an open neighborhood $\nu(\Sigma_j)$ of the submanifold $\Sigma_j$ such that the inclusion of this open set in $X$ induces a surjective map of fundamental groups. The unique continuation theorem implies that if the holonomy perturbation in the definition of $\mathcal{M}_\nu(X, w)$ is small enough, then the restriction of any element of this moduli space to $\nu(\Sigma_j)$ is irreducible [56]. We also assume that $\nu(\Sigma_j)$ and $\nu(\Sigma_k)$ intersect only if $\Sigma_j$ and $\Sigma_k$ are embedded surfaces and each point of $X$ lie on at most two such open neighborhoods. Analogous to $E$, we can form a vector bundle $E_j$ of rank $N^N$ on $B^*(\nu(\Sigma_j)) \times \nu(\Sigma_j)$. In order to produce a representative for $c_{ij}([E_j])$, we form the bundle $\text{Hom}(\mathbb{C}^{N-N-i+1}, E_j)$, and form a subspace $V_{ij}(\Sigma_j)$ of $B^*(\nu(\Sigma_j)) \times \nu(\Sigma_j)$ as in (2.7).

The vector bundles $E$ and $E_j$ are related to each other. The pull back of $E_j$ with respect to the restriction map $r_j : \mathcal{M}_\nu(X, w) \times \Sigma_j \to B^*(\nu(\Sigma_j)) \times \nu(\Sigma_j)$ is the restriction of the bundle $E$. This suggests that $D_{X,w,k}^N(z)$ can be defined as the signed count of the points in the following cut-down moduli space:

$$\mathcal{N}_\nu(X, w; z) := \{ ([A], x_1, \ldots, x_m) \in \mathcal{M}_\nu(X, w) \times \Sigma_1 \times \cdots \times \Sigma_m \mid r_j([A], x_j) \in V_{ij}(\Sigma_j) \}$$

For a generic choice of $V_{ij}(\Sigma_j)$, $\mathcal{N}_\nu(X, w; z)$ is a compact 0-dimensional space, and the orientation of $\mathcal{M}_\nu(X, w)$ fixes a sign on each point on this space [56, 13]. The compactness of the cut-down moduli space is a consequence of Uhlenbeck compactification using a standard counting argument [18, 21, 56, 13]. Counting the points of the cut-down with respect to the associated signs define a number which only depends on the homology class of $\Sigma_1, \ldots, \Sigma_m$, and this dependence for each homology class is linear. If $b^+(X) \geq 2$, we can adapt the geometric counting argument to the moduli space (2.5), and show that the invariant $D_{X,w,k}^N$ does not depend on the choice of the metric on $X$ and the holonomy perturbation of the ASD equation.

There is also a standard trick which allows us to define $D_{X,w,k}^N$ in the case that $w$ is not coprime to $N$. Suppose $\hat{X}$ denotes the blowup of $X$ at an arbitrary point. Suppose also $E$ is the exceptional sphere of $\hat{X}$. Then the cycle $w + E$ is coprime to $N$. In the non-coprime case, define:

$$D_{X,w,k}^N(z) := D_{X,w+E,k}^N(E^{N-1}z).$$

In the case that $w$ is already coprime, the above definition turns into an identity which is proved in [56].

The invariant $D_{X,w,k}^N(z)$ is defined to be zero if $\deg(z)$ is not equal to the dimension of $\mathcal{M}_\nu(X, w)$. For a fixed 2-cycle $w$ in $X$, the moduli spaces of ASD connections appear in different dimensions whose values mod $4N$ are constant. We use (1.2) to define $D_{X,w}^N(z)$, which is called the $U(N)$-polynomial.
We use a similar convention in the case that where we define where we have:

\[ \dim(z) \equiv 2(N + 1)w \cdot w - (N^2 - 1)\frac{\chi(X) + \sigma(X)}{2} \mod 4N \]

In particular, if \( N \) is an odd integer number, the invariant \( D^N_{X,w}(z) \) vanishes for the classes \( z \) that \( \dim(z) \) is not divisible by 4.

There are relationships among the polynomial invariants of \( X \) associated to different 2-cycles. If \( w \) and \( w' \) are two 2-cycles in \( X \), then:

\[ D^N_{X,w+Nw'}(z) = (-1)^{cw' \cdot w'} D^N_{X,w}(z). \tag{2.8} \]

where \( c \) is zero if \( N \) is odd or divisible by 4, and is equal to 1 if \( N \) is 2 mod 4. The invariants associated to the 2-cycles \( w \) and the same 2-cycle with the reverse orientation, denoted by \( -w \), are also related. As it is explained in [56], there is a diffeomorphism from \( \mathcal{M}_\kappa(X, w) \) to \( \mathcal{M}_\kappa(X, -w) \). This diffeomorphism is orientation preserving if \( N \) is odd, and change the orientation by the factor of \((-1)^{w \cdot w'} \) if \( N \) is even. The diffeomorphism lifts to an anti-linear isomorphism of the universal complex vector bundles. Therefore, we have:

\[ D^N_{X,-w}(z) = (-1)^{(N-1)w \cdot w} D^N_{X,w}(\tau(z)). \tag{2.9} \]

where \( \tau : \mathbb{A}(X)^{\otimes (N-1)} \rightarrow \mathbb{A}(X)^{\otimes (N-1)} \) is the algebra homomorphism that maps \( \alpha_{(r)} \) to \((-1)^r \alpha_{(r)} \).

Suppose \( \Gamma^2, \ldots, \Gamma^N \) are elements of \( H_2(X) \) and \( z \in \mathbb{A}(X)^{\otimes (N-1)} \). To avoid the convergence issue, we define \( D^N_{X,w}(ze^{\Gamma^2 + \cdots + \Gamma^N}) \) in a slightly different way in compare to the introduction:

\[ D^N_{X,w}(ze^{\Gamma^2 + \cdots + \Gamma^N}) := \sum_{0 \leq i_2, \ldots, i_N < \infty} \frac{D_{X,w}(z(e^{i_2} \Gamma^2 + \cdots + i_N \Gamma^N))}{i_2! \cdots i_N!} t_2^{i_2} \cdots t_N^{i_N} \]

where \( t_i \) is a formal variable. Therefore, the \( \U(N) \)-series \( D^N_{X,w}(ze^{\Gamma^2 + \cdots + \Gamma^N}) \) is an element of the ring of formal power series \( \mathbb{C}[[t_2, \ldots, t_N]] \). We can also define an element of \( \mathbb{C}[[t_2, \ldots, t_N]] \) for linear functionals \( f_2, \ldots, f_N : H_2(X) \rightarrow \mathbb{C} \) and a a power series \( g(x) = \sum_{i=0}^{\infty} b_i x^i \):

\[ g(f_2(\Gamma^2) + \cdots + f_N(\Gamma^N)) := \sum_{i=0}^{\infty} b_i (f_2(\Gamma^2) t_2 + \cdots + f_N(\Gamma^N) t_N)^i \tag{2.10} \]

We use a similar convention in the case that the \( f_i \) are homogeneous polynomials of higher degree (eg. the intersection form \( Q \)). These conventions allow us to rephrase Theorems 1, 2 and 3 in terms of the identities of the elements of \( \mathbb{C}[[t_2, t_3]] \).

Remark 2.11. Suppose \( X \) is a 4-manifold with \( b^+(X) = 1 \). For a generic metric and for small holonomy perturbations the moduli spaces \( \mathcal{M}_\kappa(X, w) \) contains only irreducible connections. For each such choice of metric, we can apply the construction of this section to define a \( \U(N) \)-polynomial invariant \( D^N_{X,w} \). However, this polynomial invariant depends on the choice of the metric, because a 1-parameter family of moduli spaces as in (2.5) might have reducible connections. As a result, the space of metrics on \( X \) can be divided into chambers, such that \( D^N_{X,w} \) is constant only inside the interior of each chamber. Such polynomial invariants have been studied for \( N = 2 \) in [51, 52].
2.2 Cylindrical Ends and Moduli Spaces

One of the important themes of this article is the interplay between gauge theory on 3-manifolds and 4-manifolds. One can see the interaction by considering the analogues of the geometrical objects from the previous section on 4-manifolds with boundary. Suppose \( W \) is a 4-manifold with boundary \( Y \), and fix a metric which is a product metric in a collar neighborhood of \( Y \). A smooth 2-cycle in \( W \) is a properly embedded 2-dimension submanifold of \( W \). A 2-cycle in \( w \) in \( W \) is a union of smooth 2-cycles in \( W \) whose boundary determines a smooth 1-manifold \( \gamma \subset Y \). We will say that the boundary of the pair \((W, w)\) is the pair \((Y, \gamma)\). We also form a pair of non-compact manifolds \((W^+, w^+)\) by adding the cylindrical ends \([0, \infty) \times Y\) and \([0, \infty) \times \gamma\) to \( W \) and \( w \).

As in the previous part, we can associate a \( U(N) \)-bundle \( Q \) to the pair \((Y, \gamma)\). This \( U(N) \)-bundle is trivialized on the complement of a regular neighborhood \( D(\gamma) \) of \( \gamma \), and its relative first Chern class on \( D(\gamma) \) is given by the Thom class. We will also write \( L_\gamma \) for the determinant bundle of \( Q \). Similar to the 4-dimensional case, let \( \mathcal{B}(Y, \gamma) \) be the space of equivalence classes of connections on \( Q \) whose determinant are equal to a fixed connection on \( L_\gamma \). Given \( \alpha \in \mathcal{B}(Y, \gamma) \), the stabilizer of a connection representing \( \alpha \) is denoted by \( \Gamma_\alpha \). The element \( \alpha \) is irreducible if \( \Gamma_\alpha \) is equal to the center of \( SU(N) \). The bundle \( Q \) can be extended to a \( U(N) \)-bundle \( P \) on \( W \) using the 2-cycle \( w \). The bundle \( P \) also determines a \( U(N) \)-bundle on \( W^+ \) in an obvious way which will be also denoted by \( P \).

Fix an element \( \alpha \in \mathcal{B}(Y, \gamma) \), and let \( A_0 \) and \( A_1 \) be two connections on \( P \) whose restrictions to the end \([0, \infty) \times Y\) are the pull-back of representatives of \( \alpha \). Then we say \( A_0 \) and \( A_1 \) represent the same path, if there is an automorphism \( g \) of \( P \) with determinant 1 such that \( g^*(A_1) - A_0 \) is a compactly supported 1-form. The equivalence class of a connection under this equivalence relation is called a path on \( W \) based at \( \alpha \). The the topological energy of a path \( p \) represented by a connection \( A \) is defined by the following Chern-Weil integral:

\[
\kappa(p) := \frac{1}{16N\pi^2} \int_{W^+} \text{tr}(\text{ad}(F(A)) \wedge \text{ad}(F(A)))
\]

Here \( \text{ad}(F(A)) \) is regarded as a 2-form with coefficients in \( \text{End}(\text{su}(P)) \). The product \( \wedge \) in the integrand is induced by the wedge product of differential forms and composition of the elements of \( \text{End}(\text{su}(P)) \). The above integral is independent of the chosen connection \( A \) and only depends on \( p \). The constant in front of the integral is chosen such that if \( p \) is replaced by another path \( p' \) abased at \( \alpha \), then the energy changes by an integer number.

An important special case for us is the cylinder manifold \( W = [0, 1] \times Y \). Fix connections \( \alpha, \beta \in \mathcal{B}(Y, \gamma) \) and let \( p \) be a path on \([0, 1] \times Y \) based at \( \alpha \) and \( \beta \) on \([0] \times Y \) on \([1] \times Y \). Then \( p \) induces a path, in the ordinary sense, from \( \alpha \) to \( \beta \) in \( \mathcal{B}(Y, \gamma) \). The topological energy of the path \( p \) defines a number which its value, up to an integer number, depends only on \( \alpha \) and \( \beta \). Therefore, we can fix \( \beta_0 \in \mathcal{B}(Y, \gamma) \) and define a functional \( \text{CS} : \mathcal{B}(Y, \gamma) \to \mathbb{R}/\mathbb{Z} \), called the Chern-Simon functional, where \( \text{CS}(\alpha) \) is equal to the topological energy of any path from \( \alpha \) to \( \beta_0 \). Since \( \beta_0 \) is chosen arbitrarily, \( \text{CS} \) is well-defined only up to a constant. But in the case that \( \gamma \) is empty, the trivial connection \( \Theta \) gives a canonical choice of \( \beta_0 \). Critical points of the Chern-Simons functional are represented by connections \( A \) on \( Q \) such that:

\[
F_0(A) = 0.
\]

A critical point \( \alpha \in \mathcal{B}(Y, \gamma) \) is called non-degenerate if the Hessian of the Chern-Simons functional is
non-degenerate at \( \alpha \).

Suppose \( \alpha \) is a non-degenerate critical point of the Chern-Simons function. Suppose also \( A_0 \) is a connection on \( W^+ \) that represents a path \( p \) based at \( \alpha \). Then \( \mathcal{A}_p(W, w; \alpha) \) is the following space of connections:

\[
\mathcal{A}_p(W, w; \alpha) := \{ A_0 + a \mid a \in L^2_{l,\delta}(W, \mathfrak{su}(P) \otimes \Lambda^1) \}
\]

where \( l \geq 3, \delta \) is a small positive integer number, and the weighted Sobolev space \( L^2_{l,\delta}(W, \mathfrak{su}(P)) \) is defined as follows. Let \( t \) be a function on \( W^+ \) that agrees with the cylindrical coordinate on the end of \( W^+ \). For a vector bundle \( E \) on \( W \) and a positive constant \( \delta \), the Banach space \( L^2_{l,\delta}(W, E) \) is defined as \( e^{-\delta t}L^2_{k}(W^+, E) \). Suppose \( \mathcal{G}_p(W, w; \alpha) \) is also defined as:

\[
\mathcal{G}_p(W, w; \alpha) := \{ g \in \text{Aut}(P) \mid \det(g) = 1, \nabla A_0 g \in L^2_{l,\delta}(W, \mathfrak{su}(P) \otimes \Lambda^1) \}.
\]

Then \( \mathcal{G}_p(W, w; \alpha) \) is a Banach Lie group whose Lie algebra is \( L^2_{l+1,\delta}(W, \mathfrak{su}(P)) \). This group acts on \( \mathcal{A}_p(W, w; \alpha) \) and the quotient space is denoted by \( \mathcal{B}_p(W, w; \alpha) \). The space of the elements \([A] \in \mathcal{B}_p(W, w; \alpha)\) where \( F^+_0(A) = 0 \), forms the moduli space of ASD connections associated to the path \( p \). This moduli space is denoted by \( \mathcal{M}_p(W, w; \alpha) \).

It is useful to form a framed version of the moduli space of the ASD equations. Any gauge transformation in \( \mathcal{G}_p(W, w; \alpha) \) is asymptotic to an element of \( \Gamma_\alpha \). Define the framed gauge group \( \mathcal{G}_p^0(W, w; \alpha) \) to be the subspace of the elements of \( \mathcal{G}_p(W, w; \alpha) \) which are asymptotic to the trivial element of \( \Gamma_\alpha \). Then the quotient of \( \mathcal{A}_p(W, w; \alpha) \) by \( \mathcal{G}_p^0(W, w; \alpha) \) is denoted by \( \tilde{\mathcal{B}}_p(W, w; \alpha) \). The set of the elements of \( \tilde{\mathcal{B}}_p(W, w; \alpha) \) which satisfy the ASD equation is called the framed (or based) moduli space of ASD connections associated to \( p \) and is denoted by \( \tilde{\mathcal{M}}_p(W, w; \alpha) \).

There is an important relationship between the ASD equation and the Chern-Simons functional. We can define an inner product on \( \mathcal{B}(Y, \gamma) \) using the following expression

\[
\langle a, b \rangle := -\frac{1}{16N\pi^2} \int_Y \text{tr}(\text{ad}(a) \wedge * \text{ad}(b)) = a, b \in \Omega^1(Y, \mathfrak{su}(P))
\]

where \( \text{tr} \) is defined using the trace on \( \text{End}(\mathfrak{su}(N)) \). Suppose \( \{ \alpha(t) \}_{t \in [0, 1]} \) is a path in \( \mathcal{B}(Y, \gamma) \). This path defines a trajectory of the downward gradient flow of CS with respect to the above metric if it satisfies the following equation:

\[
\frac{d\alpha(t)}{dt} = -* F_0(\alpha(t)). \quad (2.12)
\]

The path \( \{ \alpha(t) \} \) determines a connection \( A \), in temporal gauge, on \([0, 1] \times Y\), and (2.12) is equivalent to the ASD equation \( F_0^+(A) = 0 \). This relationship between the ASD equation and the Chern-Simons functional allows us to conclude from non-degeneracy of the critical points of CS that the moduli spaces \( \tilde{\mathcal{M}}_p(W, w; \alpha) \) are analytically well-behaved.

The local behavior of the framed moduli space \( \tilde{\mathcal{M}}_p(W, w; \alpha) \) around an element \([A] \) is modeled by the following elliptic complex:

\[
L^2_{l+1,\delta}(W, \mathfrak{su}(P)) \xrightarrow{d_A} L^2_{l,\delta}(W, \Lambda^1 \otimes \mathfrak{su}(P)) \xrightarrow{d_A^+} L^2_{l-1,\delta}(W, \Lambda^+ \otimes \mathfrak{su}(P)) \quad (2.13)
\]
This complex is Fredholm and its homology groups are denoted by $H^0_A$, $H^1_A$ and $H^2_A$. Then $H^0_A = 0$, and the element $[A]$ is called regular, if $H^2_A$ is also trivial. In this case, $\widetilde{\mathcal{M}}_p(W, w; \alpha)$ is smooth in a neighborhood of $A$, and $H^1_A$ gives a model for the space of the framed moduli space at $[A]$. Therefore, the index of the above complex for a (not necessarily regular) ASD connection $A$ is called the expected dimension of $\widetilde{\mathcal{M}}_p(W, w; \alpha)$ and is denoted by $\dim_e(\widetilde{\mathcal{M}}_p(W, w; \alpha))$.

We slightly generalize above discussion to include the case of 4-dimensional cobordisms. A cobordism $W : Y_0 \to Y_1$ is a 4-manifold with boundary $\overline{Y}_0 \coprod Y_1$. We also assume that a 2-cycle $w : \gamma_0 \to \gamma_1$ in $W$ is given, and $P$ is the associated $U(N)$-bundle. Suppose also $\alpha_0$ and $\alpha_1$ flat connections on $Y_0$ and $Y_1$, and $p$ is a path on $W$ from $\alpha_0$ to $\alpha_1$. In this case, $W^+$, $\mathcal{B}_p(W, w; \alpha_0, \alpha_1)$ and $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ are defined as in the previous case by regarding $W$ as a 4-manifold with boundary. However, there is an alternative elliptic complex that one can associate to the elements of $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$. Suppose $W^+$ is the Riemannian 4-manifold given by adding cylindrical ends to $W$. In this case, we identify the cylindrical end corresponding to the incoming end with $(-\infty, 0] \times Y_0$. As in the previous case, suppose $t$ is a function on $W^+$ that agrees with the cylindrical coordinates on the ends and define $L^2_{t,0}(W, E)$. Therefore, an element of $L^2_{p,\theta}(W, E)$ is allowed to have exponential growth on the incoming end and it is forced to have an exponential decay on the outgoing end. For $[A] \in \mathcal{B}_p(W, w; \alpha_0, \alpha_1)$, the ASD operator $\mathcal{D}_A$ is defined as follows:

$$d_A^* \oplus d_A^* : L^1_{t,0}(W, \Lambda^1 \otimes \mathfrak{su}(P)) \to L^2_{t-1,0}(W, (\Lambda^0 \oplus \Lambda^+) \otimes \mathfrak{su}(P)) \quad (2.14)$$

The operator $\mathcal{D}_A$ is elliptic, and the excision property of elliptic operators shows that the index of $\mathcal{D}_A$ is additive with respect to composition of cobordisms. This index can be computed explicitly using Atiyah-Patodi-Singer index theorem [80, 69]:

$$\text{index}(\mathcal{D}_A) = 4N\kappa(p) - (N^2 - 1)\frac{\chi(W) + \sigma(W)}{2} + \sum_{i=0,1} (-1)^i \frac{h^0(Y_i; \text{ad}_{\alpha_i}) - \rho_{\alpha_{\text{ad}_{\alpha_i}}}(Y_i)}{2} \quad (2.15)$$

where $h^0(Y_i; \text{ad}_{\alpha_i})$ denotes the dimension of $H^0(Y_i; \text{ad}_{\alpha_i})$. Moreover, for a flat connection $a$ on a vector bundle $V$ over $Y$, $\rho_a$ is Atiyah-Patodi-Singer $\rho$-invariant of $a$ [4]. As an example, let $\gamma_j$ be a $U(1)$-connection on $L(a, b)$ whose holonomy around the standard generator of $\pi_1(L(a, b))$ is equal to $e^{2\pi i j}$. Then it is shown in [4] that:

$$\rho_{\gamma_j}(L(a, b)) = -\frac{4}{a} \sum_{k=1}^{a-1} \cot\left(\frac{\pi k a}{a}\right) \cot\left(\frac{\pi k b}{a}\right) \sin^2\left(\frac{\pi k j}{a}\right) \quad (2.16)$$

Suppose a 4-manifold $W$ is regarded as a cobordism from the empty 3-manifold to the boundary of $W$. Then $\dim_e(\widetilde{\mathcal{M}}_p(W, w; \alpha))$ is equal to $\text{index}(\mathcal{D}_A) + h^0(\alpha)$ where $A$ is a connection that represents the path $p$.

In the case of a cylinder $[0, 1] \times Y$, the ASD operator can be used to define a relative $\mathbb{Z}/4N\mathbb{Z}$-grading on critical points of the Chern-Simons functional associated to a pair $(Y, \gamma)$. Fix an arbitrary critical point $\beta_0$ of CS, and let $\alpha$ be another critical point of CS. Let the connection $A$ represent an arbitrary path $p$ from $\alpha$ to $\beta_0$. Then the Floer grading of $\alpha$, denoted by $\deg(\alpha)$, is defined to be $\text{index}(\mathcal{D}_A) \mod 4N$. 

17
Since the choice of $\beta_0$ is arbitrary, this grading only gives rise to a relative $\mathbb{Z}/4\mathbb{Z}$-grading. In the case that $\gamma$ is empty, we can make this grading absolute by requiring $\beta_0 = \Theta$. In this case, we can invoke the index formula (2.15) to compute $\deg(\alpha)$ as follows:

$$\deg(\alpha) \equiv 4N \cdot \text{CS}(\alpha) - \frac{N^2 - 1}{2} + \frac{h^0(Y; ad_\alpha) - \rho_{ad_\alpha}(Y)}{2} \mod 4N \quad (2.17)$$

Analogous to the case of closed 4-manifolds, we can avoid non-regular points in $\mathcal{M}_p(W, w; \alpha)$ by perturbing the ASD equation. Suppose $\alpha$ is irreducible and non-degenerate. Then there are small holonomy perturbations of the ASD equation, supported in $[0, 1] \times Y \subset W^+$, such that the resulting moduli spaces consist of regular points [60]. Alternatively, if $b^+(X) \geq 2$ and $w$ is coprime to $N$, then we can arrange for a small perturbation of the ASD equation the moduli space $\mathcal{M}_p(W, w; \alpha)$, for arbitrary $\alpha$ and $p$ with $\kappa(p)$ bounded, is regular [56]. In the case that $\mathcal{M}_p(W, w; \alpha)$ consists of only regular points, it is an orientable smooth manifold.

In general, the critical points of the Chern-Simons functional might not be non-degenerate. Suppose that all critical points of the Chern-Simons functional associate to a pair $(Y, \gamma)$ are irreducible. Then, CS can be also perturbed by appropriate perturbations such that the critical points of the resulting functional are irreducible and non-degenerate [60, Proposition 3.10]. The family of perturbations that is used in [60] are also defined in terms of the holonomies of connections on $Y$. Suppose $\text{CS}_\pi$ is such a perturbation of CS by a small holonomy perturbation and $\alpha$ is a critical point of $\text{CS}_\pi$. Suppose also $(W, w)$ is a pair whose boundary is equal to $(Y, \gamma)$. The negative-gradient flow line of $\text{CS}_\pi$ determines a perturbation of the ASD equation on the end $[0, \infty) \times Y$ of $W^+$. This perturbation can be extended to $W^+$ such that the corresponding moduli space contains only regular points [60]. As in the previous case, the elliptic operator (2.14), can be used to study the local behavior of the moduli spaces. In particular, in the case of a cylinder, index of $D_A$ can be used to define a relative $\mathbb{Z}/4\mathbb{Z}$-grading on the critical points of $\text{CS}_\pi$.

### 2.3 Non-vanishing Theorem for Algebraic Surfaces

For a complex projective surface, the moduli spaces of ASD connections can be identified with the moduli spaces of stable bundles with the fixed determinant [16]. Stable bundles have been studied extensively using various techniques in algebraic geometry. Thus one can use algebro-geometric methods to extract information about the polynomial invariants of a complex projective surface. For example, the following theorem about non-vanishing of $U(N)$-polynomial invariants of algebraic surfaces is a generalization of Donaldson’s celebrated theorem about $U(2)$-invariants [18, 21]:

**Theorem 2.18.** Suppose $X$ is a complex projective surface with positive geometric genus, $h$ is a hyperplane class (or equivalently a very ample class), and $w$ is a 2-cycle representing $c_1$ of a holomorphic line bundle $L$. Suppose also $w$ is coprime to $N$. Then:

$$D^X_{X,w}(h^{d}) > 0$$

when $d$ is large enough and

$$d \equiv (N + 1)w \cdot w - (N^2 - 1) \frac{\chi(X) + \sigma(X)}{4} \mod 2N$$

18
Proof. Let \( M^N_k(X, L) \) be the moduli space of stable bundles with rank \( N \), determinant \( L \), and energy \( \kappa \). We firstly review the proof of the non-vanishing theorem in the rank 2 case. In this case, the key idea is to find a projective embedding of \( M^2_k(X, L) \) and then interpret the polynomial invariant \( D^{2N}_{X,w}(h^d_d) \) as a multiple of the degree of the moduli space. The main steps of the proof can be summarized as follows:

1. Suppose \( C \) is an algebraic curve and \( \mathcal{N}(C, d) \) is the moduli space of stable bundles of rank 2 and degree \( d \) on \( C \). Then there is a projective embedding of \( \mathcal{N}(C, d) \) into a projective space \( \mathbf{P}(W) \) [37]. Moreover, this projective embedding is given by the sections of a large power \( \mathcal{L}^d \) of the determinant line bundle over \( \mathcal{N}(C, d) \) [21].

2. For any stable bundle \( \mathcal{E} \in M^2_k(X, \mathcal{L}) \), there is \( p_0 \) such that if \( C \subset X \) is a generic curve in the linear system \( |\mathcal{O}(p)| \), for \( p \geq p_0 \), then the restriction of \( \mathcal{E} \) to \( C \) is also stable [68]. Using this result together with the fact that moduli space \( M^2_k(X, \mathcal{L}) \) has finite type, we can find a projective embedding \( J : M^2_k(X, \mathcal{L}) \to \mathbf{P}(V) \). This embedding is given by restricting the elements of \( M^2_k(X, \mathcal{L}) \) to finitely many curves in the linear system \( |\mathcal{O}(p)| \) and applying Gieseker embedding from the previous part.

3. For \( \kappa \) large enough, the moduli space \( M^2_k(X, \mathcal{L}) \) is not empty [78, 38].

4. The dimension the irregular part of \( M^2_k(X, \mathcal{L}) \) is strictly smaller than the virtual dimension of the moduli space, when \( \kappa \) is large enough [18].

By combining these facts, it can be shown that the map \( J \) can be chosen such that the degree of the quasi-projective variety \( J(M_k(X, I)) \) is equal to:

\[
K^dD^{N}_{X,w}(h^d_d)
\]

for an appropriate integer number \( K \), and for a large enough \( d \). Therefore, the invariant \( D^{N}_{X,w}(h^d_d) \) is positive. This proof can be generalized to the case that \( N > 2 \). Steps 1 and 2 are proved for an arbitrary rank in the references mentioned above. The generalization of the the third step to the higher rank case is given in [64]. The higher rank version of the fourth fact is also proved in [39]. Then the same arguments as in [18, 21] can be used to realize \( D^{N}_{X,w}(h^d_d) \) as a multiple of the degree of a quasi-projective variety, which verifies the claim in Theorem 2.18.

\[\square\]

Remark 2.19. In Theorem 2.18, we assume that \( X \) is a projective surface. But a similar non-vanishing theorem can be formulated for any Kähler surface, because Kähler surfaces can be deformed into projective surfaces [50] and the \( U(N) \)-polynomial invariants only depend on the smooth structure.

### 2.4 Negative Embedded Spheres

Motivated by [76], Fintushel and Stern used embedded 2-spheres with negative self-intersection to study polynomial invariants of a 4-manifold \( X \) [27, 26]. The same idea is exploited in [13] to obtain information about the properties of the polynomial invariants associated to higher rank bundles. Suppose \( \tau \) is an embedded sphere in a 4-manifold \( X \) which has self-intersection \( -2 \). Fix a 2-cycle \( w \) with \( w \cdot \tau = 0 \), and \( z \in \Lambda(\langle \tau \rangle^*)\otimes \mathbb{Z}^2 \). In general, \( \Lambda(V) \) for a vector subspace \( V \subseteq H_2(X) \) denotes the sub-algebra
Suppose $\text{Sym}^*(H_0(X) \oplus V) \otimes \Lambda^*(H_1(X))$, and $\langle \tau \rangle^\perp$ is the subspace of $H_2(X)$ consisting of the homology classes orthogonal to $\tau$. The following formulas about the $U(3)$-polynomial invariants of $X$ are proved in [13]:

\begin{align*}
(C_1) \quad D_{X,w}^3(\tau^2 z) &= -2D_{X,w+r}^3(z) \\
(C_2) \quad D_{X,w}^3(\tau^4 z) &= -4D_{X,w}^3(a_2 \tau^2 z) - 3D_{X,w}^3(\tau z) \\
(C_3) \quad D_{X,w}^3(\tau^2 \tau(3) z) &= -3D_{X,w}^3(a_3 \tau^2 z) - D_{X,w}^3(a_2 \tau(2) \tau(3) z)
\end{align*}

By a similar approach, we shall prove the following proposition in subsection 6.2:

**Proposition 2.20.** Suppose $X$ is a smooth 4-manifold with $b^+(X) \geq 2$ and $w$ is a 2-cycle. Suppose also $\sigma$ is an embedded sphere with intersection $-3$ and $z \in \Lambda_3(\langle \sigma \rangle^\perp)^{\otimes 2}$.

(i) If $w \cdot \sigma \equiv 1 \mod 3$, then there is a constant number $c$ such that:

\[ D_{X,w}^3((-\frac{3}{2}\sigma(3) - \frac{3}{2}\sigma(2) - a_2) z) = cD_{X,w-\sigma}^3(z). \]

(ii) If $w \cdot \sigma \equiv 2 \mod 3$, then for the same constant $c$ as above:

\[ D_{X,w}^3((\frac{3}{2}\sigma(3) - \frac{3}{2}\sigma(2) - a_2) z) = cD_{X,w+\sigma}^3(z). \]

(iii) If $w \cdot \sigma \equiv 0 \mod 3$, then the following two formulas hold:

\[ D_{X,w}^3((\sigma(2) + 4a_2 \sigma^2(2) + 3\sigma^2(3) z) = 0, \quad D_{X,w}^3((\sigma(2) \sigma(3) + 3a_3 \sigma^2(2) + a_2 \sigma(2) \sigma(3) z) = 0. \]

In subsection 4.2, we will show that the constant $c$ in the statement of this proposition is equal to $-3$.

### 2.5 Blowup Formula for 4-manifolds with Simple Type

In this subsection, we review the properties of $U(3)$-polynomial invariants of blown up 4-manifolds. This part has the same theme as the previous subsection, because the exceptional divisor of a blown up 4-manifold gives rise to a $(-1)$-sphere. We start with an exposition of the main result in Culler’s thesis [13]. Given a 4-manifold $X$, let $\hat{X}$ denote the blow up of $X$ at one point, which is diffeomorphic to the 4-manifold $X \# \mathbb{CP}^2$. We will also denote the exceptional sphere in $\hat{X}$ with $E$. If $w$ is a 2-cycle in $X$, then it induces a 2-cycle in $\hat{X}$ which will be also denoted by $w$. Similarly, we can regard $\Lambda(X)$ as a sub algebra of $\Lambda(\hat{X})$.

**Proposition 2.21.** Suppose $w$ is a 2-cycle in $X$ and $z \in \Lambda(X)^{\otimes 2}$. For $0 \leq i \leq 2$ and $0 \leq j \leq 1$, the invariant $D_{X,w+E}^3(E_j(z))$ is equal to $D_{X,w}^3(z)$ if $i = j = 0$ and it is zero otherwise. The invariant $D_{X,w+E}^3(E_{(3)} z)$ is equal to $D_{X,w}^3(z)$. For $0 \leq i \leq 5$, the invariant $D_{X,w+E}^3(E_{(2)}^i z)$ is equal to:

\[
\begin{cases}
0, & \text{if } i = 0, 1, 3; \\
D_{X,w}^3(z), & \text{if } i = 2; \\
-D_{X,w}^3(a_2 z), & \text{if } i = 4; \\
-D_{X,w}^3(a_3 z), & \text{if } i = 5.
\end{cases}
\]
Proof. As we mentioned in subsection 2.1, the identity \( D^3_{X,w+E}(E_{(2)}^2 z) = D^3_{X,w}(z) \) is proved in [56]. The other identities can be proved by a similar method. (See Proposition 62 in [13] and the succeeding discussion.)

According to this proposition, some of the polynomial invariants of \( \hat{X} \) are determined by the invariants of \( X \). The following theorem claims that a similar pattern holds for all invariants of \( \hat{X} \). This theorem is essentially proved in [13]. We just slightly expand the results of this thesis using the same methods:

**Theorem 2.22.** Suppose \( w \) is a 2-cycle in \( X \) and \( z \in \Lambda(X)^{\otimes 2} \). For non-negative integer numbers \( i \) and \( j \), there are polynomials \( B_{i,j}, S_{i,j} \in \mathbb{Q}[a_2, a_3] \) which are independent of \( X, w, z \), and they satisfy the following identities:

\[
D^3_{X,w}(e^{E(z)+E(z)} z) = D^3_{X,w}(z \sum_{i,j} B_{i,j}(a_2, a_3)t^i_2 t^j_3)
\]

and

\[
D^3_{X,w+E}(e^{E(z)+E(z)} z) = D^3_{X,w}(z \sum_{i,j} S_{i,j}(a_2, a_3)t^i_2 t^j_3).
\]

Moreover, \( B := \sum_{i,j} B_{i,j}(a_2, a_3)t^i_2 t^j_3 \) and \( S := \sum_{i,j} S_{i,j}(a_2, a_3)t^i_2 t^j_3 \), as power series in the variables \( t_2 \) and \( t_3 \) with coefficients in the polynomial ring of \( a_2, a_3 \), are uniquely determined by the initial values given in Proposition 2.21 and the following four PDEs:

\[
B_{22} - B_{2B} = -S \circ \tau \cdot S, \quad S_{22} - S_{2S} = -S \circ \tau \cdot B,
\]

(2.23)

\[
B_{2222} - 4B_{222}B_2 + 3B_{22}B_{22} = -4a_2(B_{22}B - B_2B) - 3(B_{33}B - B_3B_3)
\]

(2.24)

and

\[
B_{2223} - 3B_{223}B_2 - B_{222}B_3 + 3B_{22}B_{23} =
\]

\[
= -3a_3(B_{22}B - B_2B) - a_2(B_{33}B - B_3B_3).
\]

(2.25)

Here \( \tau \) maps \( (t_2, t_3) \) to \( (-t_2, -t_3) \). The subscript 2 means taking partial derivative with respect to 2 and the subscript 3 should be interpreted similarly.

Using (2.9), the power series \( S \) can be used to compute the invariant of \( D^3_{X,w-E} \).

**Sketch of the proof.** The main tool is a trick that due to Fintushel and Stern [27]. Suppose \( E \) and \( E' \) are the two exceptional spheres in \( X \# \Sigma \mathbb{CP}^2 \). Then the homology class \( E - E' \) is represented by a \((-2)\)-sphere. Suppose \( \hat{C}_{k,l} \) (respectively, \( \hat{C}'_{k,l} \)) is the identity that is given by applying \((C_1)\) from subsection 2.4 to \( w \) (respectively, \( w + E + E' \)) and \( \hat{z} := (E + E')((E + E')_{(2)}(E + E')_{(3)} z) \). Similarly, we can derive identities \( \hat{C}_{k,l} \) and \( \hat{C}'_{k,l} \) by applying \((C_2)\) and \((C_3)\) to \( w \) and \( \hat{z} \) as above. These identities can be used to prove the existence of \( B_{i,j} \) and \( S_{i,j} \) inductively. To be a bit more detailed, firstly one shows the existence of \( B_{k,0} \) and \( S_{k,0} \) inductively using the initial values in Proposition 2.21, \( \hat{C}_{k,0} \) and \( \hat{C}'_{k,0} \) [13, Proposition 69]. Then another inductive argument with the aid of identities \( \hat{C}_{k,l}, \hat{C}'_{k,l} \) and Proposition 2.21 shows the existence of \( B_{k,l} \) [13, Proposition 73]. Finally, \( \hat{C}_{k,l}, \hat{C}'_{k,l} \), the initial values of Proposition 2.21 and the fact that \( S_{0,1} \) is non-zero imply the existence of \( S_{k,l} \) in an inductive way. After proving the existence of the polynomials ...
B_{k,l} and S_{k,l}, the identities \( \tilde{C}_{k,l}, \tilde{C}'_{k,l}, \Gamma_{k,l} \) and \( \tilde{C}_{k,l} \) can be used to write four differential equations for \( B \) and \( S \) which are given in (2.23), (2.24) and (2.22). The existence proof shows that these PDEs and the initial values are enough to uniquely determine \( B \) and \( S \).

In general, computing the exact form of the power series \( B \) and \( S \) (equivalently, solving the PDEs in the statement of Theorem 2.22) is not straightforward. In the following corollary, we show that for 4-manifolds with simple type, the blow up formula has a simple form:

**Theorem 2.26.** Suppose \( (X, w) \) is a pair of a 4-manifold and a 2-cycle such that \( X \) has \( w \)-simple type. Suppose also \( X \) is the blowup of \( X \) at one point and \( E \) is the exceptional class. Then there are power series \( b(t_2, t_3), s(t_2, t_3) \in \mathbb{Q}[t_2, t_3] \) such that:

\[ \hat{D}_{X,w}(e^{E(2)+E(3)} z) = \hat{D}_{X,w}(z)b(t_2, t_3) \] (2.27)

and

\[ \hat{D}_{X,w+E}(e^{E(2)+E(3)} z) = \hat{D}_{X,w}(z)s(t_2, t_3) \] (2.28)

for \( z \in \mathbb{A}(X)^{\otimes 2} \). The power series \( b \) and \( s \) are given by the following formulas:

\[ b(t_2, t_3) = \frac{1}{3} e^{-\frac{t_2^2}{2}+\frac{t_3^2}{2}} [(\cosh(\sqrt{3}t_2) + 2\cos(\sqrt{3}t_3))], \] (2.29)

\[ s(t_2, t_3) = \frac{1}{3} e^{-\frac{t_2^2}{2}+\frac{t_3^2}{2}} [(\cosh(\sqrt{3}t_2) - \cos(\sqrt{3}t_3) + \sqrt{3}\sin(\sqrt{3}t_3))]. \] (2.30)

**Proof.** Evaluating \( B \) and \( S \) of Theorem 2.22 at \( a_2 = 3 \) and \( a_3 = 0 \) produces \( b \) and \( s \) with the required property. These power series satisfy equations (2.23), (2.24) and (2.22) where \( a_2 \) and \( a_3 \) in the latter two equations are replaced with 3 and 0. In fact, the same proof as the existence proof in Theorem 2.22 shows that \( b \) and \( s \) are uniquely determined by these equations and the initial values in Proposition 2.21 (with \( a_2 \) and \( a_3 \) replaced by 3 and 0). The power series (2.29) and (2.30) satisfy the required conditions. Therefore, they are equal to \( b \) and \( s \).

**Remark 2.31.** Identity (2.9) implies that:

\[ \hat{D}_{X,w-E}(e^{E(2)+E(3)} z) = \hat{D}_{X,w}(z)s(t_2, -t_3) \] (2.32)

### 3 Floer Homologies for Closed 3-manifolds

#### 3.1 Admissible Pairs

A pair \( (Y, \gamma) \) of a 3-manifold and an embedded oriented 1-manifold is **admissible** if there is an embedded oriented surface \( \Sigma \) in \( Y \) such that the integer number \( \Sigma \cdot \gamma \) is coprime to \( N \). Suppose \( Q \) is the \( U(N) \)-bundle associated to the pair \( (Y, \gamma) \). The admissibility of \( (Y, \gamma) \) is what is called the **non-integral** condition for the \( U(N) \)-bundle \( Q \) in [60]. In particular, we can use the construction of [60] and associate the **instanton**
Floer homology group $I^N_s(Y, \gamma)$ to an admissible pair $(Y, \gamma)$. Instanton Floer homology can be lifted to a functor from a cobordism category $\text{COB}_\Lambda$ to a certain category of vector spaces.

An object of the category $\text{COB}_\Lambda$ is an admissible pair. A morphism from an admissible pair $(Y_0, \gamma_0)$ to $(Y_1, \gamma_1)$ is a triple $(W, w, z)$, where $W : Y_0 \to Y_1$ is a cobordism, $w : \gamma_0 \to \gamma_1$ is a 2-cycle, and $z \in \Lambda(W)^{(N-1)}$. The composition of two morphisms:

$$(W, w, z) : (Y_0, \gamma_0) \to (Y_1, \gamma_1) \quad (W', w', z') : (Y_1, \gamma_1) \to (Y_2, \gamma_2)$$

is equal to $(W' \circ W, w' \circ w, z' \cdot z)$.

Suppose $\text{VECTOR}_n$ is the category of relatively $\mathbb{Z}/n\mathbb{Z}$-graded vector spaces over $\mathbb{C}$. An object of this category is a vector space $V$ with a direct sum decomposition:

$$V = \bigoplus_{j \in J} V_j$$

where $\mathbb{Z}/n\mathbb{Z}$ acts transitively and freely on $J$. A morphism in this category from $V = \bigoplus_{j \in J} V_j$ to $V' = \bigoplus_{j' \in J'} V'_{j'}$ is a complex linear map $f : V \to V'$ such that $f$ maps each $V_j$ to a summand $V'_{h(j)}$ of $V'$ such that $h(j + k) = h(j) + k$. Let $\text{VECTOR}_n$ be the category that has the same objects as $\text{VECTOR}_n$. A morphism in $\text{VECTOR}_n$ is a vector space homomorphism as above which is well-defined only up to a sign. Instanton Floer homology gives a functor $I^N_s : \text{COB}_\Lambda \to \text{VECTOR}_{4N}$.

**Remark 3.1.** The invariant constructed in [60] is more general than the one we described here. In [60], a version of instanton Floer homology is constructed for a triple $(Y, \gamma, K)$ where $K$ is a link in $Y$ and $\gamma$ determines a $U(N)$-bundle on $Y$ that satisfies a certain non-integral condition. We need to consider only the case that $K$ is the empty link. On the other hand, in [60], the cobordism maps $I^N_s(W, w, z)$ are defined only in the case that $z = 1$. The more general case, is a straightforward generalization and is reviewed below.

