Abstract. The long time behaviour of the survival probability of initial state and its dependence on the initial states are considered, for the one dimensional free quantum particle. We derive the asymptotic expansion of the time evolution operator at long times, in terms of the integral operators. This enables us to obtain the asymptotic formula for the survival probability of the initial state $\psi(x)$, which is assumed to decrease sufficiently rapidly at large $|x|$. We then show that the behaviour of the survival probability at long times is determined by that of the initial state $\psi$ at zero momentum $k = 0$. Indeed, it is proved that the survival probability can exhibit the various power-decays like $t^{-2m-1}$ for an arbitrary non-negative integers $m$ as $t \to \infty$, corresponding to the initial states with the condition $\hat{\psi}(k) = O(k^m)$ as $k \to 0$.

1. Introduction

The decaying quantum systems such as an $\alpha$-decaying nucleus are often described by the survival probability of initial state, which is the probability to find the initial state in the state at a later time. One of the remarkable properties of the survival probability is its power decay law at long times. This is a mathematically predicted nature for the systems which possess the continuous energy spectrum bounded from below \([1]\). It is actually seen in many models (see, e.g. \([2, 3, 4]\) and the references therein). On the other hand, there still remains the difficulty in observing such power decays in the real experiments \([5, 6, 7]\). Hence, the further theoretical and experimental investigations of the power decay law are much required.

One of the fundamental and important models that exhibits the power decay law is the free-particle system, from which we can gain many insights into the dynamics of the survival probability and also the spatial wave packet. Recently, another aspect in the power-law regime at long times is revealed for the one dimensional free particle system, in connection with the initial states. As we known, the spatial wave packets for this system are expected to decay like $t^{-1/2}$ at long times $t$. We are assured of such a decay for the Gaussian wave packet. However, it is not necessarily valid for an arbitrary initial state. In fact, if we take a spatial power-law wave packet as an initial state, the “anomalous decay” of its maximum can occur with the form $t^{-\alpha/2}$ ($1/2 < \alpha < 1$) \([8, 9, 10]\). This is obviously slower than the well-known $t^{-1/2}$ decay. The faster decay than $t^{-1/2}$ is also studied for the initial wave packets which vanish at zero-momentum, in association with the dwell time \([11]\) and the time operator (see \([12]\) and Appendix A). The latter refers to the time evolution of the survival probability. Therefore, the asymptotic decay form of the wave packet for the free particle system depends on the initial states in a considerable way. However, we seem still not to get a clear perspective of this new aspect of the power decay law. Our aim in the present paper is to find the strict condition of the initial states for the various power decays in the one dimensional free particle system, and to clarify the underlying mechanism for such decays. In particular, we restrict ourselves to the survival probability which will show the various power decays as same as the spatial wave packet.

To this end, we introduce a systematic approach which consists of the two procedures. We first derive in section 3 the asymptotic expansion of the time evolution operator $\exp(-itH_0)$ as $t \to \infty$, where $H_0$ is the free Hamiltonian for the one dimensional free particle system. It is formally written as

$$\exp(-itH_0) = \pi^{-1}\sum_{j=0}^{\infty} (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} G_{2j}, \quad (1.1)$$

where $\Gamma(z)$ is the gamma function, and $G_{2j}$'s are some integral operators. This kind of the asymptotic expansion was already developed by Rauch \([13]\), Jensen and Kato \([14]\), and Murata \([15]\) with the detailed analyses (see also a recent comment by Amrein \([16]\)). Their results concern the time evolution operator for the systems with a short-range potential $V(x)$. The asymptotic expansion \((1.1)\) for the free particle system is
The power decay of the survival probability at long times

not evaluated by the authors mentioned above, however, it can be achieved without difficulty, following their technique for the potential system. The survival probability of the initial state $\psi$ is defined by the square modulus of the survival amplitude of $\psi$, that is

$$\langle \psi, \exp(-iH_0)\psi \rangle.$$ 

We see from (1.1) that $\langle \psi, \exp(-iH_0)\psi \rangle = O(t^{-1/2})$ only if $\langle \psi, G_0 \psi \rangle \neq 0$. In other words, if the following condition,

$$\langle \psi, G_{2j} \psi \rangle = 0, \quad j = 0, 1, \ldots, m - 1,$$

(1.2)

holds for some integer $m$, we can obtain another asymptotic decay form of $\langle \psi, \exp(-iH_0)\psi \rangle$, $t^{-m-1/2}$, faster than $t^{-1/2}$. Thus, our remaining procedure is to interpret the condition (1.2) as the behaviour of the initial state $\psi$ in, e.g., the position or momentum space. This is achieved in section 4, and we will finally obtain a remarkable conclusion: if the initial state $\psi$ behaves like $\hat{\psi}(k) = O(k^m)$ at zero momentum $k = 0$, then

$$|\langle \psi, \exp(-iH_0)\psi \rangle|^2 = \pi^{-1} t^{-2m-1} \Gamma(m+1/2)^2 |\langle \psi, G_{2m} \psi \rangle|^2 + o(t^{-2m-1}),$$

(1.3)

as $t \to \infty$, where $\psi$ is assumed to decrease sufficiently rapidly at large $|x|$, but otherwise arbitrary. Hence, the behaviour of the initial $\psi$ at zero momentum, i.e., $\hat{\psi}(k) = O(k^m)$, completely characterizes the asymptotic decay form of the survival probability of $\psi$. This fact is also expected from the results on the decays faster than $t^{-1/2}$ for the one dimensional free particle system [11, 12].

The organization of the paper is as follows. We first consider in section 2 the asymptotic behaviour of the free resolvent $(H_0 - z)^{-1}$ at small and large energies. This study is necessary to the proof of Theorem 3.1 in section 3, where the asymptotic expansion (1.1) is derived. The derivation essentially follows the method used by Jensen and Kato [14]. To derive the asymptotic formula (1.3) for the survival probability, it is enough to derive that for the survival amplitude. The latter is accomplished in Theorem 4.3 in section 4. Concluding remarks are given in section 5.

