doi:10.1002/2211-5463.12054

Despite the clinical importance of Helicobacter pylori in human gastric disorders, its exact route of transmission is still uncertain. Based on the contentious hypothesis and findings of previous investigations, water may play an important role in the transmission of H. pylori to humans. This study was carried out to investigate the vacA, cagA, oipA, iceA and babA2 genotype status and antimicrobial resistance properties of H. pylori strains isolated from the drinking water samples of four major provinces in Iran. A total of 400 drinking water samples were cultured and tested. H. pylori-positive strains were analyzed for the presence of various genotypes and antimicrobial resistance. Twelve of 400 (3%) water samples were positive for H. pylori. Samples from Isfahan province had the highest, while those from Shiraz had the lowest prevalence of H. pylori. The seasonal distribution was also determined, with the highest prevalence of bacteria in the summer season (7.36%). H. pylori strains harbored the highest levels of resistance against ampicillin (100%), erythromycin (75%), clarithromycin (75%), and trimethoprim (58.3%). The most commonly detected genotypes were vacAs1a (83.3%), vacAm1a (66.6%), vacAs2 (50%) and cagA (50%). The presence of similar genotypes in the H. pylori strains of drinking water and those of human clinical samples suggest that contaminated water maybe the sources of bacteria. Spiramycin and furazolidone are suggested for the treatment of cases of H. pylori infection.

Helicobacter pylori is a gram-negative, microaerophilic and spiral-shaped bacterium that efficiently colonizes the human gastric mucosa [1]. Bacterial colonization of the gastric mucosa is the main cause of ulcers in the stomach and duodenum [1]. H. pylori is also known as a causative agent of peptic ulcer disease, type B gastritis, gastric adenocarcinoma, and mucosa-associated lymphoid tissue lymphoma [1,2]. It has been estimated that 17–86% of hospitalized patients with peptic ulcers were infected with H. pylori [2–4]. Documented data showed that the H. pylori colonizes more than 50% of the world’s population [5]. Despite the high incidence of bacteria in human populations, no reservoir outside of the human stomach has been identified [6]. Transmission presumably occurs through fecal–oral and oral–oral routes. One of the most commonly

Abbreviations
AM, ampicillin; AMX, amoxicillin; babA, blood group antigen-binding adhesion; cag, cytotoxin-associated gene; Cef, cefsulodin; CLR, clarithromycin; CLSI, Clinical Laboratory Standards Institute; ER, erythromycin; FZL, furazolidone; H. pylori, Helicobacter pylori; iceA, induced by contact with the epithelium antigen; Lev, levofloxacin; Met, metronidazole; oip, outer inflammatory protein; RIF, rifampin; Spi, spiramycin; TRP, trimethoprim; vacA, vacuolating cytotoxin.
reported reservoir of the *H. pylori* outside of human stomach is contaminated water [7,8]. An epidemiological association between water sources and the prevalence of *H. pylori* infection has been identified [8]. The hypothesis of water being a route of transmission of *H. pylori* [8–10] is supported by epidemiologic studies that have observed a higher prevalence of *H. pylori* infection in developing countries which suffered from problems related to the sanitary distribution of water among the population [11].

To appraise the pathogenicity of *H. pylori* especially in possible sources of transmission like water, evaluation of latent virulence factors and genotypes is essential. The most commonly important virulence factors among *H. pylori* strains of different clinical outcomes of human and animal beings are the vacuolating cytotoxin (*vacA*), induced by contact with the epithelium antigen (*iceA*), cytotoxin-associated gene (*cag*), blood group antigen-binding adhesion (*babA*), and outer inflammatory protein (*oip*) [12–16]. These genes are usually induced by adhesion and invasion to the gastric epithelial cells [12–16]. Genotyping using these virulence markers is considered as one of the best approaches to determine correlations between *H. pylori* isolates from different samples.

In order to appraise the pathogenicity of *H. pylori*, study the antimicrobial resistance properties is another important point. Treatment is a critical point in the epidemiology of *H. pylori* infection in humans, since therapeutic options have become somewhat limited because of the presence of multidrug-resistant strains of this bacterium [14–17]. Moreover, to the best of our knowledge, we could not find any published data on the antibiotic resistance pattern of *H. pylori* strains isolated from drinking water samples.