For an admissible pair $(Y, \gamma)$, the vector space $I^N_s(Y, \gamma)$ is defined by applying Morse homological methods to the Chern-Simons functional $CS : \mathcal{B}(Y, \gamma) \to \mathbb{R}$. The admissibility condition implies that all critical points of $CS$ are irreducible [60, Proposition 3.1]. Therefore, we can arrange for $C_{\pi}$, a perturbation of the Chern-Simons functional with a small holonomy perturbation, such that all of its critical points are irreducible and non-degenerate [60, Proposition 3.10]. Then $C_{\pi}$ has finitely many critical points. Suppose $\alpha$ and $\beta$ are two critical points of $C_{\pi}$ and $p$ is a path on $[0, 1] \times Y$ associated to the path $\alpha$ and $\beta$ on $\{0\} \times Y$ and $\{1\} \times Y$. We will write $\mathcal{M}_p(\alpha, \beta)$ for the moduli space of the solutions to the perturbed ASD equation on $\mathbb{R} \times Y$ associated to the path $p$. Here the perturbation of the ASD equation is induced by the perturbation of the Chern-Simons functional, i.e., the elements of $\mathcal{M}_p(\alpha, \beta)$ can be regarded as the downward gradient flow lines of $C_{\pi}$. We can also assume that $C_{\pi}$ is chosen such that the elements of $\mathcal{M}_p(\alpha, \beta)$ for all choices of $\alpha$, $\beta$ and $p$ are regular [60, Proposition 3.18]. There is an $\mathbb{R}$-action on $\mathcal{M}_p(\alpha, \beta)$ given by translation along the $\mathbb{R}$-factor. The quotient space is denoted by $\tilde{\mathcal{M}}(\alpha, \beta)$.

The dimension formula of the previous section implies that:

$$\dim(\tilde{\mathcal{M}}(\alpha, \beta)) = \deg(\alpha) - \deg(\beta) - 1 \mod 4N$$

Instanton Floer homology of the pair $(Y, \gamma)$ is given by the homology of a chain complex $(\mathcal{C}_s^\pi, d)$ associated to the functional $CS_{\pi}$. The vector space $\mathcal{C}_s^\pi$ is freely generated by the critical points of $CS_{\pi}$.
The differential of a generator $\alpha$ of $\mathcal{C}^\pi_*$ is also defined as:

$$d(\alpha) := \sum_{p: \alpha \rightarrow \beta} \#\mathcal{M}(\alpha, \beta)\beta$$

(3.2)

where the sum is over all paths $p$ that $\mathcal{M}_p(\alpha, \beta)$ is 0-dimensional. These 0-dimensional moduli spaces are compact and we orient them as in [60, Subsection 3.6]. Then $\#\mathcal{M}_p(\alpha, \beta)$ denotes the signed count of the points in $\mathcal{M}_p(\alpha, \beta)$. We use the Floer grading $\deg$ to define a relative $\mathbb{Z}/4\mathbb{Z}$-grading on $\mathcal{C}^\pi_*$. Then the differential $d$ decreases this grading by 1. The relatively $\mathbb{Z}/4\mathbb{Z}$-graded vector space $I^N_*(Y, \gamma)$ is defined to be the homology of the chain complex $(\mathcal{C}^\pi_*, d)$. This homology group is independent of the choice of the Riemannian metric on $Y$ and the perturbation of the Chern-Simons functional.

Suppose the Chern-Simons functional associated to the pair $(Y, \gamma)$ is Morse-Bott. That is to say, the set of critical points of $CS$ is a smooth manifold, and the Hessian of $CS$ is invertible only in the normal direction to the critical manifold. Following the above definition, we need to work with perturbations of the Chern-Simons functional to define $I^N_*(Y, \gamma)$. However, one can still derive some information about $I^N_*(Y, \gamma)$ using the unperturbed Chern-Simons functional:

**Proposition 3.3.** If the Chern-Simons functional of the pair $(Y, \gamma)$ is Morse-Bott, then $\dim(I^N_*(Y, \gamma)) \leq \dim(H_*(\text{crit}(CS)))$.

**Proof.** This claim can be verified using the standard spectral sequence that starts from the homology of the critical manifold of CS and abuts to the instanton Floer homology of $(Y, \gamma)$. \hfill \Box

Suppose $(W, w) : (Y_0, \gamma_0) \rightarrow (Y_1, \gamma_1)$ is a cobordism of admissible pairs. After fixing Riemannian metrics on $Y_0$ and $Y_1$, we form the non-compact manifold $W^+$ by adding cylindrical ends to $W$. Suppose also a perturbation of the Chern-Simons functional for $(Y_i, \gamma_i)$ is fixed such that we can form the chain complex $(\mathcal{C}^\pi_*, d)$ as above. We use a perturbation of the ASD equation on $W^+$ which is compatible with the chosen perturbations of the Chern-Simons functionals. Given a generator $\alpha_i$ of $\mathcal{C}^\pi_*$ and a path $p : \alpha_0 \rightarrow \alpha_1$, let $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ be the moduli space of the corresponding equation. We can pick a perturbation of the ASD equation on $W$ such that this moduli space is a smooth and orientable manifold. Moreover, if the moduli space is 0-dimensional, then $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ is compact.

Define a map $\mathcal{C}(W, w) : \mathcal{C}^\pi_* \rightarrow \mathcal{C}^\pi_*$ by:

$$\mathcal{C}(W, w)(\alpha_0) := \sum_{p: \alpha_0 \rightarrow \alpha_1} \#\mathcal{M}_p(W, w; \alpha_0, \alpha_1)\alpha_1$$

(3.4)

where the sum is over all paths that $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ is 0-dimensional. The term $\#\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ is equal to the signed count of the points in $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$. (For the issues related to orienting this moduli space see [60].) In fact, (3.4) defines a chain map and the induced map at the level of homology, $I^N_*(W, w, 1) : I^N_*(Y_0, \gamma_0) \rightarrow I^N_*(Y_1, \gamma_1)$, determines a morphism of the category $\text{P-VECTOR}_{4N}$. More generally, given $z \in \Lambda(W)^{\otimes(N-1)}$, we can cut down the moduli space $\mathcal{M}_p(W, w; \alpha_0, \alpha_1)$ using $z$ as in subsection (2.1), and construct a smooth submanifold $\mathcal{M}_p(W, w; \alpha_0, \alpha_1, z)$ such that:

$$\dim(\mathcal{M}_p(W, w; \alpha_0, \alpha_1, z)) = \dim(\mathcal{M}_p(W, w; \alpha_0, \alpha_1)) - \deg(z).$$

(3.5)
To be more precise, \( M_p(W, w; \alpha_0, \alpha_1, z) \) is a linear combination of the spaces whose dimensions are given by (3.5). Replacing \( M_p(W, w; \alpha_0, \alpha_1) \) in (3.4) with \( M_p(W, w; \alpha_0, \alpha_1, z) \) determines a new chain map and the associated map at the level of homology is \( I_*^N(W, w, z) : I_*^N(Y_0, \gamma_0) \to I_*^N(Y_1, \gamma_1) \). This map is well-defined, namely, it does not depend on the metric on \( W \) and the perturbation of the ASD equation. Because we fix the induced connection on the determinant bundle of \( P \), the cobordism map only depends on the \( \text{PU}(N) \)-bundle associated to \( P \). In particular, if \( w \) is replaced with \( w + nw' \), for a closed 2-cycle \( w' \), then the induced \( \text{PU}(N) \)-bundles are the same and they determine the same cobordism maps. This property is the analogue of Identity (2.8) for closed 4-manifolds.

Remark 3.6. A priori it might seem that the cycles in 3-manifolds and 4-dimensional cobordisms only keep track of the first Chern classes of \( \text{U}(N) \)-bundles. However, they have strictly more information than the characteristic cohomology classes. For example, an element of \( H^2(Y, \mathbb{Z}) \), for a 3-manifold \( Y \), determines a \( \text{U}(N) \)-bundle up to an isomorphism of \( \text{U}(N) \)-bundles. But an embedded 1-manifold \( \gamma \) in \( Y \) determines a \( \text{U}(N) \)-bundle up to a unique isomorphism. (See [59, Section 4] for more details.) As a manifestation of this issue, suppose cohomology classes \( \alpha \) and \( \alpha' \) are given on cobordisms \( W : Y_0 \to Y_1 \) and \( W' : Y_1 \to Y_2 \) such that the restriction of these classes on \( Y_1 \) agree with each other. Then there might be an ambiguity to glue these cohomology classes and construct an element of \( H^2(W' \circ W; \mathbb{Z}) \). On the other hand, there is not such an ambiguity if \( \alpha \) and \( \alpha' \) are represented by embedded surfaces \( w \subset W \) and \( w' \subset W' \) that \( w|_{Y_1} = w'|_{Y_1} \).

Remark 3.7. There is not much difficulty in extending the definition of instanton Floer homology to the case of disconnected 3-manifolds. Suppose \( Y \) is a disconnected 3-manifold and \( \gamma \subset Y \) is a 1-cycle. Then we say \((Y, \gamma)\) is admissible if for each connected component \( Y_0 \) of \( Y \), the pair \((Y_0, \gamma \cap Y_0)\) is admissible. Then we can repeat the definition analogous to the connected case and construct instanton Floer homology for the pair \((Y, \gamma)\). This instanton Floer homology can be computed in terms of the invariants for the connected components:

\[
I_*^N(Y, \gamma) := I_*^N(Y_1, \gamma_1) \otimes \cdots \otimes I_*^N(Y_n, \gamma_n)
\]

Here \( Y_i \)'s are connected components of \( Y \) and \( \gamma_i = \gamma \cap Y_i \). It is also possible to define cobordism maps for a cobordism of pairs \((W, w)\) between two (not necessarily connected) admissible pairs and \( z \in \mathbb{A}(W) \otimes \mathbb{A}(N) \). However, these maps are not as well-behaved with respect to composition as in the previous case. Consider two triples:

\[
(W, w, z) : (Y_0, \gamma_0) \to (Y_1, \gamma_1) \quad \quad (W', w', z') : (Y_1, \gamma_1) \to (Y_2, \gamma_2).
\]

If \( Y_1 \) is not connected, what we can say about the cobordism maps is:

\[
I_*^N(W' \circ W, w' \circ w, z \cdot z') = e \cdot I_*^N(W', w', z') \circ I_*^N(W, w, z)
\]

for some non-zero constant \( e \). The simplest way to fix this issue about functoriality is to work with a variation of the category \( \text{P-VECTOR}_{4N} \) where the morphisms are well-defined only up to a non-zero scalar. We follow this approach when it is necessary to work with disconnected 3-manifolds.

Remark 3.8. A slightly unsatisfying point about \( I_*^N \) is the sign ambiguity in the definition of the cobordism maps. This issue can be avoided in a straightforward way. In the case that \( N \) is an even number, we need to change the definition of the category \( \text{COB}_A \) slightly. Let \( \widetilde{\text{COB}}_A \) have the same objects as \( \text{COB}_A \). But a morphism of this new category is a quadruple \((W, w, z, \alpha_W)\) where \( W \), \( w \) and \( z \) are as before and \( \alpha_W \) is a homology orientation for \( W \) [60]. Then \( I_*^N \) can be lifted to a functor \( \widetilde{I}_*^N : \widetilde{\text{COB}}_A \to \text{VECTOR}_{4N} \). The
main point is that initially there is an ambiguity in the orientation of the moduli spaces \( \mathcal{M}_{P}(W, w; \alpha_0, \alpha_1) \) that appear in the definition of the cobordism maps, and a homology orientation of \( W \) fixes this ambiguity. In the case that \( N \) is odd, there is not such an ambiguity and one can readily lift \( I^{\mathbb{N}}_{A} \) to \( I^{\mathbb{N}}_{A} : \text{COB}_{A} \rightarrow \text{VECTOR}_{4N} \).

The definition of cobordism maps can be extended to the case that one of the ends is the empty pair. Suppose \( X \) is a 4-manifold with boundary \( Y \) and \( w \) is a properly embedded surface in \( X \) such that \( \gamma := \partial w = w \cap Y \). Assume that \((Y, \gamma)\) is an admissible pair. Given any element \( z \in \mathcal{A}(X)^{\otimes (N-1)} \), we can form an element \( D^{N}_{X, w}(z) \) of \( I^{\mathbb{N}}_{A}(Y, \gamma) \). This construction is the extension of \( U(N) \)-polynomial invariants for closed 4-manifolds in the previous section. Alternatively, \((X, w, z)\) can be regarded as a cobordism from the empty pair to the admissible pair \((Y, \gamma)\). Although the empty pair is not admissible, the formula (3.4) can be used to define \( D^{N}_{X, w}(z) \).

**Remark 3.9.** Given \( z_i \in \mathcal{A}(X_i)^{\otimes (N-1)} \), we can consider the relative elements \( D^{N}_{X_i, w_i}(z_i) \in I^{\mathbb{N}}_{A}\). Each of these relative elements lies in a graded summand of \( I^{\mathbb{N}}_{A}(Y, \gamma) \). Therefore, the difference \( \deg(D^{N}_{X_2, w_2}(z_2)) - \deg(D^{N}_{X_1, w_1}(z_1)) \) of the relative \( Z/4NZ \)-gradings is a well-defined number in \( Z/4NZ \) and is equal to:

\[
2(N + 1)(w_2^2 - w_1^2) - (N^2 - 1)\left(\frac{\chi(X_2) + \sigma(X_2)}{2} - \frac{\chi(X_1) + \sigma(X_1)}{2}\right) - (\deg(z_2) - \deg(z_1))
\]

Note that the term \( w_2^2 \) is not well-defined and depends on a framing of the 1-cycle \( \gamma \). However, the difference \( w_2^2 - w_1^2 \) is independent of the framing and the above expression is well-defined. A similar formula can be written for the difference between the gradings of two cobordisms with the same ends.

Suppose \((X, w)\) is a cobordism from an admissible pair \((Y, \gamma)\) to the empty pair, namely, \( X \) is a 4-manifold whose boundary is identified with \( \overline{Y} \), the 3-manifold \( Y \) with the reverse orientation. The boundary of the embedded surface \( w \) is also identified with \( \overline{\gamma} \). Suppose also \( z \in \mathcal{A}(X)^{\otimes (N-1)} \). Similarly, we can extend the definition of \( I^{\mathbb{N}}_{A} \) to \((W, w, z)\), and construct a functional \( D_{N}^{X, w}(z) : I^{\mathbb{N}}_{A}(Y, \gamma) \rightarrow \mathbb{C} \).

As the cobordism maps, \( D_{N}^{X, w}(z) \) and \( D_{N}^{X, w}(z) \) satisfy some functorial properties. For example, if \((X, w, z)\) and \((W, w', z')\) are chosen such that:

\[
\partial(X, w) = (Y_0, \gamma_0) \quad \partial(W, w', z') = (Y_0, \gamma_0) \rightarrow (Y_1, \gamma_1),
\]

then:

\[
D_{N}^{X, w}(z \cdot z') = D_{N}^{X, w}(W', w', z') \circ D_{N}^{X, w}(z).
\]

A similar, property holds for \( D_{N}^{X, w}(z) \). There is also an important relation among these invariants and invariants of closed manifolds form the previous section:

**Proposition 3.10.** Suppose \((Y, \gamma)\) is an admissible pair, and \(X_1\) and \(X_2\) are two smooth 4-manifolds with \( \partial X_1 = Y \) and \( \partial X_2 = \overline{Y} \). Suppose also oriented properly embedded surfaces \( w_i \subset X_i \) are given such that \( \partial w_1 = \gamma \) and \( \partial w_2 = \overline{\gamma} \). If \( b^+(X_2 \circ X_1) \geq 2 \), then for \( z_i \in \mathcal{A}(X_i)^{\otimes (N-1)} \):

\[
D_{X_2 \circ X_1, w_2 \circ w_1}(z_1 \cdot z_2) = D_{N}^{X_2, w_2}(z_2) \circ D_{N}^{X_1, w_1}(z_1)
\]

(3.11)

If \( b^+(X_2 \circ X_1) = 1 \), then a similar formula holds where the left hand side of (3.11) is interpreted as the invariant of the chamber associated to metrics with a long neck along \( Y \).
There is another way that the invariants of a closed 4-manifold can be related to the cobordism maps:

**Proposition 3.12.** Let \((Y, \gamma)\) be an admissible pair and \((W, w) : (Y, \gamma) \to (Y, \gamma)\) be a cobordism of pairs. Let \(W\) and \(Y\) be connected. Let \(\widetilde{W}\) be the closed 4-manifold, given by gluing the incoming end of \(W\) to its outgoing end. Suppose also \(\tilde{w} \subset \widetilde{W}\) is defined similarly. If \(b^+(\tilde{W}) \geq 2\), then for \(z \in \mathcal{A}(\tilde{W}) \otimes (N-1)\):

\[
D^N_{\tilde{W}, \tilde{w}}(z) = N \operatorname{tr}(i^N_{s}(W, w, z))
\]

(3.13)

If \(b^+(\tilde{W}) = 1\), then a similar formula holds where the left hand side of (3.13) is interpreted as the invariant of the chamber associated to metrics with a long neck along \(Y\).

### 3.2 Floer Homology of \(S^1 \times \Sigma\)

Suppose \(\Sigma\) is the connected oriented Riemann surface of genus \(g\). The 3-manifold \(Y_g := \Sigma \times S^1\) and the embedded 1-manifold \(\gamma_{g,d} := \{x_1, \ldots, x_d\} \times S^1\) determine an admissible pair if \((d, N) = 1\). The \(U(N)\)-bundle associated to the pair \((Y_g, \gamma_{g,d})\) is the pull-back of a \(U(N)\)-bundle \(Q_d\) of degree \(d\) on \(\Sigma\). Let also \(L_d\) denote the determinant of \(Q_d\). Recall that the space \(\mathcal{A}(Y_g, \gamma_{g,d})\) is constructed using an auxiliary connection on \(L_{g,d}\). We assume that this connection is the pull-back of a connection \(B_0\) on \(L_d\). Similar to the 3-dimensional case, \(\mathcal{A}(\Sigma, Q_d)\) is defined to be the space of \(U(N)\)-connections on \(Q_d\) whose determinant is equal to \(B_0\). The space \(\mathcal{G}_d\) is also defined to be the group of determinant 1 automorphisms of \(Q_d\).

Let \(\mathcal{V}^{N}_{g,d}\) be the vector space \(I^{N}_{s}(Y_g, \gamma_{g,d})\). The critical points of the Chern-Simons functional for the pair \((Y_g, \gamma_{g,d})\) can be identified with \(N\) copies of the following space:

\[
\mathcal{N}_{N,d} := \{ A \in \mathcal{A}(\Sigma, Q_d) \mid F_0(A) = 0 \}/\mathcal{G}_d.
\]

In fact, we can pull back any element of \(\mathcal{N}_{N,d}\) to \(\Sigma \times [0, 1]\) and then identify the connections on \(\Sigma \times \{0\}\) and \(\Sigma \times \{1\}\) using an element of \(\mathcal{G}_d\) which is induced by a central element of \(SU(N)\). The space \(\mathcal{N}_{N,d}\) is a smooth manifold of dimension \((N^2 - 1)(2g - 2)\) [2]. Moreover, the Chern-Simons functional in this case is Morse-Bott, hence \(\dim(\mathcal{V}^{N}_{g,d}) \leq N \dim(H^*(\mathcal{N}_{N,d}))\).

The space \(\mathcal{N}_{N,d}\) has been extensively studied in the literature. This space is a Kähler manifold and can be identified with the moduli space of stable bundles of rank \(N\) and degree \(d\) on a Riemann surface of genus \(g\) with a fixed determinant. The Poincaré polynomial of this manifold can be computed inductively [43, 15, 2]. Furthermore, a set of generators for the cohomology ring of this space is given [2]. We review a slightly reformulated description of these generators which are more suitable for our purposes here.

Consider the 4-manifold \(X_g := \Sigma \times S^2\) and the surface \(\chi_g := \{x_1, \ldots, x_d\} \times S^2\). The pull back of the elements of \(\mathcal{N}_{N,d}\) to \(X_g\) are ASD connections associated to the pair \((X_g, \chi_g)\) with \(\kappa = 0\). In particular, \(\mathcal{N}_{N,d}\) can be regarded as a subset of \(\mathcal{B}_0(X_g, \chi_g)\). Consider the subalgebra \(\mathcal{A}^N_g := \mathcal{A}(\Sigma) \otimes (N-1)\) of \(\mathcal{A}(X_g) \otimes (N-1)\). The \(\mu\)-map in (2.4) determines a graded algebra homomorphism \(\Psi : \mathcal{A}^N_g \to H^*(\mathcal{N}_{N,d})\). Note that this map is equivariant with respect to \(\operatorname{Diff}(\Sigma)\), the group of diffeomorphisms of \(\Sigma\).

**Proposition 3.14.** The map \(\Psi\) is surjective. In particular, the cohomology ring of \(\mathcal{N}_{N,d}\) is generated by the following elements:

\[
p_r := \Psi(a_r) \quad q^i_r := \Psi(l^i_r) \quad s_r := \Psi(\Sigma(\chi_r))
\]

(3.15)
where $2 \leq r \leq N$ and $\{l^j\}_{1\leq j \leq 2g}$ forms a set of generators for $H_1(\Sigma, \mathbb{Z})$.

The action of $\text{Diff}(\Sigma)$ on $H_1(\Sigma)$ factors through the action of the symplectic group $\text{Sp}(2g)$. Therefore, this proposition implies that the same holds for $H^*(\mathcal{N}_{N,d})$.

**Proof.** In [3], a universal $U(N)$-bundle $\mathcal{P}$ is constructed over the product manifold $\mathcal{N}_{N,d} \times \Sigma$ and it is shown that the cohomology ring of $\mathcal{N}_{N,d}$ is generated by the following classes:

$$\bar{p}_r := c_r(\mathcal{P})/\lfloor a \rfloor \quad \bar{q}_r := c_r(\mathcal{P})/\lfloor l^j \rfloor \quad \bar{s}_r := c_r(\mathcal{P})/\lfloor \Sigma \rfloor \quad (3.16)$$

The map $\Psi$ is defined similarly using the universal $\text{PU}(N)$-bundle $\mathcal{P}$ over the space $B_n(X_g, \chi_g) \times X_g$. The restriction of $\mathcal{P}$ to $\mathcal{N}_{N,d} \times \Sigma \subset B_n(X_g, \chi_g) \times X_g$ is isomorphic to the $\text{PU}(N)$-bundle associated to $\mathcal{F}$. Thus the cohomology classes in (3.16) can be identified with the corresponding ones in (3.15) and this verifies the claim. \qed

The vector space $\mathbb{V}_{g,d}^N$ admits a ring structure which is the analogue of the cup product on $H^*(\mathcal{N}_{N,d})$. Suppose $P$ is the pair of pants product cobordism from two copies of $S^1$ to one copy of $S^1$. Then the triple $(\Sigma \times P, \{x_1, \ldots, x_d\} \times P, 1)$ defines a map $m : \mathbb{V}_{g,d}^N \otimes \mathbb{V}_{g,d}^N \to \mathbb{V}_{g,d}^N$. To be more precise, we need to fix a homology orientation in the case that $N$ is even. Suppose $\Delta_g := \Sigma \times D^2$ and $\delta_{g,d} := \{x_1, \ldots, x_d\} \times D^2$ where $D^2$ is the 2-dimensional disc. We fix an arbitrary homology orientation on $\Delta_g$ and let $e := D^N_{\Delta_g, \delta_{g,d}}(1) \in \mathbb{V}_{g,d}^N$. We shall see in the proof of Proposition 3.22 that $e$ is non-zero. We choose a homology orientation on $\Sigma \times P$ such that $m(e, e) = e$. Then, Functoriality of instanton Floer homology can be used to show that $m$ defines a ring structure on $\mathbb{V}_{g,d}^N$ with the unit $e$. We turn the relative $\mathbb{Z}/4\mathbb{Z}$-grading on $\mathbb{V}_{g,d}^N$ into an absolute grading by requiring that the unit element has degree 0. With this convention, the multiplication map is $\mathbb{Z}/4\mathbb{Z}$-graded, namely, the product of two elements of degree $i_1$ and $i_2$ has degree $i_1 + i_2$.

Suppose $B$ is a cylinder, regarded as a cobordism with two circles as the incoming end and the empty outgoing end. Then the pair:

$$\Omega_g := \Sigma \times B \quad \omega_g := \{x_1, \ldots, x_d\} \times B \quad (3.17)$$

determines a pairing $\langle , \rangle : \mathbb{V}_{g,d}^N \otimes \mathbb{V}_{g,d}^N \to \mathbb{C}$ which is defined in the following way after we choose an arbitrary homology orientation on $\Omega_g$:

$$D_N^{\Omega_g, \omega_g}(1).$$

**Proposition 3.18.** The space $\mathbb{V}_{g,d}^N$ as a complex vector space with an action of $\text{Diff}(\Sigma)$, is isomorphic to $H^*(\mathcal{N}_{N,d}(\Sigma))[u]/(u^N - 1)$. In particular, the action of $\text{Diff}(\Sigma)$ on $\mathbb{V}_{g,d}^N$ factors through an action of $\text{Sp}(2g)$.

In the case that $N = 2$, one can show that $\mathbb{V}_{g,d}^N$ is isomorphic to $H^*(\mathcal{N}_{N,d}(\Sigma))[u]/(u^N - 1)$ using the results of [22]. Muñoz gave an alternative proof of this proposition for $N = 2$ [71], and the proof of the general case is based on his approach.
Proof. We can define a \( \text{Diff}(\Sigma) \)-equivariant algebra homomorphism \( \Phi : A_g^N[u]/(u^N - 1) \to \mathbb{V}_{g,d}^N \) in the following way:

\[
\Phi(u^i z) := D_{\Delta_g, \delta_g, d + i\Sigma}^N(z)
\]

where on the right hand side \( z \) is regarded as an element of \( A_g(\Delta_g)^{\otimes(N-1)} \). Let \( S : H^*(\mathcal{N}_{N,d}) \to A_g^N \) be a graded \( \text{Sp}(2g) \)-equivariant right inverse for the map \( \Psi \). Extend \( \Psi \) to an algebra homomorphism from \( A_g^N[u]/(u^N - 1) \) to \( H^*(\mathcal{N}_{N,d}(\Sigma))[u]/(u^N - 1) \) by requiring that \( \Psi(u) = u \). Similarly, we can assume \( S \) is defined on \( H^*(\mathcal{N}_{N,d}(\Sigma))[u]/(u^N - 1) \). We claim that the \( \text{Diff}(\Sigma) \)-equivariant map \( \Phi \circ S : H^*(\mathcal{N}_{N,d}(\Sigma))[u]/(u^N - 1) \to \mathbb{V}_{g,d}^N \) is injective. If the claim does not hold, then there is:

\[
p = \sum_{m=1}^{M} z_m u^{i_m} \in A_g^N[u]/(u^N - 1) \quad \text{such that} \quad \Psi(p) \neq 0 \quad \text{and} \quad \Phi(p) = 0.
\]

We assume that each \( z_m \) is non-zero and lies in one of the graded summands of \( A_g^N \). Furthermore, if \( m < n \), then \( \deg(z_m) \geq \deg(z_n) \) and equality holds only if \( i_m = i_n \). Let \( z' \in A_g^N \) be such that:

\[
\deg(z') + \deg(z_1) = (N^2 - 1)(2g - 2)
\]

and the cup product of \( \Psi(z') \) and \( \Psi(z_1) \) is non-zero. By Proposition 3.10, the pairing \( \langle \Phi(p), \Phi(u^{N-i_1}u) \rangle \) is equal to:

\[
\sum_{m=1}^{M} D_{\Sigma \times S^2, w_{g,d} + (N+i_m-i_1)}(z' z_m)
\]

where the polynomial invariants are computed in the chamber that the fiber \( \Sigma \) is small. The dimension formula shows that the dimension of each component of the moduli space associated to the pair \( (\Sigma \times S^2, w_{g,d} + k\Sigma) \) is at least \( (N^2 - 1)(2g - 2) \). Moreover, if \( k \) is not divisible by \( N \), this dimension is strictly greater than \( (N^2 - 1)(2g - 2) \). In the case that \( k = 0 \) (or divisible by \( N \)), the moduli space of dimension \( (N^2 - 1)(2g - 2) \) is given by the pull-back of the elements of \( \mathcal{N}_{N,d} \) to \( X_g \). Therefore, the only non-zero term in (3.20) is \( D_{\Sigma \times S^2, w_{g,d}}(z' z_1) \) which is given by evaluating the cohomology class \( \mu(z' z_1) \) on the pull-back of the elements of \( \mathcal{N}_{N,d} \) to \( X_g \). Note that the moduli space is compact in this case and we do not need to use the counting argument to evaluate this invariant. Therefore, \( D_{\Sigma \times S^2, w_{g,d}}(z' z_1) \) is equal to \( \Psi(z') \cup \Psi(z_1) \vert_{\mathcal{N}_{N,d}} \) which is non-zero by assumption. This contradicts the assumption that \( \Phi(p) = 0 \). Therefore, the map \( \Phi \circ S \) is injective. We already know that the dimension of \( \mathbb{V}_{g,d}^N \) is not greater than \( N \dim(H^*(\mathcal{N}_{N,d})) \). Therefore, \( \Phi \circ S \) is a bijection. In particular, the action of \( \text{Diff}(\Sigma) \) on \( \mathbb{V}_{g,d}^N \) factors through an action of \( \text{Sp}(2g) \).

\[\Box\]

Corollary 3.21. The ring \( \mathbb{V}_{g,d}^N \) is generated by the following elements:

\[
\epsilon = D_{\Delta_g, \delta_g, d}(\Sigma(1)), \quad \kappa_r = D_{\Delta_g, \delta_g, d}(\alpha_r), \quad \alpha_r^j = D_{\Delta_g, \delta_g, d}(\beta_r^j), \quad \rho_r = D_{\Delta_g, \delta_g, d}(\Sigma_r)
\]

where \( 2 \leq r \leq N \) and \( 1 \leq j \leq 2g \). Furthermore, the \( \mathbb{Z}/4N\mathbb{Z} \)-grading of these elements are given by:

\[
\deg(\epsilon) = 4 \quad \deg(\kappa_r) = -2r \quad \deg(\alpha_r^j) = -2r + 1 \quad \deg(\rho_r) = -2r + 2
\]

Proof. The first part is an immediate consequence of Proposition 3.18. The second part can be also verified easily using Remark 3.9. \[\Box\]
Fix $S : H^*(N_{N,d}) \to A_g^N$ as in the proof of Proposition 3.18. Then we can use the isomorphism $\Phi \circ S$ to carry over the ring structure, the paring and the $\mathbb{Z}/4N\mathbb{Z}$-grading of $\mathcal{V}^N_{g,d}$ into $H^*(N_{N,d})[u]/(u^N - 1)$. Suppose the new multiplication map and the paring on $H^*(N_{N,d})[u]/(u^N - 1)$ are also denoted by $m$ and $\langle , \rangle$. We also fix the cohomological $\mathbb{Z}$-grading on $H^*(N_{N,d})[u]/(u^N - 1)$ where we set $\deg(u) = 0$. The cohomological and the $\mathbb{Z}/4N\mathbb{Z}$-gradings differ by a sign after collapsing into $\mathbb{Z}/4\mathbb{Z}$-gradings. In the proof of Proposition 3.18, we show that for any element $p$ of degree $i$ in $H^*(N_{N,d})[u]/(u^N - 1)$, there is an element $q$ of degree $(N^2 - 1)(2g - 2) - i$ with $\langle p, q \rangle \neq 0$. In particular, $\langle , \rangle$ defines a non-degenerate pairing.

Suppose $p_1$ and $p_2$ are two elements of degree $i_1$ and $i_2$ in $H^*(N_{N,d})[u]/(u^N - 1)$. Then the product $m(p_1, p_2)$ consists of terms in various gradings. However, there are some constraints on the degrees of these terms. Firstly, they all have the same $\mathbb{Z}/4\mathbb{Z}$-grading because the multiplication map is graded with respect to the $\mathbb{Z}/4N\mathbb{Z}$-grading on $\mathcal{V}^N_{g,d}$. Moreover, an argument similar to that of Proposition 3.18 shows that the pairing of $m(p_1, p_2) - p_1 \cup p_2$ and any element of $H^*(N_{N,d})[u]/(u^N - 1)$ with cohomological degree less than or equal to $(N^2 - 1)(2g - 2) - i_1 - i_2$ is zero. Therefore, the degree of the terms in $m(p_1, p_2)$ are at least $i_1 + i_2$ and the term with the minimal degree is $p_1 \cup p_2$. Therefore, the product $m$ is a deformation of the cup product. We summarize these properties of $\mathcal{V}^N_{g,d}$ in the following proposition:

**Proposition 3.22.** The pairing $\langle , \rangle$ on $\mathcal{V}^N_{g,d}$ is non-degenerate and the product $m : \mathcal{V}^N_{g,d} \times \mathcal{V}^N_{g,d} \to \mathcal{V}^N_{g,d}$ is a $\mathbb{Z}/4\mathbb{Z}$-deformation of the cup product.

Multiplication with the elements of $\mathcal{V}^N_{g,d}$ constructed in Corollary 3.21, defines a series of operators on $\mathcal{V}^N_{g,d}$. We will use the same notation to denote these operators. The operator $\epsilon$ can be alternatively described as the cobordism map associated to the triple $([0, 1] \times Y_g, [0, 1] \times \gamma_{g,d} \cup \Sigma, 1)$. Similarly the remaining operators are cobordism maps associated to triples $([0, 1] \times Y_g, [0, 1] \times \gamma_{g,d}, z)$ for appropriate choices of $z$. The operators $\epsilon, \kappa_r$ and $\rho_r$ commute with each other and $\sigma^j_r$. However, $\sigma^j_r$ and $\sigma^j_r$ anti-commute with each other.

In the special case that $g = 1$, the moduli space $N_{N,d}(\Sigma)$ consists of only one point. Therefore, $\mathcal{V}^N_{1,d} \to \mathcal{V}^N_{1,d}$ has $N$ generators with exactly one generator $\alpha_i$ in degree $4i$ with respect to $\mathbb{Z}/4N\mathbb{Z}$-grading. In fact, the (non-perturbed) Chern-Simons functional associated the admissible pair $(Y_1, \gamma_{1,d})$ has irreducible and non-degenerate critical points (cf. [56]). The operator $\epsilon$ maps $\alpha_i$ to $\alpha_{i+1}$. The following proposition characterizes the action of some of the point classes in the case that $d = 1$:

**Proposition 3.23.** The operators $\kappa_i : \mathcal{V}^N_{1,1} \to \mathcal{V}^N_{1,1}$ satisfy the following identities:

\[
\kappa_2 = N \epsilon^{-1}, \quad \kappa_{2i-1} = 0 \quad (3.24)
\]

**Proof.** The second identity can be verified easily, because $\deg(\kappa_{2i-1})$ is not divisible by 4. The first claim is proved in [83]. Since $\kappa_2$ and $\epsilon$ commute with each other and $\deg(\kappa_2) = -4$, we can conclude that $\kappa_2 = c \epsilon^{-1}$. Therefore, we just need to show that $\text{tr}(\kappa_2 \circ \epsilon) = N^2$. Using Proposition 3.12, this can be reduced to show that:

\[
D^N_{T^4, T^2 \times \{pt\} \cup \{pt\} \times T^2}(\kappa_2) = N^3
\]

which is established in [83] using properties of stable bundles on abelian varieties. \qed
In [14], we will give another proof of this proposition which is independent of the results of [83].

3.3 Fukaya-Floer Homology

Suppose $X_1$ and $X_2$ are 4-manifolds with $\partial X_1 = Y, \partial X_2 = \overline{Y}$, and $X$ is given by gluing these manifolds along their boundaries. Suppose also a 1-cycle $\gamma \subset Y$ and 2-cycles $w_i \subset X_i$ are chosen such that $\partial w_1 = \gamma$ and $\partial w_2 = \overline{\gamma}$. The cycles $w_1$ and $w_2$ can be glued to each other to form a 2-cycle $w \subset X$. We also assume that $(Y, \gamma)$ is an admissible pair. Then Floer homology for this admissible pair provides a useful device to relate a $U(N)$-polynomial invariant of the following form:

$$D_{X,w}^N(z_1 \cdot z_2) \quad z_i \in \mathbb{A}(X_i)^{\otimes (N-1)} \quad (3.25)$$

to the relative invariants associated to $(X_1, w_1, z_1)$ and $(X_2, w_2, z_2)$ (cf. Proposition 3.10). As we shall see in the next section, this decomposition theorem for polynomial invariants is a useful tool for computational purposes. However, all polynomial invariants of $(X, w)$ do not have the form in (3.25). There are homology classes $\Gamma \in H_2(X)$ such that $\Gamma$ is not the sum of the elements in $H_2(X_1)$ and $H_2(X_2)$. Then, for example, $D_{X,w}(\Gamma_1^i \Gamma_2^j)$ cannot be expressed in terms of the relative invariants. In this section, we introduce an extension of Floer homology which admit relative invariants for such polynomial invariants. This extension of Floer homology was already constructed in [34, 10] for $N = 2$ and is known as Fukaya-Floer homology.

Our extension of Floer homology is a module over a ring $R_N$. Let $R_{N,k}$ be the polynomial ring over the variables $t_{i,j}$, for $2 \leq i \leq N$ and $1 \leq j \leq k$, modulo the relations $t_{i,j}^2 = 0$:

$$R_{N,k} := \mathbb{C}[t_{i,j}; 2 \leq i \leq N, 1 \leq j \leq k]/(t_{i,j}^2)$$

For $k > l$, there is an obvious map from $R_{N,k}$ to $R_{N,l}$ which maps $t_{i,j}$ to $t_{i,j}$ when $j \leq l$ and $t_{i,j}$ to 0 when $j > l$. The ring $R_N$ is defined to be the inverse limit of this system of rings. For example, for each $i$ we have an element of $R_N$ as follows:

$$s_i := \sum_{j=1}^{\infty} t_{i,j}$$

The ring of polynomials $\mathbb{C}[t_2, \ldots, t_N]$ can be regarded as a subring of $R_N$ by mapping $t_i$ to $s_i \in R_N$. Under this inclusion we have:

$$\frac{t_i^k}{k!} \to \sum_{S \subset \mathbb{N}} \prod_{j \in S} t_{i,j}^{\left|S\right|}$$

The full-version of Fukaya-Floer homology for $N = 2$, whose construction is sketched in [10], is expected to be a module over $\mathbb{C}[t_2]$. However, our construction is slightly different and we obtain a module over the ring $R_N$ for general $N$. This is partly because the definition of polynomial invariants for higher rank bundles slightly differs from the classical definition of $U(2)$-polynomial invariants. Another reason is that even for $N = 2$, the authors were not able to avoid some analytical difficulties related to the non-compactness of the moduli space of ASD connections and construct a ring over $\mathbb{C}[t_2]$.

31
Consider the admissible pair \((Y, \gamma)\), and let \(L = (l_2, \ldots, l_N)\) be an \((N - 1)\)-tuple of the elements of \(H_1(Y)\). Fukaya-Floer homology associates an \(R_N\)-module \(\mathbb{I}^N(Y, \gamma, L)\) to \((Y, \gamma, L)\). As in the case of instanton Floer homology, this module is defined as the homology of a chain complex \((\mathcal{C}^\pi_*(Y, \gamma, L), \widetilde{d})\). In fact, the module \(\mathcal{C}^\pi_*(Y, \gamma, L)\) does not depend on \(L\). Fix a perturbation of the Chern-Simons functional for the pair \((Y, \gamma)\) such that we can form the Floer chain complex \((\mathcal{C}^\pi_*(Y, \gamma), \widetilde{d})\). Then:

\[
\widetilde{\mathcal{C}}^\pi_*(Y, \gamma, L) := \mathcal{C}^\pi_*(Y, \gamma) \otimes R_N
\]

That is to say, \(\widetilde{\mathcal{C}}\) is freely generated over the ring \(R_N\) by the critical points of the perturbed Chern-Simons functional associated to the pair \((Y, \gamma)\).

The differential \(\widetilde{d}\) of the Fukaya-Floer chain complex has the following form:

\[
\widetilde{d}(\alpha) = \sum_{\bar{S} = (S_2, \ldots, S_N)} h_{\bar{S}}(\alpha, \beta) (\prod_{j \in S_i} t_{i,j}) \beta \tag{3.26}
\]

where \(S_i \subset \mathbb{N}\) and the path \(p\) is chosen such that the dimension of the moduli space associated to \(p\) is equal to:

\[
2|S_2| + 4|S_3| + \cdots + 2(N - 1)|S_N| - 1.
\]

The constant term of the differential is equal to the differential \(d\) of the Floer chain complex. The is to say, if we evaluate \(t_{i,j}\) at zero, then we recover \(d\). The definition of the other terms in (3.26) are discussed in subsection 6.3. We extend the Floer grading to \(\widetilde{\mathcal{C}}^\pi_*(Y, \gamma, L)\) by requiring that \(\deg(t_{i,j}) = 2(i - 1)\). Then the differential \(\widetilde{d}\) has degree \(-1\). The chain homotopy type of the chain complex \((\mathcal{C}^\pi_*(Y, \gamma, L), \widetilde{d})\) does not depend on the choice of the metric on \(Y\), the perturbation of the Chern-Simons functional and the other choices involved in the definition of \(h_{\bar{S}}(\alpha, \beta)\).

Suppose \((X_1, w_1)\) is a pair of a 4-manifold and a 2-cycle which fills the admissible pair \((Y, \gamma)\). Suppose also \(z_1 \in A(X_1) \otimes \Gamma^{(N - 1)}\) and \(\Gamma^2, \ldots, \Gamma^N\) are properly embedded surfaces in \(X_1\) where the boundary of \(\Gamma^i\) is \(l_i \subset Y\). Then one can associate an element of \(\mathbb{I}^N_*(Y, \gamma, l_2, \ldots, l_N)\) to \((X_1, w_1, z_1, \Gamma^2, \ldots, \Gamma^N)\) which is denoted by:

\[
D^N_{X_1, w_1} (z_1 \cdot e^{\Gamma^2 + \cdots + \Gamma^N}) \tag{3.27}
\]

Next let \((X_2, w_2)\) be a cobordism from \((Y, \gamma)\) to the empty pair. Suppose \(z_2 \in A(X_2) \otimes \Lambda^{(N - 1)}\) and \(\Lambda^2, \ldots, \Lambda^N\) are properly embedded surfaces in \(X_2\) where the boundary of \(\Lambda^j\) is equal to \(l_j\) with the reverse orientation. In this case, there is an \(R_N\)-linear map from \(\mathbb{I}^N_*(Y, \gamma, l_2, \ldots, l_N)\) to \(R_N\) associated to \((X_2, w_2, z_2, \Lambda^2, \ldots, \Lambda^N)\), which is denoted by:

\[
D^N_{N, w_2} (z_2 \cdot e^{\Lambda^2 + \cdots + \Lambda^N}) \tag{3.28}
\]

The construction of the element (3.27) and the functional (3.28) is given in subsection 6.3.

We can glue the 4-manifolds \((X_1, w_1)\) and \((X_2, w_2)\) to form a closed pair \((X_2 \circ X_1, w_2 \circ w_1)\). The embedded surfaces \(\Gamma^j\) and \(\Lambda^j\) can be also glued to each other to form a closed embedded surface \(\Gamma^j \# \Lambda^j\). Then we have:

\[
D^N_{X_2 \circ X_1, w_2 \circ w_1} (z_1 \cdot z_2 \cdot e^{(\Gamma^2 \# \Lambda^2) + \cdots + (\Gamma^N \# \Lambda^N)}) = \ldots
\]
This claim shall be proved as Proposition 6.43 in subsection 6.3. A priori, the right hand side of the above equality is an element of $R_N$. Part of the claim is that the right hand side belongs to $C\llbracket t_2, \ldots, t_N \rrbracket \subset R_N$ and is equal to the given power series.