2. The free resolvent in one dimension

We here define the free Hamiltonian in one dimension $H_0 := P^2$, where $P$ is the momentum operator defined by $P := -iD_x$, $D_x$ being the differential operator on $L^2(\mathbb{R})$. Then, the free resolvent $R_0(z) := (H_0 - z)^{-1}$ is explicitly represented as an integral operator on $L^2(\mathbb{R})$ [17]

$$(R_0(z)\psi)(x) = -\frac{1}{2iz^{1/2}} \int_{\mathbb{R}} \exp(iz^{1/2}|x-y|)\psi(y)dy,$$

(2.1)

for all $\psi \in L^2(\mathbb{R})$, where $z$ belongs to $C_+ := \{ z \in \mathbb{C} \mid \text{Im } z > 0 \}$, and $\text{Im } z^{1/2} > 0$. The resolvent $R_0(z)$ is analytic in $z$. We, however, intend to regard it as an operator which
maps $L^{2,s}(\mathbb{R})$ to $L^{2,-s'}(\mathbb{R})$ for positive $s$ and $s'$. Here $L^{2,s}(\mathbb{R})$, defined for an arbitrary real $s$, is the weighted $L^2$-space with the norm
\[
\|\psi\|_s := \left[ \int_{\mathbb{R}} (1 + x^2)^s |\psi(x)|^2 dx \right]^{1/2},
\]
where $\psi \in L^{2,s}(\mathbb{R})$ means $\|\psi\|_s < \infty$. For positive $s$ and $s'$, the relation $L^{2,s}(\mathbb{R}) \subset L^2(\mathbb{R}) \subset L^{2,-s'}(\mathbb{R})$ holds. In addition, we denote by $B(s,-s')$ the Banach space of the bounded operators $M$ from $L^{2,s}(\mathbb{R})$ to $L^{2,-s'}(\mathbb{R})$, with the norm
\[
\|M\|_{s,-s'} := \sup_{\psi \in L^{2,s}(\mathbb{R}), \psi \neq 0} \frac{\|M\psi\|_{-s'}}{\|\psi\|_s}.
\]
Notice that $M \in B(s,-s')$ means the finiteness of its norm $\|M\|_{s,-s'} < \infty$. The reason for this kind of preparation for the free resolvent will be clear in the last part of the next lemma.

**Lemma 2.1 :** For $s,s' > 1/2$, $R_0(z)$ belongs to $B(s,-s')$, and is continuously extended to $\overline{C}_+ \setminus \{0\}$ where $\overline{C}_+$ the closure of $C_+$.

**Proof :** We have an estimation
\[
\|R_0(z)\psi\|_{-s'}^2 = \int_{\mathbb{R}} (1 + x^2)^{-s'} \left| \frac{1}{2iz^{1/2}} \int_{\mathbb{R}} \exp(i z^{1/2} |x-y|) \psi(y) dy \right|^2 dx \\
\leq \frac{\|\psi\|_s^2}{|2iz^{1/2}|^2} \int_{\mathbb{R}} (1 + x^2)^{-s'} dx \int_{\mathbb{R}} (1 + y^2)^{-s} dy < \infty,
\]
for all $\psi \in L^{2,s}(\mathbb{R})$ and $z \in C_+$. This result clearly holds for $z \in \overline{C}_+ \setminus \{0\}$ and the last part of the statement is also proved. \(\square\)

We use the same symbol $R_0(z)$ for the extension of $R_0(z)$ to $\overline{C}_+ \setminus \{0\}$. The free resolvent $R_0(z)$ is formally expanded around $z = 0$,
\[
R_0(z) = \sum_{j=0}^{\infty} (i z^{1/2})^j \frac{1}{2j!} G_j,
\]
where $G_j (j = 0,1,\ldots)$ is an integral operator acting on the suitable vectors $\psi$,
\[
(G_j \psi)(x) := -\frac{1}{2j!} \int_{\mathbb{R}} |x-y|^j \psi(y) dy.
\]

**Lemma 2.2 :** The integral operator $G_j$ is a Hilbert-Schmidt operator that belongs to $B(s,-s')$ with $s,s' > j + 1/2$.

**Proof :** Note that the statement in the lemma is equivalent to $(1 + x^2)^{-s'/2} G_j (1 + y^2)^{-s/2}$ being a Hilbert-Schmidt operator on $L^2(\mathbb{R})$. The latter is easily seen from the relation
\[
\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|x-y|^{2j}}{(1 + x^2)^{s'}(1 + y^2)^s} dx dy \leq 2^{2j} \int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|x|^{2j} + |y|^{2j}}{(1 + x^2)^{s'}(1 + y^2)^s} dx dy < \infty
\]
for every $s,s' > j + 1/2$. \(\square\)

The validity of the formal expansion (2.2) is ensured at small energies, in the following sense.
Lemma 2.3: Let $k = 0, 1, \ldots$. If $R_0(z)$ is approximated by a finite series in (2.2) up to $j = k$, the remainder is $o(|z|^{(k-1)/2})$ as $|z| \to 0$, in the norm of $B(s, s')$ with $s, s' > k + 1/2$. In the same sense, (2.2) can be differentiated in $z \in \mathbb{C}_+ \setminus \{0\}$ any number of times for appropriate $s$ and $s'$, that is, the $r$-th derivative in $z$ of the approximating finite series is equal to $(d^r/dz^r)R_0(z)$ up to an error of $o(|z|(k-1/2-r))$ in the norm of $B(s, s')$ with $s, s' > k + r + 1/2$.