Data on the epidemiology and transmission of *H. pylori* is extremely significant in order to prevent its distribution and to identify high-risk populations, especially in areas that have high rates of gastritis, peptic ulcers, and gastric cancer such as Iran [13,17–19]. Considering the unclear epidemiological aspects of *H. pylori* in Iranian drinking water sources, the present investigation was carried out in order to study the exact status of *vacA*, *cagA*, *iceA*, *oipA* and *babA2* genotypes and the antibiotic resistance patterns of *H. pylori* isolates from drinking water samples.

**Materials and methods**

**Sample collection**

From January 2014 to January 2015, overall 400 drinking water samples were collected from the various parts of Isfahan, Shiraz, Yazd, and Shahrekord province, Iran. All samples were collected from various seasons of the year including summer (n = 95), autumn (n = 100), winter (n = 110), and spring (n = 95). Samples (100 mL in 1000-mL glass bottles containing 0.5 g of sodium thiosulphate for dechlorination) were transported to the lab on ice, and used within 2 h of collection. All samples were collected in aseptic conditions away from any cross-contamination in separate glass bottles. Drinking water samples of these major cities of Iran were treated using chlorination.

**Isolation of *H. pylori***

Samples were filtered through 0.45-µm filter membrane (Albet Co., Barcelona, Spain). Each membrane was then immersed into 2 mL of Tryptic Soy Broth (TSB, Merck, Darmstadt, Germany) for 1 h. After that, each 2 mL TSB was taken and cultured for *H. pylori*. Samples were cultured on Brucella agar (Merck) containing campylobacter-selective supplement (5 mg L⁻¹, Merck), trimethoprim (0.25 mg L⁻¹), colistin methanesulfonate (30 mg L⁻¹), cycloheximide (10 mg L⁻¹), nalidixic acid (30 mg L⁻¹), trimethoprim (30 mg L⁻¹), vancomycin (10 mg L⁻¹) (Sigma, St Louis, MO, USA), amphotericin B (10 mg L⁻¹), sheep blood (5%), and 7% fetal calf serum (Sigma). After 72 h incubation at 37 °C in microaerophilic condition (85% N₂, 10% CO₂ and 5% O₂) using MART system (Anoxamat, Lichtenvoorde, The Netherlands), the bacterial growth was tested and confirmed as *H. pylori* using Gram staining, urease, and oxidase tests. For comparison, a reference strain of *H. pylori* (ATCC 43504) was employed.

**Antimicrobial susceptibility testing**

Pure cultures of *H. pylori* were applied for antibiotic susceptibility test. One strain from each *H. pylori*-positive sample was selected for this aim. Antimicrobial susceptibility test was accomplished by the Kirby–Bauer disk diffusion method using Mueller–Hinton agar (Merck) supplemented with 5% defibrinated sheep blood and 7% fetal calf serum, according to the Clinical Laboratory Standards Institute (CLSI, 2012) [20]. The antimicrobial resistance of *H. pylori* was measured against the widely used antibiotics in cases of *H. pylori* gastric ulcer. The following antimicrobial disks (HIMedia Laboratories, Mumbai, India) were used: ampicillin (10 µg), metronidazole (5 µg), erythromycin (5 µg), clarithromycin (2 µg), amoxicillin (10 µg), levofloxacin (5 µg), rifampin (30 µg), cephalixin (30 µg), trimethoprim (25 µg), furazolidine (1 µg) and spiramycin (100 µg). After incubation at 37 °C for 48 h in a microaerophilic atmosphere (85% N₂, 10% CO₂, and 5% O₂), the susceptibility of the *H. pylori* was measured against each antimicrobial agents. Results were construed in accordance with interpretive criteria provided by CLSI [20]. The *H. pylori* ATCC 43504 was used as quality control organisms in antimicrobial susceptibility determination.
DNA extraction and _H. pylori_ 16S rRNA gene amplification

Suspected colonies were also identified as _H. pylori_ based on the PCR technique. Genomic DNA was extracted from the colonies with typical characters of _H. pylori_ using a DNA extraction kit for cells and tissues (Roche Applied Science, Mannheim, Germany, 11814770001) according to the manufacturer’s instructions and its concentration was assessed by optic densitometry. Extracted DNA was amplified for the 16S rRNA gene (primers: HP-F: 5'-CTGGAG AGACTAAGCCCTCC-3' and HP-R: 5'-ATTACGTACG CTGATTGTGC-3') [21]. PCR reactions were performed in a final volume of 50 µL containing 5 µL 10× buffer (Fermentas, Mannheim, Germany) + MgCl₂, 2 mM dNTP (Fermentas), 2 units of Taq DNA polymerase (Fermentas), 100 ng genomic DNA as a template, and 25 pmol of each primer. PCR was performed using a thermal cycler (Eppendorf Co., Hamburg, Germany) under the following conditions: an initial denaturation for 2 min at 94 °C; 30 cycles of 95 °C for 30 s, 60 °C for 30 s, and 72 °C for 30 s and a final extension at 72 °C for 8 min. _H. pylori_ (ATCC 43504) was employed as a positive control in this part of the study.