Fukaya-Floer homology is functorial with respect to cobordisms of admissible pairs. Suppose $(W, w) : (Y_0, \gamma_0) \to (Y_1, \gamma_1)$ is such a cobordism. For $2 \leq i \leq N$, suppose also $\Gamma_i : l_i^0 \to l_i^1$ is a properly embedded cobordism in $W$ with $l_i^0 \subset Y_j$. For any $z \in \mathbb{A}(W)$, there is a homomorphism:

$$\mathbb{F}^N(W, w, ze^{D^2(2) + \cdots + D^2(N)}) : \mathbb{F}^N(Y_0, \gamma_0, L_0) \to \mathbb{F}^N(Y_1, \gamma_1, L_1)$$

where $L_j = (l_j^2, \ldots, l_j^N)$. This construction is functorial with respect to composition of cobordisms.

Suppose $(Y_g, \gamma_{g, d})$ is the admissible pair from subsection 3.2 and $L_g = (l_2, \ldots, l_N)$ is the $(N - 1)$-tuple of the elements of $H_1(Y_g)$ where $l_i$ is an $S^1$ fiber. In this article, the main example of Fukaya-Floer homology for us is $\mathbb{F}^N(Y_g, \gamma_{g, d}, L_g)$, which is denoted by $\mathbb{F}^N_{g, d}$. Analogous to the previous subsection, we can define a ring homomorphism $\tilde{\mathcal{F}} : \mathbb{A}_g^N[\epsilon]/(\epsilon^n - 1) \to \mathbb{F}^N_{g, d}$ as follows:

$$\tilde{\mathcal{F}}(u^i z) := D^N_{\Delta_g, \delta_{g, d} + i \Sigma}(ze^{D^2(2) + \cdots + D^2(N)})$$

Recall that $D^2$ is a 2-dimensional disc and $\Delta_g = \Sigma \times D^2$ and $\delta_{g, d} = \{x_1, \ldots, x_d\} \times D^2$. Similarly, we can define a multiplication and a pairing on $\mathbb{F}^N_{g, d}$ by repeating the construction of subsection 3.2.

**Proposition 3.30.** For any non-zero element $p \in \mathbb{F}^N_{g, d}$ there are $z \in \mathbb{A}_g^N$ and $1 \leq i \leq N$ such that:

$$\langle p, D^N_{\Delta_g, \delta_{g, d} + i \Sigma}(ze^{D^2(2) + \cdots + D^2(N)}) \rangle \neq 0.$$

**Proof.** Suppose $\mathbb{C}^\pi$ is an admissible Floer chain complex for $\mathbb{F}^N_{g, d}$. Suppose also $p$ is represented by the following element of $\mathbb{C}^\pi$:

$$\sum_{\mathbf{S} = (S_2, \ldots, S_N) \in \mathcal{I}} b_{\mathbf{S}}(\prod_{j \in S_i} t_{i,j}) \alpha_{\mathbf{S}}$$

where $\mathcal{I}$ is a set of $(N - 1)$-tuples of finite subsets of $\mathbb{N}$, $b_{\mathbf{S}}$ is a non-zero complex number and $\alpha_{\mathbf{S}} \in \mathbb{C}_*$. Suppose $\mathbf{S}_0 = (S_2^0, \ldots, S_N^0) \in \mathcal{I}$ is a minimal element with respect to the partial order on $\mathcal{I}$ induced by inclusion. Then $\partial \alpha_{\mathbf{S}_0} = 0$, and by changing the representative if necessary, we can assume that $\alpha_{\mathbf{S}_0}$ is not a boundary in $\mathbb{C}_*$. Therefore, by Corollary 3.21 and Proposition 3.22, there are $z \in \mathbb{A}_g^N$ and $1 \leq i \leq N$ such that:

$$\langle \alpha_{\mathbf{S}_0}, D^N_{\Delta_g, \delta_{g, d} + i \Sigma}(z) \rangle \neq 0.$$

This implies that the coefficient of $\prod_{j \in S_i^0} t_{i,j}$ in the following pairing is non-zero:

$$\langle p, D^N_{\Delta_g, \delta_{g, d} + i \Sigma}(ze^{D^2(2) + \cdots + D^2(N)}) \rangle$$

$\square$
Remark 3.31. In Proposition 3.30, we can assume that \( z \) belongs to the image of \( S : H^*(N,\mathbb{A}_N^*) \rightarrow \mathbb{A}_N^* \) constructed in the proof of Proposition 3.18. This can be used to form an \( \Sigma(2g,\mathbb{Z}) \)-equivariant module isomorphism from \( H^*(M,N,\mathbb{A}_N^*)[\epsilon]/(\epsilon^N - 1) \otimes R_N \) to \( \mathbb{I}_N^* \).

Next, we discuss a prototype for 4-manifolds with boundary \( Y_g \) which are of interest to us. Suppose \((X_1,\Sigma)\) is a pair of a 4-manifold and an embedded surface of genus \( g \) with self-intersection 0 such that a regular neighborhood of \( \Sigma \) in \( X_1 \) is identified with \( \Delta_g \). Removing this neighborhood produces a 4-manifold whose boundary is \( Y_g \). Suppose \((X_2,\Sigma)\) is another such pair. As the notation suggests, the embedded surfaces in \( X_1 \) and \( X_2 \) are identified with each other. We use \((X_2,\Sigma)\) to define another 4-manifold with boundary \( Y_g \), and glue the resulting two 4-manifolds along their common boundaries by the orientation-reversing diffeomorphism that maps \((z,x) \in S^1 \times \Sigma\) to \((\bar{z},x)\). This 4-manifold is denoted by \( X_1 \#_\Sigma X_2 \), and is called the fiber sum of \( X_1 \) and \( X_2 \) along \( \Sigma \). We will also write \( X_i^\circ \) for the complement of a neighborhood of \( \Sigma \) in \( X_i \). Then \( X_i^\circ \) can be also regarded as a subset of \( X_1 \#_\Sigma X_2 \).

Elements of \( H_2(X_1) \) and \( H_2(X_2) \) can be glued to each other to construct elements of \( H_2(X_1 \#_\Sigma X_2) \). Suppose \( i : H_2(X_1) \rightarrow C \) denotes the map that computes the intersection number of an element of \( H_2(X_1) \) with \( \Sigma \). Suppose also \( K \) is the subspace of the elements \((\Gamma,\Lambda) \in H_2(X_1) \oplus H_2(X_2)\) such that \( \iota_1(\Gamma) = \iota_2(\Lambda) \). Then there is a homomorphism \# : \( K \rightarrow H_2(X_1 \#_\Sigma X_2) \) with the property that:

\[
j_1^\#(\Gamma \# \Lambda) = j_1^\circ(\Gamma) \quad j_2^\#(\Gamma \# \Lambda) = j_2^\circ(\Lambda)
\]

(3.32)

Here \( j_i^\circ : H_2(X_1) \rightarrow H_2(X_i^\circ, \partial X_i^\circ) \) is the composition of the map from \( H_2(X_i) \) to the relative homology \( H_2(X_i, \Delta_g) \) and the excision isomorphism. To abbreviate our notation, from now on, we will write \( \Gamma^\circ \) and \( \Lambda^\circ \) for \( j_1^\circ(\Gamma) \) and \( j_2^\circ(\Lambda) \). The maps \( j_i^\#: H_2(X_1 \#_\Sigma X_2) \rightarrow H_2(X_i^\circ, \partial X_i^\circ) \) are also defined similarly.

The homomorphism \# is not uniquely defined and we proceed as follows to fix one such homomorphism. Suppose \( \Gamma \) and \( \Lambda \) are integral homology classes. Then these homology classes can be represented by oriented embedded surfaces, which we denote with the same notation. We can assume that these surfaces are transversal to \( \Sigma \), and intersect \( \Sigma \) in the same set of points with the same signs. Then there is an obvious way to glue \( \Gamma \) and \( \Lambda \) and to produce an oriented embedded surface in \( X_1 \#_\Sigma X_2 \). The homology class \( \Gamma \# \Lambda \) is defined to be the homology of the glued up surface. We apply this construction to an integral basis of \( K \) and extend it linearly.

We use Poincaré duality to define \( L \subseteq H^2(X_1) \oplus H^2(X_2) \), the counterpart of \( K \), and the gluing map \# : \( L \rightarrow H^2(X_1 \#_\Sigma X_2) \). Suppose \((K, L) \in L \) and \((\Gamma, \Lambda) \in K \). Then we have the following equalities of the pairing of cohomology classes with homology classes:

\[
(K \# L)[\Gamma \# \Lambda] = K[\Gamma] + L[\Lambda]
\]

We can also glue two cycles \( w_1 \subset X_1 \) and \( w_2 \subset X_2 \) that intersect \( \Sigma \) transversely in the same set of points with the same signs. The resulting 2-cycle in \( X_1 \#_\Sigma X_2 \) is denoted by \( w_1 \# w_2 \). We will also write \( w_i^\circ \) for the intersection \( w_i \cap X_i^\circ \).

Proposition 3.33. For \( 1 \leq i \leq 4 \), suppose \( X_i \) is a 4-manifold and \( T \) is an embedded surface of genus one in \( X_i \). Suppose also \( w_i \subset X_i \) is a 2-cycle such that \( w_i \cdot T \) is coprime to \( N \). For each \( 2 \leq l \leq N \), suppose also \( \Gamma_i^l \) is an element of \( H_2(X_i) \) such that \( \Gamma_i^l \cdot T = 1 \). For \( 1 \leq i, k \leq 4 \), let \( D_{i,k} \) is the following
element of $\mathbb{C}[t_2, \ldots, t_N]$:

$$\sum_{j=1}^{N} D^N_{X_i \# T, X_k, w_i \# w_k + jT} \epsilon^{(\Gamma^2_i \# \Gamma^2_k)_{(2)} + \cdots + (\Gamma^N_i \# \Gamma^N_k)_{(N)}}.$$ 

Then:

$$D_{1,2} D_{3,4} = D_{1,4} D_{3,2}.$$ 

Proof. Suppose $C^p_N$ is associated to a perturbation of the Chern-Simons functional such that there are $N$ generators, one in each degree $4i$. Since the degree of the generators have the same parity, the differential of the corresponding Fukaya-Floer chain complex is zero, and $I^{N}_{1,d} = R^{|N|}_N$. The following operator has order $N$:

$$\epsilon = I^N_{p} (T \times S^1 \times [0, 1], \gamma_{1,d} \times [0, 1] + T, \epsilon^{(D^2 \times [0,1])_{(2)} + \cdots + (D^2 \times [0,1])_{(N)}}).$$

Therefore, the kernel of $\epsilon - 1$ has rank one. The following elements lie in this kernel:

$$D_i := \sum_{j=1}^{N} D^N_{X_i \# T, w_i \# jT} \epsilon^{(\Gamma^2_i \# \Gamma^2_i)_{(2)} + \cdots + (\Gamma^N_i \# \Gamma^N_i)_{(N)}}.$$ 

The identity (3.29) implies that:

$$D_{i,k} = \frac{1}{N} \langle D_i, D_k \rangle.$$ 

Because $D_i \in \ker(\epsilon - 1)$, the claim is a result of the identity in (3.34). 

\[ \square \]

3.4 An $SU(3)$–instanton Floer Homology for $\Sigma(2, 3, 23)$

In subsection 3.1, Floer homology is defined for an admissible pair $(Y, \gamma)$. Then the computation of the polynomial invariants for a closed pair $(X, w)$ which can be decomposed along a copy of $(Y, \gamma)$ can be reduced to computing relative invariants for each component of $X \setminus Y$ (Proposition 3.10). One wishes to extend the definition of Floer homology so that it can be used in studying polynomial invariants of a pair $(X, w)$ which is decomposed along a non-admissible pair. However, there is a little known in this direction even when $N = 2$. For $N = 2$, the most satisfactory answer is provided in the case that $Y$ is an integral homology sphere and $\gamma$ is empty [28] which will be denoted by $I^2_p(Y)$. The main reason that one can define $I^2_p(Y)$ for an integral homology sphere is that the only reducible flat connection on $Y$ is the non-degenerate trivial connection. In order to extend $I^2_p(Y)$ to higher values of $N$, one would face more complicated reducible connections. Due to this complication, there are some difficulties in extending the definition of Floer homology of integral homology spheres to higher values of $N$. In this section, we make a modest progress in this direction and define $I^2_p(Y)$ for the Brieskorn homology sphere $\Sigma(2, 3, 23)$. Meanwhile, we compute some of the gauge theoretical invariants for flat connections on $\Sigma(2, 3, 23)$.

Suppose the positive integer numbers $a_1$, $a_2$ and $a_3$ are pairwise coprime, and $\Sigma(a_1, a_2, a_3)$ is the associated Brieskorn sphere:

$$\Sigma(a_1, a_2, a_3) := \{(z_1, z_2, z_3) \in \mathbb{C}^3 \mid z_1^{a_1} + z_2^{a_2} + z_3^{a_3} = 0, |z_1|^2 + |z_2|^2 + |z_3|^2 = 1\}$$
This 3-manifold is an integral homology sphere. There is an $S^1$-action on this 3-manifold where:

$$e^{2\pi i \theta} \cdot (z_1, z_2, z_3) := (e^{2\pi i \alpha_2 \alpha_3 \theta} z_1, e^{2\pi i \alpha_1 \alpha_2 \theta} z_2, e^{2\pi i \alpha_1 \alpha_3 \theta} z_3)$$

This action turns $\Sigma(a_1, a_2, a_3)$ into a Seifert fiber space over $S^2$ with 3 exceptional orbits. Complex conjugation on $\mathbb{C}^3$ induces a diffeomorphism of $\Sigma(2, 3, 23)$ which will be also called complex conjugation. There is also a standard presentation of the fundamental group of this 3-manifold given as:

$$\pi_1(\Sigma(a_1, a_2, a_3)) = \langle x_1, x_2, x_3, h \mid [h, x_i] = 1, x_i a_i h \beta_i = 1, x_1 x_2 x_3 = 1 \rangle.$$

where $\beta_i$ is given by the following identity:

$$\frac{\beta_1}{a_1} + \frac{\beta_2}{a_2} + \frac{\beta_3}{a_3} = \frac{1}{a}$$

with $a = a_1 a_2 a_3$. The central element $h$ in (3.35) is represented by a generic fiber of the Seifert fibration.

Suppose $W$ is the space $(\Sigma(a_1, a_2, a_3) \times D^2)/S^1$ where the $S^1$-action is the product of the Seifert action on $\Sigma(a_1, a_2, a_3)$ and the standard action on $D^2$. Alternatively, $W$ is the mapping cylinder of the fibration of $\Sigma(a_1, a_2, a_3)$ over $S^2$. This space is an orbifold and has three singular points. A neighborhood of these singular points are diffeomorphic to cones on the lens spaces $L(a_i, \beta_i)$. Thus removing neighborhoods of the orbifold points produce a cobordism $W_0$ from the union of three lens spaces $L(a_i, \beta_i)$ to $\Sigma(a_1, a_2, a_3)$. We will denote the union of the lens spaces with $Y$.

The fundamental group of $W_0$ is equal to $\pi_1(\Sigma(a_1, a_2, a_3))/\langle h \rangle$ and the inclusion of $\Sigma(a_1, a_2, a_3)$ in $W_0$ induces the quotient map at the level of fundamental groups. Moreover, the induced map from the fundamental group of $L(a_i, \beta_i)$ to $\pi_1(\Sigma(a_1, a_2, a_3))/\langle h \rangle$ maps the standard generator of $\pi_1(L(a_i, \beta_i))$ to $x_i$. The description of the fundamental group implies that the first homology of $W_0$ is trivial. We also have the following short exact sequence:

$$0 \longrightarrow H^2(W_0, \partial W_0, \mathbb{Z}) \cong \mathbb{Z}^4 \longrightarrow H^2(W_0, \mathbb{Z}) \cong \mathbb{Z} \longrightarrow H^2(\partial W_0, \mathbb{Z}) \cong \mathbb{Z}/a\mathbb{Z} \longrightarrow 0$$

where the map $\iota$ is multiplication by $a$. The self-intersection pairing, defined on the image of $\iota$, maps a generator of $\text{im}(\iota)$ to $-a$. In particular, $b^+(W_0)$ is equal to 0.

The space $L := \Sigma \times D^2$ defines an orbifold $S^1$-bundle on $W$. In particular, the restriction of $L$ to $W_0$, denoted by $L_0$, is a smooth $S^1$-bundle. The first Chern class of $L_0$ is a generator of $H^2(W_0, \mathbb{Z})$. The restriction of this Chern class to $L(a_i, \beta_i)$ is equal to $\beta_i$ times the standard generator of $H^2(L(a_i, \beta_i), \mathbb{Z})$. In particular, for any complex line bundle on $\partial W_0$, there is $k$ such that the restriction of $L_0^k$ to the boundary is isomorphic to the given line bundle.

The rational cohomology class induced by $c_1(L_0)$ can be lifted to $H^2(W_0, \partial W_0, \mathbb{Q})$. In particular, $c_1(L_0)^2$ is well-defined and is equal to $-\frac{a}{2}$. For our purposes, we also fix a connection $B_0$ on $L_0$ whose restrictions to a neighborhood of $\partial W_0$ is the pull-back of a flat connection on $\partial W_0$. In particular, we can assume that the restriction of this connection in a regular neighborhood of $\Sigma(a_1, a_2, a_3)$ is the trivial connection.

Suppose $\alpha$ is a flat $SU(N)$-connection on $\Sigma(a_1, a_2, a_3)$ whose holonomy around the fiber is central. Therefore, $\alpha$ can be extended as a flat $PU(N)$-connection $A$ to $W_0$. The holonomy of $\alpha$ induces a
conjugacy class \( r_i \) in \( \text{PU}(N) \) corresponding to the loop \( x_i \). Then \( r_i \) has order \( a_i \) and determines a flat \( \text{PU}(N) \)-connection on \( \pi_1(L(a_i, \beta_i)) \) which matches the restriction of \( A \) to \( L(a_i, \beta_i) \). This connection will be also denoted by \( r_i \). As it was pointed in [25], the connection \( A \) can be used to compute some of the gauge theoretical invariants of \( \alpha \):

**Proposition 3.36.** Let \( \alpha \) and \( A \) be given as above. Then \( \rho_{\text{ad}(\alpha)} \) is equal to:

\[
(T_\alpha + 1 - N^2) + \sum_{i=1}^{3} \rho_{\text{ad}(r_i)}(L(a_i, \beta_i))
\]

where \( T_\alpha \) is the number of trivial summands in the irreducible decomposition of the representation associated to \( \text{ad}_\alpha \).

Using the calculations of [4] for lens spaces, Formula (3.37) allows us to compute the \( \rho \)-invariant of any connection as above.

**Proof.** According to [4]:

\[
\rho_{\text{ad}(\alpha)} - \sum_{i=1}^{3} \rho_{\text{ad}(r_i)}(L(a_i, \beta_i)) = (N^2 - 1)\sigma(W_0) - \sigma_A(W_0)
\]

where \( \sigma_A(W_0) \) denotes the signature of the twisted cohomology group \( H^2(W_0; \text{ad}(A)) \) determined by the flat \( \text{PU}(N) \)-connection \( \text{ad}(A) \). This twisted cohomology group can be decomposed according to the irreducible decomposition of \( A \) (or equivalently \( \alpha \)). The argument of [25, Lemma 2.6] shows that the contribution of the non-trivial summands is equal to 0. On the other hand, each trivial summand contributes -1 to the sum, because \( \sigma(W_0) = -1 \).

The underlying \( \text{PU}(N) \)-bundle of the connection \( A \) on \( W_0 \) can be lifted to a \( \text{U}(N) \)-bundle \( E \). There are also non-negative integer numbers \( k_1, \ldots, k_N \) such that the restriction of the connection:

\[
B_0^{k_1} \oplus \cdots \oplus B_0^{k_N}
\]

to \( Y \), the union of the three lens spaces, is equal to the restriction of \( A \) to \( Y \). In particular, \( L_0^{k_1} \oplus \cdots \oplus L_0^{k_N} \), the underlying \( \text{U}(N) \)-bundle of (3.38), has the same restriction as \( E \) on \( Y \). Therefore, the determinant of \( L_0^{k_1} \oplus \cdots \oplus L_0^{k_N} \) is equal to \( \text{det}(E) \otimes L_0^{nk} \) for an appropriate integer number \( k \). After replacing \( k_1 \) with \( k_1 + ak \), the new bundle \( L_0^{k_1} \oplus \cdots \oplus L_0^{k_N} \) has the same determinant as \( E \) and the connection in (3.38) and \( A \) give rise to the same connection after restriction to \( Y \).

Since \( A \) and the connection in (3.38) agree on boundary components except on \( \Sigma(a_1, a_2, a_3) \) where \( A \) gives the connection \( \alpha \) and \( B_0 \) restricts to the trivial connection, we can conclude that:

\[
\text{CS}(\alpha) = \mathcal{E}(B_0^{k_1} \oplus \cdots \oplus B_0^{k_N}) - \mathcal{E}(A)
\]

\[
= -\frac{1}{2N} \sum_{i<j} (k_i - k_j)^2 c_1(L)^2
\]

\[
= \frac{1}{2N} \sum_{i<j} \frac{(k_i - k_j)^2}{a}
\]

(3.39)
Therefore, this gives us a strategy to compute the Chern-Simons functional of the flat connection $\alpha$.

Now we focus on $N = 3$ and the Brieskorn homology sphere $\Sigma(2, 3, 23)$. Suppose $\alpha$ is an irreducible representation on $\Sigma(2, 3, 23)$. The irreducibility assumption implies that the holonomy of $\alpha$ along the generic fiber of the Seifert fibration is central. In fact, this central element is equal to the identity $[6]$. It is also shown in $[6]$ that there are 44 such irreducible representations which are non-degenerate. One can use the method of $[6]$ to find the conjugacy classes of holonomies corresponding to the elements $x_1, x_2$ and $x_3$ of $\pi_1(\Sigma(2, 3, 23))$. Any irreducible flat connection on $\Sigma(2, 3, 23)$ is characterized by its holonomies along $x_3$. The possible conjugacy classes for $x_3$ are listed in Table 2. On the other hand, the holonomies along $x_1$ and $x_2$ are equal to the diagonal matrices $\text{Diag}(1, -1, -1)$ and $\text{Diag}(1, \zeta, \zeta^2)$ where $\zeta = e^{2\pi i/3}$. Knowledge of these conjugacy classes allows us to apply Proposition 3.36 and Identity 3.39 to compute the $\rho$-invariants, the Chern-Simons functional and hence the degrees of irreducible flat connections on $\Sigma(2, 3, 23)$:

**Proposition 3.40.** There are ten irreducible flat connections of degree 0, five irreducible flat connections of degree 2, nine irreducible flat connections of degree 4, five irreducible flat connections of degree 6, nine irreducible flat connections of degree 8 and six irreducible flat connections of degree 10. There is not any irreducible flat connections of odd degree. The Chern-Simons functional and the $\rho$-invariants of these irreducible flat connections can be found in Tables 3 and 4.

Any reducible flat connection on $\Sigma(2, 3, 23)$ is either trivial or SU(2)-reducible, because this 3-manifold is an integral homology sphere. In particular, non-trivial reducible SU(3)-connections on $\Sigma(2, 3, 23)$ can be regarded as irreducible SU(2)-connections. The results and the methods of $[25]$ can be utilized to study such connections. The holonomy of any non-trivial flat SU(2)-connection along the fiber of the Seifert fibration is the central element $-id$. The holonomies of this connection along $x_1$ and $x_2$ are respectively conjugate to $\text{Diag}(-1, -1)$ and $\text{Diag}(e^{\pi i/3}, e^{-\pi i/3})$. As in the SU(3)-case, an irreducible flat SU(2)-connection on $\Sigma(2, 3, 23)$ is determined by the conjugacy class of its holonomy along $x_3$. The eigenvalues of holonomy term along $x_3$ are equal to $e^{2\pi ik/23}$ and $e^{-2\pi ik/23}$ for $2 \leq k \leq 9$:

**Proposition 3.41** ([25]). There are 8 irreducible SU(2)-connection on $\Sigma(2, 3, 23)$. For each degree $2i + 1 \in \mathbb{Z}/8\mathbb{Z}$, there are exactly two such irreducible connections and there is no irreducible connection of even degree.

Proposition 3.36 and Identity 3.39 give a strategy to compute the Chern-Simons functional and the $\rho$-invariants of irreducible SU(2)-connections. These computations can be used to verify the second part of the above proposition.

We also need to compute the degrees of flat SU(2)-connections when they are regarded as SU(3)-connections. To distinguish between these connections, we will write $\tilde{\alpha}$ for the SU(3)-connection associated to an SU(2)-connection $\alpha$. The values of the Chern-Simons functional of $\alpha$ and $\tilde{\alpha}$ are equal to each other. However, the $\rho$-invariants of these two connections are different because $\text{ad}_\alpha$ and $\text{ad}_{\tilde{\alpha}}$ define two different representation of the fundamental group. We cannot use Proposition 3.36 to compute the $\rho$-invariant of $\tilde{\alpha}$ because this connection does not extend to the cobordism $W_0$. In $[8]$, cut and paste methods have been utilized to compute the difference $\rho_{\text{ad}_\alpha} - \rho_{\text{ad}_{\tilde{\alpha}}}$ for SU(2)-flat connections on a family of homology spheres which include $\Sigma(2, 3, 23)$. In particular, the following proposition can be extracted from $[8]$. The claim about the non-degeneracy of reducible flat connections on $\Sigma(2, 3, 23)$ in the following
Proposition 3.42. The eight non-trivial reducible flat connections on $\Sigma(2, 3, 23)$ are non-degenerate. The SU(3)-degrees of these connections are given as follows: there are one connection of degree 1, one connection of degree 3, one connection of degree 5, two connections of degree 7, two connections of degree 9 and one connection of degree 11.

Define $I^3_4(\Sigma(2, 3, 23))$, the Floer homology of $\Sigma(2, 3, 23)$, to be the complex vector space generated by the irreducible flat connections on $\Sigma(2, 3, 23)$. The significance of this vector space for us is a gluing theorem for the 4-manifolds which split across a copy of $\Sigma(2, 3, 23)$.

The proof of the following theorem will be given in subsection 6.1:

**Proposition 3.43.** Let $X_1$ and $X_2$ be two 4-manifolds such that $b^+(X_1), b^+(X_2) \geq 1$, $\partial X_1 = \Sigma(2, 3, 23)$ and $\partial X_2 = \Sigma(2, 3, 23)$. Let $w_i$ be a closed 2-cycle in $X_i$ and $z_i \in A(X_i)^{\mathbb{Q}}$. Assume that $\deg(z_1) = -4w_1^2 - 4(\chi(z_1) + \sigma(X_1)) + 4 \mod 12$. Then there are:

$$D_{X_1,w_1}^3(z_1) \in I^3_4(\Sigma(2, 3, 23)) \quad D_{X_2,w_2}^3(z_2) : I^3_4(\Sigma(2, 3, 23)) \to \mathbb{C}$$

such that:

$$D_{X_2,w_2}^3(z_2) \circ D_{X_1,w_1}^3(z_1) = D_{\Sigma(2,3,23) \times X_2,w_1 \cup w_2}^3(z_1 \cdot z_2)$$

Moreover, $D_{X_2,w_2}^3(z_2)$ is non-zero only on the terms of the following degree:

$$4w_2^2 + 4(\chi(X_2) + \sigma(X_2)) - 4 + \deg(z_2)$$

### 4 Computing Polynomial Invariants

In this section, which is the heart of this paper, we firstly compute the $U(3)$-polynomial invariants of $E(n)$. The rank 2 invariants of elliptic surfaces were partially computed in [31, 33, 32] using algebro-geometric techniques. A complete calculation of the $U(2)$-polynomial invariants of elliptic surfaces are given in [53, 26, 65]. In [26] and [65], Gompf decomposition of elliptic surfaces play a key role in computing the invariants. In the introduction, we also recalled a construction of elliptic surfaces which give rise to a decomposition of $E(n)$ into fiber sum of $n$ copies of $E(1)$. This decomposition of elliptic surfaces can be also exploited to compute some of the $U(2)$-polynomial invariants [70, 19]. Our method for computing the $U(3)$-invariants of elliptic surfaces uses the Gompf decomposition, the fiber-sum decomposition, and the rich group of the symmetries of elliptic surfaces. In the last subsection of this section, we also give a general gluing theorem for fiber-sums. Similar results for $U(2)$-invariants are proved in [71]. The proof of the rank 3 case follows the same strategy as in [71].

In the next two sections, we mainly focus on polynomial invariants and instanton Floer homology in the case $N = 3$. Therefore, we shall drop 3 from our notation $I^3_4, D^3_{X,w}$, et cetera, when it does not make any confusion. Because we are working with an odd value of $N$, there is not any sign ambiguity in the definition of $I^3(W, w, z), D^3_{X,w}(z)$, and we do not need to fix a homology orientations for the underlying 4-manifold.
4.1 Structure of the Invariants of $E(n)$

A construction of the elliptic surface $E(n)$ was reviewed in the introduction. The simplest 4-manifold in this family, $E(1)$, can be also constructed by blowing up the projective plane $\mathbb{CP}^2$ at the nine intersection points of two generic cubics. The pencil of cubics generated by the two cubics determines an elliptic fibration of $E(1)$. The nine exceptional divisors give rise to sections of this elliptic fibrations, which are embedded sphere with self-intersection $-1$. The manifold $E(n)$ is fiber sums of $n$ copies of $E(1)$ along the fibers of the elliptic fibration. The fibration of $E(1)$ induces an elliptic fibration for $E(n)$, and we will write $f$ for a regular fiber of this fibration. By taking the connected sums of the exceptional sections of $E(1)$, we can form nine disjoint embedded spheres in $E(n)$. These are sections of the elliptic fibration of $E(n)$ and have self-intersection $-n$. We fix one of these sections and we will denote it by $\sigma$. When it does make any confusion, we will use the same notation to denote the homology and the cohomology classes associated to $f$ and $\sigma$.

We can assume that there is a cusp fiber in the elliptic fibration of $E(1)$ by choosing appropriate cubics. This gives a cusp fiber $f_0$ in the fibration of $E(n)$. A regular neighborhood of $\sigma \cup f_0$ is a 4-manifold with boundary $\Sigma(2, 3, 6n - 1)$ which is called the Gompf nucleus and is denoted by $G(n)$ [40]. The intersection form of $G(n)$ is given as follows:

$$
\begin{bmatrix}
0 & 1 \\
1 & -n
\end{bmatrix}
$$

The complement of $G(n)$ in $E(n)$, denoted by $B(2, 3, 6n - 1)$, is a Milnor fiber and its intersection form is given by:

$$
n(-E_8) \oplus 2(n - 1) \begin{bmatrix} 0 & 1 \\ 1 & -2 \end{bmatrix}.
$$

(4.1)

Here each $-E_8$ summand has a basis of embedded spheres with self-intersection $-2$ which intersect each other according to $-E_8$. The $i^{th}$ summand of the second type in (4.1) has a basis of an embedded torus $g_i$ with self-intersection 0 and an embedded $(-2)$-sphere $\tau_i$ where $g_i$ and $\tau_i$ intersect each other positively at one point [41].

The 4-manifold $E(2)$, which is a $K3$ surface, plays a special role in this family. For example, $E(2)$ enjoys a rich group of symmetries. As a manifestation of this fact, we have the following proposition:

**Lemma 4.2.** Suppose $e$ and $e'$ are two non-zero elements of $H^2(E(2), \mathbb{Z})$ with $e \cup e \equiv e' \cup e'$ mod 3. Then there is $\Phi \in \text{Diff}(E(2))$ such that $\Phi^*(e) \equiv e' \mod 3$. In particular, the action of $\text{Diff}(E(2))$ on $H^2(E(2), \mathbb{Z}/3\mathbb{Z})$ has four orbits.

**Proof.** Let $e_1, e_2 \in H^2(E(2), \mathbb{Z})$ such that $e_i \cup e_j$ is zero when $i = j$, and is equal to 1 when $i \neq j$. Because the action of $\text{Diff}(E(2))$ on the primitive cohomology classes of a fixed self-intersection is transitive, there is an element $\Psi$ of $\text{Diff}(E(2))$ such that $\Psi^*(e) = m(e_1 + ne_2)$ for $m, n \in \mathbb{Z}$. Therefore $\Psi^*(e), \mod 3$, is equal to one of the following elements:

$$
\begin{array}{ccc}
0 & e_1 & e_1 - e_2 \\
e_1 + e_2 & & \\
\end{array}
$$

(4.3)

The non-zero classes in (4.3) can be distinguished from each other by their self-intersection. Therefore, there is $\Psi' \in \text{Diff}(E(2))$ such that $\Psi^*(e) = \Psi'^*(e')$ which verifies the claim.  

40
For $1 \leq i \leq 3$, suppose $w_i$ is the 2-cycle in $E(2)$ given by $\sigma - (i - 1)f$. Then $w_i^2 \equiv i \mod 3$. Therefore, these 2-cycles and the empty cycle give representative for the orbits of the action of the diffeomorphism group of $E(2)$ on $H^2(E(2), \mathbb{Z}/3\mathbb{Z})$. Alternatively, we can consider the union of $i$ sections of the nine sections of an elliptic fibration in $E(2)$ that were constructed above. We will write $w_i'$ for this 2-cycle. If $i$ is a positive integer number and $i \equiv j \mod 3$ with $1 \leq j \leq 3$, then let $w_i = w_j$ and $w_i' = w_j'$. We also define $w_0$ and $w_0'$ to be the empty cycles.

The group of diffeomorphisms of $E(n)$, for $n \geq 3$, is more constrained than that of $E(2)$. For example, any diffeomorphism of $E(n)$ maps the homology class $f$ to $\pm f$. Therefore, we cannot expect that the analogue of Lemma 4.2 holds for an arbitrary $n$. However, $E(n)$ still has a big diffeomorphism group and we can prove the following weakened version of Lemma 4.2:

**Lemma 4.4.** Suppose the integer numbers $n \geq 3$ and $1 \leq i \leq 3$ are given and $u \in H^2(B(2, 3, 6n - 1))$, satisfying $u \cup u \equiv i \mod 3$, is fixed. Suppose also $e \in H^2(E(n), \mathbb{Z})$ is such that $e \cup f \equiv 0 \mod 3$ and $e \cup e \equiv i \mod 3$. Then there is an element $\Phi$ of $\text{Diff}(E(n))$ such that:

$$\Phi^*(e) \equiv kf + u \quad \text{or} \quad kf \quad \text{mod } 3$$

(4.5)

where $k = 0$ or $1$. Moreover, the map induced by $\Phi$ on $H^2(G(n), \mathbb{Z})$ is $\pm \text{id}$. In particular, the action of $\text{Diff}(E(n))$ on $\langle f \rangle^i$ in $H^2(E(n), \mathbb{Z}/3\mathbb{Z})$ has eight orbits.

In the statement of Lemma, we regard $u$ as an element of $H^2(E(n), \mathbb{Z})$ using the inclusion of $B(2, 3, 6n - 1)$ in $E(n)$. Note also that the second case in (4.5) holds only if $i = 3$.

**Proof.** The element $e$ can be written as the sum:

$$rf + s\sigma + v$$

where $v \in H^2(B(2, 3, 6n - 1), \mathbb{Z}) \subset H^2(E(n), \mathbb{Z})$. Because $e \cup f \equiv 0 \mod 3$, $s$ is divisible by 3. There is also a diffeomorphism of $E(n)$ that maps $f$ to $-f$ and $\sigma$ to $-\sigma$ [40, Lemma 3.7]. After applying this diffeomorphism if it is necessary, we can assume $e \equiv kf + v \mod 3$ where $k = 0$ or $1$. Suppose $SO(H^2(E(n), \mathbb{Z}))$ denotes an element of the special orthogonal group of the lattice $H^2(E(n), \mathbb{Z})$ with respect to the intersection bi-linear form. According to [42, Proposition 3.3], there is a spinor norm one element of $SO(H^2(E(n), \mathbb{Z}))$ that fixes $f, \sigma$, and maps $v$ to an element of the form $m(\tau_1 + \tau_2)$. This element can be realized by a diffeomorphism of $E(n)$[33]. This can be used to verify the claim as in Lemma 4.2. \qed

The eight orbits in Lemma 4.4 can be represented by $w_{k,0} = kf$ and $w_{k,l} = kf + \tau_1 - (l - 1)g_1$ for $k = 0, 1$ and $l = 1, 2, 3$. Alternatively, we can use $w'_{k,l} = kf + \tau_1 + \cdots + \tau_l$ if $i$ is a positive integer number and $l \equiv j \mod 3$ with $1 \leq j \leq 3$, then let $w_{k,l} = w_{k,j}$ and $w'_{k,l} = w'_{k,j}$.

Consider the $U(3)$-polynomial invariant $D^3_{E(n),w}(\Gamma^i_{(2)}, \Lambda^j_{(3)})$ for the homology classes $\Gamma$ and $\Lambda$. This polynomial is invariant with respect to the action of the diffeomorphism group of $E(n)$ on $(w, \Gamma, \Lambda)$. Therefore, we can use Lemmas 4.2 and 4.4 to focus on a smaller subset of possible values for $w$. Since changing $w \mod 3$ would not change the polynomial invariant and $H^2(E(n), \mathbb{Z}/3\mathbb{Z})$ is finite,
As another manifestation of the big diffeomorphism group of \( \text{Diff}(E(n)) \) on \((\Gamma, \Lambda)\). This action of the diffeomorphism group factors through the action of the algebraic group \( \text{O}(H_2(E(n))) \). Here the orthogonal group is defined using the intersection form on the complex vector space \( H_2(E(n)) \). Suppose also \( \text{SO}(H_2(E(n)); f) \) is the subgroup of \( \text{O}(H_2(E(n))) \) consisting of the orthogonal transformations that map \( f \in H_2(E(n)) \) to itself and have determinant 1. As another manifestation of the big diffeomorphism group of \( E(n) \), it is shown in [33] that the image of any finite index subgroup of \( \text{Diff}(E(n)) \) in \( (H_2(E(n))) \) contains an algebraically dense subgroup of \( \text{SO}(H_2(E(n)); f) \). Therefore, the polynomial \( D^3_{E(n),w}(\Gamma, \Lambda) \) is invariant with respect to the action of \( \text{SO}(H_2(E(n))); f \) on \((\Gamma, \Lambda)\). In the case that \( n = 2 \), one can even replace \( \text{SO}(H_2(E(n)); f) \) with \( \text{SO}(H_2(E(n))) \).

**Lemma 4.6.** Suppose \((V, Q)\) is a pair of a complex vector space of dimension greater than 2 and a quadratic form. Suppose also \( \tau_1 \) and \( \tau_2 \) are two vectors orthogonal to each other such that \( Q(\tau_1) \) and \( Q(\tau_2) \) are non-zero. Suppose \( P : V \oplus V \to \mathbb{C} \) is a bi-homogeneous polynomial of bi-degree \((d_1, d_2)\) that is invariant with respect to the diagonal action of \( \text{SO}(V) \) on \( V \oplus V \). Then \( P \) is determined by its value on \( W_0 \oplus W_1 \) where \( W_0 \) is the span of \( \tau_1 \), and \( W_1 \) is the span of \( \tau_1 \) and \( \tau_2 \). Moreover, \( P \) has the following form:

\[
P(x, y) = \sum_{i,j,k \geq 0} c_{i,j,k} Q(x)^i Q(y)^j Q(y)^k
\]

for appropriate constants \( c_{i,j,k} \in \mathbb{C} \).

In our application, \( V \) will be \( H_2(E(2)) \), and \( \tau_1, \tau_2 \) will be two disjoint embedded spheres in \( E(2) \).

**Proof.** Suppose \((\alpha, \beta) \in V \oplus V \) are such that \( Q(\alpha) \neq 0 \). Then the vector \( \beta \) can be written as the sum \( \beta_0 + \beta_1 \) where \( \beta_0 \) is a multiple of \( \alpha \), and \( \beta_1 \) is orthogonal to \( \alpha \). We also assume that \( Q(\beta_1) \neq 0 \). It is straightforward to find an element of \( \text{SO}(V) \) which maps \((\alpha, \beta)\) to an element of the form \( W_0 \oplus W_1 \). The set of vectors \((\alpha, \beta)\) as above is also dense in \( V \oplus V \). Therefore, \( P \) is determined by its values on \( W_0 \oplus W_1 \).

By evaluating \( P \) on elements of \( W_0 \oplus W_1 \), we have:

\[
P(\lambda \tau_1, \mu_1 \tau_1 + \mu_2 \tau_2) = \sum a_{b,c}^b \mu_1^b \mu_2^c.
\]

There is an element of \( \text{SO}(V) \) which maps \( \tau_1 \) to itself (respectively, \(-\tau_1\)) and \( \tau_2 \) to \(-\tau_2\) (respectively, itself). Therefore, \( a_{b,c}^b \) is non-zero only if \( a + b \) and \( c \) are even. This implies that there are constants \( c_{i,j,k} \) such that:

\[
P(x, y) = \sum_{2i+j=d_1, j+2k=d_2} c_{i,j,k} Q(x)^i Q(y)^j Q(y)^k
\]

for \((x, y) \in W_0 \oplus W_1 \), where \( j \) and \( k \) are non-negative integer numbers. This implies the second part of the lemma because both sides of the above equality is invariant with respect to the action of \( \text{SO}(V) \).

Arguing as in [33, Chapter 6, Lemma 2.2], we can also assume that \( i \) only takes non-negative integer numbers. \( \square \)
Lemma 4.7. Suppose \((V, Q)\) is a pair of a complex vector space of dimension greater than 3 and a quadratic form. Fix a vector \(f \in V\) with \(Q(f) = 0\) and let the vectors \(k, \tau\) be chosen such that \(Q(k, f)\) and \(Q(\tau)\) are non-zero, and \(Q(\tau, k) = Q(\tau, f) = 0\). Suppose also \(P : V \oplus V \to \mathbb{C}\) is a polynomial that is invariant with respect to the diagonal action of \(\text{SO}(V; f)\). Then \(P(x, y)\) is determined by its values on \(W_0 \oplus W_1\) where \(W_0\) is the span of the vectors \(f\) and \(k\), and \(W_1\) is the span of \(f, k\) and \(\tau\).

In our application, \(V, f, k\) and \(\tau\) will be \(H_2(E(n))\), \(f, \sigma\) and an embedded sphere in \(B(2, 3, 6n - 1)\), respectively.

Proof. The proof is similar to that of the first part of Lemma 4.6. For a given \((\alpha, \beta) \in V \oplus V\), assume \(Q(\alpha, f) \neq 0\). Then the vector \(\beta\) can be uniquely written as \(\beta_0 + \beta_1\) where \(\beta_0 \in \text{Span}(f, \alpha)\), and \(\beta_1\) is orthogonal to \(\text{Span}(f, \alpha)\). As another assumption, we require that \(Q(\beta_1) \neq 0\). These assumptions hold for a dense subset of \(V \oplus V\). It can be easily checked that there is an element of \(\text{SO}(V; k)\) which maps \((\alpha, \beta)\) to \(W_0 \oplus W_1\). Therefore, \(P|_{W_0 \oplus W_1}\) determines \(P\) on \(V \oplus V\).

4.2 Invariants of \(E(2)\)

In this section, we study the \(\mathbb{U}(3)\)- polynomial invariants of \(E(2)\) and a 2-cycle \(w\). Lemma 4.4 shows that we can assume that the 2-cycle \(w\) is either empty or \(w_i\), for \(1 \leq i \leq 3\). Equivalently, we can replace \(w_i\) with \(w'_i\). Throughout this subsection, we will follow the same notation as in the previous part to denote the surfaces \(\sigma, \tau_i\) and \(g_i\) embedded in \(E(2)\).