Proof: We first consider the case of $k = 0$. Suppose that $r$ is a non-negative integer, $s, s' > r + 1/2$, and $\psi \in L^2-s(\mathbb{R})$. Then it follows that

$$
\left\| \frac{d^r R_0(z)}{dz^r} \psi - \frac{d^r(i z^{1/2})^{-1}}{dz^r} G_0 \psi \right\|_{-s'}^2
= \int_{\mathbb{R}} (1 + x^2)^{-s'} \left| \int_{\mathbb{R}} \frac{d^r}{dz^r} \left[ \frac{1}{2iz^{1/2}} \left( \exp(i z^{1/2} |x - y|) - 1 \right) \right] \psi(y) dy \right|^2 dx
\leq \frac{\|\psi\|_2^2}{4} \int_{\mathbb{R}} \left( 1 + x^2 \right)^{-s'} \left( 1 + y^2 \right)^{-s} \left[ A |z|^{-1-2r} \exp(i z^{1/2} |x - y|) - 1 \right]^2 + \sum_{m, m'} A_{m, m'} |z|^m |x - y|^{m'} \right] dx dy
$$

where $A$ and $A_{m, m'}$ are positive constants, and $m$ and $m'$ are integers, satisfying $-1 - 2r < m \leq -1 - r$ and $0 < m' \leq 2r$, respectively. When $r = 0$, there is no contribution from the summation $\sum_{m, m'}$. By the dominated convergence theorem, we see that (2.4) divided by $|z|^{-1-2r}$ goes to 0 as $z \to 0$. In the same way, for $k = 1, 2, \ldots$, we have

$$
\left\| \frac{d^r R_0(z)}{dz^r} \psi - \sum_{j=0}^k \frac{d^r(i z^{1/2})^{j-1}}{dz^r} G_j \psi \right\|_{-s'}^2
= \int_{\mathbb{R}} (1 + x^2)^{-s'} \left| \int_{\mathbb{R}} \frac{d^r}{dz^r} \left[ \left( \frac{i z^{1/2}}{2(k-1)!} \right)^{k-1} \left( \int_0^t t^{k-1} \exp(i z^{1/2} |x - y|(1 - t)) dt - \frac{1}{k} \right) \right] \psi(y) dy \right|^2 dx
\leq \frac{\|\psi\|_2^2}{2(k-1)!^2} \int_{\mathbb{R}} \left( 1 + x^2 \right)^{-s'} \left( 1 + y^2 \right)^{-s} \left[ B |z|^{k-1-2r} |x - y|^{2k} \right]^2 \left| \int_0^1 t^{k-1} \exp(i z^{1/2} |x - y|(1 - t)) dt - \frac{1}{k} \right|^2 + \sum_{m, m'} B_{m, m'} |z|^m |x - y|^{m'} \right] dx dy
$$

for $s, s' > k + r + 1/2$, where $B$ and $B_{m, m'}$ are positive constants, and $m$ and $m'$ are integers, satisfying $k - 1 - 2r < m \leq k - 1 - r$ and $2k < m' \leq 2(k + r)$, respectively. Taking the limit $z \to 0$, one can see that (2.3) divided by $|z|^{k-1-2r}$ goes to 0. This completes the proof of the lemma.

On the other hand, we also have the following lemma with respect to the asymptotic behaviour of $R_0(z)$ at large energies.
Lemma 2.4: Let \( k = 0, 1, \ldots \) and \( s, s' > k + 1/2 \). Then \( R_0(z) \) is \( k \)-times differentiable in \( z \in \mathbb{C} \setminus \{0\} \), in \( B(s, -s') \), and it behaves like
\[
\frac{d^r R_0(z)}{dz^r} = O(|z|^{-(r+1)/2}), \quad r = 0, 1, \ldots, k,
\]
as \( |z| \to \infty \) in the norm of \( B(s, -s') \).

Proof: Suppose that \( s, s' > k + 1/2 \) and \( \psi \in L^2, s(R) \), we have
\[
\left\| \frac{d^r R_0(z)}{dz^r} \psi \right\|_{s}^2 \leq \frac{\|\psi\|^2_s}{4} \int \frac{1}{(1 + x^2)^s'} \int \frac{1}{(1 + y^2)^s} \left[D |z|^{-1-r}|x - y|^{2r} + \sum_{m, m'} D_{m, m'} |z|^m |x - y|^{m'} \right] < \infty,
\]
where \( D \) and \( D_{m, m'} \) are positive constants, and \( m \) and \( m' \) are integers, satisfying \(-1 - 2r \leq m < -1 - r \) and \( 0 \leq m' < 2r \), respectively. Then, the right-hand side is \( O(|z|^{1-r}) \) as \( |z| \to \infty \). \( \square \)

3. Asymptotic expansion of the time evolution operator

In order to derive the asymptotic expansion of \( \exp(-i t H_0) \) in (3.1), we first define the spectral density denoted by \( E'(\lambda) := (2\pi)^{-1} (R_0(\lambda) - \overline{R_0(\lambda)}) \) for all \( \lambda > 0 \), where
\[
(\overline{R_0(\lambda)} \psi)(x) := \frac{1}{2i\lambda^{1/2}} \int \exp(-i\lambda^{1/2}|x - y|) \psi(y),
\]
for every \( \psi \in L^2, s(R) \) with \( s > 1/2 \). The operator \( \overline{R_0(\lambda)} \) is considered as the limit of \( R_0(\lambda + i\epsilon) \) in \( \epsilon \uparrow 0 \). \( E'(\lambda) \) clearly belongs to \( B(s, -s') \) with \( s, s' > 1/2 \), and it has the same properties as \( R_0(\lambda) \) described in Lemmas 2.1, 2.3, and 2.4. Substituting the expansion (2.2) and the corresponding one of \( \overline{R_0(\lambda)} \) into \( E'(\lambda) \), we have
\[
E'(\lambda) = \pi^{-1} \sum_{j=0}^{n} (-1)^{j-1} \lambda^{j-1/2} G_{2j} + F_n(\lambda), \quad (3.1)
\]
where \( F_n(\lambda) \) is the remainder. It should be noted that there are no integer powers in \( \lambda \). We next focus our attention on the following formula
\[
\exp(-it H_0) = \lim_{R \to \infty} \lim_{\epsilon \downarrow 0} \int_{-R}^{R} E'(\lambda) e^{-it\lambda} d\lambda, \quad (3.2)
\]
valid in \( B(s, -s') \) for \( s, s' > 1/2 \). The integration in the above can be also regarded as the complex integral of \( (2\pi i)^{-1} R_0(z) e^{-itz} \) with the contour enclosing the spectrum of \( H_0 \), i.e., \([0, \infty)\). This formula is shown in Appendix B. Then, the asymptotic expansion of \( \exp(-it H_0) \) at large \( t \) is obtained from the formula (3.2) together with the expansion (3.1). To be precise, we can show