Genotyping of vacA, cagA, iceA, babA2, and oipA genotypes in the _H. pylori_ isolates of drinking water

The genotype data refer to pooled colonies (individual water samples) and not individual isolates of _H. pylori_. The presence of the iceA1, iceA2, oipA, cagA, babA2 genotypes and also various genotypes of vacA alleles (s1a, s1b, s1c, m1a, m1b and m2) were determined using PCR technique. List of primers and PCR program are shown in Table 1 [22–30]. PCR amplifications were performed in a programmable thermal cycler (Master Cycle Gradient; Eppendorf) and all runs included one negative DNA control consisting of PCR grade water and two or more positive controls (26695, 399, SS1, Tx30, 88-23 and 84-183).

Gel electrophoresis

The PCR amplification products (10 µL) were subjected to electrophoresis in a 2% agarose gel in 1× TBE buffer (Fermentas) at 80 V for 30 min, stained with ethidium bromide, and images were obtained in a UVidoc gel documentation systems (UK). The PCR products were identified by 100 bp DNA size marker (Fermentas).

Statistical analysis

Data were transferred to Microsoft Excel spreadsheet (Microsoft Corp., Redmond, WA, USA) for analysis. Using spss 16.0 statistical software (SPSS Inc., Chicago, IL, USA), Chi-square test and Fisher’s exact two-tailed test were performed and differences were considered significant at values of _P_ < 0.05. The distribution of _H. pylori_ genotypes isolated from drinking water was statistically analyzed.

Results

A total of 400 drinking water samples were studied for the presence of _H. pylori_, its genotypes and antimicrobial resistance properties. Table 2 shows the total distribution of _H. pylori_ in the drinking water samples of four major province of Iran. Of 400 drinking water samples collected, 12 samples (3%) were contaminated with _H. pylori_. The results of culture method were confirmed using the 16S rRNA-based PCR technique. The water samples of Isfahan province were the most contaminated, while those of Shiraz province were less contaminated. Statistically significant difference was seen between the distributions of _H. pylori_ and zone of sample collection (_P_ < 0.05). Seasonal distribution of _H. pylori_ in the drinking water samples of various parts of Iran is shown in Fig. 1. We found that the drinking water samples of summer seasons had the highest levels of _H. pylori_-contamination (7.36%), followed by spring and autumn (2.1% and 2% respectively). Statistically significant difference was seen between the distributions of _H. pylori_ and season of sample collection (_P_ < 0.05).

The results of antimicrobial resistance patterns of _H. pylori_ isolates of Iranian drinking water samples is shown in Table 3. _H. pylori_ strains of our investigation harbored the highest levels of resistance against ampicillin (100%), erythromycin (75%), clarithromycin (75%) and trimethoprim (58.3%) antimicrobial agents. There were statistically significant differences in the levels of antibiotic resistance between ampicillin and rifampin (_P_ = 0.022), ampicillin and cefsulodin (_P_ = 0.028), clarithromycin and furazolidone (_P_ = 0.033), ampicillin and spiramycin (_P_ = 0.034), and amoxicillin and furazolidone (_P_ = 0.029).

Distribution of various genotypes of vacA alleles, cagA, iceA1, iceA2, oipA and babA2 is shown in table 4. The most commonly detected genotypes among the _H. pylori_ isolates of drinking water were vacAs1a (83.3%), vacAm1a (66.6%), vacAs2 (50%) and cagA (50%). The prevalence of iceA1, iceA2, oipA and babA2 genotypes were 41.6%, 16.6%, 33.3% and 16.6%, respectively.