Proposition 4.8. The invariant \(D_{E(2), w_i}\) satisfies the following identities:

\[
D_{E(2), w_i}(\beta) = D_{E(2), w_{i+1}}(z) \quad D_{E(2), w_i}(a_i z) = 0
\]

for \(z \in \mathbb{A}(E(2))^0\). In particular, for \(1 \leq i \leq 3\), \(E(2)\) has \(w_i\)-simple type and \(D_{E(2), w_i}(e^{x+\lambda(x)})\) is independent of the choice of \(i\).

Proof. Suppose \(N(f)\) is a neighborhood of a regular fiber and \(X\) is the complement of \(N(f)\). We also identify the boundary of \(X\) with \(Y_1 = S^1 \times f\). The 4-manifold \(X\) contains a copy of \(B(2, 3, 11)\). Therefore, we can find two disjoint embedded spheres \(\tau_1\) and \(\tau_2\) of self-intersection \(-2\) in \(X\). Let \(S\) be the subspace of \(H_2(X)\) spanned by the vectors \(\tau_1\) and \(\tau_2\), and \(\mathbb{A}(S)\) be the sub-algebra \(\text{Sym}^*(H_0(X) \otimes V)\) of \(\mathbb{A}(X)\). Then \(w_i\) can be decomposed as \(w\#w'\) where \(w\) (respectively, \(w')\) is a 2-cycle in \(X\) (respectively, \(N(f)\)), and \(w, w'\) intersect \(Y_1\) in \(\gamma := S^1 \times \{\text{pt}\}\). For \(z \in \mathbb{A}(S)^0\), Proposition 3.23 with the aid of the functoriality properties discussed in subsection 3.1 implies that:

\[
D_{E(2), w_i}(a_i^2 d_3^k z) = D^{N(f), w'}(1) \circ I_*(Y_1 \times [0, 1], \gamma \times [0, 1], a_i^2 d_3^k) \circ D_{X, w}(z) \\
= 3^{j_0} D^{N(f), w'}(1) \circ I_*(Y_1 \times [0, 1], \gamma \times [0, 1] - j_0, 1) \circ D_{X, w}(z) \\
= 3^{j_0} D_{E(2), w_i - j_0}(z).
\]
This verifies (4.9) for the case $z \in \mathbb{A}(S)^{\otimes 2}$. Using Lemma 4.6, the same claim holds for general $z$, and as a result $\hat{D}_{E(2),w_{i}}(e^{\Gamma(2)+\Lambda(3)})$ is equal to:

$$D_{E(2),w_{3}}(e^{\Gamma(2)+\Lambda(3)}) + D_{E(2),w_{2}}(e^{\Gamma(2)+\Lambda(3)}) + D_{E(2),w_{3}}(e^{\Gamma(2)+\Lambda(3)}).$$

In particular, $\hat{D}_{E(2),w_{i}}(e^{\Gamma(2)+\Lambda(3)})$ does not depend on $i$. 

A similar argument, using Lemma 4.7 instead of Lemma 4.6, proves the following analogous statement for $E(n)$:

**Proposition 4.10.** The polynomial invariants $D_{E(n),w_{k,l}}$ for $1 \leq l \leq 3$, satisfies the following identities:

$$D_{E(n),w_{k,l}}((\frac{a_{2}^{2}}{3})z) = D_{E(2),w_{k,l+j}}(z) \quad D_{E(n),w_{k,l}}(a_{3}z) = 0 \quad (4.11)$$

for $z \in \mathbb{A}(E(n))^{\otimes 2}$. In particular, for $1 \leq l \leq 3$, $E(n)$ has $w_{k,l}$-simple type and $\hat{D}_{E(n),w_{k,l}}(e^{\Gamma(2)+\Lambda(3)})$ is independent of the choice of $l$.

**Proposition 4.12.** For $1 \leq i \leq 3$, we have:

$$\hat{D}_{E(2),w_{i}}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Gamma)}{2} - Q(\Lambda)} \quad (4.13)$$

The two sides of (4.13) are power series in $t_{2}$ and $t_{3}$ where the coefficients of $t_{2}^{i}t_{3}^{j}$ are bi-homogeneous polynomials on $H_{2}(E(2)) \oplus H_{2}(E(2))$ of degree $(i, j)$. Identity (4.18) means for each choice of $(i, j)$ these coefficients equate to each other.

**Proof.** Using Lemma 4.6, we can find a power series $g(r, s, t) \in \mathbb{C}[[r, s, t]]$ such that:

$$\hat{D}_{E(2),w_{i}}(e^{\Gamma(2)+\Lambda(3)}) \cdot e^{-\frac{Q(\Gamma)}{2} + Q(\Lambda)} = g(Q(\Gamma), Q(\Gamma, \Lambda), Q(\Lambda))$$

The constant term of $g$ is equal to 1 [56]. Suppose $\tau$ is an embedded sphere in $E(2)$ of self-intersection -2 such that $w_{i} \cdot \tau = 0$. Identities $(C_{1})$, $(C_{2})$ and $(C_{3})$ of subsection 2.4 for $\tau$ imply that:

$$\frac{\partial g}{\partial r}(r, s, t) = 0 \quad 4\frac{\partial^{2}g}{\partial r^{2}}(r, s, t) - \frac{\partial g}{\partial t}(r, s, t) = 0 \quad 2\frac{\partial^{2}g}{\partial s \partial r}(r, s, t) + \frac{\partial g}{\partial s}(r, s, t) = 0$$

Therefore, $g$ is equal to the constant power series 1. 

Suppose $X$ is the blowup of $E(2)$ and $w$ is the 2-cycle $f$ in $X$. If $E$ is the exceptional sphere in $X$, then Corollary 2.26 can be used to compute the invariants of $(X, w)$:

$$\hat{D}_{X,w}(e^{\Gamma(2)+\Lambda(3)}) = \frac{1}{3}e^{\frac{Q(\Gamma)}{2} - Q(\Lambda)}(\cosh(\sqrt{3}E \cdot \Gamma) + 2 \cos(\sqrt{3}E \cdot \Lambda)).$$

The homology class $\sigma + E$ can be represented by an embedded (-3)-sphere $\sigma'$ in $X$. Fix $\Gamma, \Lambda \in H_{2}(X)$ which are orthogonal to $\sigma'$. Then the above formula can be used to show:

$$\hat{D}_{X,w}((-\frac{3}{2}\sigma'_{(3)} - \frac{3}{2}\sigma'_{(2)} - a_{2})e^{\Gamma(2)+\Lambda(3)}) =$$
\[ e^{\frac{Q(\Gamma)}{2}} Q(\Lambda)(-\sqrt{3} \sin(\sqrt{3} E \cdot \Lambda) + \cos(\sqrt{3} E \cdot \Lambda) - \cosh(\sqrt{3} E \cdot \Gamma)). \] (4.14)

By another application of Theorem 2.26 and Remark 2.31, \( \hat{D}_{X,w-\sigma'}(e^{\Gamma(2)+\Lambda(3)}) \) is equal to:

\[ \frac{1}{3} e^{\frac{Q(\Gamma)}{2}} Q(\Lambda)(\cosh(\sqrt{3} E \cdot \Gamma) - \cos(\sqrt{3} E \cdot \Lambda) + \sqrt{3} \sin(\sqrt{3} E \cdot \Lambda)). \] (4.15)

Using Proposition 2.20 and comparing these two identities, we can find the undetermined constant \( c \) in Proposition 2.20:

**Proposition 4.16.** The constant \( c \) is equal to \(-3\).

Now we are ready to complete the computation of the invariants of \( E(2) \):

**Theorem 4.17.** Suppose \( w \) is a 2-cycle in \( E(2) \). Then \( E(2) \) has \( w \)-simple type and the \( \U(3) \)-series of \( E(2) \) is given by the following formula:

\[ \hat{D}_{E(2),w}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Gamma)}{2}} Q(\Lambda) \] (4.18)

**Proof.** In the light of Lemma 4.2 and Proposition 4.12, it suffices to consider only the empty 2-cycle \( w_0 \). Let \( \sigma' \) be the embedded (-3)-sphere in \( E(2)\#\mathbb{CP}^2 \) constructed above. Consider the 2-cycle \( w' := \sigma \) of \( E(2)\#\mathbb{CP}^2 \) and the element \( z := (\sigma(2) - 2E(2))^2 z' \) of \( \mathbb{A}(E(2)\#\mathbb{CP}^2)^{2\otimes 2} \) where \( z' \in \mathbb{A}((\sigma)^{-1})^{2\otimes 2} \cap \mathbb{A}(E(2))^{2\otimes 2} \). By Proposition 2.21, the following invariant of \( E(2)\#\mathbb{CP}^2 \) is equal to \( 4D_{E(2),w_0}(z') \):

\[ D_{E(2)\#\mathbb{CP}^2,w'-\sigma'}((\sigma(2) - 2E(2))^2 z'). \] (4.19)

Moreover, the first identity of Proposition 2.20 can be used to show (4.19) is equal to \( D_{E(2)\#\mathbb{CP}^2,w''}(z'') \) for an appropriate choice of \( z'' \in \mathbb{A}(E(2)\#\mathbb{CP}^2)^{2\otimes 2} \). Replacing \( w' \) with \( w'' := \sigma + \tau_1 + g_1 \) shows that:

\[ 4D_{E(2),\tau_1+g_1}(z') = D_{E(2)\#\mathbb{CP}^2,w''}(z''). \]

Since \( w' \cdot w' = w'' \cdot w'' \mod 3 \), the left hand side of the above identity is equal to \( D_{E(2)\#\mathbb{CP}^2,w''}(z'') \) by the blowup formula. Therefore, we can deduce that:

\[ D_{E(2),w_0}(z') = D_{E(2),\tau_1+g_1}(z') \] (4.20)

for \( z' \in \mathbb{A}((\sigma)^{-1})^{2\otimes 2} \). As a consequence of Lemma 4.6, Identity (4.20) holds for any choice of \( z' \). In particular, \( E(2) \) has simple type with respect to \( w_0 \) and (4.18) holds for this choice of \( w \). \( \square \)

**Proposition 4.21.** Suppose \( \Gamma, \Lambda \in H_2(B(2,3,6n-1)) \subseteq H_2(E(n)) \) and \( \Gamma', \Lambda' \in H_2(G(n)) \subseteq H_2(E(n)) \). Then:

\[ \hat{D}_{E(n),w_0}(e^{(\Gamma+\Gamma')(2)+(\Lambda+\Lambda')(3)}) = e^{\frac{Q(\Gamma)}{2}} Q(\Lambda) \hat{D}_{E(n),w_0}(e^{(\Gamma')(2)+(\Lambda')(3)}) \] (4.22)
Furthermore, Theorem 4.23. The following is Theorem when we only use the fact that for any 2-cycle \( w \) in \( E(3) \) and \( \Gamma, \Lambda \in H_2(E(3)) \), the series \( \hat{D}_{E(3),w}(e^{\Gamma(2)+\Lambda(3)}) \) is equal to \( \hat{D}_{E(3),w}(e^{\Gamma(2)+\Lambda(3)}) \). This also can be achieved with the method of the proof of Theorem 4.17.

By Proposition 4.10, we already know that \( E(n) \) has \( w_{k,l} \)-simple type for \( 1 \leq l \leq 3 \). The above proof can be used to show that \( E(n) \) has \( w_{k,0} \)-simple type, too.

### 4.3 Invariants of \( E(3) \)

In this section, we study the \( U(3) \)-polynomial invariants of \( E(3) \) up to a constant and a sign ambiguity. The following is Theorem 2 form the introduction:

**Theorem 4.23.** The 4-manifold \( E(3) \) has simple type. There are also real numbers \( h_1 \) and \( h_2 \) such that for any 2-cycle \( w \) in \( E(3) \) and \( \Gamma, \Lambda \in H_2(E(3)) \), the series \( \hat{D}_{E(3),w}(e^{\Gamma(2)+\Lambda(3)}) \) is equal to:

\[
e^{Q(\Gamma)-Q(\Lambda)}(h_1 \cosh(\sqrt{3}f \cdot \Gamma) - 2h_2 \cos\left(-\frac{2\pi}{3}w \cdot f + \sqrt{3}f \cdot \Lambda\right)).
\]

Furthermore, \( h_1 + h_2 = \pm 1 \) for an appropriate choice of the sign.

In [14], it is shown that the constants \( h_1 = \frac{2}{3} \) and \( h_2 = \frac{1}{3} \). However, we do not need the exact values of these constant in this paper. Later, we only use the fact that \( h_1 \) and \( h_2 \) are non-zero. To abbreviate our notation, define:

\[
G(\Gamma, \Lambda, j) := h_1 \cosh(\sqrt{3}f \cdot \Gamma) - 2h_2 \cos(-\frac{2\pi}{3}j + \sqrt{3}f \cdot \Lambda).
\]

**Proposition 4.25.** Suppose \( w \) is a 2-cycle in \( E(3) \) with \( w \cdot f \not\equiv 0 \) mod 3. Then:

\[
\hat{D}_{E(3),w}(\left(\frac{a_2}{3}\right)^2z) = \hat{D}_{E(3),w}(zf)(z) \quad \hat{D}_{E(3),w}(a_3z) = 0
\]

for \( z \in \mathbb{A}(E(3))^\otimes 3 \). In particular, \( E(3) \) has \( w \)-simple type. Furthermore, there is a power series \( g \in \mathbb{Q}[t_2, t_3] \) such that for \( \Gamma, \Lambda \in H_2(E(3)) \):

\[
\hat{D}_{E(3),w}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Gamma)}{2}-Q(\Lambda)}g(\Gamma \cdot f, \Lambda \cdot f)
\]

when \( w \cdot f \equiv 1 \) mod 3, and

\[
\hat{D}_{E(3),w}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Gamma)}{2}-Q(\Lambda)}g(-\Gamma \cdot f, -\Lambda \cdot f)
\]

when \( w \cdot f \equiv 2 \) mod 3. Furthermore, \( g \) is even with respect to the variable \( t_2 \) and its constant term is equal to \( \pm 1 \).
Proof. The 4-manifold $E(3)$ is given as the fiber sum $E(2)\#_f E(1)$. In this proof, let $\sigma_n$ denote a section of the elliptic fibration of $E(n)$, which is a sphere of self-intersection $-n$. We can assume $\sigma_3 = \sigma_2 \# \sigma_1$. Firstly, consider the case $w \cdot f \equiv 1 \mod 3$. Arguing as in Lemma Lemma 4.4, we can assume that $w = w_1 \# \sigma_1$ where $w_1$ is a 2-cycle in $E(2)$ with $w_1 \cdot f = 1$. Suppose $\Gamma_0$ and $\Lambda_0$ are two elements of $H_2(E(2))$ such that $\Gamma_0 \cdot f = \Lambda_0 \cdot f = 1$. Then Proposition 3.33 for $X_1 = E(2), X_2 = E(1)$ and $X_3 = X_4 = S^2 \times f$ implies that:

$$p(t_2, t_3) \sum_{0 \leq j \leq 2} D_{E(2), \#_f E(1), w+jf} \left( e^{(\Gamma_0 \# \sigma_1)(2) + (\Lambda_0 \# \sigma_1)(3)} \right) =$$

$$= q(t_2, t_3) \sum_{0 \leq j \leq 2} D_{E(2), \#_f S^2 \times f, w_2+jf} \left( e^{(\Gamma_0)(2) + (\Lambda_0)(3)} \right)$$

where:

$$p(t_2, t_3) = \sum_{0 \leq j \leq 2} D_{S^2 \times f, S^2 \times \{pt\} + jf} \left( e^{\Delta(2) + \Delta(3)} \right)$$

and

$$q(t_2, t_3) = \sum_{0 \leq j \leq 2} D_{E(1), w_1+jf} \left( e^{(\sigma_1)(2) + (\sigma_1)(3)} \right).$$

Note that $b^+(S^2 \times f) = b^+(E(1)) = 1$ and we use the invariants with respect to the metrics that have long necks along $f$ in the above identities. The power series $p(t_2, t_3)$ is invertible, because $p(0, 0) = 1$. Therefore, we can conclude there is a power series $g(t_2, t_3)$ such that:

$$\sum_{0 \leq j \leq 2} D_{E(3), w+jf} \left( e^{\Gamma(2) + \Lambda(3)} \right) = e^{\frac{Q(\Gamma)}{2} - Q(\Lambda)} g(t_2, t_3) \quad (4.27)$$

with $\Gamma = \Gamma_0 \# \sigma_1, \Lambda = \Lambda_0 \# \sigma_1$ for $\Gamma_0$ and $\Lambda_0$ given as above. Then Lemma 4.7 implies that (4.27) holds for arbitrary $\Gamma$ and $\Lambda$ with $\Gamma \cdot f = \Lambda \cdot f = 1$. By Proposition 4.8, we can use a similar argument as above to show:

$$\sum_{0 \leq j \leq 2} D_{E(3), w+jf} \left( P(a_2, a_3) e^{\Gamma(2) + \Lambda(3)} \right) = P(3, 0) e^{\frac{Q(\Gamma)}{2} - Q(\Lambda)} g(t_2, t_3)$$

In particular, this shows that:

$$D_{E(3), w} \left( \left( \frac{a_2}{3} \right)^2 e^{\pi(2) + t\Lambda(3)} \right) = D_{E(3), w-jf} \left( e^{\Gamma(2) + \Lambda(3)} \right), \quad D_{E(3), w} \left( a_3 e^{\pi(2) + t\Lambda(3)} \right) = 0$$

The power series $g$ is even with respect to $t_2$, because $D(e^{\pi(2) + \Lambda(3)})$ is even with respect to $t_2$. A similar application of Proposition 3.33 for $X_1 = X_2 = E(1)$ and $X_3 = X_4 = S^2 \times f$ shows that:

$$e^{-t_2^2 + 2t_2^2} p(t_2, t_3) = q(t_2, t_3)^2.$$ 

The constant term of the above equality and the identity $p(0, 0) = 1$ shows that the constant term of $g$ is equal to $\pm 1$. This fact completes the proof for the case that $w \cdot f \equiv 1 \mod 3$. Using a isometry of $E(3)$ which maps $f$ to $-f$, we can also treat the case that $w \cdot f \equiv 2 \mod 3$. 

□
In order to determine the power series \( g \), let \( \sigma \) and \( \sigma' \) be two disjoint sections of the elliptic fibration of \( E(3) \). Let also \( w \) be chosen such that \( w \cdot f = 1 \) and \( w \cdot \sigma = 2 \). Then:

\[
\hat{D}_{E(3),w}(e^{(s\sigma+s'\sigma')(2)+(r\sigma+r'\sigma')(3)}) = e^{-3t_2^2(\frac{r^2+r'}{2})+3t_3^2(r^2+r'^2)}g((s+s')t_2,(r+r')t_3)
\]

By taking derivative with respect to \( s \) and \( r \), we can conclude that:

\[
\hat{D}_{E(3),w}(\sigma^{(2)}_i\sigma^{(3)}_r) = h \frac{d^i}{ds^i} \frac{d^j}{dr^j}|_{s=t=0} e^{-3t_2^2(\frac{r^2+r'}{2})+3t_3^2(r^2+r'^2)}g((s+s')t_2,(r+r')t_3)
\]

where \( z = e^{s'\sigma(2)+r'\sigma(3)} \) and \( h = e^{-3t_2^2(\frac{r^2+r'}{2})+3t_3^2(r^2+r'^2)} \). By applying these identities to the second formula in Proposition 2.20, we can conclude:

\[
-\frac{1}{2}g_3 + \frac{1}{2}g_{22} - \frac{1}{2}g = g \circ \tau \tag{4.28}
\]

where \( g_{22} \) means the second derivative of the power series \( g(t_2,t_3) \) with respect to \( t_2 \), and so on. Moreover, \( \tau \) maps \((t_2,t_3)\) to \((-t_2,-t_3)\). We can use (4.28) to derive the following identity:

\[
\frac{1}{2}(g \circ \tau)_3 + \frac{1}{2}(g \circ \tau)_{22} - \frac{1}{2}g \circ \tau = g \tag{4.29}
\]

Replacing \( g \circ \tau \) in (4.29) with the left hand side of (4.28) gives rise to the following PDE for \( g \):

\[
g_{2222} - g_{33} - 2g_{22} - 3g = 0 \tag{4.30}
\]

Next, let \( w' \) be a 2-cycle with \( w' \cdot f = 1 \) and \( w' \cdot \sigma = 0 \) and consider

\[
\hat{D}_{E(3),w'}(e^{(s\sigma+s'\sigma')(2)+(r\sigma+r'\sigma')(3)})
\]

instead. With the same argument, the last part of Proposition 2.20 implies that:

\[
g_{2222} - 6g_{22} + 3g_{33} + 9g = 0 \quad g_{2223} - 6g_{23} = 0 \tag{4.31}
\]

We can combine (4.30) and the first equation in (4.31) to come up with the following simpler PDE:

\[
g_{33} - g_{22} + 3g = 0 \tag{4.32}
\]

The second PDE in (4.31) and the fact that \( g \) is even with respect to the variable \( t_2 \) imply that \( g_{3t} = p(t) \cosh(\sqrt{6}t) \). The equations (4.30) and (4.32) can be used to write two linear ordinary differential equations for \( p \). It is straightforward to check that the only solution of these ODEs is \( p(t) = 0 \). Therefore, the power series \( g \) has the form \( q_1(t) + q_2(s) \). Equation (4.32) can be used to find differential equations for \( q_1 \) and \( q_2 \). By solving these ODEs and using the fact that \( g \) is even with respect to \( t_2 \), we can conclude:

\[
g(t_2,t_3) = a \cosh(\sqrt{3}t_2) + b \cos(\sqrt{3}t_3) + c \sin(\sqrt{3}t_3) \tag{4.33}
\]

If \( g(0,0) = 1 \), then the initial value and (4.28) imply the following constraints on \( a, b \) and \( c \) which can be used to prove Theorem 4.23 in the case \( w \cdot f \neq 0 \mod 3 \):

\[
a + b = 1 \quad a - \frac{1}{2}b - \frac{\sqrt{3}}{2}c = 1.
\]
A similar argument can be used in the case that \( g(0, 0) = -1 \).

Next, let \( w \cdot f \equiv 0 \mod 3 \). Using Lemma 4.4 and Proposition 4.10, it suffices to consider the case that \( w = w_{k,1} \) for \( k = 0 \) or \( 1 \). The following proposition computes the invariants of \( E(3) \) for this choice of 2-cycle. In this proof, we use the basis for the homology of \( H_2(E(3), \mathbb{Z}) \) which is introduced in subsection 4.1:

**Proposition 4.34.** For any \((\Gamma, \Lambda) \in H_2(E(3)) \oplus H_2(E(3))\):

\[
\hat{D}_{E(3), w_{k,1}}(e^{\Gamma(2)} + \Lambda(3)) = e^{\frac{Q(\Gamma)}{2}} - Q(\Lambda)G(\Gamma, \Lambda, 0)
\]  

(4.35)

**Proof.** Let \( \sigma' \) be a section of the elliptic fibration of \( E(3) \) which is disjoint from \( \sigma \). Then the homology class of \( \sigma' \) is equal to \( \sigma + 3f + u \) where \( u \in H_2(B(2, 3, 17), \mathbb{Z}) \) and \( u \cdot u = -6 \). Arguing as in Lemma 4.4, there is a diffeomorphism \( \Phi \) of \( E(3) \) that fixes \( H_2(G(3)) \) and maps \( u \) to a linear combination of \( g_1 \) and \( \tau_1 \). Furthermore, \( \Phi_\ast(u) \equiv 2g_1 - \tau_1 \mod 3 \). In particular, \( \alpha := \Phi(\sigma') \) is a \((-3)\)-sphere with \( \alpha \cdot w_{k,1} \equiv 1 \mod 3 \). Suppose \( W \) is the subspace of the elements of \( H_2(E(3)) \) whose intersection numbers with \( \alpha \) are equal to 0. Using Proposition 2.20, the series \( \hat{D}_{E(3), w_{k,1}}(e^{\Gamma(2)} + \Lambda(3)) \), for any \((\Gamma, \Lambda) \in W \oplus W\), is equal to:

\[
-\frac{1}{3} \hat{D}_{E(3), w_{k,1}} + \alpha \left( \frac{3}{2} \alpha(3) - 3 \alpha(2) - a_2 \right) e^{\Gamma(2) + \Lambda(3)}
\]  

(4.36)

Since \((w_{k,1} + \alpha) \cdot f = 1\), we can evaluate the expression (4.36) using our current knowledge of the invariants of \( E(3) \). It is straightforward to check that the resulting series is equal to (4.35).

The homology classes \( f, k : = \sigma + \frac{3}{2}f \) and \( \tau_2 \) satisfy the assumption of Lemma 4.7 for \( V = H_2(E(3)) \). Suppose \( W_0 \) and \( W_1 \) are given as in Lemma 4.7, and \( U \) is the subset of \( W_0 \oplus W_1 \) consisting of the pairs that satisfy (4.35). Then \( U \) is a Zariski closed subset of \( W_0 \oplus W_1 \). In order to complete the proof, we shall show that \( U \) contains a Euclidean open set in \( W_0 \oplus W_1 \) and hence \( U = W_0 \oplus W_1 \). Let \((\Gamma, \Lambda) \in W_0 \oplus W_1\) be given as below:

\[
\Gamma := af + bk \quad \Lambda := a'f + b'k + c\tau_2.
\]

Consider the homology classes \( u_1 := \frac{\tau_1 + \tau_2}{\sqrt{2}} \) and \( u_2 := \frac{\tau_1 - \tau_2}{\sqrt{2}} \) which have non-zero intersection with \( \alpha \). There is an element \( A_{t, \theta} \in SO(H_2(E(n)); f) \) such that:

\[
A_{t, \theta}(\Gamma) := af + b(k + t^2f + tu_1)
\]

\[
A_{t, \theta}(\Lambda) := a'f + b'(k + t^2f + tu_1) + c'(\cos(\theta)\tau_2 + \sin(\theta)u_2)
\]

If \( a \) and \( a' \) are close enough to each other and \( b, b' \) and \( c' \) are close enough to 1, then \( t \) and \( \theta \) can be chosen such that \( A_{t, \theta}(\Gamma), A_{t, \theta}(\Lambda) \in W \). Therefore, \( U \) contains an open subset of \( W_0 \oplus W_1 \). \( \square \)

### 4.4 Invariants of \( E(n) \)

In this section, we compute the invariants of the elliptic surface \( E(n) \). We start with the simpler case that \( w \cdot f \not\equiv 0 \mod 3 \):

---

49
Proposition 4.37. Suppose $w$ is a 2-cycle in $E(n)$ with $w \cdot f \neq 0 \mod 3$. Then $E(n)$ has $w$-simple type, and for $\Gamma, \Lambda \in H_2(E(n))$:

$$
\hat{D}_{E(n), w}(w^{(\Gamma)} + \Lambda^{(3)}) = e^{\frac{Q(\Gamma)}{2} - Q(\Lambda)} G(\Gamma, \Lambda, w \cdot f)^{n-2}.
$$

Proof. The proof of this proposition is similar to that of Proposition 4.25. Applying Proposition 3.33 for $X_1 = E(n-2)$, $X_2 = E(2)$ and $X_3 = X_4 = E(1)$ gives us enough relations to verify the proposition by induction. \hfill \square

In the blown up elliptic surface $E(n) \# \CP^2$, there is an embedded sphere with self-intersection $-(n+1)$, given by tubing a section of the elliptic fibration and the exceptional sphere in $\CP^2$. Therefore, there is a copy of the Gompf nucleus $G(n+1)$ in $G(n)\#\CP^2$. The homology class $E + f$ can be realized by an embedded surface $\tilde{E}$ in $M_n := G(n)\#\CP^2 \setminus G(n+1)$. The surface $\tilde{E}$ determines a generator of $H_2(M_n)$. Similarly, the nucleus $G(n+2)$ can be embedded in $G(n)\#2\CP^2$. Therefore, there are copies of $G(4)$ in the 4-manifolds $E(4)$, $E(3)\#\CP^2$ and $E(2)\#2\CP^2$. Let $Z_0 \subset E(4)$, $Z_1 \subset E(3)\#\CP^2$ and $Z_2 \subset E(2)\#2\CP^2$ be the complements of $G(4)$ in these manifolds. Then the boundary of $Z_i$ is diffeomorphic to $\Sigma(2,3,23)$. It is clear from the inductive construction of $E(n)$ that there is an embedding of $Z_i$ in $E(n-i)\#i\CP^2$ for $n \geq 4$. In fact, if $W(n)$ is the fiber sum $E(n-4)\#fG(4)$, then $E(n-i)\#i\CP^2$ is diffeomorphic to $Z_i\#\Sigma(2,3,23)W(n)$.

The 4-manifold $Z_i$ gives rise to elements of $I_{\#}(\Sigma(2,3,23))$ as it is explained in Proposition 3.43. Suppose $V_0 \subseteq I_{\#}(\Sigma(2,3,23))$ is the vector space generated by the element $D_{Z_0,v_0}(1)$ where $v_0$ is a 2-cycle in $Z_0$ with $v_0^2 \equiv 0 \mod 3$. Similarly, define $V_1$ to be the vector space generated by the three elements $D_{Z_1,w}(1)$ where $w$ is one of the following elements which satisfy $w^2 \equiv 1 \mod 3$:

$$v_1 := \tilde{E} + \tau_1 - g_1 \quad v_2 := -\tilde{E} + \tau_1 - g_1 \quad v_3 := \tau_1$$

Finally, let $V_2$ be the subspace of $I_{\#}(\Sigma(2,3,23))$ which is generated by the elements of the form $D_{Z_2,w}(1)$ where $w^2 \equiv 2 \mod 3$.

Proposition 4.38. The space $V_i$ is a subspace of $I_{\#}(\Sigma(2,3,23))$. Furthermore, the dimension of $V_i$ is at least $\frac{(i+1)(i+2)}{2}$.

Proof. The first part of the proposition is an immediate consequence of Proposition 3.43. In order to show that $\dim(V_0) = 1$, let $D_{Z_0,v_0}(1) = 0$. By Proposition 3.43, $D_{E(4),v_0+w_0}(z)$ vanishes for a 2-cycle $w_0$ in $G(4)$ and $z \in H(G(4))^{\otimes 2}$. If $w_0$ is chosen such that $w_0 \cdot f \neq 0 \mod 3$, then Proposition 4.37 asserts that there is $z$ such that $D_{E(4),v_0+w_0}(z) \neq 0$ which is a contradiction.

Next, we consider the case that $i = 1$. By Proposition 3.43, a linear relation among the vectors $D_{Z_1,v_1}(1)$, for $1 \leq l \leq 3$, implies that there are constant numbers $c_l$ such that:

$$
\sum_{1 \leq l \leq 3} c_l \hat{D}_{E(3),w}(v_l+w_0, e^{\sigma(z)+\sigma(3)}) = 0.
$$

(4.39)

50
Here \( w_0 \) is a 2-cycle in \( G(4) \) and \( \sigma \) is the embedded \((-4)\)-sphere in \( G(4) \). We can use the blow up formula and the results of the previous subsection to evaluate the above power series and to conclude that:

\[
\sum_{1 \leq l \leq 3} c_l (\cosh(\sqrt{3} t_2) + \zeta^{-(v_1 + w_0)} e^{i \sqrt{3} t_3} + \zeta^{(v_1 + w_0)} e^{-i \sqrt{3} t_3}) = 0
\]

Since \( v \cdot E \equiv -l \mod 3 \), the constants \( c_l \) are equal to zero. Therefore, \( \dim(V_1) = 3 \). Similar proofs can be applied to the case \( i = 2 \).

Since the dimension of \( I_4(\Sigma(2,3,23)) \) is equal to 9, Proposition 4.38 implies that there are vectors \( \phi_i \in V_i \) such that:

\[
\phi_0 + \phi_1 + \phi_2 = 0 \tag{4.40}
\]

We use this identity to compute the remaining invariants of \( E(n) \) inductively. Firstly, consider the case that \( \phi_0 \neq 0 \). Therefore, we can assume that \( \phi_0 = D_{Z_0,v_0}(1) \). There are also 2-cycles \( w_1, \ldots, w_k \) in \( Z_2 \) and constant numbers \( c_1, c_2, c_3, c'_1, \ldots, c'_k \) such that:

\[
\phi_1 = \sum_{i=1}^{3} c_i D_{Z_1,v_i}(1) \quad \phi_2 = \sum_{j=1}^{k} c'_j D_{Z_2,w_j}(1) \tag{4.41}
\]

Suppose \( \Gamma, \Lambda \in H_2(W(n)) \) and \( w \) is a 2-cycle in \( W(n) \). Then Proposition 3.43 implies that the \( U(3) \)-series \( \hat{D}_{E(n),v_0+w}(e^{\Gamma(2)+\Lambda(3)}) \) is equal to:

\[
-\sum_{l} c_l \hat{D}_{E(n-1)\#CP^2,v_l+w}(e^{\Gamma(2)+\Lambda(3)}) - \sum_{j} c'_j \hat{D}_{E(n-2)\#2CP^2,w_j+w}(e^{\Gamma(2)+\Lambda(3)}) =
\]

\[
eq e^{\frac{Q(\Gamma)}{2}-Q(\Lambda)} G(\Gamma,\Lambda,w \cdot f)^{n-4} A(\Gamma,\Lambda) \tag{4.42}
\]

where the term \( A(\Gamma,\Lambda) \) is a linear combination of the following six expressions:

\[
\cosh(\sqrt{3} f \cdot \Gamma)^2, \cosh(\sqrt{3} f \cdot \Gamma) \zeta^{w \cdot f} e^{\pm i \sqrt{3} f \Lambda}, \zeta^{2w \cdot f} e^{\pm 2i \sqrt{3} f \Lambda}, 1 \tag{4.43}
\]

and the coefficients of this this linear combination do not depend on \( w \). To derive (4.42) we use the fact that \( \Gamma \cdot E = -\Gamma \cdot f \) and \( \Lambda \cdot E = -\Lambda \cdot f \). In the case \( w \cdot f \equiv 0 \mod 3 \), \( A(\Gamma,\Lambda) \) is equal to \( G(\Gamma,\Lambda,w \cdot f)^2 \) using Proposition 4.37. This identity holds also in the case that \( w \cdot f \equiv 0 \mod 3 \), because \( A(\Gamma,\Lambda) \) is a linear combination of the terms in (4.43) with coefficients which are independent of \( w \). Therefore, for a general 2-cycle \( w \) in \( W(n) \) and \( \Gamma, \Lambda \in H_2(W(n)) \):

\[
\hat{D}_{E(n),v_0+w}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Gamma)}{2}-Q(\Lambda)} G(\Gamma,\Lambda,w \cdot f)^{n-2}
\]

Then Proposition 4.21 implies that \( \hat{D}_{E(n),w}(e^{\Gamma(2)+\Lambda(3)}) \) is equal to \( e^{\frac{Q(\Gamma)}{2}-Q(\Lambda)} G(\Gamma,\Lambda,w)^{n-2} \) for any 2-cycle \( w \) in \( E(n) \) and \( \Gamma, \Lambda \in H_2(E(n)) \).

Next, assume that \( \phi_0 = 0 \). We assume that the non-zero vectors \( \phi_1 \) and \( \phi_2 \) are given as in (4.41). Fix an arbitrary 2-cycle \( w \) in \( W(n+1) \) and homology classes \( \Gamma, \Lambda \in H_2(W(n+1)) \). Another application of Proposition 3.44 shows that:

\[
\sum_{1 \leq l \leq 3} c_l \hat{D}_{E(n)\#CP^2,v_l+w}(e^{\Gamma(2)+\Lambda(3)}) \tag{4.44}
\]
is equal to:
\[
\sum_j c_j \hat{D}_{E(n-1)\#2\mathbb{CP}^2, w_j + w}(e^\Gamma(\gamma + \Lambda(\gamma))).
\]
By our inductive calculation of the invariants of \( E(n) \), the latter expression is equal to:
\[
e^{-Q(\gamma)/2 - Q(\Lambda)} G(\Gamma, \Lambda, w \cdot f)^{n-3} B(\Gamma, \Lambda).
\]
Here \( B(\Gamma, \Lambda) \) is a linear combination of the following six expressions:
\[
cosh(\sqrt{3}f \cdot \Gamma)^2 \quad \cosh(\sqrt{3}f \cdot \Gamma) \zeta^w f e^{\pm \sqrt{3}f \cdot \Lambda} \quad \zeta^{\pm 2w} f e^{\pm 2\sqrt{3}f \cdot \Lambda} 1
\]
As in the previous case, the coefficients of the above linear combination is determined by \( c_j \) and \( w_j \). In particular, they do not depend on \( w \). Therefore, we can determine this coefficient by considering the case that \( w \cdot f \neq 0 \mod 3 \) for which we already computed the invariants. Therefore, \( B(\Gamma, \Lambda) \) is equal to:
\[
G(\Gamma, \Lambda, w \cdot f) \sum_{1 \leq i \leq 3} \frac{c_i}{3} (cosh(\sqrt{3}E \cdot \Gamma) + \zeta^{-w} e^{\sqrt{3}E \cdot \Lambda} + \zeta^w e^{\sqrt{3}E \cdot \Lambda})
\]
For an arbitrary 2-cycle \( w \subset E(n)\#\mathbb{CP}^2 \) and \( \Gamma, \Lambda \in E(n)\#\mathbb{CP}^2 \), let \( \hat{D}_w(\Gamma, \Lambda) \) be the power series given by subtracting \( \hat{D}_w(e^\Gamma(\gamma + \Lambda(\gamma))) \) from the following power series:
\[
e^{-Q(\gamma)/2 - Q(\Lambda)} G(\Gamma, \Lambda, w \cdot f)^{n-2} \frac{1}{3} (cosh(\sqrt{3}E \cdot \Gamma) + \zeta^{-w} e^{\sqrt{3}E \cdot \Lambda} + \zeta^w e^{\sqrt{3}E \cdot \Lambda}).
\]
Then we can rephrase our conclusion in the form of the following identity:
\[
\sum_{1 \leq i \leq 3} c_i \hat{P}_{w_i+w}(\Gamma, \Lambda) = 0 \tag{4.45}
\]
where \( w \) is a 2-cycle in \( W(n+1) \) and \( \Gamma, \Lambda \in H_2(W(n+1)) \). Suppose \( p_{w, (i, j)} \) is the polynomial on \( H_2(E(n)\#\mathbb{CP}^2) \oplus H_2(E(n)\#\mathbb{CP}^2) \) of bi-degree \((i, j)\), determined by the coefficient of \( t^i \bar{t}^j \) in \( \hat{P}_w \). Then \( p_{w, (i, j)} \) can be evaluated at:
\[(\Gamma_1, \ldots, \Gamma_i; \Lambda_1, \ldots, \Lambda_j)\]
for \( \Gamma_k, \Lambda_k \in H_2(E(n)\#\mathbb{CP}^2) \). By induction on \( i + j \), we shall show that \( p_{w, (i, j)} \) vanishes for all possible choices of \( w \). By considering the constant terms of Equation (4.45) for empty \( w \), we have:
\[
c_1 p_{v_1, 0} + c_2 p_{v_2, 0} + c_3 p_{v_3, 0} = 0
\]
The blowup formula asserts that \( p_{v_1, 0} = p_{v_2, 0} = 0 \). Therefore, if \( c_3 \neq 0 \), then \( p_{v_3, 0} = 0 \). Thus Proposition 4.21 and the blowup formula show that \( p_{w, 0} = 0 \) for all 2-cycles \( w \) in \( E(n)\#\mathbb{CP}^2 \). If \( c_3 = 0 \), then by (4.45):
\[
c_1 p_{v_1, 0}(\sigma + E, \sigma + E) + c_2 p_{v_2, 0}(\sigma + E, \sigma + E) = 0
\]
and
\[
c_1 p_{v_1, 0}(\sigma + E) + c_2 p_{v_2, 0}(\sigma + E) = 0.
\]
The blowup formula asserts that:

\[ c_1 p_{v_1-E}^{0,0} + c_2 p_{v_2+E}^{0,0} = 0 \quad c_1 p_{v_1-E}^{0,0} - c_2 p_{v_2+E}^{0,0} = 0 \]

Consequently, at least one of the numbers \( p_{v_1-E}^{0,0} \) and \( p_{v_2+E}^{0,0} \) is zero and we can derive the same conclusion as in the previous case.

Now assume that the polynomial \( p_{v_1}^{i,j} \) vanishes for \( i + j \leq k \) and any 2-cycle in \( E(n) \# \mathbb{CP}^2 \). Fix \((i, j), \tilde{\Gamma}_1, \ldots, \tilde{\Gamma}_i, \tilde{\Lambda}_1, \ldots \) and \( \tilde{\Lambda}_j \) such that \( i + j = k + 1 \) and \( \tilde{\Gamma}_i, \tilde{\Lambda}_v \) are either equal to \( \sigma + E \) or \( f \). Then apply (4.45) to conclude that:

\[
\sum_{1 \leq l \leq 3} c_l p^{i,j}_{v_1} (\tilde{\Gamma}_1, \ldots, \tilde{\Gamma}_i; \tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_j) = 0 \tag{4.46}
\]

Blowup formula and the induction hypothesis imply that every term of the form \( \sigma + E \) can be replaced with \( \sigma \). Thus if \( c_3 \neq 0 \), then:

\[
p^{i,j}_{v_1} (\Gamma_1, \ldots, \Gamma_i; \Lambda_1, \ldots, \Lambda_j) = 0 \tag{4.47}
\]

for \( \Gamma_k, \Lambda_k \in H_2(G(n)) \). Therefore, Proposition 4.21 and the blowup formula allows us to complete the verification of the induction step. If \( c_3 = 0 \), we can use the analogue of (4.46) for:

\[
(\sigma + E, \sigma + E, \tilde{\Gamma}_1, \ldots, \tilde{\Gamma}_i; \tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_j) \quad (\tilde{\Gamma}_1, \ldots, \tilde{\Gamma}_i; \sigma + E, \tilde{\Lambda}_1, \ldots, \tilde{\Lambda}_j)
\]

and argue as in the basis of the induction. This completes the proof of the following theorem:

**Theorem 4.48.** Suppose \( w \) is a 2-cycle in \( E(n) \) and \( \Gamma, \Lambda \in H_2(E(n)) \). Then:

\[
\hat{D}_{E(n),w}(e^{\Gamma(2)} + \Lambda(3)) = e^{\frac{Q(\Gamma)}{2}} - Q(\Lambda)G(\Gamma, \Lambda, w \cdot f)^{n-2}
\]

### 4.5 Gluing 4-manifolds along Surfaces of Self-intersection Zero

In this subsection, we use the calculation of \( U(3) \)-polynomial invariants for elliptic surfaces to study invariants of another family of closed 4-manifolds:

**Definition 4.49.** Suppose \( X \) is a smooth 4-manifold, \( \Sigma \) is an oriented surface of genus \( g \geq 1 \) embedded in \( X \), \( w \) is a 2-cycle in \( X \), and \( \mathcal{H} \) is a subspace of \( H_2(X) \). Then \( (X, \Sigma, w) \) is permissible with respect to the subspace \( \mathcal{H} \), if the following properties hold:

(i) \( b^1(X) = 0, b^+(X) > 1 \);

(ii) \( \Sigma \cdot \Sigma = 0 \);

(iii) \( w \cdot \Sigma \equiv 0 \mod 3 \);

(iv) let \( z \in \Lambda(\mathcal{H}) \otimes \mathbb{Z} \) and \( u \) be the 2-cycle \( w + l\Sigma \) for \( l = 0, 1 \) or \( 2 \). Then:

\[
D_{X,u}(\left(\frac{a_2}{3}\right)^3 z) = D_{X,u}(z) \quad D_{X,u}(a_3 z) = 0. \tag{4.50}
\]
Moreover, there are cohomology classes $K_i \in H^2(X, \mathbb{Z})$ such that $K_i$ is an integral lift of $w_2(TX)$, $|K_i \cdot \Sigma| \leq 2g - 2$, and for $\Gamma, \Lambda \in \mathcal{H}$, the power series $D_{X,u}(e^{\Gamma(2)+\Lambda(3)})$ is equal to:

$$e^{\frac{Q(\Sigma)}{2} - Q(\Lambda)} \sum_{i,j} c_{ij} \zeta^{-i\Sigma} \frac{i}{2} (K_i + K_j) \cdot \Gamma + \frac{\sqrt{2}}{2}(K_i - K_j) \cdot \Lambda$$

(4.51)

The cohomology class $K_i$ is called a basic class of the triple $(X, \Sigma, w)$ and $c_{ij}$ is called the coefficient associated to the pair $(K_i, K_j)$. In the case that $\mathcal{H} = H_2(X)$, we say $(X, \Sigma, w)$ is permissible.