Theorem 3.1: Let \( n = 0, 1, \ldots \) and \( s, s' > \max\{3n + 3/2, 5/2\} \). Then it follows that
\[
\exp(-it H_0) = \pi^{-1} \sum_{j=0}^{n} (-1)^{j-1} \Gamma(j + 1/2) (it)^{-j-1/2} G_{2j} + o(t^{-n-1/2}) \quad (3.3)
\]
as \( t \to \infty \), in the norm of \( B(s, -s') \).
Note that the asymptotic form of \( \exp(-itH_0) \) at large times is only determined by the behaviour of the free resolvent \( R_0(z) \) at small energies. Our proof follows the procedure proposed by Jensen and Kato [14], and it is given in Appendix C.

It is interesting to rewrite the formula (3.3) by using the “generalized” zero-energy eigenfunction of \( H_0 \), i.e., \( \phi_0(x) := (2\pi)^{-1/2} \). Since \( G_0 = -\pi \langle \phi_0, \cdot \rangle \phi_0 \) from (2.3), we have an alternative expression of (3.3) as

\[
\exp(-itH_0) = \pi^{1/2} (it)^{-1/2} \langle \phi_0, \cdot \rangle \phi_0 + o(t^{-1/2}), \quad t \to \infty. 
\]

Note that this has the same structure as the asymptotic expansions of the one and three dimensional systems with short-range potential \( V \), which have no zero-energy eigenstate but zero-energy resonance. The existence of the former implies that there is a zero-energy eigenfunction belonging to the \( L^2 \)-space, while that of the latter corresponds to the situation in which there is a function \( \psi_0 \), that is not in \( L^2(\mathbb{R}) \) but satisfies \( G_0 V \psi_0 = 0 \) for one dimension or \( (1 + G_0^{(3)}(\mathbb{R})) \psi_0 = 0 \) for three dimension. The system with the zero-energy resonance is known not to be “generic” [16, 13, 14, 15], and in such a case \( \phi_0 \) in (3.4) is replaced by \( \psi_0 \). In this sense, the one-dimensional free particle system is considered to be exceptional. On the contrary, the three-dimensional free particle system seems to be generic, since the \( t^{-1/2} \)-term does not appear in the expansion of \( \exp(-itH_0) \). This is because the free resolvent for the three dimensional case has no singularity at the origin, while it appears in (2.1) (see also [18]). To be precise, the asymptotic expansion of the free resolvent for the three-dimensional case is

\[
R_0(z) = \sum_{j=0}^{\infty} (iz^{1/2})^j G_j^{(3)},
\]

where \( G_j^{(3)} \) is the integral operator with the kernel \( |x - y|^{-1}/4\pi j! \) and \( x, y \in \mathbb{R}^3 \). Therefore the asymptote of \( \exp(-itH_0) \) for the three-dimensional case becomes

\[
\exp(-itH_0) = \pi^{3/2} (it)^{-3/2} \langle \phi_0^{(3)}, \cdot \rangle \phi_0^{(3)} + o(t^{-3/2}), \quad t \to \infty,
\]

in \( \mathcal{B}(s, s') \), with large enough \( s \) and \( s' \). Here \( \phi_0^{(3)}(x) := (2\pi)^{-3/2} \) is the zero-energy eigenfunction of \( H_0 \). Notice that \( \phi_0^{(3)} \) does not yield the \( t^{-1/2} \)-term in the expansion series, unlikely in the one-dimensional case.

The formula (3.3) does not bring us the information at each point \( x \). However, it is useful for calculating the quantities through the norm or the inner product, such as the survival probability. Suppose \( s, s' > j + 1/2, \sigma \in \mathbb{R} \), and \( M \in \mathcal{B}(-s', \sigma) \). Then, since \( G_j \) is considered as a vector in \( \mathcal{B}(s, -s') \), we see that \( \|MG_j\psi\|_{\sigma} \) is well defined for all \( \psi \in L^{2,s}(\mathbb{R}) \). Therefore, for \( s, s' > \max\{3n + 3/2, 5/2\} \) and \( M \in \mathcal{B}(-s', \sigma) \), we have from (3.3)