Discussion

The present investigation was carried out to study the prevalence of _H. pylori_ in the drinking water samples
of four major provinces in Iran as well as to determine the \( \text{vacA} \), \( \text{cagA} \), \( \text{iceA} \), \( \text{oipA} \) and \( \text{babA2} \) genotype status and antibiotic resistance properties of bacterial isolates. Our results showed that 3% of drinking water samples were contaminated with \( \text{H. pylori} \). Although the prevalence of bacterium is low, according to daily and high consumption of water, it is very impressive. Despite the results of a previous study which revealed

|                |                                               |                      |                                                | 72 °C for 8 min                     |
that viable helicobacters were not detected in any of the 151 samples from the United Kingdom [31], the results of our investigation showed that all of the H. pylori isolates of drinking water were viable in culture media. Bahrami et al. [32] tried to detect H. pylori in city water, dental units’ water, and bottled mineral water of Iran. Their results showed that the prevalence of H. pylori in 2 of 50 tap water samples (4%), 2 of 35 dental units’ water (5.8%) samples, and 1 of 40 water coolers in public places (3%) were contaminated with H. pylori. Some possible reasons for the high prevalence of H. pylori in drinking water samples in Iran are (a) the lack of efficient methods for water purification, (b) using river water for drinking in some areas of Iran like Isfahan and Yazd province, (c) the possibility of the presence of bacterial colonies as a biofilm in the pipes used for water transfer, (d) application of open water accumulation sources in some areas like Shahrekord and Shiraz, (e) the possibility of leakage of household, industrial, and agricultural wastewater to the sources of drinking water, and finally (f) lack of personal hygiene of refinery rooms’ staff. One possible explanation for the higher prevalence of H. pylori in the drinking water of Isfahan province is due to primary contamination of the Zayande-rood River. The Zayande-rood River is the main source of drinking water supply of the Isfahan province. This river comes from the Zagros Mountains. After passing through several towns, agricultural lands, and industrial areas, the river reaches the Isfahan steel company and then enters the Isfahan purification facility. Several sources of pollution including Isfahan steel company, towns, villages, industrial factories, and agriculture exist along the path of this river. Entrance of industrial, agricultural, urban and rural waste, and waste waters into the Zayande-rood River are the main source of water contamination. In addition to Isfahan, the Zayande-rood River are the main source of water supply for Yazd province. Therefore, primary contamination of Zayande-rood River and weak performance of refinery rooms are two important factors which support the significant presence of H. pylori in the drinking water of Yazd province. Despite our finding, no H. pylori was found in the water sources of several studies

Table 2. Total distribution of Helicobacter pylori in the drinking water samples in four major provinces of Iran.

| Province | No. of samples collected | No. of H. pylori-positive samples (%) | No. of H. pylori-positive samples confirmed by PCR (%) |
|----------|--------------------------|-------------------------------------|-----------------------------------------------------|
| Isfahan  | 120                      | 5 (4.16)                            | 5 (4.16)                                            |
| Shiraz   | 110                      | 2 (1.8)                             | 2 (1.8)                                             |
| Yazd     | 100                      | 3 (3)                               | 3 (3)                                               |
| Shahrekord | 70                       | 2 (2.8)                             | 2 (2.8)                                             |
| Total    | 400                      | 12 (3)                              | 12 (3)                                              |

Fig. 1. Seasonal distribution of Helicobacter pylori in Iranian drinking water samples. The number of samples collected in summer, autumn, winter, and spring seasons were 95, 100, 110 and 95, respectively. Number of positive strains obtained from the water samples collected from summer, autumn, winter, and spring seasons were seven, two, one, and two strains, respectively. Prevalence of H. pylori in each season is shown by percentage.

Table 3. Antimicrobial resistance pattern of Helicobacter pylori isolates from Iranian drinking water samples.

| Types of Samples (no. positive results) | Pattern of antibiotic resistance (%) |
|----------------------------------------|-------------------------------------|
|                                        | AM10* | Met5 | ERS | CLR2 | AMX10 | Lev5 | Rif30 | Cef30 | TRP25 | FZL1 | Spi100 |
| Isfahan (5)                            | 5 (100) | 3 (60) | 4 (80) | 4 (80) | 3 (60) | 3 (60) | 2 (40) | 2 (40) | 3 (60) | 1 (20) | 1 (20) |
| Shiraz (2)                             | 2 (100) | 1 (50) | 2 (100) | 2 (100) | 1 (50) | 1 (50) | 1 (50) | 1 (50) | 1 (50) | – | – |
| Yazd (3)                               | 3 (100) | 1 (33.3) | 2 (66.6) | 2 (66.6) | 1 (33.3) | 1 (33.3) | – | – | 2 (66.6) | – | – |
| Shahrekord (2)                         | 2 (100) | 1 (50) | 1 (50) | 1 (50) | 1 (50) | 1 (50) | – | – | 1 (50) | 1 (50) | 1 (50) |
| Total (12)                             | 12 (100) | 6 (50) | 9 (75) | 9 (75) | 6 (50) | 6 (50) | 3 (25) | 3 (25) | 7 (58.3) | 1 (8.3) | 2 (16.6) |