**Example 4.52.** The results of subsection 4.2 shows that the triple $(E(2), f, w)$ forms a permissible triple where $f$ is a fiber in an elliptic fibration of $E(2)$ and $w$ is a 2-cycle that $w \cdot f \not\equiv 0 \mod 3$. In this case, the only basic class in (4.51) is the zero cohomology class. More generally, we can embed a surface of genus $g$ in $E(2)$ whose self-intersection is equal to $2g - 2$. For example, we can construct such an embedded surface by considering the union of $g$ fibers and a section of the fibration, and then smoothing out the intersection points. Let $\Sigma$ be the proper transform of this surface after blowing up $E(2)$ at $2g - 2$ points on the surface. Let also $w$ be a 2-cycle in $E(2) \# (2g - 2)\mathbb{CP}^2$ such that $w \cdot \Sigma \not\equiv 0 \mod 3$. Then the blow up formula implies that $(E(2) \# (2g - 2)\mathbb{CP}^2, \Sigma, w)$ is a permissible triple. If $E_1, \ldots, E_{2g-2}$ are the exceptional classes, then a basic class of this triple has the form $\pm E_1 \pm \cdots \pm E_{2g-2}$.

**Example 4.53.** One can further generalize the previous example by considering a surface $\Sigma$ with self-intersection 0, embedded in the 4-manifold $E(n) \# k\mathbb{CP}^2$. Let $w$ be a 2-cycle in $X$ such that $w \cdot \Sigma \not\equiv 0 \mod 3$. Then the blowup formula and Theorem 4.48 can be utilized to verify most requirements of Definition 4.49 for permissibility of $(X, \Sigma, w)$. The only missing part is to verify the inequality $|K \cdot \Sigma| \leq 2g - 2$ for basic classes $K$ of $X$. To check this inequality, note that our basic classes for $(X, \Sigma, w)$ are the same as $U(2)$-basic classes for $X$ [53, 26, 65, 54, 27]. Therefore, the desired inequality is a consequence of the Adjunction inequality in [54]. In fact, we expect that any tripe $(X, w, \Sigma)$, satisfying properties (i), (ii) and (iii), automatically meets the requirements in (iv), as long as $X$ has simple type in the sense of [54]. However, pursuing this direction is beyond the scope of this paper.

**Proposition 4.54.** Suppose $(a, b)$ is a pair of integer numbers such that $|a| + |b| \leq 2g - 2$, and $a, b$ have the same parity. Then there are a permissible triple $(X, w, \Sigma)$ and basic classes $K_i$ and $K_j$ of the triple such that $\Sigma$ has genus $g$ and:

$$a = \frac{(K_i + K_j)}{2} \cdot \Sigma \quad b = \frac{(K_i - K_j)}{2} \cdot \Sigma$$

(4.55)

This proposition can be verified using the permissible triples provided by Example 4.52. For $g \geq 1$, the set of integer pairs that satisfy the assumption of this proposition is denoted by $C_g$. We will write $N_g$ for the number of the elements of $C_g$ which is equal to $2g(g - 1) + 1$.

For a permissible triple $(X, \Sigma, w)$, define:

$$D_{X,u,\Sigma}(e^{\Gamma(2)+\Lambda(3)}) := \sum_{0 \leq l \leq 2} D_{X,u+l\Sigma}(e^{\Gamma(2)+\Lambda(3)})$$

More generally, $D_{X,u,\Sigma}(z)$ is defined to be the sum $D_{X,u+l\Sigma}(z)$ for different values of $0 \leq l \leq 2$. A dimension counting argument shows that if all terms in $z$ have a fixed degree, then only one of the 2-cycles $w + l\Sigma$ is involved in the definition of $D_{X,u,\Sigma}(z)$.
**Lemma 4.56.** Suppose \((X, w, \Sigma)\) is a permissible triple as above and \(d_w \in \mathbb{Z}/3\mathbb{Z}\) is defined to be \(b^+ + 1 - w \cdot w\). Then \(\text{DX}_w,\Sigma((\frac{a_2}{3})^m e^\Gamma(2)+\Lambda(3))\) is equal to:

\[
\sum c_{i,j} \zeta_{i,j}(d_w-m)\zeta^i_{i,j}(\frac{2Q}{3}+\frac{2z_Q}{3}(K_i-K_j)\cdot\Lambda) + \zeta^i_{i,j}(-Q(\Lambda)+\frac{2z_Q}{3}(K_i+K_j)\cdot\Gamma)
\]

where the inner sum is over all pairs of basic classes \((K_i, K_j)\). Moreover, \(l_{i,j} \in \mathbb{Z}/3\mathbb{Z}\) is equal to \((w \cdot \Sigma)(\frac{K_i-K_j}{2}) \cdot \Sigma\).

**Proof.** For a 4-manifold \(W\) with simple type, the power series \(\text{DX}_w,\Sigma\) can be recovered from \(\hat{D}_{X,w}\) in the following way:

\[
\text{DX}_w((\frac{a_2}{3})^m e^\Gamma(2)+\Lambda(3)) = \frac{1}{3} \sum_{0 \leq k \leq 2} \zeta^k(d_w-m)\hat{D}_{X,w}(e^k\Gamma(2)+\zeta^k\Lambda(3))
\]

Therefore:

\[
\sum_{0 \leq l \leq 2} \text{DX}_{w+l\Sigma}((\frac{a_2}{3})^m e^\Gamma(2)+\Lambda(3)) = \frac{1}{3} \sum_{0 \leq k,l \leq 2} \zeta^k(d_w+l\Sigma-m)\hat{D}_{X,w+l\Sigma}(e^k\Gamma(2)+\zeta^k\Lambda(3))
\]

Then, we can use the permissibility of \((X, w, \Sigma)\) to rewrite the right hand side in terms of basic classes. A straightforward simplification gives the desired result. \(\square\)

Suppose \((X, w, \Sigma)\) and \((X', w', \Sigma)\) are two permissible triples such that the embedded surfaces of genus \(g\) are identified with each other, and this identification is lifted to the normal bundles. Suppose also \(w\) and \(w'\) intersect \(\Sigma\) in the same number of points with the same signs. As it is explained in subsection 3.3, we can form the triple \((X\#_\Sigma X', w\# w', \Sigma)\). There is also a subspace \(K \subset H_2(X) \oplus H_2(X')\) such that there is a map \# : \(K \to H_2(X\#_\Sigma X')\). The main goal of this section is to compute \(\hat{D}_{X\#_\Sigma X',w\# w'}(e^\Gamma(2)+\Lambda(3))\), for \(\Gamma, \Lambda \in \text{im}(\#)\), in terms of the invariants of the pairs \((X, w)\) and \((X', w')\).

The basic idea to achieve this goal is to use the gluing property in (3.29). Therefore, the \(R_N\)-module \(\mathbb{I}_{g,d}^N\), introduced in subsection 3.3, for \(N = 3\) and \(d = w \cdot \Sigma\), plays a key role in computing the invariants of \((X\#_\Sigma X', w\# w')\). In fact, we can replace \(\mathbb{I}_{g,d}^3\) with a smaller module. Before giving the definition of this smaller module, we introduce some conventions. Form now on, we drop 3 from our notation and denote this Fukaya-Floer homology module with \(\mathbb{I}_{g,d}\). Moreover, for a permissible triple \((X, w, \Sigma)\) the intersection \(w \cdot \Sigma\) is denoted by \(d\), unless otherwise is stated.

Let \(\mathbb{I}_{g,d} \subseteq \mathbb{I}_{g,d}\) be the \(C[[t_2, t_3]]\)-module generated by the following relative elements in \(\mathbb{I}_{g,d}\):

\[
\text{DX}_{w,\Sigma}(e^\Gamma(2)+\Lambda(3)) := \sum_{l \in \mathbb{Z}/3\mathbb{Z}} \text{DX}_{w+l\Sigma}(e^\Gamma(2)+\Lambda(3))
\]

(4.57)

where \((X, w, \Sigma)\) is a permissible triple, \(\Gamma, \Lambda \in H_2(X, \mathbb{Z})\) with \(\Gamma \cdot \Sigma = \Lambda \cdot \Sigma = 1\). By Identity 3.29, the pairing of this element with \(\Delta_\gamma,\delta_\gamma(x^\Gamma(2)+D(3))\) is equal to the following element of \(C[[t_2, t_3]]\):

\[
\text{DX}_{w,\Sigma}(\gamma x^\Gamma(2)+\Lambda(3))
\]

(4.58)
Suppose \( \mathbb{C}[[t_2, t_3]][x, y, z] \) is the ring of polynomials of three variables with coefficients in \( \mathbb{C}[[t_2, t_3]] \) and \( z = P(a_2, \Sigma(2), \Sigma(3)) \) for \( P \in \mathbb{C}[[t_2, t_3]][x, y, z] \). Then Lemma 4.56 shows that the pairing of (4.57) and \( \Delta_{g, \delta} (ze^{D(3)} + D(3)) \) is equal to:

\[
\sum_{(a, b) \in C_g} \zeta^{d_{db}} P(u(a, b)) \sum_{i,j} c_{i,j} e^{2db(\frac{Q(\Gamma)}{2} + \frac{\sqrt{2}t}{2}(K_i - K_j) \cdot \Lambda) + \zeta^{db}(-Q(\Lambda) + \frac{\sqrt{2}}{2}(K_i + K_j) \cdot \Gamma)}
\]

where the inner sum is over all pairs of basic classes \((K_i, K_j)\) such that:

\[
\frac{(K_i + K_j)}{2} \cdot \Sigma = a \quad \frac{(K_i - K_j)}{2} \cdot \Sigma = b.
\]

and:

\[
u(a, b) := (3\zeta^{2db}, \zeta^{db} \sqrt{3} a + \zeta^{2db} t_2, \zeta^{2db} \sqrt{3} b - 2\zeta^{db} t_3).
\]

For \( \lambda = (\alpha, \beta) \in C_g \), fix a polynomial \( P_\lambda \in \mathbb{C}[[t_2, t_3]][x, y, z] \) such that:

\[
P_\lambda(u(\alpha, \beta)) = \begin{cases} 1 & \text{for } (a, b) = (\alpha, \beta) \\ 0 & \text{for } (a, b) \neq (\alpha, \beta) \end{cases}
\]

Define a map \( \Phi : \overline{I}_{g,d} \rightarrow \mathbb{C}[[t_1, t_2]]^{N_g} \) in the following way:

\[
\Phi(\eta) := \{ \langle \xi, \Delta_{g, \delta} P_\lambda(a_2, \Sigma(2), \Sigma(3)) e^{D(3)} \rangle \}_{\lambda \in C_g}
\]

By (3.29), the homomorphism \( \Phi \) maps the relative element in (4.57) to an element of \( \mathbb{C}^{N_g}[[t_2, t_3]] \), whose component corresponding to \( \lambda = (a, b) \), denoted by \( c_{X,w,\Sigma}^\lambda (\Gamma, \Lambda) \), is equal to:

\[
\zeta^{d_{db}} \sum_{i,j} c_{i,j} e^{2db(\frac{Q(\Gamma)}{2} + \frac{\sqrt{2}t}{2}(K_i - K_j) \cdot \Lambda) + \zeta^{db}(-Q(\Lambda) + \frac{\sqrt{2}}{2}(K_i + K_j) \cdot \Gamma)}
\]

where the sum is over the pairs of basic classes \((K_i, K_j)\) that satisfy (4.59). Let \( \mathbb{C}((t_1, t_2)) \) denote the field of fractions of \( \mathbb{C}[[t_2, t_3]] \). Then \( \Phi \) induces a map \( \overline{\Phi} : \overline{I}_{g,d} \otimes \mathbb{C}[[t_1, t_2]] \rightarrow \mathbb{C}((t_1, t_2))^{N_g} \).

**Proposition 4.63.** The map \( \Phi \) is injective. Moreover, \( \overline{\Phi} \) is an isomorphism of vector spaces.

**Proof.** Suppose \( \mathcal{I} \) is the ideal in \( \mathbb{A}_g^3 \otimes \mathbb{C} \mathbb{C}[[t_2, t_3]] \) that is generated by \( a_3, \gamma(2), \gamma(3) \) and the elements \( P(a_2, \Sigma(2), \Sigma(3)) \) where \( P \in \mathbb{C}[[t_2, t_3]][x, y, z] \) is a polynomial evaluating to zero at the points in (4.60). Then the pairing of (4.57) and \( \Delta_{g, \delta} (ze^{D(3)} + D(3)) \) vanishes when \( z \in \mathcal{I} \). The element (4.57) is also invariant with respect to the action of \( \epsilon \). Any \( z \in \mathbb{A}_g^3 \otimes \mathbb{C} \mathbb{C}[[t_2, t_3]] \) can be written as a sum of an element of \( \mathcal{I} \) and a \( \mathbb{C}[[t_2, t_3]] \)-linear combination of the polynomials \( \{P_\lambda\}_{\lambda \in C_g} \). Therefore, injectivity of \( \Phi \) is a consequence of Proposition 3.30.

For a given \( \lambda_0 \in C_g \), Proposition 4.54 gives a permissible triple \( (X, w, \Sigma) \) such that the component of the relative element (4.57) corresponding to \( \lambda_0 \) is non-zero. Furthermore, we can change the relative class as in (4.57) by replacing \( \Gamma \) with \( \Gamma + s\Sigma \) and \( \Lambda \) with \( \Lambda + s\Sigma \). The component of this relative element corresponding to \( \lambda = (a, b) \) picks the factor \( e^{s(\zeta^{2b}\sqrt{3}t_2 + \zeta^{b}\sqrt{3}t_3 + \zeta^{2b}t_3 - 2\zeta^{db}t_3)} \). Therefore, by taking \( \mathbb{C}[[t_1, t_2]] \)-linear combinations of such expressions for different values of \( s \), we can produce elements of \( \overline{I}_{g,d} \) such that the component corresponding to \( \lambda_0 \) is the only non-zero element. This verifies the second part of the proposition. 

\[56\]
Consider the restriction of the pairing \(\langle \cdot, \cdot \rangle\) on \(I_{g,d}\). Above proposition implies that this pairing induces a pairing on \(C((t_1, t_2))^{N_\theta}\) using the map \(\overline{\Phi}\):

\[
\langle \cdot, \cdot \rangle : C((t_1, t_2))^{N_\theta} \times C((t_1, t_2))^{N_\theta} \to C((t_1, t_2))
\]

(4.64)

Suppose this pairing is given by \(\{\zeta^{2bd(g-1)}h_{\lambda,\lambda'}^{g,d}\}_{\lambda,\lambda'\in C_g}\) with respect to the standard basis of \(C((t_1, t_2))^{N_\theta}\) where \(b\) is the second coordinate of \(\lambda\). The constant \(\zeta^{2bd(g-1)}\) does not play an important role here. It will be used to obtain slightly simpler form for our glueing formulas in Proposition 4.67.

**Proposition 4.65.** The element \(h_{\lambda,\lambda'}^{g,d}(t_2, t_3) \in C((t_1, t_2))\) is non-zero only if \(\lambda = \lambda'\). Furthermore, if \(\lambda = (a, b)\) and \(\lambda_1 := |a| + |b| < 2g - 2\), then \(h_{\lambda,\lambda'}^{g,d}\) is also zero.

**Proof.** Suppose \((X, w, \Sigma)\) and \((X', w', \Sigma)\) are two permissible triples such that \(w\) and \(w'\) intersect \(\Sigma\) in the same set of points with the same signs. Suppose the homology classes \(\Gamma', \Lambda' \in H_2(X')\) are chosen such that their intersection with \(\Sigma\) is equal to 1. Then Identity (3.29) asserts that:

\[
D_{X\#_{\Sigma'}X', w\#_w\Sigma'}\left(e^{(\Gamma\#\Gamma')_2} + (\Lambda\#\Lambda')_3\right) = \sum_{\lambda,\lambda'\in C_g} \zeta^{2bd(g-1)}h_{\lambda,\lambda'}^{g,d} c_{X,w,\Sigma}^\lambda (\Gamma, \Lambda) c_{X',w',\Sigma'}^{\lambda'} (\Gamma', \Lambda')
\]

(4.66)

Replacing \(\Gamma, \Gamma', \Lambda\) and \(\Lambda'\) with \(\Gamma + r\Sigma, \Gamma' - r\Sigma, \Lambda + s\Sigma\) and \(\Lambda' - s\Sigma\) does not change the left hand side of the above identity. In the right hand side, the term corresponding to \(\lambda\) and \(\lambda'\) changes by a factor of the form \(e^{r\cdot f(\lambda, \lambda') + s\cdot g(\lambda, \lambda')}\). Here \(f(\lambda, \lambda')\) and \(g(\lambda, \lambda')\), which can be computed explicitly, are zero if and only if \(\lambda = \lambda'\). Therefore, \(h_{\lambda,\lambda'}^{g,d}\) has to be non-zero when \(\lambda \neq \lambda'\).

Let \((X, w, \Sigma)\) be the permissible triple of Example 4.52 where \(\Sigma\) has genus \(g - 1\). Then taking the connected sum of \(\Sigma\) and a homologically trivial torus, embedded in a 4-ball, produces a permissible triple \((X, w, \Sigma')\) such that \(\Sigma'\) has genus \(g\). Then \(X\#_{\Sigma'}X\) can be decomposed as the connected sum of \(S^2 \times S^2\) and another 4-manifold with \(b^+ > 0\). Then Theorem 6.14 asserts that, for \(\Gamma, \Lambda, \Gamma'\) and \(\Lambda' \in H_2(X)\), the following invariant vanishes:

\[
D_{X\#_{\Sigma'}X', w\#_w\Sigma'}\left(e^{(\Gamma\#\Gamma')_2} + (\Lambda\#\Lambda')_3\right)
\]

If \(|\lambda|_1 < 2g - 2\), then we can find \(\Gamma\) and \(\Lambda\) such that \(c_{X,w,\Sigma'}^{\lambda}(\Gamma, \Lambda)\) is non-zero. Consequently, \(h_{\lambda,\lambda'}^{g,d}\) is zero for this choice of \(\lambda\). \(\square\)

In the light of above proposition, let \(h_{a,b}^{g,d}\) be \(h_{\lambda,\lambda'}^{g,d}\) for \(\lambda = (a, b)\) \(\in C_g \setminus C_{g-1}\). These are the only non-zero terms among the coefficients of the pairing.

**Proposition 4.67.** Suppose \((X, w, \Sigma)\) and \((X', w', \Sigma)\) are two permissible triples such that \(w\) and \(w'\) intersect \(\Sigma\) in the same set of points with the same signs. Then:

\[
D_{X\#_{\Sigma}X', w\#_w(\frac{a_2}{3})^3 z} = D_{X\#_{\Sigma}X', w\#_w(z)} \quad D_{X\#_{\Sigma}X', w\#_w(a_2 z)} = 0
\]

(4.68)
for \( z \in \text{Sym}^*(H_0(X \#_2 X') \oplus \text{im}(\#)) \otimes \mathbb{Q} \). Suppose also the intersection number of homology classes \( \Gamma, \Lambda \in H_2(X) \) and \( \Gamma', \Lambda' \in H_2(X') \) with \( \Sigma \) is equal to 1. Then \( \tilde{D}_{X \#_2 X', w \# w'} (e^{(\Gamma' \# \Gamma') (2) + (\Lambda' \# \Lambda') (3)}) \) is equal to:

\[
\sum_{(a, b) \in C_0 \cup C_{g-1}} h_{a, b}^{g, d}(t_2, t_3) \sum_{i, i'} c_{i, i'} d_{i, i'} e^{(\Sigma_i + \Sigma_{i'}) \Gamma' \# \Gamma + \frac{\Sigma_i \Sigma_{i'}}{2} \text{II} (M_{i, i'} - M_{i, j'}) \# \Lambda' \# \Lambda}
\]

For each \((a, b)\), the second sum is over the pairs of basic classes \((K_i, K_j)\) and \((L_i', L_j')\) such that:

\[
\frac{(K_i + K_j)}{2} \cdot \Sigma = \frac{(L_i' + L_j')}{2} \cdot \Sigma = a \quad \frac{(K_i - K_j)}{2} \cdot \Sigma = \frac{(L_i' - L_j')}{2} \cdot \Sigma = b \tag{4.69}
\]

and \(M_{i, i'}, M_{j, j'}\) are respectively equal to \(K_i \# L_i', K_j \# L_j'\).

**Proof.** The series \( D_{X \#_2 X', w \# w'} (e^{(\Gamma' \# \Gamma') (2) + (\Lambda' \# \Lambda') (3)}) \) can be computed in terms of the cohomology classes \( M_{i, i'} \) by plugging (4.62) into (4.66) and applying Proposition 4.65. Then we argue as in Lemma 4.56 to obtain the desired formula for the \( U(N)\)-series \( \tilde{D}_{X \#_2 X', w \# w'} (e^{(\Gamma' \# \Gamma') (2) + (\Lambda' \# \Lambda') (3)}) \). We can follow a similar strategy to compute \( \tilde{D}_{X \#_2 X', w \# w'} (a_1^2 a_3^2 e^{(\Gamma' \# \Gamma') (2) + (\Lambda' \# \Lambda') (3)}) \) in terms of the classes \( M_{i, i'} \). The resulting formulas prove the identities in (4.68). \( \square \)

The goal of the remaining part of this section is to determine the power series \( h_{a, b}^{g, d}(t_2, t_3) \), up to two constants. Firstly, one can obtain a constraint on this power series by changing the orientation of \( \Sigma \):

\[
h_{a, b}^{g, 2}(t_2, t_3) = h_{-a, -b}^{g, 1}(-t_2, -t_3) \tag{4.70}
\]

We shall obtain more constraints by looking at some explicit 4-manifolds. In the case \( g = 1 \), in fact we can determine \( h_{0, 0}^{1, d}(t_2, t_3) \) completely using our calculation of the invariants of \( E(n) \):

**Corollary 4.71.** For \( g = 1 \), the only non-zero term among the pairing coefficients is given by:

\[
h_{0, 0}^{1, d}(t_2, t_3) = (h_1 \cosh(\sqrt{3} t_2) - 2h_2 \cos(-\frac{2\pi}{3} t_2 + \sqrt{3} t_3))^2.
\]

In particular, if \((X, w, \Sigma)\) and \((X', w', \Sigma)\) are permissible triples such that the genus of \( \Sigma \) is equal to 1, and \( w, w' \) intersect \( \Sigma \) in the same set of points with the same signs, then:

\[
\tilde{D}_{X \#_2 X', w \# w'} (e^{(\Gamma' \# \Gamma') (2) + (\Lambda' \# \Lambda') (3)}) = h_{0, 0}^{1, d} \tilde{D}_{X, w} (e^{(\Gamma + \Lambda) (2)}) \tilde{D}_{X', w'} (e^{(\Gamma' + \Lambda') (2)}). \tag{4.72}
\]

**Remark 4.73.** Identity (4.72) is a consequence of Proposition 3.33, and it holds even if we only require (i), (ii) and (iii) of Definition 4.49 for the triples \((X, w, \Sigma)\) and \((X', w', \Sigma)\).

The 4-manifold \( B(1) := E(1) \# \mathbb{CP}^2 \) has two elliptic fibrations with fibers \( f \) and \( f' \) such that \( f \cdot f' = 1 \). There are also disjoint embedded spheres \( E \) and \( E' \) in \( B(1) \) such that \( E \) (respectively, \( E' \)) intersects \( f \) (respectively, \( f' \)) positively in one point and is disjoint from \( f' \) (respectively, \( f \)). The fiber sum of \( n \) copies of \( B(1) \) along \( f' \) produces a 4-manifold \( B(n) \) which is diffeomorphic to \( E(n) \# n \mathbb{CP}^2 \) (Figure 1). The exceptional spheres of \( B(n) \) are denoted by \( E^1, \ldots, E^n \) where \( E^i \) is given by the exceptional
sphere $E$ in the $i$th summand of $B(n)^4$. Furthermore, one can glue copies of $f$ to produce a surface $f_n$ of genus $n$ with self-intersection zero. The homology class of $f_n$ is equal to $[S] - [E^1] - \cdots - [E^n]$ for an appropriate surface $S$ of genus $n$ in $E(n)$. Similarly, one can glue copies of $E^i$ to produce $\sigma_n$, a sphere of self-intersection $-n$, that is disjoint form $f_n$ and the exceptional spheres. The intersection number of $\sigma_n$ and $f'$ is equal to 1. The following proposition shows that $(B(n), f_n, w)$ is permissible if $w \cdot f \neq 0 \mod 3$:

**Proposition 4.74.** Suppose $w$ is a 2-cycle in $B(n)$ such that $w \cdot f_n \neq 0 \mod 3$. For $n \geq 2$, the triple $(B(n), w, f_n)$ is permissible and $\overline{D}(B(n), w(e^{\Gamma + \Lambda})), for \quad \Gamma, \Lambda \in H_2(B(n))$, is given by:

$$e^{G'(\Gamma)} G'(\Gamma, \Lambda, w \cdot f')^{n-2} \prod_i \frac{1}{3} \left( \cosh(\sqrt{3} E^i \cdot \Gamma) + 2 \cos \left( -\frac{2\pi}{3} w \cdot E^i + \sqrt{3} E^i \cdot \Lambda \right) \right)$$

Here $G'$ is given by (4.24) after replacing $f$ with $f'$. In particular, a basic class of $B(n)$ has the following form:

$$(n - 2k)f' \pm E^1 \pm \cdots \pm E^n$$

for $1 \leq k \leq n - 1$.

**Proof.** This follows from the Blow-up formula and Theorem 4.23. \qed

From the construction, it is clear that there is a diffeomorphism (see Figures 2 and 3):

$$\Phi_n : B(n) \# f_n B(n) \to B(2) \# f_2 \cdots \# f_2 B(2) \quad (4.75)$$

---

4For the special case of exceptional spheres in $B(n)$, we deviate from our previous notation and put $i$ as a superscript.
Figure 2: A schematic picture of $B(n) \# f_n B(n)$

Figure 3: A schematic picture of $B(2) \# f_2 \ldots \# f_2 B(2)$

This diffeomorphism maps $f_n$ and $f'_n := f' f$ in $B(n) \# f_n B(n)$ to $f'_n := f' \ldots \# f'$ and $f_2$ in $B(2) \# f_2 \ldots \# f_2 B(2)$. The sphere $\sigma_n \subset B(n)$ determines two spheres of self-intersection $-n$ in $B(n) \# f_n B(n)$ which are denoted by $\sigma_n^1$ and $\sigma_n^2$. The diffeomorphism $\Phi_n$ maps $\sigma_n^1$ to $E_n^1 := E^1 \ldots \# E^1$. Therefore, the following elements of $C[[r_2, s_2, r_3, s_3, t_2, t_3]]$ are equal to each other:

$$
\hat{D}_{B(n) \# f_n B(n), k f_2 + t f_n} \left( e^{(r_2 f_n + s_2 f'_2)_{(2)} + (r_3 f_n + s_3 f'_2)_{(3)}} \right) = \\
= \hat{D}_{B(2) \# f_2 \ldots \# f_2 B(2), k f_2 + t f_n} \left( e^{(r_2 f'_n + s_2 f_2)_{(2)} + (r_3 f'_n + s_3 f_2)_{(3)}} \right)
$$

(4.76)

**Proposition 4.77.** Suppose $(a, b) \in C_2 \setminus \{(0, 0)\}$. Then:

$$
h_{a, b}^{2, d}(t_2, t_3) = \sum_{(\gamma, n) \in C_2 \setminus \{(0, 0)\}} h_{a, b, \gamma, n}^{2, d} e^{\sqrt{3} t_2 + \sqrt{3} \ln t_3}
$$

(4.78)
where $h^2_d_{a,b,\gamma,\eta}$ is a constant number.

**Proof.** The triple $(B(2), df' + 2df_2, f_2)$ is permissible, and Proposition 4.67 can be utilized to compute the following element of $C[[r_2, r_3, s_2, s_3, t_2, t_3]]$:

$$\tilde{D}_{B(2)\# f_2 B(2), df' + 2df_2} (e^{(s_2 f'_2 + r_2 f_2)(2)} + (s_3 f'_2 + r_3 f_2)(3)).$$

We can evaluate this series at $t_2 = t_3 = 1$ to obtain a well-defined element of $C[[r_2, r_3, s_2, s_3]]$. This power series is equal to:

$$e^{r_2 s_2 - 2r_3 s_3} \sum_{(a,b)\in \mathbb{C} \setminus \{(0,0)\}} h^2_d_{a,b}(s_2, s_3) e^{\sqrt{3}ar_2 + \sqrt{3}br_3} \left( \sum_{(K_i, K_j)} c_{ij} \right)^2$$

(4.79)

where the inner sum is over all pairs of basis classes $(K_i, K_j)$ of $(B(2), df' + 2df_2, f_2)$ such that:

$$\frac{(K_i + K_j)}{2} \cdot f_2 = a \quad \frac{(K_i - K_j)}{2} \cdot f_2 = b.$$

For each choice of $(a,b)$, the inner sum is non-zero. The identity (4.76) shows that the expression (4.79) is invariant with respect to the symmetry of $C[[r_2, r_3, s_2, s_3]]$ that switches $r_2$ with $s_2$ and $r_3$ with $s_3$. This can be used to show that $h^2_d_{a,b}(t_2, t_3)$ has the form in (4.78). \(\square\)

![Figure 4](image-url)

**Figure 4:** A schematic picture of $B(2)\# f_2 B(2)$: reflection with respect to the dashed line represents the diffeomorphism $\Phi_2$ of this 4-manifold

**Proposition 4.80.** The constant numbers $h^2_d_{a,b,\gamma,\eta}$ are zero except possibly the following ones:

$$h^2_d_{0,0,2,0} \quad h^2_d_{0,2,0,2} \quad h^2_d_{0,-2,0,-2} \quad h^2_d_{-2,0,-2,0}.$$

Furthermore, there are real numbers $h_3$ and $h_4$ such that:

$$h^2_d_{0,0,2,0} = h^2_d_{-2,0,-2,0} = h_3 \quad h^2_d_{0,2,0,2} = \zeta^d h_4 \quad h^2_d_{0,-2,0,-2} = \zeta^{-d} h_4.$$  

(4.81)
Proof. Firstly, for the purpose of brevity, let:

$$N_{X, w}(\Gamma, \Lambda) := \hat{D}_{X, w}(e^{\Gamma(w) + \Lambda(w)}) e^{-Q(\Gamma) + Q(\Lambda)}.$$  

Proposition 4.77 implies that $N_{B(2)\#f_2 B(2), df_2 + df_2}(\Gamma, \Lambda)$, for $\Gamma, \Lambda \in \text{im}((#))$, has the following form:

$$\sum M^{d', d''}_{a, b, \gamma, \eta}(i, j', i', j') e^{\frac{\sqrt{3}}{2}(K_i K_j + K_j K_j' + 2\gamma f_2)} + \frac{\sqrt{3}}{2} i(K_i K_j - K_j K_j' + 2\eta f_2) \cdot \lambda)$$

where the sum is over the pairs $(a, b), (\gamma, \eta) \in C_2 \setminus \{(0, 0)\}$ and the basic classes $K_i, K_j, K_i', K_j'$ of the permissible triple $(B(2), df', 2d' df_2, f_2)$ such that:

$$\frac{(K_i + K_j)}{2} \cdot f_2 = \frac{(K_i' + K_j')}{2} \cdot f_2 = a \quad \frac{(K_i - K_j)}{2} \cdot f_2 = \frac{(K_i' - K_j')}{2} \cdot f_2 = b.$$

In the above expression, the constant number $M^{d', d''}_{a, b, \gamma, \eta}(i, j, i', j')$ is equal to $h^{2d, d'}_{a, b, \gamma, \eta} c_{ij} c_{i'j'}$ where $c_{ij}$ and $c_{i'j'}$ are the coefficients associated to the pairs of basic classes $(K_i, K_j)$ and $(K_i', K_j')$ for the permissible triple $(B(2), df', 2d' df_2, f_2)$. We need the following elementary lemma:

**Lemma 4.82.** Suppose $V$ is a vector space and $\{f_i\}_{i \leq N}$ is a finite set of distinct complex valued linear functionals on $V$. Then the functions $\{e^{f_i}\}_{i \leq N}$ are linearly independent over $\mathbb{C}$.

This Lemma is an immediate consequence of the existence of a line $l \subseteq V$ such that the restrictions $f_i|_l$ are distinct. We apply this lemma in the case that $V$ is the following subspace of $H_2(B(2)\#f_2 B(2))^{\oplus 2}$:

$$(\text{im}((#)) \cap (\Phi_2)_*(\text{im}((#)))) \oplus (\text{im}((#)) \cap (\Phi_2)_*(\text{im}((#))))$$

Since $\Phi$ maps $df_2' + df_2$ to $df_2 + df_2'$, we have:

$$N_{B(2)\#f_2 B(2), df_2 + df_2}(\Gamma, \Lambda) = N_{B(2)\#f_2 B(2), df_2 + df_2}((\Phi_2)_*(\Gamma), (\Phi_2)_*(\Lambda))$$

for $(\Gamma, \Lambda) \in V$. This identity implies that:

$$\sum M^{d', d''}_{a, b, \gamma, \eta}(i, j, i', j') e^{\frac{\sqrt{3}}{2}(K_i K_j + K_j K_j' + 2\gamma f_2)} + \frac{\sqrt{3}}{2} i(K_i K_j - K_j K_j' + 2\eta f_2) \cdot \lambda) = 0. \quad (4.83)$$

Here $f_{a, b, \gamma, \eta}^{i, j, i', j'}$ is defined by the following pair of cohomology classes:

$$\left(\frac{\sqrt{3}}{2}(K_i K_j + K_j K_j' + 2\gamma f_2), \frac{\sqrt{3}}{2} i(K_i K_j - K_j K_j' + 2\eta f_2)\right)$$

and $g_{a, b, \gamma, \eta}^{i, j, i', j'} = \Phi^*_2 (g_{a, b, \gamma, \eta}^{i, j, i', j'})$. In the case of $f_{a, b, \gamma, \eta}^{i, j, i', j'}$, this pair is equal to:

$$\left(\frac{\sqrt{3}}{2}(L_m^\delta + L_m'^\delta), \frac{\sqrt{3}}{2} i(L_m^\delta - L_m'^\delta)\right)$$

for an appropriate choice of $m$ and $\delta$, where $L_m^\delta$ is defined in the following table:
Table 1: Pairing of the cohomology classes \( L_m^\delta \) and \( J_m^\delta \) with some elements of \((\text{im}(\#) \cap (\Phi_2)_*(\text{im}(\#)))\)

| \( L_m^\delta \) \( \mapsto E_m^2 + \delta f_m \) | \( J_m^\delta \) \( \mapsto E_m^2 + \delta f_m \) | \( f_2 \) | \( f_2' \) | \( E_2^2 \) | \( E_2'^2 \) | \( \sigma_2^2 \) | \( \sigma_2'^2 \) |
|---|---|---|---|---|---|---|---|
| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

There are similar formulas for \( \delta_{a,b,c,d} \), where \( L_m^\delta \) and \( L_m'^\delta \) are replaced with \( J_m^\delta \) and \( J_m'^\delta \). In the above table, the cohomology classes \( \zeta_1 \) and \( \zeta_2 \) are equal to \( E^1 \# E^2 \) and \( E^2 \# E^1 \). Moreover, \( \xi_i : = (\Phi)_i(\zeta_i) \). The table contains evaluations of \( L_m \) and \( J_m \) at some elements of \((\text{im}(\#) \cap (\Phi_2)_*(\text{im}(\#)))\). The evaluations of this table shows that the only possible identities among the following functionals on \( V \):

\[
L_i^\delta, J_i^\delta, \quad 1 \leq i \leq 4
\]

are the identities of the elements in the pairs \((L_1^2, J_1^2)\) and \((L_2^2, J_2^2)\). Therefore, Lemma 4.8.2 can be used to prove the first part of the proposition. The second part, is a consequence of the remaining information in (4.83), Identity (4.70) and rationality of polynomial invariants.

Proposition 4.84. The constant number \( h_3 \) is non-zero.

Proof. Recall that the 4-manifold \( X(m,n) \) is a branched double cover of \( W(m,n) \) which is the blow up of \( \mathbb{CP}^1 \times \mathbb{CP}^1 \) at \( 4mn \) points. Suppose \( \pi : X(m,n) \to W(m,n) \) is the covering map. Since \( \pi \) does not contract any curve, the pullback of any ample divisor is still ample by Nakai-Moishezon Criterion and projection formula [44]. In particular, the following divisor is ample:

\[
\pi^*\{p\} \times \mathbb{CP}^1 + \mathbb{CP}^1 \times \{q\} - \sum_{i=1}^{4mn} E_i = f_{n-1} + f_{m-1} - \sum_{i=1}^{4mn} \pi^*(E_i)
\]

where \( \{E_i\}_{1 \leq i \leq 4mn} \) is the set of exceptional classes.

Next we focus on the 4-manifold \( X(3,4) \). Suppose \( w_1 = f_3 \) and \( w_2 = f_2 + f_2 \). Thus there is a holomorphic line bundle \( L_i \) on \( X(3,4) \) that \( c_1(L_i) \) is represented by \( w_1 \) and \( w_2 \) can be decomposed as \( w_1 \# w_2 \) with respect to the decomposition of \( X(3,4) \) as \( E(3) \# E(3) \). Let \( S \) denote the ample class \( f_2 + f_3 \). According to Theorem 2.18, the coefficient of \( t_2^3 \) in the series \( \tilde{D}_{X(3,4)}(w_1(e^{S})) \in \mathbb{Z} \) at
Furthermore, we have:

\[
\hat{D}_{X(3),w_1}(e^{S(2)}) = e^{\frac{Q(S)}{2}}\left[\frac{1}{2} h_1^2 h_3 \cosh(\sqrt{3}(f_3 + 2f_2) \cdot S) + 2h_2^2 h_4 \cos(\frac{2\pi}{3} w_1 \cdot (f_3 + 2f_2))\right]
\]

Therefore:

\[
2\hat{D}_{X(3),w_1}(e^{S(2)}) + \hat{D}_{X(3),w_2}(e^{S(2)}) = \frac{3}{2} h_1^2 h_3 e^{\frac{Q(S)}{2}} \cosh(\sqrt{3}(f_3 + 2f_2) \cdot S).
\]

This implies that \(h_3\) is a positive number (and \(h_1\) is non-zero).

\[\Box\]

**Proposition 4.85.** The power series \(h_{a,b}^{g,d}(t_2,t_3)\) is zero, unless:

\((a, b) \in \{(\pm(2g - 2), 0), (0, \pm(2g - 2))\}\).

Furthermore, we have:

\[
h_{\pm(2g-2),0}^{g,d}(t_2,t_3) = h_3^{-1} \left(\frac{2}{h_1}\right)^{2g-4} e^{\pm \sqrt{3}t_2} \quad h_{0,\pm(2g-2)}^{g,d}(t_2,t_3) = h_4^{-1} h_2^{4-2g} \zeta^\pm \frac{2}{3} e^{\pm \sqrt{3}t_3}.
\]

**Proof.** This theorem can be proved by exploiting the diffeomorphism in (4.75) for \(n = g\). Let the 2-cycle \(w\) in \(B(g)\#_f B(g)\) be equal to \(df'_2 + df_g\). Using Propositions 4.67 and 4.74, we can show that \(N_{B(g)\#_f B(g)}(\Gamma, \Lambda)\), for \(\Gamma, \Lambda \in \mathcal{H} := \text{im}(\#)\), is equal to:

\[
\sum_{(a,b) \in C_g \cap C_{g-1}} h_{a,b}^{g,d}(t_2,t_3) \sum c_{ij} c_{i'j'} e^{\frac{\pi}{2}(M_{i,i'} + M_{j,j'})} \Gamma + \frac{\pi}{2}(M_{i',i} - M_{j',j}) \cdot \Lambda \tag{4.86}
\]

where the second sum is over the pairs of basic classes \((K_i, K_j)\) and \((K_{i'}, K_{j'})\) of the permissible triple \((B(g), df' + 2df_g, f_g)\) such that:

\[
(K_i + K_j) \cdot f_g = \frac{(K_{i'} + K_{j'})}{2} \cdot f_g = a \quad (K_i - K_j) \cdot f_g = \frac{(K_{i'} - K_{j'})}{2} \cdot f_g = b \tag{4.87}
\]

and \(M_{i,i'} = K_i \# K_{i'}\) and \(M_{j,j'} = K_j \# K_{j'}\).

Recall that the 4-manifolds \(B(g)\#_f B(g)\) and \(B(2)\#_f B(2)\#_f \ldots \#_f B(2)\) are diffeomorphic to each other using the diffeomorphism \(\Phi_g\). Therefore, \(N_{B(g)\#_f B(g)}(\Gamma, \Lambda)\) can be also computed by regarding \(B(g)\#_f B(g)\) as the fiber sum of \(g\) copies of \(B(2)\) along surfaces of genus 2. In particular, Propositions 4.77 and 4.80 allow us to obtain the following explicit form for \(N_{B(g)\#_f B(g)}(\Gamma, \Lambda)\):

\[
h_3^{-1}\left(\frac{1}{36}\right)^{g} e^{\sqrt{3}M_g} \Gamma + h_3^{-1}\left(\frac{1}{36}\right)^{g} e^{-\sqrt{3}M_g} \Gamma + h_4^{-1}\left(\frac{\zeta}{9}\right)^g e^{\sqrt{3}M_g} \Lambda + h_4^{-1}\left(\frac{\zeta}{9}\right)^g e^{-\sqrt{3}M_g} \Lambda \tag{4.88}
\]

where \(M_g = \sigma_g^1 + \sigma_g^2 + 2(g - 1)f_2\). However, this approach works for the homology classes \(\Gamma, \Lambda \in \mathcal{H}'\) where \(\mathcal{H}'\) is the image of the iterated applications of \# using the decomposition of \(B(g)\#_f B(g)\) as the fiber sum of \(g\) copies of \(B(2)\). Therefore, (4.86) and (4.88) are equal to each other for \(\Gamma, \Lambda \in \mathcal{H} \cap \mathcal{H}'\). Fix \(\Gamma, \Lambda \in \mathcal{H} \cap \mathcal{H}'\) and let:

\[
l := \{\Gamma + sf_g \mid s \in \mathbb{C}\} \quad l' := \{\Lambda + sf_g \mid s \in \mathbb{C}\}
\]

64
Applying Lemma 4.82 to the subspace $l \oplus l'$ of $(\mathcal{H} \cap \mathcal{H}')^\otimes 2$ shows that:

$$h_{g,d}^{g,d}(t_2, t_3) = h_{2g-4}^{g,d}(\frac{1}{2}) h_1^{2g-4} e^{\pm \sqrt{3} M_\gamma} = h_3^{g-1} \left( \frac{1}{36} \right) g \cdot e^{\pm \sqrt{3} M_\gamma}$$

for $M_\gamma := (g - 2) f_2' + E_2'$. Since $h_1$ and $h_2$ are non-zero [14], the above identity proves the second part of the proposition. If $(a, b) \notin \{(\pm (2g - 2), 0), (0, \pm (2g - 2))\}$, then the same argument shows that:

$$h_{a,b}^{g,d}(t_2, t_3) \sum c_{ij} d_{j,i} e^{\frac{2}{\pi}(M_i + M_i', M_{j,j}')} = 0$$

for $\Gamma, \Lambda \in \mathcal{H} \cap \mathcal{H}'$. This sum is over the pairs that satisfy (4.87). Another application of Lemma 4.82 for the following homology classes in $\mathcal{H} \cap \mathcal{H}'$:

$$\Gamma = s(E_2' + \cdots + E_2') \quad \Lambda = s(E_2' + \cdots + E_2')$$

shows that $h_{a,b}^{g,d}(t_2, t_3)$ has to be zero.