\[
\left\| M \exp(-itH_0) \psi \right\|_\sigma - \pi^{-1} \left\| \sum_{j=0}^{n} (-1)^j \Gamma(j + 1/2) (it)^{-j-1/2} MG_2j \psi \right\|_\sigma \leq \left\| \exp(-itH_0) \right\|_{s, -s'} - \pi^{-1} \sum_{j=0}^{n} (-1)^j \Gamma(j + 1/2) (it)^{-j-1/2} \left\| MG_2j \psi \right\|_{s', \sigma} = o(t^{-n-1/2}), \quad (3.6)
\]
for all $\psi \in L^{2,s}(\mathbb{R})$. For example, we can take $(1 + x^2)^{s'/2}E(B)$ for $M$ with $\sigma = -s'$, where $E(B)$ is the spectral measure of the position operator and $B$ an arbitrary bounded interval of $\mathbb{R}$, i.e. $(E(B)\psi)(x) = \psi(x)$ $(x \in B)$ or 0 $(x \notin B)$. Then, 
$$
\|M \exp(-itH_0)\psi\|_{s'}^2 = \|E(B)\exp(-itH_0)\psi\|^2 = \int_B |\psi(x,t)|^2 dx,
$$
and the last quantity is called the nonecape probability, which is the probability to find the particle in $B$ at a time $t$. From a similar argument, we also have,

$$
\left| \langle \phi, \exp(-itH_0)\psi \rangle - \pi^{-1} \sum_{j=0}^n (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} \langle \phi, G_{2j}\psi \rangle \|\phi\|_s^{-1} \|\psi\|_s^{-1} \right| 
\leq \left| \exp(-itH_0) - \pi^{-1} \sum_{j=0}^n (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} G_{2j} \right|_{s-s'} = o(t^{-n-1/2}), \quad (3.7)
$$

for $s, s' > \max\{3n + 3/2, 5/2\}$ with $s \geq s'$ and all $\phi, \psi \in L^{2,s}(\mathbb{R})$. The asymptotic formula for the survival amplitude of $\psi$ is the special case of (3.7).

4. Dependence on the initial momentum distribution

In practical situations, it sometimes happens that there are no contributions from some of the $G_{2j}$’s to such quantities like $\|M \exp(-itH_0)\psi\|_\sigma$ or $\langle \phi, \exp(-itH_0)\psi \rangle$, when they act on a certain vector $\psi$. In this section, we confine ourselves to such situations for the survival amplitude $\langle \psi, \exp(-itH_0)\psi \rangle$.

**Lemma 4.1**: Let $n = 0, 1, \ldots$. If $s > n + 1/2$ and $\psi \in L^{2,s}(\mathbb{R})$, then $x^j \psi(x) \in L^1(\mathbb{R})$, for all $j = 0, 1, \ldots, n$.

**Proof**: The statement is obtained straightforwardly: 
$$
\int_\mathbb{R} |x^j \psi(x)| dx = \int_\mathbb{R} (1 + x^2)^{-(s-j)/2}(1 + x^2)^{(s-j)/2}|x^j \psi(x)| dx \leq \left[ \int_\mathbb{R} (1 + x^2)^{-(s-j)/2} dx \right]^{1/2} \left[ \int_\mathbb{R} (1 + x^2)^{(s-j)/2} |\psi(x)|^2 dx \right]^{1/2} < \infty \text{ for all } j = 0, 1, \ldots, n \text{ with } s > n + 1/2. \ \Box
$$

**Lemma 4.2**: Let $m = 1, 2, \ldots$. If $s > \max\{2(m-1), m\} + 1/2$ and $\psi \in L^{2,s}(\mathbb{R})$, then the following three statements are equivalent:

(a) $\hat{\psi}(k) = O(k^m)$, $k \to 0$.

(b) $\langle \psi, G_{2j}\psi \rangle = 0$, $j = 0, 1, \ldots, m - 1$.

(c) $\int_\mathbb{R} x^j \psi(x) dx = 0$, $j = 0, 1, \ldots, m - 1$.

In particular, we have $G_{2j}\psi = 0$, $j = 0, 1, \ldots, (m-1)/2$ for odd $m$, or $G_{2j}\psi = 0$, $j = 0, 1, \ldots, m/2 - 1$ for even $m$.

**Proof**: Suppose that $\psi \in L^{2,s}(\mathbb{R})$ with $s > \max\{2(m-1), m\} + 1/2$. Then by Lemma [1], we first see that $x^j \psi(x) \in L^1(\mathbb{R})$ for $j = 0, 1, \ldots, \max\{2(m-1), m\}$. Since 
$$
e^{-ikx} = \sum_{j=0}^{m-1} \frac{(-ikx)^j}{j!} + (-ikx)^m \int_0^1 t^{m-1} e^{-ikx(1-t)} dt / (m-1)!,
$$
the fact that (c) implies (a) immediately follows, by using 

$$
|\hat{\psi}(k)| = \left| \frac{1}{\sqrt{2\pi}} \int_\mathbb{R} \left[ \sum_{j=0}^{m-1} \frac{(-ikx)^j}{j!} + \frac{(-ikx)^m}{(m-1)!} \int_0^1 t^{m-1} e^{-ikx(1-t)} dt \right] \psi(x) dx \right| \leq \frac{|k|^m}{\sqrt{2\pi}(m-1)!} \int_\mathbb{R} |x^m \psi(x)| dx = O(k^m), \quad k \to 0.
$$

(4.1)
To prove the fact that (a) implies (c), let us remember that \( \hat{\psi}(k) = O(k^m) \) \((k \to 0)\) means that for some \( \delta \) and some finite \( C \geq 0 \), \(|\hat{\psi}(k)/k^m| \leq C\) for all \( k \) satisfying \( 0 < |k| < \delta \). Then, from (4.1), \( \int_{\mathbb{R}} x^j \psi(x) dx \) should vanish for all \( j = 0, 1, \ldots, m \). The fact that (c) implies (b) follows straightforwardly from the identity,

\[
-2(2j)!\langle \psi, G_{2j}\psi \rangle = \sum_{i=0}^{2j} \frac{(-1)^{2j-i}(2j)!}{i!} \int_{\mathbb{R}} x^{2j-i}\psi(x) dx \int_{\mathbb{R}} y^i\psi(y) dy, \quad (4.2)
\]

where the bar (\( \bar{\cdot} \)) denotes the complex conjugate. To prove the fact that (b) implies (c), we first use the assumption that \(-2\langle \psi, \hat{G}_0\psi \rangle = |\int_{\mathbb{R}} \psi(x) dx|^2 = 0\). Then from (4.2) for \( j = 1 \) we have \( |\int_{\mathbb{R}} x\psi(x) dx|^2 = 0 \), from which the remaining equalities recursively follow. For the proof of the last part of the lemma, we note that for \( s, s' > 2j + 1/2 \) and \( \psi \in L^{2,s}(\mathbb{R}) \),

\[
G_{2j}\psi = 0 \iff \|G_{2j}\psi\|_{-s'} = 0 \iff \int_{\mathbb{R}} x^i\psi(x) dx = 0 \quad (i = 0, 1, \ldots, 2j).
\]