*AM10: ampicillin (10 µg), Met5: metronidazole (5 µg), ERS: erythromycin (5 µg), CLR2: clarithromycin (2 µg), AMX10: amoxicillin (10 µg), Lev5: levofloxacin (5 µg), Rif30: rifampin (30 µg), Cef30: cefuroxime (30 µg), TRP25: trimethoprim (25 µg), FZL1: furazolidone (1 µg), and Spi100: spiramycin (100 µg).
The prevalence of resistance against human-based antimicrobial agents in the \( H. pylori \) strains of drinking water samples could indirectly confirm the human-based routes of water infections. One possible explanation for the high prevalence of resistance against ampicillin (100%), erythromycin (75%), clarithromycin (75%), trimethoprim (58.3%), metronidazole (50%), amoxicillin (50%) and levofloxacin (50%) antimicrobial agents in our study maybe the excessive and indiscriminate prescription of these antibiotics in the treatment of cases of \( H. pylori \) infections in Iran. The possibility of considering spiramycin and furazolidone antibiotics as an alternative for treatment of \( H. pylori \) could be suggested in Iranian cases of infections. We found impressive high percentage of resistances to clarithromycin (75%), ampicillin (100%), and amoxycillin (50%), which were much higher than those reported by other investigations worldwide [40–42]. These antibiotics are one of the first-choice treatment agents for \( H. pylori \) infection and the high prevalence of resistance against these antibiotics are due to the irregular, intense, and illegal prescription of clarithromycin not only for the cases of \( H. pylori \) infections but also for all types of infectious diseases of the digestive tract. This matter has serious country-based concern.

Genotyping of \( H. pylori \) isolates showed that in the water samples of all studied areas of Iran, \( vacAs1a \) (83.3%), \( vacAm1a \) (66.6%), \( vacAs2 \) (50%) and \( cagA \) (50%) genotypes were high. As far as we know, only one study tried to study the genotype status of these four seasons in Isfahan province (17 °C for spring, 32 °C for summer, 16 °C for autumn and 5 °C for winter), it was determined that the prevalence rate of \( H. pylori \) strains in each season is related with their average temperatures. Yahaghi et al. [15] reported the similar seasonal distribution of the \( H. pylori \) strains in vegetable and salad samples. They showed statistically significant differences in the incidence of \( H. pylori \) between hot and cold seasons of the year.

The results of our study revealed that the presence of \( H. pylori \) in drinking water could be associated with clinical infections. It is because of the high presence of resistant and virulent strains of \( H. pylori \) in Iranian drinking water samples. We found that the bacterial strains of our investigation harbored the high levels of resistance against ampicillin (100%), erythromycin (75%), clarithromycin (75%), trimethoprim (58.3%), metronidazole (50%), amoxicillin (50%) and levofloxacin (50%) antimicrobial agents. Similar findings have been reported previously by Thayagarajan et al. [37], Yahaghi et al. [15], Bang et al. [38], and Secka et al. [39]. Bang et al. [38] reported that the \( H. pylori \) isolates of human clinical samples were highly resistant to metronidazole (34.7%), clarithromycin (16.7%), and amoxicillin (11.8%). Mirzaei et al. [40] reported that the prevalence of resistance of \( H. pylori \) isolates of Iranian clinical samples against metronidazole, clarithromycin, and amoxicillin were 56.3%, 14.6% and 4.2%, respectively. Previous study which was conducted on drinking water showed that the \( H. pylori \) isolates were resistant against metronidazole (36.4%), clarithromycin (0.9%), amoxicillin (0%), tetracycline (1.8%) and furazolidone (4.5%) [41]. Epidemiological investigations of Iran, Nigeria, India, Senegal, China, Saudi Arabia, Taiwan, Colombia, Thailand, Brazil, Egypt and Argentina showed that the \( H. pylori \) isolates of human clinical specimens had the highest levels of resistance against metronidazole, amoxicillin, quinolones, and tetracycline (WGO [42]) which was similar to our results.