The following theorem summarizes our results in this subsection:

**Theorem 4.89.** Suppose $(X, w, \Sigma)$ and $(X', w', \Sigma)$ are two permissible triples and the genus of $\Sigma$ is at least 2. Then the triple $(X \# X', w \# w', \Sigma)$ is permissible with respect to the image of the map $# : K \to H_2(X \# X')$. The basic classes for $(X \# X', w \# w', \Sigma)$ are:

$$M_{i,j}^\gamma = K_i \# L_{i'} + 2\gamma \Sigma$$

where $K_i, L_{i'}$ are basic classes of $(X, w, \Sigma), (X', w', \Sigma), K_i \cdot \Sigma = L_{i'} \cdot \Sigma$ and:

$$(K_i \cdot \Sigma, \gamma) \in \{(2g - 2, 1), (-2g - 2, -1)\}.$$

For a pair of basic classes $M_{i,j}^\gamma = K_i \# L_{i'} + 2\gamma \Sigma$ and $M_{j,j'}^\gamma = K_j \# L_{j'} + 2\gamma \Sigma$, let:

$$\left( \frac{K_i + K_j}{2} \right) \cdot \Sigma = \left( L_{i'} + L_{j'} \right) \cdot \Sigma = a \quad \left( \frac{K_i - K_j}{2} \right) \cdot \Sigma = \left( L_{i'} - L_{j'} \right) \cdot \Sigma = b$$

Then the coefficient associated to this pair is equal to $c_{i,j} d_{i,j'} h_{a,b,\gamma,\eta}^{g,d}$ where $c_{i,j}$ is the coefficient associated to $(K_i, K_j)$ for the triple $(X, w, \Sigma)$, $d_{i,j'}$ is the coefficient associated to $(L_{i'}, L_{j'})$ for the triple $(X', w', \Sigma)$, and $h_{a,b,\gamma,\eta}^{g,d}$ is given by the following identities:

$$h_{2g-2,0,1,0}^{g,d} = h_{-2g-2,0,-1,0}^{g,d} = h_3^{g-1} \left( \frac{2}{h_1} \right)^{2g-4}$$

$$h_{0,(2g-2),0,1}^{g,d} = h_{2g-4}^{g-1} \zeta^{d} \quad h_{0,-(2g-2),0,1}^{g,d} = h_4^{g-1} \left( \frac{2}{h_2} \right)^{2g-4} \zeta^{-d}.$$
5 Sutured Floer Homology

5.1 Eigenvectors

We introduce a set of generators of the algebra $\mathbb{V}^{N}_{g,d}$, for arbitrary $N$, in Corollary 3.21. In particular, in the special case that $N = 3$, we have the following generators of $\mathbb{V}^{3}_{g,d}$ (which will be denoted by $\mathbb{V}_{g,d}$ from now on):

$$\epsilon = D_{\Delta_{g,d} + \Sigma}(1) \quad \kappa_{r} = D_{\Delta_{g,d}}(a_{r}) \quad \alpha_{\epsilon}^{r} = D_{\Delta_{g,d}}(l_{(r)}^{\epsilon}) \quad \rho_{r} = D_{\Delta_{g,d}}(\Sigma(r))$$  

(5.1)

where $r = 2, 3$ and $\{l_{i}\}_{1 \leq j \leq 2g}$ is a set of generators for $H_{1}(\Sigma, \mathbb{Z})$. If $y$ is one of the above elements, then the product $m(\cdot, y)$ defines an operator on $\mathbb{V}_{g,d}$ which is still denoted by $y$. Recall that there is also a pairing on $\mathbb{V}_{g,d}$ which is denoted by $\langle \cdot, \cdot \rangle$.

The operator $\epsilon$ is equal to $I_{*}(Y_{g} \times [0, 1], \gamma_{g,d} \times [0, 1] \cup \Sigma, 1)$ and the remaining operators can be described as:

$$I_{*}(Y_{g} \times [0, 1], \gamma_{g,d} \times [0, 1], y)$$  

(5.2)

where $q = a_{r}, l_{(r)}^{\epsilon}$ or $\Sigma(r)$. This alternative description allows us to extend the definition of these operators to arbitrary admissible pairs. Suppose $(Y, \gamma)$ is an admissible pair, and $\Sigma$ is an embedded surface of genus $g$. Then by replacing $(Y_{g}, \gamma_{g,d})$ with $(Y, \gamma)$, we can define analogues of the operators $\epsilon, \kappa_{r}, \alpha_{\epsilon}^{r}$ and $\rho_{r}$ on $I_{*}(Y, \gamma)$.

**Definition 5.3.** An element $\alpha \in \mathbb{V}_{g,d}$ is called an exhaustive eigenvector if it is a simultaneous eigenvector of the action of the operators in (5.1). An exhaustive eigenspace is the set of all exhaustive eigenvectors which have the same eigenvalues with respect to these operators. An exhaustive eigenvector $v$ is called non-degenerate if the pairing $\langle v, v \rangle \neq 0$.

**Remark 5.4.** Since $(\alpha_{\epsilon}^{r})^{2} = 0$, the only eigenvalue of this operator is zero.

Suppose $(X, w, \Sigma)$ is a permissible triple and $\Sigma$ is a surface of genus $g$ and $w \cdot \Sigma = d$. For a pair of basic classes $(K_{i}, K_{j})$ of this triple, let $c_{i,j}$ denote the associated coefficient. Suppose also for a fixed $\lambda = (\alpha, \beta) \in C_{g}$:

$$\sum_{(K_{i}, K_{j})} c_{i,j} \neq 0$$  

(5.5)

where the sum is over all pairs of basic classes $(K_{i}, K_{j})$ that satisfy the following equality for $(a, b) = (\alpha, \beta)$:

$$\frac{(K_{i} + K_{j})}{2} \cdot \Sigma = a \quad \frac{(K_{i} - K_{j})}{2} \cdot \Sigma = b.$$  

(5.6)

Recall that $P_{\lambda}$ is the polynomial that satisfies (4.61). Suppose $Q_{\lambda} \in \mathbb{C}[x, y, z]$ is defined as the evaluation of $P_{(a, b)}$ at $t_{2} = t_{3} = 0$ and consider the following element of $\mathbb{V}_{g,d}$:

$$v_{(\alpha, \beta)} := D_{X, w, \Sigma}(Q_{\lambda}(a_{2}, \Sigma(2), \Sigma(3))).$$
Proposition 5.7. The element \( v_{(\alpha, \beta)} \in \mathbb{V}_{g,d} \) is a non-zero exhaustive eigenvector. The eigenvalues of \( v_{(\alpha, \beta)} \) with respect to the actions of \( \epsilon, \mathbb{N}_2, \mathbb{N}_3, \rho_2 \) and \( \rho_3 \) are respectively equal to \( 1, 3\zeta^{2\beta}, 0, \zeta^{4\beta}\sqrt{3} \alpha \) and \( \zeta^{2\beta}\sqrt{3} \beta \). Furthermore, if \( (\alpha, \beta) = \pm(2g-2, 0) \), then the eigenvector \( v_{(\alpha, \beta)} \) is non-degenerate.

Proof. Lemma 4.56 can be used to show that for an arbitrary polynomial \( P \in \mathbb{C}[x, y, z] \):

\[
D_{X,w,\Sigma}(P(a_2, \Sigma(2), \Sigma(3))) = \sum_{(a,b)\in\mathcal{C}_g} \zeta^{db} P(3\zeta^{2db}, \zeta^{bd}\sqrt{3}a, \zeta^{2bd}\sqrt{3}b) \sum_{(K_i,K_j)} c_{i,j}
\]

(5.8)

where the inner sum is over all pairs of basic classes \( (K_i, K_j) \) that satisfy (5.6) and \( c_{i,j} \) is the coefficient associated to the pair \( (K_i, K_j) \). Functorial properties of Floer homology imply that the pairing of \( v_{(\alpha, \beta)} \) and \( D_{\Delta,\delta,g,d}(1) \) is equal to \( D_{X,w,\Sigma}(Q\lambda(a_2, \Sigma(2), \Sigma(3))) \) which is non-zero. Therefore, \( v_{(\alpha, \beta)} \) is a non-zero vector. Using the non-degeneracy of the pairing on \( \mathbb{V}_{g,d} \), the claim that \( v_{(\alpha, \beta)} \) is an exhaustive eigenvector can be translated to claims about the \( U(3) \)-invariants of \( (X, w) \). In particular, (5.8) shows that \( v_{(\alpha, \beta)} \) is an eigenvector of \( \epsilon, \mathbb{N}_2, \rho_2 \) and \( \rho_3 \). The vector \( v_{(\alpha, \beta)} \) is in the kernel of the operators \( \mathbb{N}_3 \) and \( \mathcal{O}_t^\beta \) because \( X \) has \( w \)-simple type and \( b_1(X) = 0 \). The pairing \( \langle v_{(\alpha, \beta)}, v_{(\alpha, \beta)} \rangle \) can be also computed using Theorem 4.89. Using Proposition 4.84, this number is non-zero for \( (\alpha, \beta) = \pm(2g-2, 0) \).

Example 4.52 gives a permissible triple such that the condition in (5.5) is satisfied for any \( \lambda \in \mathcal{C}_g \). Therefore, for each \( \lambda \) there is an exhaustive eigenvector in \( \mathbb{V}_{g,d} \). The condition in (5.5) is not very essential in constructing such an eigenvector. This condition is used to show that \( v_{(\alpha, \beta)} \) is a non-zero element of \( \mathbb{V}_{g,d} \). It is possible to replace \( v_{(\alpha, \beta)} \) with the following element:

\[
v'_{(\alpha, \beta)} := D_{X^\infty, w^\infty, \Sigma}(Q\lambda(a_2, \Sigma(2), \Sigma(3))) z
\]

where \( z \in \mathbb{A}(X^\infty)^{\otimes 2} \). If the triple \( (X, w, \Sigma) \) has at least one pair of basic classes \( (K_i, K_j) \) which satisfy (5.6) for \( (a, b) = (\alpha, \beta) \), then \( z \) can be chosen such that the above element of \( \mathbb{V}_{g,d} \) is non-zero.

Proposition 5.9. An exhaustive eigenspace is 1-dimensional.

Proof. Suppose \( V \subset \mathbb{V}_{g,d} \) is an exhaustive eigenspace, and \( s_1, s_2, s_3, s_4 \) and \( s_5 \) are respectively the corresponding eigenvalues of \( \epsilon, \mathbb{N}_2, \mathbb{N}_3, \rho_2 \) and \( \rho_3 \). Suppose also \( \mathcal{J} \subset \mathbb{V}_{g,d} \) is the ideal generated by the elements of the following set:

\[
G := \{ \epsilon - s_1, \mathbb{N}_2 - s_2, \mathbb{N}_3 - s_3, \rho_2 - s_4, \rho_3 - s_5 \} \cup \{ \mathcal{O}_r^j | 1 \leq j \leq 2g, 1 \leq r \leq 2 \}
\]

(5.10)

Then an element of \( \mathcal{J} \) is the sum of the elements of the form \( m(x, y) \) with \( x \in G \) and \( y \in \mathbb{V}_{g,d} \). For any \( v \in V \):

\[
\langle v, m(x, y) \rangle = \langle m(v, x), y \rangle = 0
\]

Therefore, \( V \) is orthogonal to \( \mathcal{J} \). Since \( \mathbb{V}_{g,d}/\mathcal{J} \) is a 1-dimensional vector space and the pairing is non-degenerate, the dimension of the vector space \( V \) is at most 1. \( \square \)
Lemma 5.11. Suppose $\alpha \in \mathcal{V}_{g,d}$ is a non-degenerate exhaustive eigenvector, and $s_1, s_2, s_3, s_4$ and $s_5$ are respectively the corresponding eigenvalues of $\varepsilon, \eta_2, \eta_3, \rho_2$ and $\rho_3$. Then the following space:

$$H := \ker_{\text{gen}}(\varepsilon - s_1) \cap \ker_{\text{gen}}(\eta_2 - s_2) \cap \ker_{\text{gen}}(\eta_3 - s_3) \cap \ker_{\text{gen}}(\rho_2 - s_4) \cap \ker_{\text{gen}}(\rho_3 - s_5)$$

is 1-dimensional. Here $\ker_{\text{gen}}(T)$, for an operator $T$, is the union of the kernel of the operators $T^k$ for all values of $k$.

Proof. Suppose the claim does not hold and $\beta \in H$ is a vector which is linearly independent of $\alpha$. Let $G$ be defined as in (5.10). All the operators involved in the definition of $H$ have even degree with respect to the $\mathbb{Z}/2\mathbb{Z}$-grading of $\mathcal{V}_{g,d}$, induced by the $\mathbb{Z}/12\mathbb{Z}$-grading. Therefore, $H$ can be decomposed as $H_0 \oplus H_1$ with respect to the $\mathbb{Z}/2\mathbb{Z}$-grading of $\mathcal{V}_{g,d}$, and we can assume that $\beta \in H_i$ for $i = 0$ or 1. By Proposition 5.9, there is $x_0 \in G$ such that $m(\beta, x_0) \neq 0$. Since the restriction of the elements of $G$ on $H$ are nilpotent, without loss of generality, we can also assume that the products $m(\beta, m(x_0, x_0))$ and $m(\beta, x)$ for $x \in G \setminus \{x_0\}$ are zero. Therefore, $m(\beta, x_0) = c \alpha$ for a non-zero complex number $c$. This implies that:

$$\langle m(\beta, x_0), m(\beta, x_0) \rangle = \langle c\alpha, c\alpha \rangle \neq 0$$

On the other hand, we have:

$$\langle m(\beta, x_0), m(\beta, x_0) \rangle = \pm \langle m(\beta, x_0), x_0 \rangle, \beta \rangle = 0$$

which is a contradiction. \qed

By Proposition 5.7, $v_{2g-2,0}$ is a non-degenerate exhaustive eigenvector of $\mathcal{V}_{g,d}$. Suppose $s^g_1, s^g_2, s^g_3, s^g_4$ and $s^g_5$ denote the corresponding eigenvalues of $\varepsilon, \eta_2, \eta_3, \rho_2$ and $\rho_3$. Then $s^g_1 = 1, s^g_2 = 3, s^g_3 = 0, s^g_4 = \sqrt{3}(2g - 2)$ and $s^g_5 = 0$. Following [58], we can define a variation of instanton Floer homology in the following way. Suppose $(Y, \gamma)$ is an admissible pair and $\Sigma$ is an embedded surface in $Y$ of genus $g$ such that $\gamma \cdot \Sigma \equiv d \mod 3$. Then $I^g_s(Y, \gamma|\Sigma)$ is defined as:

$$\ker_{\text{gen}}(\varepsilon - s^g_1) \cap \ker_{\text{gen}}(\eta_2 - s^g_2) \cap \ker_{\text{gen}}(\eta_3 - s^g_3) \cap \ker_{\text{gen}}(\rho_2 - s^g_4) \cap \ker_{\text{gen}}(\rho_3 - s^g_5)$$

In this definition, we can allow $\Sigma$ to have more than one connected components. In that case, each connected component $\Sigma'$ of $\Sigma$ is required to have genus $g$ and $\gamma \cdot \Sigma' \equiv d \mod 3$. In the definition of $I^g_s(Y, \gamma|\Sigma)$, we include the operators $\rho_2 - s^g_4$ and $\rho_2 - s^g_4$ in the above expression for each connected component $\Sigma'$ of $\Sigma$.

This variant of instanton Floer homology is also functorial with respect to cobordisms. Suppose $(W, w) : (Y_0, \gamma_0) \to (Y_1, \gamma_1)$ is a cobordism of admissible pairs, $z \in \mathcal{A}(W)^{\otimes 2}$, and $\Sigma_i$ is an oriented and connected surface in $Y_i$ such that $\gamma_i \cdot \Sigma_i = d$, and $\Sigma_0, \Sigma_1$ induce the same homology classes of $W$. More generally, if $\Sigma_2$ is disconnected, then each connected component of $\Sigma_2$ is required to be homologous to a connected component of $\Sigma_1$ inside $W$. Properties of instanton Floer homology discussed in subsection 3.1 implies that $I^g_s(W, w, z)$ maps $I^g_s(Y_0, \gamma_0|\Sigma_0) \subseteq I^g_s(Y_0, \gamma_0)$ to $I^g_s(Y_1, \gamma_1|\Sigma_1) \subseteq I^g_s(Y_1, \gamma_1)$. Moreover, suppose $(X, w)$ is a cobordism from an admissible pair $(Y, \gamma)$ to the empty pair and $z \in \mathcal{A}(X)^{\otimes 2}$. Then the restriction of the map $D^X_{w}(z)$ gives rise to a functional on $I^g_s(Y, \gamma|\Sigma)$ which is denoted with the same notation.
Lemma 5.11 asserts that $I_\ast(Y_g, \gamma,g,d|\Sigma)$ is 1-dimensional. The following pairs from subsection 3.2 define cobordisms from two copies of $(Y_g, \gamma,g,d)$ to the empty pair:

$$(\Omega_g, \omega_{g,d}) \quad (\Delta_g \coprod \Delta_g, \delta_{g,d} \coprod \delta_{g,d}).$$

Therefore, they determine two functionals $D_{\Omega_g,\omega_{g,d}}(1)$ and $D_{\Delta_g,\delta_{g,d}}(1) \otimes D_{\delta_{g,d}}(1)$ on the 1-dimensional vector space $I_\ast(Y_g, \gamma,g,d|\Sigma) \otimes I_\ast(Y_g, \gamma,g,d|\Sigma)$. The non-degeneracy of the exhaustive eigenvector involved in the definition of $I_\ast(Y_g, \gamma,g,d|\Sigma)$ implies that the former functional is non-zero. Therefore, we have the following lemma which provides the distinguishing property of working with a non-degenerate exhaustive eigenspace for us:

**Lemma 5.12.** The map $D_{\Delta_g,\delta_{g,d}}(1) \otimes D_{\delta_{g,d}}(1) : I_\ast(Y_g, \gamma,g,d|\Sigma) \otimes I_\ast(Y_g, \gamma,g,d|\Sigma) \to C$ is a multiple of $D_{\Omega_g,\omega_{g,d}}(1) : I_\ast(Y_g, \gamma,g,d|\Sigma) \otimes I_\ast(Y_g, \gamma,g,d|\Sigma) \to C$.

### 5.2 Excision and Sutured Manifolds Invariants

Suppose $R_1$ and $R_2$ are two embedded surfaces of genus $g \geq 1$ in a 3-manifold $Y$. Suppose also there is a 1-cycle $\gamma$ in $Y$ such that $\gamma \cdot R_1 = \gamma \cdot R_2$. We also assume $\gamma$ intersects $R_1$ and $R_2$ transversally and all the intersection points have the same sign. Fix a diffeomorphism $\phi : R_1 \to R_2$ such that $\phi$ maps $\gamma \cap R_1$ to $\gamma \cap R_2$. Then we cut $Y$ along the surfaces $R_1$, $R_2$, and then identify the four boundary components of the resulting 3-manifold using $\phi$ such that the final 3-manifold, $\tilde{Y}$, is an oriented closed 3-manifold with embedded surfaces $\tilde{R}_1$ and $\tilde{R}_2$. Our assumption on $\phi$ implies that $\gamma$ determines a 1-cycle $\tilde{\gamma}$ in $\tilde{Y}$. We will also write $R$ (respectively $\tilde{R}$) for the union $R_1 \cup R_2$ (respectively, $\tilde{R}_1 \cup \tilde{R}_2$). Now we are ready to state our excision theorem:

**Theorem 5.13.** The following Floer homology groups are isomorphic:

$$I_\ast(Y, \gamma|R) = I_\ast(\tilde{Y}, \tilde{\gamma}|	ilde{R})$$

*Proof.* This theorem is the analogue of excision theorem for $U(2)$-instanton Floer homology. The $U(2)$ version of the excision theorem is proved in [29] for $g = 1$ (see also [9]) and in [58] for higher values of $g$. We follow the same strategy as in the $U(2)$ case to prove the theorem. In particular, the isomorphism between $I_\ast(Y, \gamma|R)$ and $I_\ast(\tilde{Y}, \tilde{\gamma}|	ilde{R})$ is induced by a cobordism of pairs $(W, w) : (Y, \gamma) \to (\tilde{Y}, \tilde{\gamma})$. Let $Y^\circ$ be the complement of a regular neighborhood of $R$ in $Y$. Then the cobordism $W$ is the result of gluing $[0, 1] \times Y^\circ$ and $P \times R_1$ where $P$ is the saddle cobordism in Figure 5. The boundary of the 3-manifold $Y^\circ$ is equal to $R_1 \cup \tilde{R}_1 \cup R_2 \cup \tilde{R}_2$. Then $[0, 1] \times (R_1 \cup \tilde{R}_1) \subset [0, 1] \times Y^\circ$ is glued to $\partial^\circ P \times R_1$ by the identity map and $[0, 1] \times (R_2 \cup \tilde{R}_2) \subset [0, 1] \times Y^\circ$ is glued to $\partial^\circ P \times R_1$ by the map $\phi$. (For the definition of $\partial^\circ P$ and $\partial^\circ P$ see Figure 5.) The surface cobordism $w : \gamma \to \tilde{\gamma}$ is also constructed in a similar way. This surface is given by gluing one copy of $P$ for each intersection point in $\gamma \cap R_1$ to $[0, 1] \times (\gamma \cap Y^\circ)$. Reversing the cobordism $(W, w)$ determines another cobordism $(\tilde{W}, \tilde{w}) : (\tilde{Y}, \tilde{\gamma}) \to (Y, \gamma)$. In order to prove the excision theorem, we claim that:

$$I_\ast(\tilde{W}, \tilde{w}) \circ I_\ast(W, w) : I_\ast(Y, \gamma|R) \to (Y, \gamma|R), \quad I_\ast(\tilde{W}, \tilde{w}) \circ I_\ast(W, w) : I_\ast(\tilde{Y}, \tilde{\gamma}|	ilde{R}) \to (\tilde{Y}, \tilde{\gamma}|	ilde{R})$$

are non-zero multiples of the identity map. In the composite cobordism $\tilde{W} \circ W : Y \to Y$, a copy of $P \times R_1$ is glued to another copy of $P \times R_1$ with the reverse orientation. In this part of $\tilde{W} \circ W$, the
union of the two copies of $\delta \times R_1$ gives rise to a copy of $Y_g := S^1 \times R_1$. The intersection of $\overline{w} \circ w$ with $S^1 \times R_1$ produces a copy of $\gamma_{g,d}$. According to Lemma 5.12 and functoriality of $I_*$, replacing a neighborhood of $S^1 \times R_1$ with $p \cdot g \leq g, g,d \leq g,d \cdot q$ does not change the map $I_*(\overline{W} \circ W, \overline{w} \circ w)$, up to multiplication by a constant number. But the resulting cobordism of the pair is the product cobordism $pr_0, pr_1 \pi_Y, pr_0, pr_1 \pi_R$. Therefore, the first map in (5.14) is a non-zero multiple of the identity map.

The following proposition is the analogue of Corollary 4.8 in [58] and can be proved in a similar way using the excision theorem:

**Proposition 5.15.** Let $Y$ be a 3-manifold, $\gamma$ be a 1-cycle in $Y$, and $R \subset Y$ be a connected surface of genus $g \geq 1$ such that $\gamma \cdot R \neq 0 \mod 3$ and the intersection points of $\gamma \cap R$ are transversal and have the same signs. Let $\tilde{Y}$ be the 3-manifold obtained by cutting $Y$ along $R$ and regluing by an orientation preserving diffeomorphism $\phi : R \to R$. Suppose $\phi$ maps $R \cap \gamma$ to $R \cap \gamma$, and $\tilde{\gamma}, \tilde{R}$ are the induced 1-cycle and the embedded surface in $\tilde{Y}$. Then

$$I(Y, \gamma|R) \cong I(\tilde{Y}, \tilde{\gamma}|R).$$

Now we can define invariants for balanced sutured manifolds almost verbatim from [58]. Firstly we recall the definition of balanced sutured manifolds (cf. [36, 47, 58]):

**Definition 5.16.** A sutured manifold $(M, \alpha)$ consists of an oriented 3-manifold $M$, an oriented closed 1-manifold $\alpha$ in $\partial M$ and a decomposition of $\partial M$ as:

$$\partial M = R_+ \cup A(\alpha) \cup R_-.$$  \hspace{1cm} (5.17)

Each connected component of $\alpha$ is called a suture and $A(\alpha)$ is the closure of a tubular neighborhood of $\alpha$. The spaces $R_+$ and $R_-$ are disjoint and each of them is a union of some of the connected components of $\overline{M \setminus A(\alpha)}$. In particular, each component of $\partial R_+$ and $\partial R_-$ is a parallel copy of a suture. Suppose
$R_+$ and $R_-$ are oriented with the outward-normal-first convention. Similarly, each component of $\partial R_+$ (respectively, $\partial R_-$) inherits an orientation from $R_+$ (respectively, $R_-$). This orientation is required to agree (respectively, disagree) with the orientation of the corresponding suture. The sutured manifold $(M, \alpha)$ is balanced if neither $M$ nor $R_{\pm}$ has closed components, and $\chi(R_+) = \chi(R_-)$. We also require that $R_+$ and $R_-$ are not a union of 2-dimensional discs.

The last condition on balanced sutured manifolds is not standard and we fix it here for our convenience.

**Example 5.18.** Suppose $F_{g,k}$ is a surface of genus $g$ with $k \geq 1$ boundary components which is not the 2-dimensional disc. Then $([-1, 1] \times F_{g,k}, \partial F_{g,k} \times \{0\})$ determines a balanced sutured manifold. The decomposition of the boundary of this product sutured manifold is given as below:

$$R_+ = \{1\} \times F_{g,k}, \quad A(\alpha) = [-1, 1] \times \partial F_{g,k}, \quad R_- = \{-1\} \times F_{g,k}. \quad (5.19)$$

**Example 5.20.** Suppose $Y$ is a 3-manifold and $K \subset Y$ is a knot. Let $M(K)$ be the complement of a regular neighborhood of $K$ in $Y$, and $\alpha(K)$ be the union of two oppositely oriented meridional curve on the boundary of $M(K)$. Then $(M(K), \alpha(K))$ determines a balanced sutured manifold. The manifolds $R_+$ and $R_-$ are homeomorphic to $[0, 1] \times S^1$.

Given a balanced sutured manifold $(M, \alpha)$, we attach the product sutured manifold $([-1, 1] \times F_{0,k}, \{0\} \times \partial F_{0,k})$ to $(M, \alpha)$ where $k$ is the number of sutures of $(M, \alpha)$. More precisely, we glue $M$ to $[-1, 1] \times F_{0,k}$ by identifying $A(\alpha)$ with $[-1, 1] \times \partial F_{0,k}$ using an orientation reversing map. The resulting manifold is oriented and has two boundary components which are given as below:

$$\bar{R}_+ = R_+ \cup \{1\} \times F_{0,k}, \quad \bar{R}_- = R_- \cup \{-1\} \times F_{0,k}.$$

Since $(M, \alpha)$ is balanced, the oriented surfaces $\bar{R}_+$ and $\bar{R}_-$ have the same positive genus. We choose an orientation reversing diffeomorphism $\phi : \bar{R}_+ \to \bar{R}_-$. Identifying $\bar{R}_+$ and $\bar{R}_-$ using the map $\phi$ determines a closed 3-manifold $Y_\phi$ which is called a closure of the sutured manifold $(M, \alpha)$. The 3-manifold $Y_\phi$ only depends on $(M, \alpha)$ and the choice of the diffeomorphism $\phi$. The surface $\bar{R}_+$ also induces an oriented surface in $Y_\phi$ which is denoted by $\bar{R}$. We also fix a point $y$ on $F_{0,k}$ and require that $\phi$ maps $(1, y) \in \bar{R}_+$ to $(-1, y) \in \bar{R}_-$. Therefore, the path $[-1, 1] \times \{y\} \subset [-1, 1] \times F_{0,k}$ induces a 1-cycle in $Y_\phi$.

**Definition 5.21.** The sutured instanton homology of the sutured manifold $(M, \alpha)$ is defined as

$$\text{SHI}_*(M, \alpha) := L_*(Y_\phi, \gamma|\bar{R}).$$

Proposition 5.15 implies that sutured instanton homology $\text{SHI}_*$ is well-defined.

**Remark 5.22.** In the definition of a closed of the sutured manifold $(M, \alpha)$, we can replace $F_{0,k}$ with $F_{g,k}$ for an arbitrary $g$. Then for each choice of $g$, we can define a sutured Floer homology group as above. In fact, if $g \geq 1$, then we do not require that $R_{\pm} \subset \partial M$ is not a union of discs. Using our excision theorem and the method of [58], we can show that the rank of these sutured Floer homology groups is increasing in $g$. In fact, we expect that these sutured Floer homology groups for various choices of $g$ are isomorphic to each other. However, proving this seems to need a further study the algebra $W_{g,1}$. We hope to come back to this issue elsewhere.
5.3 Instanton Knot Homology

Given a knot \( K \) in a 3-manifold \( Y \), let \( (M(K), \alpha(K)) \) be the sutured manifold of Example 5.20:

**Definition 5.23.** Given a knot \( K \) in a 3-manifold \( Y \), the U(3)-Knot homology, denoted by \( \text{KHI}_*(Y, K) \), is defined to be \( \text{SHI}_*(M(K), \alpha(K)) \).

As it is explained in [58, Lemma 5.2], a closure of \( (M(K), \alpha(K)) \) can be described as follows. Suppose \( F \) is a genus 1 surface with one boundary component, and \( c, c' \subset F \) are two oriented non-separating simple closed curves which intersect in exactly one point and \( c \cdot c' = 1 \). Let \( Z(K) \) be the result of gluing the knot complement \( M(K) \) to the product 3-manifold \( F \times S^1 \) such that the meridian of \( K \) is identified with \( \{ \text{point} \} \times S^1 \) and the longitude of \( K \) is identified with \( \partial F \times \{ \text{point} \} \). Suppose also \( \gamma(K) \subset Z(K) \) is the 1-cycle given by \( c \times \{ \text{point} \} \subset F \times S^1 \). Then \( Z(K) \) is a closure of the sutured manifold \( (M(K), \alpha(K)) \) and \( \gamma(K) \) is the corresponding 1-cycle. The embedded surface \( \hat{R} \) is also given by the torus \( T = c' \times S^1 \subset F \times S^1 \). Consequently:

\[
\text{KHI}(Y, K) = I_*(Z(K), \gamma(K)|T)
\]

Next, we characterize the set of the critical points of the Chern-Simons functional associated to the pair \( (Z(K), \gamma(K)) \):

**Proposition 5.24.** For a knot \( K \) in a 3-manifold \( Y \), the set of the critical points of the Chern-Simons functional associated to the admissible pair \( (Z(K), \gamma(K)) \) is a 3-sheeted covering space of

\[
\mathcal{R} = \{ \rho : \pi_1(Y \setminus K) \to \text{SU}(3) \mid \rho(\mu) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \zeta & 0 \\ 0 & 0 & \zeta^2 \end{bmatrix} \}.
\]

Recall that \( \mu \) is a meridian of \( K \) and \( \zeta = e^{2\pi i/3} \).

**Proof.** The set of the critical points of the Chern-Simons functional is given by the conjugacy classes of representations \( \rho : \pi_1(Z(K) \setminus K) \to \text{SU}(3) \) such that a meridian of the closed curve \( \gamma(K) \) is mapped to \( \zeta \). We fix a base point for \( Z(K) \) on the torus \( c' \times S^1 \subset F \times S^1 \). Suppose \( J_1 = \rho(c' \times \{ \text{point} \}) \) and \( J_2 = \{ \text{point} \} \times S^1 \). Since \( c' \times S^1 \) intersects \( c \) in one point, we can assume:

\[
[J_2, J_1] = \zeta \cdot \text{id}.
\]

Therefore, there is a unique representative for the conjugacy class of \( \rho \) such that:

\[
J_1 = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad J_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \zeta & 0 \\ 0 & 0 & \zeta^2 \end{bmatrix}
\]

Therefore, the conjugacy class of the representation \( \rho|_{\pi_1(F \times S^1 \setminus \gamma(K))} \) is uniquely determined by \( J_3 \in \text{SU}(3) \) which is equal to the image of \( \rho \) for a parallel copy of \( c \). Since \( J_3 \) has to commute with \( J_2 \) it is a diagonal matrix. Therefore, the restriction of the above representative of \( \rho \) to the knot group \( \pi_1(M(K)) \) determines an element of \( \mathcal{R} \). Furthermore, \( \rho \) maps the longitude of \( K \) to \([J_3, J_1]\). Now the claim can be easily verified, because the map that sends a diagonal matrix \( J_3 \) to \([J_3, J_1]\) is 3 to 1. \( \Box \)
If $K$ is a knot in $S^3$, we simplify the notation and write $\text{KHI}(K)$ for the instanton knot homology of $K$. For the unknot $U$, $(Z(U), \gamma(U))$ is equal to $(S^3, S^1 \times \{y_2\} \times \{y_3\})$ and $R = \{x_1\} \times T^2$. Therefore $\text{KHI}(U) = C$. The characterization of the representation variety in Proposition 5.24 implies that:

**Corollary 5.25.** Suppose $K$ is a knot in $S^3$. If $\dim(\text{KHI}(K)) > 1$, then there exists a non-abelian representation $\rho : \pi_1(S^3 \setminus K) \to \text{SU}(3)$ such that the image of the meridian is conjugate to

$$
\begin{bmatrix}
1 & 0 & 0 \\
0 & \zeta & 0 \\
0 & 0 & \zeta^2
\end{bmatrix}
$$

**Proof.** Suppose there is not a representation with this property. Then the Chern-Simon functional of the pair $(Z(K), \gamma(K))$ has three irreducible and non-degenerate critical points associated to the abelian element of (5.24). Therefore, $I_{\sigma}(Z(K), \gamma(K))$ is the homology of a chain complex which has three generators. Since the order three map $\epsilon$ has degree 4 with respect to the $\mathbb{Z}/12\mathbb{Z}$ grading, the three eigenspaces of this operator has the same dimensions. Therefore, $\ker(\epsilon - 1)$ has to be at 1-dimensional, which is a contradiction. \qed

Therefore, if the following conjecture holds, then the answer to Question 1.1 is positive for any non-trivial knot and $N = 3$:

**Conjecture 5.26.** If $K$ is a non-trivial knot in $S^3$, then $\dim(\text{KHI}(K)) > 1$.

## 6 Gluing Theory

### 6.1 Moduli Spaces on Manifolds with Long Neck

Suppose $Y$ is a connected 3-manifold and $\gamma \subset Y$ is a (not necessarily admissible) cycle in $X$. Suppose also $(X, w)$ is a pair with boundary $(Y, \gamma)$. As it is explained in subsection 2.2, we can form moduli spaces $\mathcal{M}_p(X, w)$ and their framed counterparts $\widetilde{\mathcal{M}}_p(X, w)$ by working with perturbations of the ASD equation. Uhlenbeck compactness theorem of subsection 2.1 has an analogue for 4-manifolds with cylindrical ends. A proof of this result for $N = 2$ is given in [20, Chapter 5], and it can be extended to the higher rank by following the arguments of [56]:

**Theorem 6.1.** Suppose $\{[A_i]\}_{i \in \mathbb{N}}$ is a sequence of connections in the moduli space $\widetilde{\mathcal{M}}_p(X, w)$. Then there is an element $([B], [C_1], \ldots, [C_k])$ of the following space

$$
\widetilde{\mathcal{M}}_{p_0}(X, w; \alpha_0) \times_{\Gamma_{\alpha_0}} \widetilde{\mathcal{M}}_{p_1}(\alpha_0, \alpha_1) \times_{\Gamma_{\alpha_1}} \cdots \times_{\Gamma_{\alpha_{k-1}}} \widetilde{\mathcal{M}}_{p_k}(\alpha_{k-1}, \alpha_k)
$$

(6.2)

and an element $(x, y_1, \ldots, y_k)$ of the space:

$$(X^+)^{m_0}/S_{m_0} \times (Y \times \mathbb{R})^{m_1}/S_{m_1} \times \cdots \times (Y \times \mathbb{R})^{m_k}/S_{m_k}
$$

(6.3)

for appropriate non-negative integer numbers $m_i$ such that $\{[A_i]\}_{i \in \mathbb{N}}$, after passing to a sequence is weakly chain convergent to $(([B], x), ([C_1], y_1), \ldots, ([C_k], y_k))$. Furthermore, we have:

$$
\kappa(p) = \kappa(p_0) + \kappa(p_1) + \cdots + \kappa(p_k) + m_0 + m_1 + \cdots + m_k
$$

(6.4)
Note that \( \widetilde{\mathcal{M}}_q(\alpha, \beta) \) is the moduli space of framed connections associated to a path \( p : \alpha \rightarrow \beta \) over \( (Y \times \mathbb{R}, \gamma \times \mathbb{R}) \). This moduli space is equipped with an action of \( \Gamma_\alpha \times \Gamma_\beta \). The weakly chain convergence of \( \{A_i\}_{i \in \mathbb{N}} \) to \( \{([B], x), ([C_1], y_1), \ldots, ([C_k], y_k)\} \) means that the following holds [20]: the sequence \( \{[A_i]\}_{i \in \mathbb{N}} \) is \( L_1^p \)-convergent to \( [B] \) on compact sets in \( X \setminus x \). Moreover, there is a sequence of real numbers:

\[
0 < t_1^i < \cdots < t_k^i
\]

with \( \lim_{i \to \infty} t_i^j = \infty \) such that the translation of \( A_i|_{Y \times [0, \infty)} \) by the constant \( t_i^j \) is \( L_1^p \) convergent to \( C_j \) on compact sets of \( Y \times \mathbb{R} \setminus y_j \). Identity (6.4) implies that:

\[
\text{index}(\mathcal{D}_{A_i}) \geq \text{index}(\mathcal{D}_{B_1}) + \text{index}(\mathcal{D}_{C_1}) + \cdots + \text{index}(\mathcal{D}_{C_k}) \quad (6.5)
\]

and the two sides of the inequality are also equal to each other mod \( 4N \). In (6.5), equality holds if and only if the integer numbers \( m_j \) are all zero, and in this case, \( L_1^p \) convergence on compact sets can be improved to \( C^\infty \) convergence.

**Remark 6.6.** Theorem 6.1 can be extended to the case that \( W \) has more than one boundary components in an obvious way. In this case, we need to fix a chain of the elements of moduli spaces for each boundary component.

There is another compactness theorem we need to review, in which we stretch a 4-manifold along a neck and consider the associated moduli spaces. Suppose \((X_1, w_1)\) and \((X_2, w_2)\) is a pair whose boundaries are \((Y, \gamma)\) and \((\bar{Y}, \bar{\gamma})\), respectively. Then we can glue these pairs to form \((X, w)\). We also fix Riemannian metrics on \(X_i\) which are product metrics in neighborhoods of their boundaries associated to a fixed metric on \(Y\). These metrics induce a metric on \(X\) which has an isometric copy of \(Y \times (-T, T)\) as a neck along \(Y\). We will denote this Riemannian manifold by \(X^T\). The proof of the following theorem is similar to that of Theorem 6.1.