Hence, if (c) holds, we obtain the equality \( G_{2j}\psi = 0 \) for all \( j \) satisfying \( 2j \leq m - 1 \). This completes the proof. \( \square \)

Now we shall derive the asymptotic formula for the survival amplitude by combining Theorem 3.1 with Lemma 4.2. The asymptotic formula itself immediately follows from (3.7) with \( \phi = \psi \), under the assumption in Theorem 3.1. We also see that \( \max\{3n + 3/2, 5/2\} \geq 3n + 3/2 \geq \max\{2(m - 1), m\} + 1/2 \) for \( m \leq n \), and thus the assumption in Lemma 4.2 is included in that in Theorem 3.1. Hence, we finally obtain the following theorem for the survival amplitude of \( \psi \), which is closely connected to the behaviour of \( \psi \) at zero momentum.

**Theorem 4.3 :** Let \( m, n, m \leq n \) be non-negative integers, \( s > \max\{3n + 3/2, 5/2\} \), and \( \psi \in L^{2,s}(\mathbb{R}) \). Then it follows that

\[
\langle \psi, \exp(-itH_0)\psi \rangle = \pi^{-1} \sum_{j=0}^{n} (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} \langle \psi, G_{2j}\psi \rangle + o(t^{-n-1/2}). \quad (4.3)
\]

In particular, for some \( m \geq 1 \), if \( \hat{\psi}(k) = O(k^m) \) as \( k \to 0 \), then \( \langle \psi, G_{2j}\psi \rangle = 0 \) for all \( j = 0, 1, \ldots, m - 1 \), and vice versa.

The asymptotic formula (4.3) can also be written as the form without use of \( G_{2j}\)’s.

Let \( n = 0, 1, \ldots \). If \( s > n + 1/2 \) and \( \psi \in L^{2,s}(\mathbb{R}) \), \( \hat{\psi}(k) \) is \( n \)-times continuously differentiable in \( k \) with \( \hat{\psi}^{(n)}(k) = (-i)^n(2\pi)^{-1/2} \int_{\mathbb{R}} x^n e^{-ikx} \psi(x) dx \). Then, we have from Lemma 4.2 and (1.2) that if \( \hat{\psi}(k) = O(k^m) \) as \( k \to 0 \),

\[
\langle \psi, G_{2m}\psi \rangle = -\frac{(-1)^m}{2(2m)!} \frac{(2m)!}{m!} \int_{\mathbb{R}} x^m \psi(x) dx \int_{\mathbb{R}} y\psi(y) dy = -\frac{(-1)^m\pi}{(ml)^2} |\hat{\psi}^{(m)}(0)|^2. \quad (4.4)
\]

This expression also holds for \( m = 0 \) [see (3.4)]. Therefore, we obtain from (4.3) the asymptotic formula for the survival probability

\[
|\langle \psi, \exp(-itH_0)\psi \rangle|^2 = t^{-2m-1} \frac{\Gamma(m + 1/2)^2}{(ml)^4} |\hat{\psi}^{(m)}(0)|^4 + o(t^{-2m-1}). \quad (4.5)
\]
In Theorem 4.3, the assumption that \( \psi \in L^{2,s}(\mathbb{R}) \) with sufficiently large \( s \) is technically required. According to the expression in (4.5), it is worth reviewing this assumption in the momentum representation. Let \( \psi \in L^{2,s}(\mathbb{R}) \) \((s \geq 0)\) and \([s] \) denote the smallest integer less than or equal to \( s \). Then, by the Plancherel theorem, we have

\[
\infty > \int_{\mathbb{R}} (1 + x^2)^n |\psi(x)|^2 dx \geq \int_{\mathbb{R}} |x^n \psi(x)|^2 dx = \int_{\mathbb{R}_k} |\hat{\psi}^{(n)}(k)|^2 dk
\]

for all \( n = 0, 1, \ldots [s] \). It should be noted here that \( \hat{\psi}(k) \) is implicitly guaranteed to be \([s]-\)times differentiable. Hence, as an obvious case, we can find the following subspace

\[
\mathcal{D} := \{ \hat{\psi} \in C^{\infty}(\mathbb{R}_k) \mid \hat{\psi}^{(n)} \in L^2(\mathbb{R}_k), \ n = 0, 1, \ldots \}, \quad (4.6)
\]

which satisfies \( \mathcal{D} \subset \{ \hat{\psi} \in L^2(\mathbb{R}_k) \mid \psi \in L^{2,s}(\mathbb{R}) \} \) for all \( s \geq 0 \). Then, Equations (3.6) and (3.7) with an arbitrary \( n \) can be applied to the wave functions belonging to the above \( \mathcal{D} \). Examples of such (initial) wave functions include \( k^l/(1 + k^{2m})^{\alpha} \) and \( k^n \exp(-k^2) \), where \( l, m, n = 0, 1, \ldots \) and \( \alpha > 0 \) with \( 2ma_l - l > 1/2 \).