The prevalence of resistance against human-based antimicrobial agents in the \( H. pylori \) strains of drinking water samples could indirectly confirm the human-based routes of water infections. One possible explanation for the high prevalence of resistance against ampicillin (100%), erythromycin (75%), clarithromycin (75%), trimethoprim (58.3%), metronidazole (50%), amoxicillin (50%) and levofloxacin (50%) antimicrobial agents in our study maybe the excessive and indiscriminate prescription of these antibiotics in the treatment of cases of \( H. pylori \) infections in Iran. The possibility of considering spiramycin and furazolidone antibiotics as an alternative for treatment of \( H. pylori \) could be suggested in Iranian cases of infections. We found impressive high percentage of resistances to clarithromycin (75%), ampicillin (100%), and amoxycillin (50%), which were much higher than those reported by other investigations worldwide [40–42]. These antibiotics are one of the first-choice treatment agents for \( H. pylori \) infection and the high prevalence of resistance against these antibiotics are due to the irregular, intense, and illegal prescription of clarithromycin not only for the cases of \( H. pylori \) infections but also for all types of infectious diseases of the digestive tract. This matter has serious country-based concern.

Genotyping of \( H. pylori \) isolates showed that in the water samples of all studied areas of Iran, \( vacAs1a \) (83.3%), \( vacAm1a \) (66.6%), \( vacAs2 \) (50%) and \( cagA \) (50%) genotypes were high. As far as we know, only one study tried to study the genotype status of

H. pylori strains of untreated municipal waste water samples [43]. The results of this study showed the high presence of vacAs1a, vacAm1a, and vacAs1am1a. High presence of vacAs1a, vacAm1a, vacAs2, cagA alleles and also slam1a, s2m1a, slbm1a, slbm1b, sla m2, s2m2 and mLAN2 genotypes in the H. pylori strains of human clinical samples such as gastric biopsy, feces, and saliva have been reported previously [44-46].

Total prevalence of iceAI, iceAII, oipA and babA2 genotypes in the H. pylori strains of our survey were 41.6%, 16.6%, 33.3% and 16.6%, respectively. In a study which was conducted in Iran on human clinical samples [47], the prevalence of cagA, iceAI, iceAII, oipA and babA2 genotypes were 62.2%, 48.6%, 16.2%, 81.1% and 94.6%, respectively. Similarity in the genotyping pattern of H. pylori in all provinces of our study and its close proximity with those of human clinical samples of other investigations have indirectly shown the human-based contamination of drinking water samples in these areas of Iran.

Helicobacter pylori strains carrying the s1m1 mosaic combination of the gene vacA exhibit higher levels of cytotoxic activity than s1m2 strains, while s2m2 strains secrete the toxin with low or no vacuolating activity in vitro and is rarely associated with gastric disease [13–15,48]. The severity of diseases caused by strains which express babA is greater than diseases by strains that do not express the gene [49]. The expression of iceAI is upregulated on contact between H. pylori and human epithelial cells, and may be related with peptic ulcer disease. The expression of oipA is associated with IL-8 induction and is related with severe clinical outcomes [13–15,48].

With respect to the high levels of similarities in the H. pylori strains of drinking water of our study and those of other investigations which were conducted on clinical samples, it could be concluded that contaminated water may be the sources of H. pylori infection for humans. However, there are significant differences between the drinking water isolates and those from patients: resistance to clarithromycin and amoxicillin was much higher in the drinking water isolates than those found in Iranian clinical samples, and the presence of oipA- and babA2-positive strains was much higher in clinical isolates than those from the drinking water in this study. The main reasons for the above findings are higher resistance of H. pylori strains of water samples than those of clinical isolates.

**Conclusion**

In conclusion, drinking water samples in Iran harbor H. pylori similar in genotypes of vacA, cagA, iceA, oipA and babA2 alleles with isolates recovered from various types of human clinical samples. High prevalence of H. pylori in our samples suggest that contaminated drinking water in these area of Iran maybe the sources of the bacteria and that it entered the human population after a period of time. There was no high diversity in the genotyping pattern of H. pylori between the different areas of Iran which may have shown that there was one source of contamination for drinking water. Prescrip- tion of spiramycin and furazolidone antibiotics as an alternative approach for treatment of H. pylori could be suggested.