**Theorem 6.7.** Suppose \(A_i\) is a connection on the moduli space \(\mathcal{M}_k(X^T, w)\) such that \(\lim_{i \to \infty} T_i = \infty\). Then there is an element \(([B_1], [C_1], \ldots, [C_k], [B_2])\) of

\[
\widetilde{\mathcal{M}}_p(X_1, w_1; \alpha_0) \times_{\Gamma_{\alpha_0}} \widetilde{\mathcal{M}}_{p_1}(\alpha_0, \alpha_1) \times_{\Gamma_{\alpha_1}} \cdots \times_{\Gamma_{\alpha_{k-1}}} \widetilde{\mathcal{M}}_{p_k}(\alpha_{k-1}, \alpha_k) \times_{\Gamma_{\alpha_k}} \widetilde{\mathcal{M}}_{p'}(X_2, w_2; \alpha_k) \quad (6.8)
\]

and an element \((x_1, y_1, \ldots, y_k, x_2)\) of the space:

\[
(X_1^+)^{m_0}/S_{m_0} \times (Y \times \mathbb{R})^{m_1}/S_{m_1} \times \cdots \times (Y \times \mathbb{R})^{m_k}/S_{m_k} \times (X_2^+)^{m_{k+1}}/S_{m_{k+1}} \quad (6.9)
\]

such that \(\{A_i\}_{i \in \mathbb{N}}\) is weakly chain convergent to \(\{([B_1], x_1), ([C_1], y_1), \ldots, ([C_k], y_k), ([B_2], x_2)\}\). Moreover, we have:

\[
\kappa = \kappa(p) + \kappa(p_1) + \cdots + \kappa(p_k) + \kappa(p') + m_0 + m_1 + \cdots + m_k + m_{k+1} \quad (6.10)
\]

The following gluing theorem can be regarded as an inverse to Theorem 6.7. There are various places in the literature that similar gluing theorems are discussed [80, 69, 20, 57]. Theorem 6.11 can be proved with similar strategies (see e.g. [20, Theorem 4.17 and Section 4.7.1]):
**Theorem 6.11.** Let \((X_i, w_i)\) be given as above. For \(1 \leq i \leq k\), let \(p_i : \alpha_{i-1} \to \alpha_i\) be a path on \((Y \times \mathbb{R}, w \times \mathbb{R})\), and let \(\tilde{N}_i\) be a compact \((\Gamma_{\alpha_{i-1}} \times \Gamma_{\alpha_i})\)-invariant subspace of \(\tilde{\mathcal{M}}_{p_i}(\alpha_{i-1}, \alpha_i)\), which consists of regular points. Suppose also we are given two other compact spaces as below, which contain only regular points and are respectively invariant with respect to the action of \(\Gamma_{\alpha_0}\) and \(\Gamma_{\alpha_k}\):

\[
\tilde{N}_0 \subset \tilde{\mathcal{M}}_p(X_1, w_1; \alpha_0) \quad \tilde{N}_{k+1} \subset \tilde{\mathcal{M}}_{p'}(X_2, w_2; \alpha_k)
\]

Then there is a space \(\tilde{U}_i\) containing \(\tilde{N}_i\), which is an open subset of the relevant moduli space and is invariant with respect to the action of the relevant group. Moreover, for large enough values of \(T\), there is a gluing map:

\[
\Phi_T : \tilde{U}_0 \times_{\Gamma_{\alpha_0}} \tilde{U}_1 \times_{\Gamma_{\alpha_1}} \cdots \times_{\Gamma_{\alpha_k}} \tilde{U}_{k+1} \to \mathcal{M}_\kappa(X^T, w)
\]

where:

\[
\kappa = \kappa(p) + \kappa(p_1) + \cdots + \kappa(p_k) + \kappa(p').
\]

(6.12)

**Remark 6.13.** Theorem 6.7 is strong enough to study the cut-down moduli spaces on a 4-manifold with a long neck. To demonstrate this in the context of an example, suppose \((X_i, w_i)\) is as above and \(b^+(X_i) \geq 1\). Let \(\Sigma\) be an embedded surface in \(X_1\). Let \(\nu(\Sigma) \subset X_1\) be an open neighborhood of \(\Sigma\) such that the inclusion of \(\nu(\Sigma)\) in \(X_1\) induces a surjection of fundamental groups. Let \(\kappa\) be chosen such that \(\mathcal{M}_\kappa(X^T, w)\) has expected dimension two. We make the simplifying assumption that all critical points of the Chern-Simons functional on \((Y, w)\) are irreducible and non-degenerate, and all the moduli spaces on \(Y \times \mathbb{R}\) are regular. We form the moduli spaces \(\mathcal{M}_\kappa(X_i, w_i; \alpha)\) by choosing small holonomy perturbations. By choosing these perturbations small enough, we can assume that the restriction of any element of \(\mathcal{M}_p(X_1, w_1, \alpha)\) to \(\nu(\Sigma)\) is irreducible. Therefore, we have a well-defined map from \(r : \mathcal{M}_p(X_1, w_1, \alpha) \times \Sigma \to B^*(\nu(\Sigma)) \times \nu(\Sigma)\). As in the first section, we can form a representative \(V_2(\Sigma)\), which is transversal to \(r\) for all choices of \(p\) that \(\dim(\mathcal{M}_p(X_1, w_1, \alpha)) \leq 2\). Suppose \(\mathcal{N}_p(X_1, w_1; \alpha, \Sigma)\) denotes the cut-down moduli space. The elements of the moduli space \(\mathcal{M}_\kappa(X^T, w)\) are chain convergent to the elements of the moduli spaces:

\[
\mathcal{M}_p(X_1, w_1; \alpha_0) \times \mathcal{M}_{p_1}(\alpha_0, \alpha_1) \times \cdots \times \mathcal{M}_{p_k}((\alpha_{k-1}, \alpha_k) \times \mathcal{M}_{p'}(X_2, w_2; \alpha_k).
\]

Thus for large enough values of \(T\), the space \(\mathcal{M}_\kappa(X^T, w) \times \Sigma\) is also cut-down transversely by \(V_2(\Sigma)\) and the resulting space is compact. Furthermore, the elements in the cut-down space \(\mathcal{N}_\kappa(X^T, w; \Sigma)\) are in correspondence with the elements of the following space:

\[
\bigcup_{\kappa(p_1) + \kappa(p_2) = \kappa} \mathcal{N}_{p_1}(X_1, w_1; \alpha, \Sigma) \times \mathcal{M}_{p_2}(X_2, w_2, \alpha).
\]

In the following, we use a similar strategy to study the cut-down moduli spaces on 4-manifolds with long necks, without going into details.
Theorem 6.14. Suppose \( X_1 \) and \( X_2 \) are two 4-manifolds with \( b^+(X_i) \geq 1 \). Then for any 2-cycle \( w \) in the connected sum \( X_1 \# X_2 \) and any \( z \in \mathbb{H}(X_1 \# X_2)^{\otimes 2} \), the number \( D_{X_1 \# X_2, w}(z) \) is equal to zero.

Proof. We can assume that \( w = w_1 \cup w_2 \) and \( z = z_1 \cdot z_2 \) where \( w_i \) is a 2-cycle in \( X_i \) and \( z_i \in \mathbb{H}(X_i)^{\otimes 2} \). By replacing \( X_i \), \( w_i \) and \( z_i \) with \( X_i \# \mathbb{CP}^2 \), \( w_i \cup E_i \) and \( z_i \cdot (E_i)^2_{(2)} \), we can also assume that \( w_i \) is coprime to \( N \). Here \( E_i \) is the exceptional class in \( X_i \# \mathbb{CP}^2 \). We fix a Riemannian metric on \( X_1 \# X_2 \) whose restriction to the connected sum region is isometric to the product metric \([-T, T] \times S^3\) where \( T \) is a large constant and \( S^3 \) has the standard metric. Using the standard metric on \( S^3 \) allows us to ensure that all the framed moduli spaces on the cylinder \( \mathbb{R} \times S^3 \) are regular. We can also use the ideas of [56] to fix a holonomy perturbation of the ASD equation on \( X_i \) such that the perturbation is supported outside of a neighborhood of the connected sum region, and the cut-down moduli spaces \( \mathcal{N}_p(X_i, w_i; \Theta, z_i) \) of dimension at most zero are regular. Here \( \Theta \) is the trivial connection, which is the only flat connection on \( S^3 \). Now we can use Theorem 6.11 to conclude that the 0-dimensional moduli space \( \mathcal{N}_\kappa(X_1 \# X_2, w_1 \cup w_2; z_1 \cdot z_2) \) is empty when \( T \) is large enough.

Next, we utilize the gluing and the compactness theorem to prove Proposition 3.43 on connected sums along \( \Sigma(2, 3, 23) \). Recall that in addition to the trivial connections, there are 44 irreducible and 8 \( SU(2) \)-reducible connections on the trivial \( SU(3) \)-bundle over \( \Sigma(2, 3, 23) \). All these connections are non-degenerate. We choose a perturbation of the Chern-Simons functional of \( \Sigma(2, 3, 23) \) (and the empty cycle) such that the critical points of the perturbed functional is the same as the Chern-Simons functional and the following assumption about the regularity of the elements of \([A] \in \mathcal{M}_p(\Sigma(2, 3, 23); \alpha, \beta)\) holds: if \( A \) is irreducible, then we require that \( A \) is regular and if \( A \) is reducible and induced by an \( SU(2) \)-connection, we require that \( A \) is regular as a solution of the (perturbed) ASD equation for \( SU(2) \)-connections [20, 60].

Suppose \( X_1 \) is a 4-manifold with \( b^+(X_1) \geq 1 \) and \( \partial X_1 = \Sigma(2, 3, 23) \). Suppose also \( w_1 \) is a closed 2-cycle in \( X_1 \) which is coprime to 3. Fix a metric with cylindrical ends on \( X_1 \) and a small holonomy perturbation of the ASD equation which is compatible with the perturbation of the Chern-Simons functional. Let \( \mathcal{M}_p(X_1, w_1; \alpha) \) be the moduli space of solutions to a perturbation of the ASD equation associated to the pair \( (X_1, w_1) \) and the path \( p \).

Proposition 6.15. Suppose \( \alpha \) is an irreducible flat \( SU(3) \)-connection on \( \Sigma(2, 3, 23) \) of degree 4. The metric and the perturbation of the ASD equation on \( X_1 \) can be chosen such that the moduli space \( \mathcal{M}_p(X_1, w_1; \alpha) \) consists of regular solutions and does not have any reducible connection. Suppose \( z_1 \in \mathbb{H}(X)^{\otimes 2} \) such that:

\[
d_{X_1, w_1} := -4w_1^2 - 4(\chi(X_1) + \sigma(X_1)) - 4 \equiv \deg(z_1) + 4 \mod 12.
\]

Suppose also \( p \) is a path that the expected dimension of \( \mathcal{N}_p(X_1, w_1; \alpha, z_1) \) is zero. Then for a generic choice of the geometric representative for \( z_1 \), the cut-down moduli space \( \mathcal{N}_p(X_1, w_1; \alpha, z_1) \) is compact.

Note that \( \mathcal{N}_p(X_1, w_1; \alpha, z_1) \) might be a linear combination of different spaces. Then compactness of this space is defined to be the compactness of all the involved spaces in the linear combination. In what follows, we gloss over this point about the nature of the spaces \( \mathcal{N}_p(X_1, w_1; \alpha, z_1) \).
Proof. We fix a metric and a perturbation of the ASD equation on $X_1$ which are compatible with the metric and the perturbation on $\Sigma(2, 3, 23)$. The arguments of [56] can be used to show that the metric and the perturbation can be chosen such that $M_p(X_1, w_1; \alpha)$ is regular and does not contain any reducible solution. Suppose the dimension of $M_p(X_1, w_1; \alpha)$ is equal to $\text{deg}(z_1)$, and $\{A_i\}_i$ is a sequence of connections in the cut-down moduli space $N_p(X_1, w_1; \alpha, z_1)$. By Theorem 6.1 this sequence converges to an element $([B], \{x\}, ([C_1], x), \ldots, ([C_k], y_k))$ where $[B] \in N_p(X_1, w_1; \alpha_0, z_1)$, $[C_i] \in \tilde{M}_{p_l}(\alpha_{i-1}, \alpha_i)$, $\alpha_k = \alpha$, and:

$$\text{deg}(z_1) \geq \text{index}(D_B) + \text{index}(D_{C_1}) + \cdots + \text{index}(D_{C_k}).$$

(6.16)

and the equality holds if and only if the multi-sets $x$, $y_1$, $y_k$ are empty. The connection $B$ is irreducible and $\text{index}(D_B) \geq \text{deg}(z_1)$. Similarly, if $C_i$ is irreducible, then $\text{index}(D_{C_i})$ is positive. In the case that $C_i$ is reducible, we cannot guarantee that $\text{index}(D_{C_i})$ is positive. However, the index of $D_{C_i}$ as an SU(2)-connection is positive. Using Table 5, it is straightforward to check that for such a reducible connection $C_i \in \tilde{M}_{p_l}(\mathbf{R} \times \Sigma(2, 3, 23); \alpha_{i-1}, \alpha_i)$, the flat connection $\alpha_i$ has to be $\beta_8$, and $\alpha_i$ is equal to either the trivial connection $\Theta$ or the SU(2)-connection $\beta_2$. In the first case, $\text{index}(D_{C_l})$ is equal to $-3$ and in the latter case $\text{index}(D_{C_l})$ is equal to $-2$. Suppose:

$$\{i_1, \ldots, i_l\} \subseteq \{0, \ldots, k - 1\}$$

is the set of indices such that $\alpha_{i_j} = \beta_8$. Firstly, assume that $l \geq 1$. The index formula (2.15) shows:

$$\text{index}(D_B) + \text{index}(D_{C_{i_1}}) + \cdots + \text{index}(D_{C_{i_l}}) \equiv d_{X_1, w_1} - 3 \equiv \text{deg}(z_1) + 1 \mod 12$$

(6.17)

and:

$$\text{index}(D_{C_{i_j+1}}) + \text{index}(D_{C_{i_{j+2}}}) + \cdots + \text{index}(D_{C_{i_{j+1}}}) \equiv 0 \mod 12$$

(6.18)

for $1 \leq j \leq k - 1$. In (6.17), the first term on the left hand side is not less than $\text{deg}(z_1)$, the last term is not less than $-3$, and the remaining terms are positive. Therefore, the sum on the left hand side is not less than $\text{deg}(z_1) + 1$. In (6.17), the last term is at least $-3$ and the other terms are positive. Therefore, the sum in (6.17) is non-negative. The following sum of the remaining terms consists of positive terms:

$$\text{index}(D_{C_{i_{j+1}}}) + \text{index}(D_{C_{i_{j+2}}}) + \cdots + \text{index}(D_{C_{k}}).$$

Therefore, the right hand side of (6.16) is at least $\text{deg}(z_1) + 1$ which is a contradiction and as a result $l = 0$. Therefore, in (6.16), $\text{index}(D_{C_l})$ is always positive. This also implies that $k = 0$ and $x$ is empty. Consequently, $N_p(X_1, w_1; \alpha, z_1)$ is compact. 

Form the moduli spaces $M_p(X_1, w_1; \alpha)$ with the perturbations from Proposition 6.15, and define the following element of $I_4(\Sigma(2, 3, 23))$:

$$D_{X_1, w_1}(z_1) := \sum \#N_p(X_1, w_1; \alpha, z_1) \cdot \alpha$$

(6.19)

where the sum is over all irreducible connections $\alpha$ in $\Sigma(2, 3, 23)$ and the paths $p$ such that:

$$N_p(X_1, w_1; \alpha, z_1)$$

(6.20)
is 0-dimensional. Here we follow the standard conventions to orient (6.20) [60, 56]. Since \( N = 3 \), we do not need a homology orientation of \( (X_1, w_1) \) to fix a sign for \( D_{X_1,w_1}(z_1) \).

Next, let \( X_2 \) be a 4-manifold with \( b^+(X_2) \geq 1 \) and \( \partial X_2 = \Sigma(2, 3, 23) \). Let also \( w_2 \) be a closed 2-cycle in \( X_2 \) which is coprime to 3. Fix a metric with cylindrical ends on \( X_2 \) and a small holonomy perturbation of the ASD equation which is compatible with the perturbation of the Chern-Simons functional:

**Proposition 6.21.** Suppose \( \alpha \) is an irreducible connection on \( \Sigma(2, 3, 23) \). The metric and the perturbation of the ASD equation on \( X_2 \) can be chosen such that the moduli space \( \mathcal{M}_p(X_2, w_2; \alpha) \) consists of regular solutions and contains no reducible connection. Suppose \( z_2 \in \mathbb{A}(X)^{\otimes 2} \) such that \( \deg(z) \) is divisible by 4. Then for a generic choice of \( V(z_2) \), the 0-dimensional cut down moduli spaces \( \mathcal{N}_p(X_2, w_2; \alpha, z_2) \) are compact.

The proof of this proposition is analogous to that of Proposition 6.15, and we leave it to the reader. The cut-down moduli spaces in Proposition 6.21 can be used to define the following functional on \( I_*(\Sigma(2, 3, 23)) \):

\[
D^{X_2,w_2}(z_2)(\alpha) := \#\mathcal{N}_p(X_2, w_2; \alpha, z_2)
\]

(6.22)

where \( \alpha \) is an irreducible connection on \( \Sigma(2, 3, 23) \) and the path \( p \) is chosen such that \( \mathcal{N}_p(X_2, w_2; \alpha, z_2) \) is 0-dimensional. The index formula shows that the space (6.20) is 0-dimensional only if:

\[
\deg(\alpha) = 4w_2^2 + 4(\chi(X_2) + \sigma(X_2)) - 4 + \deg(z_2).
\]

(6.23)

Therefore, \( D^{X_2,w_2}(z_2) \) is non-zero on the elements of \( I_*(\Sigma(2, 3, 23)) \) that satisfy (6.23).

**Proposition 6.24.** For \( i = 1, 2 \), suppose \( (X_i, w_i) \) and \( z_i \) are as in Propositions 6.15 and 6.21. Then:

\[
D_{X_1\circ X_2,w_1\cup w_2}(z_1 \cdot z_2) = D^{X_2,w_2}(z_2) \circ D_{X_1,w_1}(z_1)
\]

(6.25)

**Proof.** Use Propositions 6.15 and 6.21 to fix metrics on \( X_1 \) and \( X_2 \). Let also \( X_1 \circ X_2 \) be equipped with a Riemannian metric, which is compatible with the metrics on \( X_1, X_2 \) and has a long neck along \( \Sigma(2, 3, 23) \). The perturbations of the ASD equation in these propositions also induce a perturbation of the ASD equation on \( X_1 \circ X_2 \). By applying Theorem 6.11 and the similar arguments as in the proof of Proposition 6.15, we can conclude that, for a long enough neck along \( \Sigma(2, 3, 23) \), we have the following diffeomorphism of 0-dimensional moduli spaces:

\[
\mathcal{N}_\kappa(X_1 \circ X_2, w_1 \cup w_2, z_1 \cdot z_2) \cong \bigcup_{\alpha} \mathcal{N}_{p_1}(X_1, w_1; \alpha, z_1) \times \mathcal{N}_{p_2}(X_2, w_2; \alpha, z_2).
\]

Here \( \alpha \) is an irreducible connection on \( \Sigma(2, 3, 23) \), and \( \kappa, p_1 \) and \( p_2 \) are chosen such that all the above cut down moduli spaces are 0-dimensional. Standard arguments show that the above diffeomorphism is compatible with respect to the orientation of the involved moduli spaces. This diffeomorphism imply the claim in (6.25).

This proposition essentially proves Theorem 3.43 from subsection 3.4. We only need to extend the above proposition to the case that \( w_1 \) and \( w_2 \) are not necessarily coprime to 3 and \( \deg(z_2) \) is not divisible by 4. The assumption on \( w_i \) can be removed by the blowing up trick. The dimension of the moduli space of rank 3 instantons on the closed 4-manifold \( X_1 \circ X_2 \) is always divisible by 4. Therefore, if we define \( D^{X_2,w_2}(z_2) = 0 \) in the case that \( \deg(z_2) \neq 0 \mod 4 \), then the above theorem still holds.
### 6.2 Gluing Theory for Negative Embedded Spheres

In this subsection, we give a proof of Proposition 2.20 based on the techniques which are discussed in subsection 6.1. Suppose \( X \) is a smooth 4-manifold with \( b^+(X) \geq 2 \). Suppose also \( \sigma \) is an embedded sphere in \( X \) with \( \sigma \cdot \sigma = -3 \). A tubular neighborhood of \( \sigma \), denoted by \( Z \), is a disc bundle over \( \sigma \) with Euler class \(-3\) and the boundary \( Y = \partial(3,-1) \). Thus \( X \) can be split as \( Z \circ X_1 \) where \( X_1 \) is the complement of \( Z \). We will also write \( w_0 \) for a fiber of the disc bundle \( Z \). Fix the orientation on \( w_0 \) such that \( w_0 \) intersects \( \sigma \) negatively in one point.

Fix a Riemannian metric with cylindrical end on \( Z \). Let also \( L \) be the complex line bundle over \( Z \) associated to the 2-cycle \( w_0 \). Since \( b^+(Z) = b^1(Z) = 0 \), there is a unique ASD connection on \( L \) with finite energy. This connection, denoted by \( B \), is asymptotic to a flat connection \( \chi \) which maps the generator of \( \pi_1(Y) \) to \( \zeta = e^{2\pi i/3} \). Consider the ASD \( U(N) \)-connection \( A := B^{k_1} \oplus \cdots \oplus B^{k_N} \), asymptotic to the flat connection \( \alpha := \chi^{k_1} \oplus \cdots \oplus \chi^{k_N} \). The first Chern class of the underlying \( U(N) \)-connection is equal to \( (k_1 + \cdots + k_N)P.D.[w_0] \). The topological energy of \( A \) is given by the following formula:

\[
\kappa(A) = \frac{1}{12N} \sum_{1 \leq i,j \leq N} (k_i - k_j)^2.
\]

Therefore, we can use (2.15) to compute the index of \( D_A \). In particular, if \(|k_i - k_j| \leq 3\) for all \( i, j \), then (2.15) shows that:

\[
\text{index}(D_A) = 1 - N^2 + \sum_{1 \leq i,j \leq N} |k_i - k_j|
\]

The following table consists of various choices of \( U(3) \)-connections. For each connection \( A \), the first Chern class of the underlying bundle of \( A \) is equal to \( kP.D.[w_0] \) where \( k \) is in the following table:

| \( A \) | \( \alpha \) | \( c_1(A) \) | \text{index}(D_A) | \text{dim}(\tilde{M}(A)) | \Gamma_\alpha |
|---|---|---|---|---|---|
| \( B^{-2} \oplus 1 \oplus 1 \) | \( \chi \oplus 1 \oplus 1 \) | \(-2\) | \( 0 \) | \( 4 \) | \( S(U(1) \times U(2)) \) |
| \( B^{-1} \oplus B^{-1} \oplus 1 \) | \( \chi^{-1} \oplus \chi^{-1} \oplus 1 \) | \(-2\) | \( -4 \) | \( 0 \) | \( S(U(2) \times U(1)) \) |
| \( B \oplus 1 \oplus 1 \) | \( \chi \oplus 1 \oplus 1 \) | \( 1 \) | \(-4 \) | \( 0 \) | \( S(U(1) \times U(2)) \) |
| \( B^{-1} \oplus B \oplus B \) | \( \chi^{-1} \oplus \chi \oplus \chi \) | \( 1 \) | \( 0 \) | \( 4 \) | \( S(U(1) \times U(2)) \) |

We will write \( M(A) \) (respectively, \( \tilde{M}(A) \)) for the moduli space (respectively, the framed moduli space) of connections on \( Z \) corresponding to the path which is represented by \( A \). From now on, we assume that an anti-self-dual metric with positive scalar curvature is fixed on \( Z \) [63, 62].

**Proposition 6.26.** For each \( A \) in this table, \( A \) has the minimal topological energy among all ASD connections with the same limiting flat connection as \( A \) and the same \( c_1 \).

**Proof.** If there is an ASD connection \( A' \) with a smaller topological energy, then \( \text{dim}(\tilde{M}(A)) - \text{dim}(\tilde{M}(A')) \) is at least 12. On the other hand, any such connection is regular. Therefore, the dimension of \( \tilde{M}(A') \) is at least \( \text{dim}(\Gamma_\alpha) - \text{dim}(\Gamma_\alpha') \). This can be used to rule out the existence of \( A' \). \( \square \)
We study the moduli spaces \( \widetilde{M}(A) \) for various choices of \( A \). In the case \( A = B^{-1} \oplus B^{-1} \oplus 1 \), the moduli space has only the completely reducible connection \( A \). Because if \( A' \) is an element of this moduli space, then the dimension of the framed moduli space is at least \( \dim(\Gamma_n) - \dim(\Gamma_{n'}) \). Similarly, if \( A = B \oplus 1 \oplus 1 \), then the moduli space consists of a single point. In fact, taking tensor product with the complex line bundle \( L \), equipped with the connection \( B \), maps the former moduli space to the latter one.

Next we turn to the case that \( A = B^{-2} \oplus 1 \oplus 1 \). There are three types of connections in this space:

- irreducible connections;
- the complete reducible connection \( A = B^{-2} \oplus 1 \oplus 1 \);
- reducible connection \( R \oplus B^r \), where \( R \) is an irreducible \( U(2) \)-connection.

The connection \( R \) in the last part belongs to one of the moduli spaces \( \mathcal{M}(1 \oplus 1) \) and \( \mathcal{M}(B^{-2} \oplus 1) \). Since the dimension of \( \mathcal{M}(1 \oplus 1) \) is \(-3\), this moduli space does not contain any irreducible connection. Therefore, \( r = 0 \) and \( R \) is an irreducible element of the 1-dimensional moduli space \( \mathcal{M}(B^{-2} \oplus 1) \).

**Proposition 6.27.** The unique component of \( \mathcal{M}(B^{-2} \oplus 1) \) containing \( B^{-2} \oplus 1 \) is a half-line \([0, \infty)\). All the other components are either circles or copies of \( \mathbb{R} \) consisting of only irreducible connections. The corresponding components of \( \widetilde{M}(B^{-2} \oplus 1 \oplus 1) \) are \( \mathbb{C}^2 \), \( S^3 \times S^1 \) and \( S^3 \times \mathbb{R} \).

**Proof.** The proof of the first part is straightforward. For the second part, note that the orbit of the connection \( R \oplus 1 \) in the framed moduli space is \( \Gamma_n / \Gamma_{R \oplus 1} = S(U(1) \times U(2))/S(U(1)_2 \times U(1)) = S^3 \), where \( U(1)_2 \times U(1) \) denotes \( 3 \times 3 \) diagonal matrices where the first two diagonal entries are equal to each other. \( \square \)

Now we are ready to prove the first part of Proposition 2.20:

**Proposition 6.28.** Suppose \( X \) and \( \sigma \) are as above and \( z \in A(\langle \sigma \rangle^{-1})^\otimes 2 \). Suppose also \( w \) is a 2-cycle in \( X \) such that \( w \cdot \sigma \equiv 1 \mod 3 \). Then there is a constant \( c \) such that:

\[
D^3_{X,w}((-\frac{3}{2} \sigma(3) - \frac{3}{2} \sigma(2) - a_2)z) = cD^3_{X,w-a}(z).
\]

**Proof.** For the simplicity of the exposition, we assume that \( z = 1 \). A similar proof works in the more general case. Equip \( X \) with a Riemannian metric that has a neck of length \( T \) along the lens space \( Y \), and denote the resulting Riemannian manifold by \( X^T \). Let \( \kappa \) be chosen such that the expected dimension of \( \mathcal{M}_{\kappa}(X^T, w) \) is equal to 4. We firstly study the 4-dimensional moduli spaces of the form \( \mathcal{M}_{\kappa}(X^T, w) \) for large values of \( T \). We can assume that this moduli space is compact. In particular, we do not need the geometric representatives for the \( \mu \)-map to evaluate the \( U(3) \)-polynomial invariants. Let \( \alpha_1 \) and \( \alpha_2 \) denote the flat connections \( \chi^{-2} \oplus 1 \oplus 1 \) and \( \chi^{-1} \oplus \chi^{-1} \oplus 1 \). By Theorem 6.11, the moduli space \( \mathcal{M}_{\kappa}(X^T, w) \) can be covered with two open sets \( \mathcal{U} \) and \( \mathcal{V} \) of the following form:

\[
\mathcal{U} = \widetilde{M}_{p_1}(X_1, w \cap X_1; \alpha_1) \times_{\Gamma_{\alpha_1}} \widetilde{M}(B^{-2} \oplus 1 \oplus 1) \quad \mathcal{V} = \widetilde{M}_{p_2}(X_1, w \cap X_1; \alpha_1) \times_{\Gamma_{\alpha_2}} \widetilde{M}(B^{-1} \oplus B^{-1} \oplus 1)
\]

80
where framed moduli spaces $\widetilde{M}_{p_1}(X_1, w \cap X_1; \alpha_1)$ and $\widetilde{M}_{p_2}(X_1, w \cap X_1; \alpha_1)$ are of dimension 4 and 8, respectively, and the groups $\Gamma_{\alpha_1}$ and $\Gamma_{\alpha_1}$ act freely on these spaces.

Next, we describe the universal bundle over $U \times \sigma$. Suppose $q_1$ is the path over $Z$ determined by the connection $B^{-2} \oplus 1 \oplus 1$. We can form an equivariant universal bundle $\overline{P}_1$ over $B_{q_1}(Z, w \cap Z; \alpha) \times Z$ similar to the universal bundles in subsection 2.1. There is an action of $\Gamma_{\alpha_1}$ on $\overline{P}_1$ which lifts the obvious action of this group on $B_{q_1}(Z, w \cap Z; \alpha) \times Z$. The universal bundle over $U \times \sigma$ is given by the restriction of $\widetilde{M}_{p_1}(X_1, w \cap X_1; \alpha_1) \times_{\Gamma_{\alpha_1}} \overline{P}_1$ to $U \times \sigma$. (This fact is an extension of Theorem 6.11 and can be verified by going through the proof of this gluing theorem.) The restriction of the $\Gamma_{\alpha_1}$-equivariant bundle $\overline{P}_1$ to the $\Gamma_{\alpha_1}$-space $C^2 \subseteq \widetilde{M}(B^{-2} \oplus 1 \oplus 1) \times \sigma$ is equal to $[13$, Proposition 46$]$

$$\widetilde{E}_1 = Q \boxtimes L^{-2} \oplus G.$$  

(6.29)

where $G$ is the $\Gamma_{\alpha_1}$-equivariant rank 2 bundle associated to the standard $U(2)$-representation of $\Gamma_{\alpha_1} = S(U(1) \times U(2))$ and $Q$ comes from the standard $U(1)$-representation of $\Gamma_{\alpha_1}$. (To be more precise, the $U(3)$-bundle in (6.29) is a lift of the universal bundle which is a $PU(3)$-bundle.) Suppose $R \in M(B^{-2} \oplus 1)$ is an irreducible connection. Another application of $[13$, Proposition 46$]$ shows that the restriction of the universal bundle over $\Gamma_{\alpha_1}/\Gamma_{R \oplus 1}$, the orbit of $R \oplus 1$, has the following form:

$$Q \boxtimes L^{-2} \oplus Q \boxtimes Q^{-2}.$$  

This allows us to show that:

$$\left(\frac{3}{2} \left(\frac{\partial}{\partial x} \right)^2 \sigma \right) - \left(\frac{3}{2} \left(\frac{\partial}{\partial x} \right)^2 \sigma \right)^2 - \frac{3}{2} \left(\frac{\partial}{\partial x} \right)^2 \sigma = 0$$  

(6.30)

Here the normalized Chern class $c_i$ of a $U(N)$-bundle $V$ is defined to be the $i$th-Chern class of the $PU(N)$-bundle associated to $V$. Note that (6.30) holds trivially for the irreducible components of $\widetilde{M}(B^{-2} \oplus 1 \oplus 1)$, where the action of $\Gamma_{\alpha_1}$ is free.

The universal bundle over $V \times N$ is induced by the universal $\Gamma_{\alpha_2}$-bundle over $\widetilde{M}(B^{-1} \oplus B^{-1} \oplus 1) \times \sigma$. Recall that $\widetilde{M}(B^{-1} \oplus B^{-1} \oplus 1)$ consists of one point. The equivariant universal bundle can be described as:

$$\widetilde{E}_2 = F \boxtimes L^{-1} \oplus P.$$  

(6.31)

where $F$ and $P$ are the standard $U(2)$- and $U(1)$-representations of $\Gamma_{\alpha_2}$. The following identity is a consequence of this description of $\widetilde{E}_2$:

$$\frac{3}{2} \left(\frac{\partial}{\partial x} \right)^2 \sigma - \left(\frac{3}{2} \left(\frac{\partial}{\partial x} \right)^2 \sigma \right)^2 = 0$$

Identities (6.30) and (6.31) imply that:

$$D^3_{X, w}(\frac{3}{2} \sigma(3) - \frac{3}{2} \sigma(2) - a_2) = c \cdot \#(\widetilde{M}_{p_1}(X_1, w \cap X_1; \alpha_1) \times_{\Gamma_{\alpha_1}} \{B^{-2} \oplus 1 \oplus 1\})$$

$$= c \cdot \#(\widetilde{M}_{p_1}(X_1, w \cap X_1; \alpha_1))$$

81
for an appropriate constant $c$. Since $\widetilde{\mathcal{M}}(B \oplus 1 \oplus 1)$ consists of a single point, we have:

$$\mathcal{M}_{p_1}(X_1, w \cap X_1; \alpha_1) = \mathcal{M}_{p_1}(X_1, w \cap X_1; \alpha_1) \times \Gamma_{\alpha_1} \widetilde{\mathcal{M}}(B \oplus 1 \oplus 1) = \mathcal{M}_{\kappa_1}(X^T, w - \sigma)$$

Here $\kappa_1$ is chosen such that the space $\mathcal{M}_{\kappa_1}(X^T, w - \sigma)$ is 0-dimensional. We also use Theorem 6.11 to conclude the second identity. \hfill \Box

The second part of Proposition 2.20 can be proved by applying the first part to the $(-3)$-sphere $\sigma$ with the reverse orientation. Next we turn to the proof of the last part of Proposition 2.20. As in the previous case, we need to study some low dimensional moduli spaces over $Z$. The following table consists of various choices of $U(3)$-connections on $Z$ with vanishing $c_1$. The proof of Proposition 6.26 shows that each connection $A$ in this table has the minimal energy among all ASD connections with the same limiting flat connection and vanishing $c_1$.

| $A$                      | $\alpha$       | index($\mathcal{D}_A$) | dim($\widetilde{\mathcal{M}}(A)$) | $\Gamma_{\alpha}$ |
|-------------------------|----------------|-------------------------|-----------------------------------|------------------|
| $1 \oplus 1 \oplus 1$   | $1 \oplus 1 \oplus 1$ | -8                      | 0                                | SU(3)            |
| $B \oplus B^{-1} \oplus 1$ | $\chi \oplus \chi^2 \oplus 1$ | 0                       | 2                                | $S(U(1) \times U(1) \times U(1))$ |
| $B \oplus B \oplus B^{-2}$ | $\chi \oplus \chi \oplus \chi$ | 4                       | 12                               | SU(3)            |
| $B^{-1} \oplus B^{-1} \oplus B^2$ | $\chi^2 \oplus \chi^2 \oplus \chi^2$ | 4                       | 12                               | SU(3)            |

For $A = B \oplus B^{-1} \oplus 1$, the moduli space $\mathcal{M}(A)$ contains three types of connections:

- irreducible connections;
- the complete reducible $A = B \oplus B^{-1} \oplus 1$;
- reducible connection $R \oplus B^r$ where $R$ is an irreducible $U(2)$-connection.

The connection $R$ in the last part belongs to one of the moduli spaces $\mathcal{M}(B \oplus 1)$, $\mathcal{M}(B^{-1} \oplus 1)$ or $\mathcal{M}(B \oplus B^{-1})$. The virtual dimension of $\mathcal{M}(B \oplus 1)$ and $\mathcal{M}(B^{-1} \oplus 1)$ is $-1$. Thus they contain no irreducible connection. Therefore, $r = 1$ and $R \in \mathcal{M}(B \oplus B^{-1})$. Note that index($\mathcal{D}_{B \oplus B^{-1}}$) = 1.

**Proposition 6.32.** The connected component of $\mathcal{M}(B \oplus B^{-1})$ which contains $B \oplus B^{-1}$ is a half-line $[0, \infty)$. All the other components are either circles or copies of $R$ consisting of only irreducible connections. The corresponding components of $\mathcal{M}(A)$ are $C$, $S^1 \times S^1$ and $S^1 \times R$, and the action of $\Gamma_{\alpha} = S^1$ is standard.

**Proposition 6.33.** Suppose $X$ and $\sigma$ are as above and $z \in \mathcal{A}(\langle \sigma \rangle^{-1}) \otimes \mathbb{R}$. Suppose also $w$ is a 2-cycle in $X_1$. Then the following formulas hold:

- $D^2_{X,w}((\sigma(2)^4 + 4a_2\sigma(2)^2 + 3\sigma(3)^2)z) = 0$
\[ D_X, w((\sigma^3_2\sigma(3) + 3\sigma^2_3\sigma(2) + a_2\sigma(2)\sigma(3))z) = 0 \]

**Proof.** Similar to the proof of Proposition 6.28, we may assume that \( z = 1 \). We need to study the 8-dimensional moduli space for the first identity and the 10-dimensional moduli space for the second identity. Suppose \( \kappa_0 \) is a constant number such that the expected dimension of the moduli space \( \mathcal{M}_{\kappa_0}(X^T, w) \) is 8 or 10. In particular, we can assume the moduli space \( \mathcal{M}_{\kappa_0}(X^T, w) \) is compact for large values of \( T \). We can stretch the neck and use Theorems 6.7 and 6.11 to study the moduli spaces for a long neck along \( Y \).

Part of the moduli space can be covered by the following space:

\[ \mathcal{U} = C \times \Gamma_\alpha \tilde{\mathcal{M}}_{p_0}(X_1, w; \alpha) \quad (6.34) \]

where \( \alpha = \chi \oplus \chi^2 \oplus 1 \), \( C \) denotes the reducible part of the moduli space \( \tilde{\mathcal{M}}(A) \) for \( A = B \oplus B^{-1} \oplus 1 \), and \( p_0 \) is a path over \( X_1 \) based at \( \alpha \) with \( \kappa_0 = \kappa(A) + \kappa(p_0) \).

The restriction of the \( \Gamma_\alpha \)-equivariant universal bundle to the \( \Gamma_\alpha \)-space \( C \times \sigma \subset \tilde{\mathcal{M}}(A) \times \sigma \) is equal to:

\[ \tilde{E} := P \boxtimes L \oplus Q \boxtimes L^{-1} \oplus R \boxtimes C \]

where \( P, Q, R \) are \( \Gamma_\alpha \)-equivariant line bundles over \( C \) [13, Proposition 46]. Similarly, the restriction of \( \tilde{P} \) to \( \Gamma_\alpha/\Gamma_{\mathbb{C}\otimes 1} \times \sigma \cong S^1 \times \sigma \), for an irreducible connection \( C \in \mathcal{M}(B \oplus B^{-1}) \), is given by:

\[ \Gamma_\alpha \times \Gamma_{\mathbb{C}\otimes 1} (L \oplus L^{-1} \oplus C) \to S^1 \times \sigma \]

This implies that the restriction of the bundles \( P \) and \( Q \) to \( (C \setminus \{0\}) \times \sigma \) are equal to each other. Suppose \( p, q \in H_{\Gamma_\alpha}^2(C) \) denote the equivariant first Chern classes of these bundles. Then:

\[ \tilde{\sigma}_2 := \tilde{c}_2(\tilde{E})/\sigma = \tilde{c}_1(P) - \tilde{c}_1(Q) = p - q, \]

\[ \tilde{\sigma}_3 := \tilde{c}_3(\tilde{E})/\sigma = q^2 - p^2 \]

Therefore, \( \tilde{\sigma}_i \) are the images of compactly supported \( \Gamma_\alpha \)-equivariant cohomology classes of \( C \). We also have:

\[ \tilde{a}_2 := \tilde{c}_2(\tilde{E})/\sigma = c_2(P \oplus Q \oplus R) = pq - (p + q)^2, \]

\[ \tilde{a}_3 := \tilde{c}_3(\tilde{E})/\sigma = \tilde{c}_3(x) = c_3(P \oplus Q \oplus R) = -pq(p + q) \]

Using these identities, it is easy to check that the following compactly supported \( \Gamma_\alpha \)-equivariant cohomology classes are zero:

\[ \tilde{\sigma}_2^4 + 4\tilde{a}_2\tilde{\sigma}_2^2 + 3\tilde{a}_2^2 + \tilde{\sigma}_2\tilde{\sigma}_3 + 3\tilde{a}_3\tilde{\sigma}_2 + \tilde{a}_2\tilde{\sigma}_2\tilde{\sigma}_3 \]

The restriction of these equivariant cohomology classes to the irreducible components of \( \tilde{\mathcal{M}}(A) \) are also zero for obvious reasons. These vanishing results, Theorem 6.11 and [13, Proposition 47] can be employed to show that the restriction of cohomology classes \( \sigma_2^4 + 4a_2\sigma_2^2 + 3\sigma_2^2 \) and \( \sigma_2^3\sigma_3 + 3a_3\sigma_2 + a_2\sigma_2\sigma_3 \) to \( \mathcal{M}_{\kappa_0}(X^T, w) \) are equal to zero.

\[ \square \]
6.3 Gluing Theory for Fukaya-Floer Homology

Suppose \((Y, \gamma)\) is an admissible pair, and \(L = (l_2, \ldots, l_N)\) is an \((N - 1)\)-tuple of the elements of \(H_1(Y)\). Fix a perturbation \(CS_\pi\) of the Chern-Simons functional associated to \((Y, \gamma)\) such that all critical points of \(CS_\pi\) are irreducible and non-degenerate, and all moduli spaces \(\mathcal{M}_p(\alpha, \beta)\) consists of regular points. Let \(c_\pi^p(Y, \gamma)\) be the Floer chain complex associated to \(CS_\pi\). Fukaya-Floer homology of \((Y, \gamma, L)\) is the homology of a chain complex whose chain group is:

\[
\tilde{c}_\pi^p(Y, \gamma, L) := c_\pi^p(Y, \gamma) \otimes R_N
\]

Recall that the ring \(R_N\) is defined in subsection 3.3.

One of the primary goals of this subsection is to define the Fukaya-Floer differential on (6.35). For the simplicity of exposition, we assume that \(l_3 = \cdots = l_N = 0\) and \(l_1\) is an integral homology class. Later we shall explain how the definition should be adapted to an arbitrary case. For each \(i \in \mathbb{N}\), let \(\eta_i\) be a closed curve that represents \(l_i\). We assume that the curves \(\eta_i\) are disjoint. For any path \(p\) between two critical points \(\alpha\) and \(\beta\) of \(CS_\pi\) and \(S = \{i_1, \ldots, i_k\} \subset \mathbb{N}\), we have the diagonal \(\mathbb{R}\)-action \(\{\sigma_t\}_{t \in \mathbb{R}}\) on the following space:

\[
\mathcal{M}_p(\alpha, \beta) \times (\eta_{i_1} \times \mathbb{R}) \times \cdots \times (\eta_{i_k} \times \mathbb{R})
\]

Here the action of \(r \in \mathbb{R}\) maps \((x, t) \in \eta_i \times \mathbb{R}\) to \((x, t - r)\). If \(p\) is not the constant path or \(S\) is not the empty set, then this action is free and we will write \(\mathcal{M}_p(\alpha, \beta; S)\) for the quotient space. Otherwise, \(\mathcal{M}_p(\alpha, \beta; S)\) is defined to be empty. In the case that \(S\) is empty, the quotient space is the space \(\mathcal{M}_p(\alpha, \beta)\).

If \(S' \subset S\), then there is an obvious projection map from \(\mathcal{M}_p(\alpha, \beta; S)\) to \(\mathcal{M}_p(\alpha, \beta; S')\), which is denoted by \(\pi_{S \to S'}\).

We can form a partial compactification of \(\mathcal{M}_p(\alpha, \beta; S)\) by defining

\[
\mathcal{M}_p^+(\alpha, \beta; S) := \bigcup_k \bigcup_{(p_i, S_j)} \prod_{j=1}^k \mathcal{M}_p(\alpha_{j-1}, \alpha_j; S_j)
\]

where \(S_j \subset S\) and \(p_j : \alpha_{j-1} \to \alpha_j\) is a path between two critical points of \(CS_\pi\) such that the sets \(S_j\) are disjoint, their union is equal to \(S\), and the composition \(p_1 \circ \cdots \circ p_k\) is equal to \(p\). Note that the set \(S_j\) may be empty. A sequence \(u_i \in \mathcal{M}_p(\alpha, \beta; S)\) is chain convergent to \(u_\infty = (u_{\infty 1}, \cdots, u_{\infty k}) \in \prod_{j=1}^k \mathcal{M}_p(\alpha_{j-1}, \alpha_j; S_j)\), if there is a sequence of \(k\)-tuple of real numbers \((t_i^1, \cdots, t_i^k)\) such that:

\[
t_i^1 \prec \cdots \prec t_i^k
\]

and

\[
\sigma_{t_i^i} \circ \pi_{S \to S_j}(u_i) \xrightarrow{C^\infty_{t_i}} u_{\infty i}^j.
\]

We use this notion of convergence to define a topology on \(\mathcal{M}_p^+(\alpha, \beta; S)\).

Remark 6.37. Due to the possibility of bubbling off instantons, the space \(\mathcal{M}_p^+(\alpha, \beta; S)\) is not necessarily compact.
Example 6.38. Suppose $A \in \mathcal{M}_p(\alpha, \beta)$ where $p : \alpha \to \beta$ is a non-trivial path between two critical points of the perturbed Chern-Simons functional. Suppose also $x \in \eta_1$ is fixed. Then $u_i = [A, (x, i)]$ defines a sequence of the elements of $\mathcal{M}_p(\alpha, \beta; S)$ where $S = \{1\}$. This sequence is convergent to $(u_1^1, u_2^2)$:

$$u_1^1 := [A] \in \mathcal{M}_p(\alpha, \beta) \quad u_2^2 := [\pi^*(\beta), (x, 0)] \in \mathcal{M}_q(\beta, \beta; S)$$

Here $q$ is the constant path from $\beta$ to $\beta$, and $\pi^*(\beta)$ is the pull back of the connection $\beta$ to $\mathbb{R} \times Y$.