In order to see some implications of Theorem 4.3, let us refer to the following two examples. We first consider the rapidly decreasing functions, \( \hat{\phi}_m(k) = N_m k^m \exp(-a_0 k^2) \), as initial wave functions, where \( m = 0, 1, \ldots, a_0 > 0 \), and \( N_m := [\Gamma(m + 1/2)/(2a_0)^{m+1/2}]^{-1/2} \) being the normalization constants. Then it is obtained through the Laplace transform

\[
\langle \phi_m, \exp(-itH_0)\phi_m \rangle = \int_{-\infty}^{\infty} |\phi_m(k)|^2 \exp(-itk^2) dk
\]

\[
= [1 + it/(2a_0)]^{-(m+1/2)} = (it/2a_0)^{-(m+1/2)[1 + O(t^{-1})]]. \quad (4.7)
\]

On the other hand, we see that the right-hand side of (4.3) exactly corresponds to that in (4.7) in the leading order. The other example is a special case that \( \hat{\psi}^{(n)}(0) = 0 \) for all \( n = 0, 1, \ldots \). It is worth noticing that for such a initial wave function we clearly see from (4.3) that

\[
|\langle \psi, \exp(-itH_0)\psi \rangle|^2 = o(t^{-2n-1}),
\]

for every \( n \geq 0 \). That is, the survival probability decays faster than any power of \( t^{-1} \). However, it must decay slower than any exponential at long times for \( H_0 \geq 0 \). This strange decay behaviour is also found in a study of the time operator (Proposition 3.2 in [12]). The set of such a special wave function is given, e.g., by \( \mathcal{C}_i := \{ \hat{\psi} \in C^\infty_0(\mathbb{R}_k) \mid \exists k_0 > 0; \hat{\psi}(k) = 0, \text{for } k \in [-k_0, k_0] \} \). We see from (4.6) that \( \mathcal{C}_i \subset \mathcal{D} \). A wave function in \( \mathcal{C}_i \) has a positive lower-bound \( k_0^2 \) on energy. For instance, the following function

\[
\hat{\psi}(k) = \begin{cases} 
\exp(-1/[k_0^2 - (k - d)^2]) & (|k - d| < k_0) \\
0 & (|k - d| \geq k_0)
\end{cases}
\]

where \( d > k_0 > 0 \), surely belongs to \( \mathcal{C}_i \).

---

**The power decay of the survival probability at long times**

10
5. Concluding remarks

We have derived the asymptotic expansion of the time evolution operator for the one-dimensional free particle system, in terms of the operators which are expansion coefficients of the free resolvent at small energies. This enables us to obtain the asymptotic formula for the survival probability of \( \psi \), and also to evaluate, in a systematic way, the condition for the initial wave function \( \psi \) which makes the first several terms of the asymptotic formula vanish. We have found that if \( \hat{\psi}(k) = O(k^m) \) for some non-negative integer \( m \) at zero momentum, the asymptotic power of \( t^{-1} \) for the survival probability must be \( 2m+1 \). In other words, the information about the initial momentum distribution in the vicinity of zero momentum is reflected in the asymptotic decay form \( t^{-2m-1} \) at long times. Our results are essentially due to the choice of the initial wave functions \( \psi \) in \( L^{2,s} (\mathbb{R}) \) with sufficiently large \( s \). This guarantees the existence of the higher derivatives at zero momentum (see Remark ??). However, there is another wave function such that \( \hat{\psi}^{(n)}(0) = 0 \) up to \( n = m - 1 \), while its \( m \)-th derivative \( \hat{\psi}^{(m)}(0) \) diverges. Related wave functions are considered in \[8, 9, 10, 11\]. For such states, the asymptotic formula (4.5) is not correct. Indeed, the actual asymptotic decay form of the survival probability includes terms of non-odd power of \( t^{-1} \). We hope to address this issue in the future.

Acknowledgements

The author would like to thank Professor I. Ohba and Professor H. Nakazato for useful and helpful discussions.

Appendix A

Dependence of the survival probability on the initial state \( \psi \) for one-dimensional free particle system can be seen in the following inequality (Theorem 4.1 and section VI in \[12\]),

\[
|\langle \psi, \exp(-itH_0)\psi \rangle|^2 \leq \frac{4\|T_0\psi\|^2\|\psi\|^2}{t^2}, \quad t \in \mathbb{R},
\]

where \( T_0 \) is the Aharonov-Bohm time operator \[19\]. This brings us with an interpretation of \( \|T_0\psi\| \), or of the time uncertainty calculated from \( T_0 \). The relevant information herein is that for any \( L^2 \)-function \( \psi \) whose several moments are finite, e.g., \( \psi \in L^{2,s}(\mathbb{R}) \) \((s > 3/2)\), we have

\[
\|T_0\psi\| < \infty \iff \hat{\psi}(k) = O(k^2), \quad k \to 0.
\]

This implies, together with (\[A1\]), that the condition (\[A2\]) at zero momentum imposes on the survival amplitude \( \langle \psi, \exp(-itH_0)\psi \rangle \) a decay faster than \( t^{-1} \), which is obviously faster than \( t^{-1/2} \) of the usual decay law for the one dimensional free particle system.
To prove the relation (A2), we first define the Aharonov-Bohm time operator $T_0$, which is mathematically well treated in the scheme of the axiomatic quantum mechanics \cite{12, 20}. We define this operator as follows: the domain of $T_0$ is

$$D(T_0) := \left\{ \psi \in L^2(R) \mid \lim_{k \to 0} \frac{\hat{\psi}(k)}{|k|^{1/2}} = 0 \text{ and } (T_0 \psi)(k) \in L^2(R_k) \right\},$$

(A3)

and its action

$$(T_0 \psi)(k) = \frac{i}{4} \left( k \frac{d\hat{\psi}(k)}{dk} + \frac{1}{k} \frac{dk}{d\psi}(k) \right), \quad \text{a.e. } k \in R_k, \quad \psi \in D(T_0),$$