For each $\eta_i$ we take a neighborhood $\nu(\eta_i) \subset Y$ such that the inclusion in $Y$ induces a surjective map on the fundamental groups. We also require these neighborhoods to be disjoint. For $S = \{i_1, \ldots, i_k\}$, define the map $\Phi_S$ as follows:

$$\Phi_S : \tilde{\mathcal{M}}_p(\alpha, \beta ; S) \to \prod_{r \in S} \mathcal{B}^*(\nu(\eta_r) \times (0, 1)) \times \eta_r$$

$$\Phi_s([A, (x_{i_1}, t_{i_1}) \ldots, (x_{i_k}, t_{i_k})]) = ((T_{t_{i_1}}^* A|_{\nu(\eta_{i_1}) \times [0, 1]}, x_{i_1}), \ldots, (T_{t_{i_k}}^* A|_{\nu(\eta_{i_k}) \times [0, 1]}, x_{i_k})).$$

where $T_{t_r} : \mathbb{R} \times Y \to \mathbb{R} \times Y$ denotes the translation that maps $(x, t)$ to $(x, t + t_r)$. This map extends to $\tilde{\mathcal{M}}_p^+(\alpha, \beta ; S)$ in the obvious way and the extension is continuous. As in subsection 2.1, we can form a universal $PU(N)$-bundle $\mathbb{P}_r$ and an associated $SU(N^N)$ vector bundle over $\mathbb{E}_r$ on $\mathcal{B}^*(\nu(\eta_r) \times (0, 1)) \times \eta_r$.

We need to find a subspace of $\mathcal{B}^*(\nu(\eta_r) \times (0, 1)) \times \eta_r$ which represents $c_2(\mathbb{P}_r)$ or equivalently $\frac{1}{2N} c_2(\mathbb{E}_r)$, and use the inverse image of this representative to cut down the moduli space $\tilde{\mathcal{M}}_p(\alpha, \beta ; S)$. We can proceed as in subsection 2.1. The rank stratification of the vector bundle $\text{Hom}(\mathcal{C}^{N,N-1}, \mathbb{E}_r)$ determines a codimension four representative $V_2(\eta_r)$ for the second Chern class of the universal bundle. For all choices of $\alpha, \beta$ and $p$, we can assume that $V_2(\eta_r)$ is transversal to the restrictions of $\pi_r \circ \Phi_S$ to the smooth strata of $\tilde{\mathcal{M}}_p(\alpha, \beta ; S)$ [56, 13]. Here $\pi_r$ is projection to the space $\mathcal{B}^*(\nu(\eta_r) \times (0, 1)) \times \eta_r$. Let $\tilde{\mathcal{N}}_p(\alpha, \beta; S)$ be the following cut-down moduli space:

$$\Phi_S^{-1}(V_2(\eta_{i_1}) \times \cdots \times V_2(\eta_{i_k}))$$

Then the closure of $\tilde{\mathcal{N}}_p(\alpha, \beta; S)$ in $\tilde{\mathcal{M}}_p^+(\alpha, \beta; S)$, denoted by $\bar{\mathcal{N}}_p^+(\alpha, \beta; S)$, is also a stratified space with smooth strata of the following form:

$$\bigcap_{j=1}^k \mathcal{N}_p(\alpha_{j-1} - 1, \alpha_j; S_j).$$

Lemma 6.39. If $\dim \mathcal{N}_p^+(\alpha, \beta; S) \leq 1$, then it is compact.

Proof. This is a consequence of Theorem 6.6 and the standard dimension counting argument used for the definition of the polynomial invariants for closed 4-manifolds.

Now we are in a position to define the differential. Firstly consider the operator:

$$d_S : \mathcal{C}_p^\tau(Y, \gamma) \to \mathcal{C}_p^\tau(Y, \gamma)$$

85
we can use the auxiliary complex vector bundles of rank
where the sum is over all paths \( p \) from \( \alpha \) to another critical point of \( CS_n \) such that the dimension of the
moduli space \( \mathcal{M}_p(\alpha, \beta) \) is equal to \( 2|S| + 1 \). According to Lemma 6.44, the cut-down moduli space
\( \tilde{\mathcal{N}}^+_p(\alpha, \beta; S) \) is compact in this case. Finally, the Fukaya-Floer differential on \( \tilde{C}_n^*(Y, \gamma, L) \) is defined as:

\[
\tilde{d} := \sum_{S \subset \mathbb{N}^+} \frac{\prod_{j \in S} t_{2,j}}{\mathbb{N}^{|S|}} d_S
\]

The term \( \mathbb{N}^{|S|} \) appears in the above expression due to the the relationship between \( c_2(\mathbb{P}_r) \) and \( c_2(\mathbb{E}_r) \).

**Proposition 6.40.** The map \( \tilde{d} \) defines a differential, i.e., \( \tilde{d}^2 = 0 \).

**Proof.** For critical points \( \alpha \) and \( \beta \) of \( CS_n \) and \( S \subset \mathbb{N} \), let \( h_S(\alpha, \beta) \) be a number that satisfies the following identity:

\[
d^2 \alpha = \sum_{\beta, S} h_S(\alpha, \beta) \left( \prod_{j \in S} t_{2,j} \right) \beta.
\]

Fix \( \alpha, \beta \) and \( S \), and suppose \( p : \alpha \to \beta \) is a path that \( \dim(\mathcal{M}_p(\alpha, \beta)) \) is equal to \( 2|S| + 2 \). Then the term
\( h_S(\alpha, \beta) \) is equal to:

\[
h_S(\alpha, \beta) = \sum_{p_1: \alpha \to \beta} \sum_{p_2: \gamma \to \beta} \#\tilde{\mathcal{N}}^+_p(\alpha, \gamma; S_1) \cdot \#\tilde{\mathcal{N}}^+_p(\gamma, \beta; S_2)
\]

such that \( p_1 \circ p_2 = p \), \( S_1 \cup S_2 = S \), \( S_1 \) and \( S_2 \) are disjoint, and:

\[
\dim(\mathcal{M}_{p_1}(\alpha, \gamma)) = 2|S_1| + 1 \quad \dim(\mathcal{M}_{p_2}(\gamma, \beta)) = 2|S_2| + 1.
\]

Therefore, \( h_S(\alpha, \beta) \) is equal to the signed count of the boundary points of the compact 1-manifold
\( \tilde{\mathcal{N}}^+_p(\alpha, \beta; S) \). This implies that \( h_S(\alpha, \beta) \) is equal to zero. \( \square \)

Next, we explain how the above set up should be generalized to the case of arbitrary \((N - 1)\)-tuple \((l_2, \ldots, l_N)\). For each \( l_i \), we choose a sequence of disjoint representatives \( \{\eta_{i, j}\}_{j \in \mathbb{N}} \). We keep assuming that \( \eta_{i, j} \) is a simple closed curve in \( Y \). In a more general case that \( l_i \) is a homology class with complex coefficient we need to consider the straightforward generalization that \( \eta_{i, j} \) is a linear combination of disjoint closed curves. Then for each \((N - 1)\)-tuple \( \mathcal{S} = (S_2, \ldots, S_N) \) of subsets of \( \mathbb{N} \), we can form the moduli space \( \hat{\mathcal{M}}_p(\alpha, \beta; \mathcal{S}) \) and its partial compactification \( \hat{\mathcal{M}}^+_p(\alpha, \beta; \mathcal{S}) \). As in the previous case, each stratum of the partial compactification is a product of moduli spaces of the form \( \hat{\mathcal{M}}_p(\alpha, \beta; \mathcal{S}) \). The next step is to cut down \( \hat{\mathcal{M}}^+_p(\alpha, \beta; \mathcal{S}) \) with divisors \( V_i(\eta_{i, r}) \) for \( r \in S_i \). As in the case of closed 4-manifolds, we can use the auxiliary complex vector bundles of rank \( \mathbb{N}^N \) associated to the universal \( PU(N) \)-bundle and construct geometric representatives for \( V_i(\eta_{i, r}) \). The desired representative is a linear combination of codimension 2i stratified spaces with smooth strata. We will write \( \tilde{\mathcal{N}}^+_p(\alpha, \beta; \mathcal{S}) \) for the cut-down moduli space. A generic choice of these divisors allow us to obtain a cut-down moduli space which is a linear combination of smooth manifolds. This manifold (with boundary) is compact when its dimension is less than or equal to 1.
We combine these operators to form:
\[
d\tilde{\alpha} = \sum_{p\alpha\to\beta} \#\tilde{N}_p^+(\alpha, \beta; \bar{S}) \cdot \beta.
\]

As in the previous case, the 1-dimensional moduli space can be used to show that \(\tilde{d}^2 = 0\). Fukaya-Floer homology is defined to be the following \(R_N\)-module:
\[
\tilde{\Pi}^N_{\ast}(Y, \gamma, L) := H_{\ast}(\tilde{\mathcal{C}}^\pi_{\ast}(Y, \gamma, L), \tilde{d}).
\]

Standard arguments can be used to show that \(\tilde{\Pi}^N_{\ast}(Y, \gamma, L)\) only depends on \((Y, \gamma)\) and the homology classes of the elements in \(L\).

Let \((X, w)\) be a pair whose boundary is \((Y, \gamma)\). Suppose \(\Gamma^2, \ldots, \Gamma^N\) are properly embedded surfaces in \(X\) such that \([\partial \Gamma^j] = l_i \in H_1(Y)\). For \(z \in \mathbb{A}(X)^{N-1}\), we want to define the relative invariant:
\[
\mathcal{D}^N_{X, w, z}(\sum_{i=1}^N \Gamma^j(i)) \in \tilde{\Pi}^N_{\ast}(Y, \gamma, L)
\]
where \(L = (l_2, \ldots, l_N)\). This is similar to the definition of the differential of the Fukaya-Floer chain complex. For the simplicity of exposition, we assume that \(\Gamma^3 = \cdots = \Gamma^N = 0\), and \(z = 1\). As in the case of the definition of the differential in Fukaya-Floer homology, the more general case is just slightly different. In the manifold \(X^+\) with cylindrical end, let \(\{\Sigma_j\}_{j \in \mathbb{N}}\) be a sequence of surfaces which are given by perturbing the surface \(\Gamma^2\). We assume that these surfaces intersect generically and their intersections with \(\mathbb{R}^\geq_0 \times Y\) are equal to the disjoint product surfaces \(\{\eta_j \times \mathbb{R}^\geq_0\}_{j \in \mathbb{N}}\). We choose a holonomy perturbation of the ASD equation on \(W^+\), compatible with the chosen perturbation of the Chern-Simons functional of \(Y\), such that all moduli spaces \(\mathcal{M}_p(W, w; \beta)\) consist of regular points. Given a subset \(S = \{j_1, \ldots, j_k\} \subset \mathbb{N}\) and a path \(p\) on \(W\) based at the critical point \(\beta\) of \(CS_{\pi}\), consider the space:
\[
\mathcal{M}_p(X, w; \beta, S) := \mathcal{M}_p(X, w; \beta) \times \Sigma_{j_1} \times \cdots \times \Sigma_{j_k}.
\]  
(6.41)

For \(S' \subset S\), the obvious projection map \(\mathcal{M}_p(X, w; \beta, S)\) to \(\mathcal{M}_p(X, w; \beta, S')\) is denoted by \(\pi_{S \to S'}\). There is also a partially defined translation map for \(\mathcal{M}_p(X, w; \beta, S)\). Suppose \(\mathcal{M}_p^{cd}(X, w; \beta, S)\) denotes the following subset of \(\mathcal{M}_p(X, w; \beta, S)\):
\[
\mathcal{M}_p(X, w; \beta) \times (\eta_{j_1} \times \mathbb{R}^\geq_0) \times \cdots \times (\eta_{j_k} \times \mathbb{R}^\geq_0)
\]
For \(u = ([A], (x_1, t_1), \ldots, (x_k, t_k)) \in \mathcal{M}_p^{cd}(X, w; \beta, S)\) define \(\sigma_t(u)\) to be the following element:
\[
([T^*_t(A)|_{Y \times \mathbb{R}^\geq_0}], (x_1, t_1 - t), \ldots, (x_k, t_k - t)).
\]
Note that the connection \(T^*_t(A)|_{Y \times \mathbb{R}^\geq_0}\) is partially defined on the cylinder \(Y \times \mathbb{R}\).
As in the cylinder case, we form a partial compactification of \( \mathcal{M}_p(X, w; \beta, S) \) given by:

\[
\mathcal{M}_p^+(X, w; \beta, S) := \bigcup_{k} \bigcup_{(p_j, S_j)_{1 \leq j \leq k}} \mathcal{M}_{p_1}(X, w, \alpha_1, S_1) \times \prod_{j=2}^{k} \mathcal{M}_{p_j}(\alpha_{j-1}, \alpha_j; S_j)
\]

where \( \alpha_1, \ldots, \alpha_k \) are critical points of \( \text{CS}_\pi \), \( \alpha_k = \beta \), \( p_1 = \pi \) is a path on \( X \), \( p_j : \alpha_{j-1} \to \alpha_j \) is a path over the cylinder, \( p = p_1 \circ \cdots \circ p_k \), the sets \( S_j \) are disjoint and their union is equal to \( S \). As before, \( S_j \) may be empty. In a little more detail, a sequence \( u_i \in \mathcal{M}_p(X, w; \beta, S) \) is chain convergent to \( u_\infty = (u_{i_1}^1, \ldots, u_{i_k}^k) \in \mathcal{M}_{p_1}(X, w, \alpha_1, S_1) \times \prod_{j=2}^{k} \mathcal{M}_{p_j}(\alpha_{j-1}, \alpha_j; S_j) \), if there is a sequence of \( (k-1) \)-tuple of real numbers \( (t_{i_1}^1, \ldots, t_{i_k}^k) \) such that:

\[
0 < t_{i_1}^2 < \cdots < t_{i_k}^k
\]

and

\[
\pi_{S \to S_1}(u_i) \xrightarrow{C_{loc}} u_{i_1}^1 \quad \sigma_{i_j} \circ \pi_{S \to S_j}(u_i) \xrightarrow{C_{loc}} u_{i_j}^j \quad j \geq 2.
\]

Here part of the assumption is that \( \sigma_{i_j} \circ \pi_{S \to S_j}(u_i) \) is well-defined for \( j \geq 2 \). That is to say, \( \pi_{S \to S_j}(u_i) \in \mathcal{M}_p^{\text{gal}}(X, w; \beta, S_j) \).

For a moment, assume that \( S = \{1\} \). Suppose \( \nu(S_1) \) is an open neighborhood of \( S_1 \) such that the inclusion map of \( \nu(S_1) \) induces a surjective map. Suppose also \( \mathcal{B}^*(\nu(S_1)) \) is the set of connections on \( \nu(S_1) \) whose restrictions to the sets of the from \( \eta_1 \times (t-1, t) \) are irreducible. The unique continuation property can be used to show that the restriction map \( r_1 : \mathcal{M}_p(X, w; \beta, S) \to \mathcal{B}^*(\nu(S_1)) \times \Sigma_1 \) is well-defined. We can form a universal \( \text{PU}(N) \)-bundle \( \mathbb{P}_1 \) and the associated \( \text{SU}(N^N) \)-bundle \( \Sigma_1 \) on \( \mathcal{B}^*(\nu(S_1)) \times \Sigma_1 \). Our goal is to define a geometric representative for \( c_2(\Sigma_1) \) or equivalently \( N^N, c_2(\mathbb{P}_1) \), which is compatible with our choice of the geometric representative in the case of cylinders. Note that \( \mathcal{M}_p(X, w; \beta, S) \) is the union of the following two sets:

\[
B_1 = \mathcal{M}_p(X, w; \beta) \times (\eta_1 \times [1, \infty)) \quad B_2 = \mathcal{M}_p(X, w; \beta) \times (\Sigma_1 \setminus (\eta_1 \times (2, \infty))
\]

The map \( r_1|_{B_1} \) can be composed with the following map:

\[
F : \mathcal{B}^*(\nu(S_1)) \times (\eta_1 \times [1, \infty)) \to \mathcal{B}^*(\nu(\eta_1) \times (0, 1)) \times \eta_1
\]

\[
F([A], (x, t)) \equiv ([A|_{\nu(S_1 \times (t-1, t)}], x)
\]

Therefore, we can choose the geometric representative \( V_2(S_1) \subset \mathcal{B}^*(\nu(S_1)) \times \Sigma_1 \) for \( c_2(\Sigma_1) \) such that:

\[
V_2(S_1) \cap \mathcal{B}^*(\nu(S_1)) \times (\eta_1 \times [1, \infty)) = F^{-1}(V_2(\eta_1)).
\]

Arguing as in [56], we can also assume that \( V_2(S_1) \) is transversal to the map \( r_1 \) for all choices of the path \( p \). In this process, we firstly change \( V_2(\eta_1) \) to make the map \( r_1|_{B_1} \) transversal. Then we extend \( F^{-1}(V_2(\eta_1)) \) to \( \mathcal{B}^*(\nu(S_1)) \times \Sigma_1 \) such that \( r_1|_{B_2} \) is also transversal. We will write \( \mathcal{N}_p(X, w; \beta, S) \) for the cut-down moduli space \( r_1^{-1}(V_2(S_1)) \). Similarly, one can construct \( \mathcal{N}_p(X, w; \beta, S) \) in the case that \( S \) has more than one element. The closure of \( \mathcal{N}_p(X, w; \beta, S) \) in \( \mathcal{M}_p^+(X, w; \beta, S) \), denoted by \( \mathcal{N}_p^+(X, w; \beta, S) \), is also a stratified space with smooth strata of the following form:

\[
\mathcal{N}_{p_i}(X, w, \alpha_1, S_1) \times \prod_{j=2}^{k} \mathcal{N}_{p_j}(\alpha_{j-1}, \alpha_j; S_j).
\]
As in the cylinder case, the cut-down moduli space $N^+_p{(X, w; \beta, S)}$ is compact when its dimension is at most one. The relative invariant $D^N_{X, w}(e^{P^2})$ is defined using 0-dimensional moduli spaces as below:

\[
D^N_{X, w}(e^{P^2}) := \sum_{S \subseteq \mathbb{N}} \frac{\prod_{j \in S} t_{2j}}{N^{N |S|} \# N^+_p{(\beta; S)}} \beta \in \tilde{\mathbb{E}}^N_p{(Y, \gamma, L)} \tag{6.42}
\]

Following the proof of Proposition 6.40, we can show that (6.42) determines a cycle in $\tilde{\mathbb{E}}^N_p{(Y, \gamma, L)}$. We will denote the corresponding element in $\mathbb{E}^N_p{(Y, \gamma, L)}$ with the same notation.

Definition of the relative element in (6.42) can be extended to similar situations. For example, suppose $(Y_0, \gamma_0)$ and $(Y_1, \gamma_1)$ are two admissible pairs and $L_i = (l_i^2, \ldots, l_i^N)$ is an $(N-1)$-tuple of the elements in $H_1(\Sigma_i)$. Suppose also $(W, w, z)$ is a morphism from $(Y_0, \gamma_0)$ to $(Y_1, \gamma_1)$, and $\Gamma^j$ is a properly embedded surface in $W$ such that $[\partial_i \Gamma^j] = l_i^j$. Then there is a chain map:

\[
\tilde{\mathbb{E}}(W, w, z e^{P^2} + \cdots + \Gamma^N) : \tilde{\mathbb{E}}^{P^2}_*(Y_0, \gamma_0, L_0) \rightarrow \tilde{\mathbb{E}}^{P^2}_*(Y_1, \gamma_1, L_1)
\]

which induces a map at the level of homology:

\[
\mathbb{E}^*(W, w, z e^{P^2} + \cdots + \Gamma^N) : \mathbb{E}^*(Y_0, \gamma_0, L_0) \rightarrow \mathbb{E}^*(Y_1, \gamma_1, L_1).
\]

Alternatively, if $(X, w)$ is a 4-manifold whose boundary is equal to the admissible pair $(\overline{Y}, \overline{\gamma})$, and $\Gamma^j \in H_2(W, \partial W)$ is a homology class with $\partial \Gamma^j = l_j$, then we have an $R_N$-linear map:

\[
D^N_{X, w}(z e^{P^2} + \cdots + \Gamma^N) : \mathbb{E}^N(Y, \gamma, L) \rightarrow R_N.
\]

Here $L = (l_2, \ldots, l_N)$.

Now we are ready to give a proof of (3.29). For the convenience of the reader, we restate the claim as the following proposition:

**Proposition 6.43.** Let $(X_1, w_1)$ be a pair whose boundary is equal to an admissible pair $(Y, \gamma)$. Let $(X_2, w_2)$ be another pair whose boundary is equal to $(\overline{Y}, \overline{\gamma})$. Let $z_1 \in \mathbb{A}(X_1)^{\otimes (N-1)}$ and $z_2 \in \mathbb{A}(X_2)^{\otimes (N-1)}$. Let $\Gamma^j$ be a properly embedded surface in $X_1$ with boundary $l_j$. Let $\Lambda^j$ be a properly embedded surface in $X_2$ whose boundary is equal to $l_j$ with the reverse orientation. Then we can form the closed 4-manifold $X_2 \times X_1$ and the 2-cycle $w_2 \times w_1$. The embedded surfaces $\Gamma^j$ and $\Lambda^j$ can be glued to each other along their boundary to form a closed surface $\Gamma^j \# \Lambda^j$. Then the following invariant of the closed 4-manifold $X_2 \times X_1$:

\[
D^N_{X_2 \times X_1, w_2 \times w_1}(z_1 \cdot z_2 \cdot e^{P^2 \# \Lambda^2} + \cdots + (P^N \# \Lambda^N)(N)) \in \mathbb{R}^N \subseteq R_N
\]

is equal to:

\[
D^N_{X_2, w_2}(z_2 \cdot e^{\Lambda^2} + \cdots + \Lambda^N(N)) \cdot D^N_{X_1, w_1}(z_1 \cdot e^{P^2} + \cdots + P^N(N)).
\]

**Proof.** We make simplifying assumptions as before; assume $z_1 = z_2 = 1$ and $\Gamma^3, \ldots, \Gamma^N, \Lambda^3, \ldots, \Lambda^N$ are empty. Choose two series of properly embedded surfaces $\Sigma_i \subseteq X_1$ and $T_i \subseteq X_2$ such that $\Sigma_i$ (respectively, $T_i$) is given by perturbing $\Gamma^2$ (respectively, $\Lambda^2$). We also assume that $\partial \Sigma_i$
We assume that \( \partial T_i \) is equal to \( \eta_i \) (respectively, \( \eta_i \) with the reverse orientation), the curves \( \eta_i \) are disjoint, the embedded surfaces \( \Sigma_i \) and \( T_i \) intersect generically. We fix metrics on \( X_1 \) and \( X_2 \) which are product in a neighborhood of their boundaries corresponding to a fixed metric on \( Y \). Then we proceed as before to define open sets \( \nu(\eta_i) \subset Y \), \( \nu(\Sigma_i) \subset X_1 \), \( \nu(T_i) \subset X_2 \) and the geometric representatives:

\[
V_2(\eta_i) \subset B^*(\nu(\eta_i) \times (0,1)) \times \eta_i \quad V_2(\Sigma_i) \subset B^{**}(\nu(\Sigma_i)) \times \Sigma_i \quad V_2(T_i) \subset B^{**}(\nu(T_i)) \times T_i
\]

suitable for the definition of the differential of the Fukaya-Floer chain complex and the relative elements \( D_{X_1,w_1}(e^{T_2}|\alpha) \) and \( D_{X_2,w_2}(e^{A^2}|\alpha) \).

Suppose \( X^T \) is the metric on \( X_2 \circ X_1 \) induced by the metrics on \( X_1 \) and \( X_2 \) with a neck of length \( T \) along \( Y \). Suppose \( w \subset X^T \) is the 2-cycle induced by \( w_1 \) and \( w_2 \), and \( R^T_i \subset X^T \) is the embedded surface induced by the surfaces \( \Sigma_i \) and \( T_i \). The 4-manifold \( X \) can be decomposed into three pieces:

\[
X_1 \quad X_2 \quad Y \times \left[ -\frac{T}{2}, \frac{T}{2} \right] \quad \text{respectively.}
\]

We assume that \( X_1 \) and \( X_2 \) are disjoint and they intersect \( Y \times \left[ -\frac{T}{2}, \frac{T}{2} \right] \) in \( Y \times \left[ -\frac{T}{2}, -\frac{T}{2} + 2 \right] \) and \( Y \times \left[ \frac{T}{2} - 2, \frac{T}{2} \right] \), respectively. The Riemann surface \( R^T_i \) can be decomposed into union of three sets:

\[
\Sigma_i^c \subset X_1 \quad T_i^c \subset X_2 \quad \eta_i \times \left[ -\frac{T}{2} + 1, \frac{T}{2} - 1 \right] \subset Y \times \left[ -\frac{T}{2} + 1, \frac{T}{2} - 1 \right].
\]

Suppose \( B^*_\kappa(X^T, w) \) is the subset of \( B^*_\kappa(X, w) \) which consists of connections whose restriction to any set of the following form is irreducible:

\[
\nu(\eta_i) \times (t-1, t) \quad -T + 1 < t < T
\]

Then unique continuation and gluing theory show that for large enough values of \( T \), the moduli space \( \mathcal{M}_\kappa(X^T, w) \) is a subset of \( B^*_\kappa(X^T, w) \). Similar to the case of 4-manifolds with cylindrical ends, \( V_2(\eta_i) \), \( V_2(\Sigma_i) \) and \( V_2(T_i) \) can be used to define a geometric representative \( V(R^T_i) \subset B^{**}(X^T, w) \times \nu(R^T_i) \). We extend this stratified space to \( B^*_\kappa(X, w) \times \nu(R^T_i) \) and denote it with the same notation. Another application of gluing theory shows that for large enough values of \( T \), these divisors determine a transversal cut of \( \mathcal{M}_\kappa(X^T, w) \times R^T_1 \times \cdots \times R^T_k \) for any set \( S = i_1, \ldots, i_k \subset \mathbb{N} \). In the case that, the cut down moduli space is zero dimensional, it can be identified with the following set for large values of \( T \):

\[
\bigcup_{p_1, p_2, S_1, S_2} \mathcal{N}_{p_1}(X_1, w_1, \alpha, S_1) \times \mathcal{N}_{p_2}(X_2, w_2, \alpha, S_2)
\]

where \( p_i \) is a loop over \( X_i \) based at the connection \( \alpha \) such that \( \kappa = \kappa(p_1) + \kappa(p_2) \). Moreover, \( S_1 \) and \( S_2 \) are disjoint sets with \( S = S_1 \cup S_2 \). This geometric results for different choices of \( S \) can be translated to the following algebraic identity:

\[
D_{X_2,w_2}(e^{A^2}|\alpha) \circ D_{X_1,w_1}(e^{T_2}|\alpha) = \sum_{S \subset \mathbb{N}} \left( \prod_{j \in S} (t_{2,j}) \right) D_{X^T,w}(e^{\tau_2}(\Gamma^2 \# \Lambda^2)|S)
\]

In the second equality, we used the fact that \( R^T_i \) represents the homology class of \( \Gamma^2 \# \Lambda^2 \). The term in (6.44) lies in \( \mathbb{C}[t_2, \ldots, t_N] \) and is equal to \( D_{X^T,w}(e^{\Gamma^2 \# \Lambda^2}|\alpha) \). \( \square \)
Questions and Conjectures

In this section, we propose some questions and conjectures for future directions. This section is divided into two parts: the first subsection is concerned with the polynomial invariants of 4-manifolds. In the second part, we discuss some conjectures related to the algebra \( \mathcal{V}^N_{g,d} \).

7.1 Structure of Polynomial Invariants and 4-manifolds with Simple type

In subsection 2.5, the simple type property of 4-manifolds is defined using \( U^p_{2q} \)-polynomial invariants. As we pointed out earlier, the definition is motivated by Kronheimer and Mrowka’s simple type property, defined by \( U^p_{2q} \)-polynomial invariants [54]. There is another version of simple type property defined by Seiberg-Witten invariants. It is unknown if there is an example of a smooth 4-manifolds with \( b^+ \geq 2 \) which do not have Kronheimer-Mrowka simple type or Seiberg-Witten simple type. It is also shown in [24] that many 4-manifolds with Seiberg-Witten simple type has Kronheimer-Mrowka simple type. Therefore, it is natural to ask whether there is any relationship among \( U^p_{3q} \)-simple type, Kronheimer-Mrowka simple type and Seiberg-Witten simple type. A more challenging question would be to investigate whether there is a 4-manifold with \( b^+ \geq 2 \) which does not have \( U^p_{3q} \)-simple type. A more approachable question is the following:

**Question 7.1.** What is the analogue of the simple type condition with respect to \( U(N) \)-polynomial invariants?

As in the \( U(2) \) and the \( U(3) \) case, the simple condition has to be formulated in terms of point classes. In the light of Proposition 3.23, it is plausible that one of the required conditions is:

\[
D^N_{X,w}(a^N_2 z) = N^N D^N_{X,w}(z).
\]

For \( N = 2, 3 \), the blowup formula for \( U(N) \) simple type manifolds have simpler form [27, 13]. One might hope that the same holds for higher values of \( N \), and follows this direction to gain more insights into the correct definition for the simple type condition. The physics literature [66, 23] suggests that the blowup formula for an arbitrary \( N \) is related to function theory on a hyper-elliptic curve with coefficients in \( \mathbb{Q}\[a_2, \ldots, a_N]\). Evaluation of \( (a_2, \ldots, a_N) \) determines hyper-elliptic curve on complex numbers, and the simple type condition is related to the evaluations that produce a fully degenerate curve.

The relationship between \( U(2) \)-polynomial invariants and Seiberg-Witten invariants goes beyond the simple type conditions. In [54], Kronheimer and Mrowka prove that \( U(2) \)-polynomial invariants are completely determined by a finite set of cohomology classes (known as Kronheimer-Mrowka basic classes) and a set of rational numbers, one for each basic class. In [82], Witten argues that basic classes and corresponding rational numbers can be determined in terms of Seiberg-Witten invariants. To be more detailed, recall that for each spin\(^c\) structure \( s \) on a 4-manifold \( X \) (satisfying appropriate conditions such as \( b^+(X) \geq 2 \)), there is a Seiberg-Witten invariant \( SW_X(s) \). Then Witten’s conjecture states that any basic class of \( X \) is equal to \( c_1(S^+_s) \) where \( s \) is a spin\(^c\) structure with non-zero \( SW_X(s) \) and \( S^+_s \) is the half-spin bundle associated to \( s \). Witten’s conjecture is generalized to higher values of \( N \) in [66]. The calculations of \( U(3) \)-polynomial invariants in this paper agree with the Moore-Mariño Conjecture in [66] and can be
exploited to fix the undetermined constants in this conjecture. In particular, a modified version of the Moore-Mariño Conjecture states that:

**Conjecture 7.2.** Let $X$ be a four-manifold which has $U(3)$-simple type. Let $\{K_i\}$ be the set of Kronheimer-Mrowka basic classes. Then the $U(3)$-series of $X$ has the following form:

$$\hat{D}_{X,w}(e^{\Gamma(2)+\Lambda(3)}) = e^{\frac{Q(\Upsilon)}{2}} - \sum_{i,j} c_{ij} e^{-w(K_i-K_j)} e^{\frac{\sqrt{3}}{2}(K_i+K_j) + \sqrt{3}i(K_i-K_j) \cdot \Lambda}$$

where $c_{ij}$ is given as:

$$2^{\chi} + \frac{3}{4} \sigma + \frac{1}{2} K_i \cdot K_j \cdot 2^2 + \frac{7}{4} \chi + \frac{11}{2} \sigma \cdot SW_X(s_i) SW_X(s_j)$$

Here $s_i$ is chosen such that the associated basic class is equal to $K_i$.

### 7.2 The Algebra $V_{g,d}$

In subsection 5.1, a list of simultaneous eigenvectors for the operators $\epsilon, \eta_2, \eta_3, \rho(2)$ and $\rho(3)$, acting on $V_{g,d}^\beta$, is constructed. We also showed that there is at least one non-degenerate simultaneous eigenvector, which is the essential ingredient to prove the excision theorem in subsection 5.2. However, we do not know whether our approach produces all simultaneous eigenvectors:

**Conjecture 7.3.** Suppose $V_{g,d}^N \subset V_{g,d}^\beta$ is the set of vectors which are invariant with respect to the action of $\epsilon$. Then for $N = 3$, any simultaneous eigenvector of the operators acting on $V_{g,d}^{\beta'}$ that are induced by $\eta_2, \eta_3, \rho(2)$ and $\rho(3)$, have the form $3\zeta^{2\beta}, 0, \zeta^{2\beta} \sqrt{3} \alpha$ and $\zeta^{2\beta} \sqrt{3} \beta$ with $(\alpha, \beta) \in \mathbb{C}_g$.

For $N = 2$, there are three operators $\epsilon, \eta_2$ and $\rho(2)$. In this case, Muñoz obtains a complete understanding of the action of $\epsilon, \eta_2$ and $\rho(2)$ in [73]. In particular, his results show that the simultaneous eigenvectors of $\eta_2$ and $\rho(2)$, acting on $V_{g,d}^\alpha$, have the following form:

$$((-1)^r, \pm 2r)$$

$$0 \leq r \leq g - 1$$

All of these eigenvalues can be produced using the method of Proposition 5.7. Therefore, the analogue of Conjecture 7.3 holds for $N = 2$. Muñoz’s method of understanding the action of $\epsilon, \eta_2$ and $\rho(2)$ is based on the characterization of the ring structure of the cohomology ring $\mathbb{H}_{d}(\mathbb{N}_g)$ in [84, 48, 77, 5], which is not available for higher values of $N$.

If Conjecture 7.3 holds, then we can use the method of [58] and show that $\text{SHI}(M, \alpha)$ is non-zero for a taut balanced sutured manifold [47, 58]. This non-vanishing result can be used to show that $KHI(K)$ detects the genus of $K$. Moreover, $KHI(K)$ is not 1-dimensional for a non-trivial knot. That is to say, Conjecture 5.26 holds. Thus Corollary 5.25 can be used to show that the answer to Question 1.1 is positive for $N = 3$. In fact, in order to make this series of conclusions, we need the following weaker version of Conjecture 7.3:

**Conjecture 7.4.** If $(x, y)$ is a pair of simultaneous eigenvalues for $(\rho(2), \rho(3))$ in $V_{g,d}$, then $|x| + |y| \leq \sqrt{3}(2g - 2)$. 

92
There is also a symplectic analogue of the algebra \( V_{g,d}^N \). The manifold \( N_{N,d}(\Sigma_g) \) is Kähler and the associated Gromov-Witten invariants can be used to define the Quantum Cohomology ring \( QH^*(N_{N,d}) \) [75, 67]. The underlying vector space of \( QH^*(N_{N,d}) \) is \( H^*(N_{N,d}) \) and the ring structure is also a deformation of the cup product. Therefore, it has similar structure to \( V_{g,d}^N = \ker(\epsilon - 1) \), and it is natural to make the following conjecture:

**Conjecture 7.5.** The ring \( V_{g,d}^N \) is isomorphic to \( QH^*(N_{N,d}) \).

This conjecture for \( N = 2 \) is proved by Muñoz [72] using the characterization of the cohomology ring \( H^*(N_{N,d}) \) in [84, 48, 77, 5].

### A Invariants of Flat Connections on \( \Sigma(2, 3, 23) \)

There are 44 irreducible flat SU(3)-connections on \( \Sigma(2, 3, 23) \) [6]. These flat connections are determined by their holonomies along the loop \( x_3 \) in the standard presentation of the fundamental group of \( \Sigma(2, 3, 23) \) (see (3.35)). For each flat connection, the conjugacy class of this holonomy is determined by its eigenvalues which have the form \( e^{2\pi i k/23} \), \( e^{2\pi i l/23} \) and \( e^{2\pi i m/23} \). The possible values of \( \{k, l, m\} \) are given in Table 2.

The complex conjugation diffeomorphism of \( \Sigma(2, 3, 23) \) maps a flat connection with the associated triple \( \{k, l, m\} \) to the flat connection with the associated triple \( \{23 - k, 23 - l, 23 - m\} \). If this pair gives the same flat connections, we denote this connection with \( \alpha_j \) for an appropriate choice of the integer number \( j \). Otherwise, the resulting connections are denoted by \( \alpha_j^1 \) and \( \alpha_j^2 \).

| \( \alpha_1 \) | \{0, 4, 19\} | \( \alpha_2 \) | \{0, 5, 18\} | \( \alpha_3 \) | \{0, 6, 17\} | \( \alpha_4 \) | \{0, 7, 16\} |
|---|---|---|---|---|---|---|---|
| \( \alpha_5 \) | \{0, 8, 15\} | \( \alpha_6 \) | \{0, 9, 14\} | \( \alpha_7 \) | \{0, 10, 13\} | \( \alpha_8 \) | \{0, 11, 12\} |
| \( \alpha_9 \) | \{1, 4, 18\} | \( \alpha_9 \) | \{5, 19, 22\} | \( \alpha_{10} \) | \{1, 5, 17\} | \( \alpha_{10} \) | \{6, 18, 22\} |
| \( \alpha_{11} \) | \{1, 6, 16\} | \( \alpha_{11} \) | \{7, 17, 22\} | \( \alpha_{12} \) | \{1, 7, 15\} | \( \alpha_{12} \) | \{8, 16, 22\} |
| \( \alpha_{13} \) | \{1, 8, 14\} | \( \alpha_{13} \) | \{9, 15, 22\} | \( \alpha_{14} \) | \{1, 9, 13\} | \( \alpha_{14} \) | \{10, 14, 22\} |
| \( \alpha_{15} \) | \{1, 10, 12\} | \( \alpha_{15} \) | \{11, 13, 22\} | \( \alpha_{16} \) | \{2, 4, 17\} | \( \alpha_{16} \) | \{6, 19, 21\} |
| \( \alpha_{17} \) | \{2, 5, 16\} | \( \alpha_{17} \) | \{7, 18, 21\} | \( \alpha_{18} \) | \{2, 6, 15\} | \( \alpha_{18} \) | \{8, 17, 21\} |
| \( \alpha_{19} \) | \{2, 7, 14\} | \( \alpha_{19} \) | \{9, 16, 21\} | \( \alpha_{20} \) | \{2, 8, 13\} | \( \alpha_{20} \) | \{10, 15, 21\} |
| \( \alpha_{21} \) | \{2, 9, 12\} | \( \alpha_{21} \) | \{11, 14, 21\} | \( \alpha_{22} \) | \{3, 4, 16\} | \( \alpha_{22} \) | \{7, 19, 20\} |

Table 2: Holonomies of irreducible flat SU(3)-connections on \( \Sigma(2, 3, 23) \) along \( x_3 \)

The gauge theoretical invariants of these flat connections are given in the following tables:
Table 3: Gauge theoretical invariants of irreducible flat SU(3)-connections on $\Sigma(2, 3, 23)$ (first part)

| $\alpha$ | $\alpha_1$ | $\alpha_2$ | $\alpha_3$ | $\alpha_4$ | $\alpha_5$ | $\alpha_6$ | $\alpha_7$ | $\alpha_8$ | $\alpha_9$ | $\alpha_{10}$ | $\alpha_{11}$ | $\alpha_{12}$ | $\alpha_{13}$ |
|-----------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| $CS(\alpha)$ | $\frac{1}{138}$ | $\frac{49}{138}$ | $\frac{31}{138}$ | $\frac{85}{138}$ | $\frac{73}{138}$ | $\frac{133}{138}$ | $\frac{127}{138}$ | $\frac{55}{138}$ | $\frac{43}{138}$ | $\frac{127}{138}$ | $\frac{7}{138}$ | $\frac{97}{138}$ | $\frac{121}{138}$ |
| $\rho_{ad}$ | $\frac{-364}{23}$ | $\frac{-540}{23}$ | $\frac{-520}{23}$ | $\frac{-488}{23}$ | $\frac{-444}{23}$ | $\frac{-572}{23}$ | $\frac{-704}{23}$ | $\frac{-424}{23}$ | $\frac{-472}{23}$ | $\frac{-412}{23}$ | $\frac{-524}{23}$ | $\frac{-582}{23}$ | $\frac{-528}{23}$ |
| $\deg$ | 4 | 0 | 10 | 2 | 0 | 8 | 6 | 10 | 4 | 8 | 4 | 6 |

Table 4: Gauge theoretical invariants of irreducible flat SU(3)-connections on $\Sigma(2, 3, 23)$ (second part)

| $\alpha$ | $\alpha_{14}$ | $\alpha_{15}$ | $\alpha_{16}$ | $\alpha_{17}$ | $\alpha_{18}$ | $\alpha_{19}$ | $\alpha_{20}$ | $\alpha_{21}$ | $\alpha_{22}$ | $\alpha_{23}$ | $\alpha_{24}$ | $\alpha_{25}$ | $\alpha_{26}$ |
|-----------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| $CS(\alpha)$ | $\frac{79}{138}$ | $\frac{109}{138}$ | $\frac{19}{138}$ | $\frac{1}{138}$ | $\frac{55}{138}$ | $\frac{43}{138}$ | $\frac{103}{138}$ | $\frac{97}{138}$ | $\frac{67}{138}$ | $\frac{85}{138}$ | $\frac{37}{138}$ | $\frac{61}{138}$ | $\frac{19}{138}$ |
| $\rho_{ad}$ | $\frac{-420}{23}$ | $\frac{-484}{23}$ | $\frac{-476}{23}$ | $\frac{-456}{23}$ | $\frac{-516}{23}$ | $\frac{-472}{23}$ | $\frac{-508}{23}$ | $\frac{-440}{23}$ | $\frac{-468}{23}$ | $\frac{-488}{23}$ | $\frac{-404}{23}$ | $\frac{-492}{23}$ | $\frac{-476}{23}$ |
| $\deg$ | 0 | 4 | 8 | 6 | 0 | 10 | 4 | 2 | 0 | 2 | 8 | 0 | 8 |

There are 8 non-trivial flat SU(2)-connections on $\Sigma(2, 3, 23)$. As in the irreducible case, these connections are determined by the conjugacy class of their holonomies along $x_3$. For each $2 \leq k \leq 9$, there is a unique flat SU(2)-connection on $\Sigma(2, 3, 23)$ where the eigenvalues of holonomy along $x_3$ are equal to by $e^{2\pi ik/23}$ and $e^{-2\pi ik/23}$. We will write $\beta_k$ for this connection. The gauge theoretical invariants of these connections are given in Table 5. In this table, $\tilde{\alpha}$ denotes the reducible SU(3)-connection associated to an SU(2)-connection $\alpha$. 
| $\alpha$ | $\beta_2$ | $\beta_3$ | $\beta_4$ | $\beta_5$ | $\beta_6$ | $\beta_7$ | $\beta_8$ | $\beta_9$ |
|-------|--------|--------|--------|--------|--------|--------|--------|--------|
| $CS(\alpha)$ | $\frac{1}{552}$ | $\frac{169}{552}$ | $\frac{73}{552}$ | $\frac{265}{552}$ | $\frac{193}{552}$ | $\frac{409}{552}$ | $\frac{361}{552}$ | $\frac{49}{552}$ |
| $\rho_{ad_\alpha}$ | $\frac{-343}{69}$ | $\frac{-559}{69}$ | $\frac{-475}{69}$ | $\frac{-643}{69}$ | $\frac{-511}{69}$ | $\frac{-631}{69}$ | $\frac{-451}{69}$ | $\frac{-533}{69}$ |
| $\rho_{ad_\alpha}$ | $\frac{-206}{23}$ | $\frac{-406}{23}$ | $\frac{-410}{23}$ | $\frac{-402}{23}$ | $\frac{-382}{23}$ | $\frac{534}{23}$ | $\frac{-490}{23}$ | $\frac{-434}{23}$ |
| $\text{deg}(\alpha)$ | 1 | 5 | 3 | 7 | 5 | 1 | 7 | 3 |
| $\text{deg}(\tilde{\alpha})$ | 1 | 9 | 7 | 11 | 9 | 5 | 3 | 7 |

Table 5: Gauge theoretical invariants of reducible flat SU(3)-connections on $\Sigma(2, 3, 23)$