(A4)

where $\hat{\psi}(k)$ is assumed to be differentiable everywhere except the origin. For a $\psi$ that belongs to $L^{2,s}(R)$ ($s > 3/2$), $\psi(x)$ and $x \psi(x)$ in $L^1(R)$ by Lemma \cite{41}. This implies $\hat{\psi}(k)$ to be differentiable everywhere including the origin. Then, it follows as in \cite{41} that for $k \to 0$

$$\hat{\psi}(k) = \hat{\psi}(0) + k \hat{\psi}'(0) + O(k^2), \quad \hat{\psi}'(k) = \hat{\psi}'(0) + O(k).$$

(A5)

Hence

$$(T_0 \psi)(k) = \frac{i}{4} \left( -\frac{\hat{\psi}(0)}{k^2} + \frac{\hat{\psi}'(0)}{k} \right) + O(1)$$

(A6)

for small $k$. Furthermore, since $\psi \in L^{2,s}(R) \subset L^{2,1}(R)$, \(\int_R |x \psi(x)|^2 dx = \int_{R_k} |\hat{\psi}(k)|^2 dk < \infty\). Thus, $(T_0 \psi)(k)$ is assured to be square integrable on $(-\infty, -\delta) \cup [\delta, \infty)$ for an arbitrary $\delta > 0$.

Now, to prove the fact that $\|T_0 \psi\| < \infty$ implies $\hat{\psi}(k) = O(k^2)$, $k \to 0$ in the relation (A2), let us suppose that $(T_0 \psi)(k) \in L^2(R_k)$. Then, from the general property of $L^2$-functions, we see that $(T_0 \psi)(k) \in L^1([-\delta, \delta])$. This contradicts with (A6) unless $\hat{\psi}(0) = \hat{\psi}'(0) = 0$. Thus we have that $\hat{\psi}(k) = O(k^2)$. Conversely, if $\hat{\psi}(k) = O(k^2)$, it follows from (A3) that $\hat{\psi}(0) = \hat{\psi}'(0) = 0$. Then, (A6) implies that $(T_0 \psi)(k) \in L^2([-\delta, \delta])$. Hence, $(T_0 \psi)(k)$ belongs to $L^2(R_k)$, and the proof of the relation (A2) is completed.

**Appendix B**

In this appendix, we derive the formula (B2) which directly relates $\exp(-itH_0)$ to the spectral density. Let us remember that the time evolution operator for one dimensional free particle system is explicitly represented as

$$\psi(x, t) = \exp(-itH_0)\psi(x) = (4\pi it)^{-1/2} \int_R \exp(i|x-y|^2/4t)\psi(y) \, dy = O(t^{-1/2}),$$

(B1)

for all $\psi \in L^1(R) \cap L^2(R)$ and $t \neq 0$ \cite{17}. Note that $L^{2,s}(R) \subset L^1(R)$ for $s > 1/2$. Then, $\exp(-itH_0)$ is considered as an integral operator belonging to $B(s, -s')$ for $s, s' > 1/2$.

Let $s, s' > 1/2$ and $\psi \in L^{2,s}(R)$. We have an equality

$$\left( \int_0^R E'(\lambda)e^{-it\lambda}d\lambda \psi \right)(x) = \int_R d\lambda \left[ \int_0^R \cos(\lambda^{1/2}|x-y|)e^{-it\lambda} \right] \psi(y), \quad \text{a.e. } x \in R,$$

where
The power decay of the survival probability at long times

dr for positive $r$ and $R$. Then it follows from (B1) that
\[
\left\| \int_r^R E'(\lambda)e^{-it\lambda}d\lambda \psi - \exp(-itH_0)\psi \right\|_{-s'}^2 \left\| \psi \right\|^{-2}.
\]
\[
\leq \int_R \int_r \left| \int_r^R \frac{\cos(\lambda^{1/2}|x-y|)e^{-it\lambda}}{2\pi \lambda^{1/2}}d\lambda - \frac{\exp(-|x-y|^2/4it)}{(4\pi it)^{1/2}} \right|^2 dxdy \frac{1}{(1+x^2)^s(1+y^2)^s}. \quad (B2)
\]
We here see that
\[
\sup_{x \in \mathbb{R}, R > 0} \left| \int_0^R \frac{\cos(\lambda^{1/2}|x|)e^{-it\lambda}}{2\pi \lambda^{1/2}}d\lambda \right| < \infty. \quad (B3)
\]
To derive this, we have assumed $t > 0$, however, the following argument can be applied to negative $t$,
\[
\left| \int_0^R \frac{\cos(\lambda^{1/2}|x|)e^{-it\lambda}}{2\pi \lambda^{1/2}}d\lambda \right| = (2\pi)^{-1} \int_{-R^{1/2}}^{R^{1/2}} \exp(-it(\xi + a)^2)d\xi
\]
\[
= (2\pi)^{-1} \left[ \int_0^{R^{1/2}+a} \exp(-it\xi^2)d\xi + \int_0^{R^{1/2}+a} \exp(-it\xi^2)d\xi \right] \quad \text{if } a = |x|/2t.
\]
The last two integrals are estimated, by the complex integrals with the contour in fourth quadrant, to be
\[
\left| \int_0^{R^{1/2}+a} \exp(-it\xi^2)d\xi \right| \leq \frac{\pi(1-\exp(-t|R^{1/2}+a|^2))}{4t|R^{1/2}+a|} + \int_0^{R^{1/2}+a} \exp(-tr^2)dr
\]
\[
\leq \frac{\pi}{4t} \sup_{x > 0} \frac{1-\exp(-tx^2)}{x} + \frac{\sqrt{\pi}}{2t} < \infty.
\]
This leads to (B3). We also see straightforwardly
\[
\lim_{R \to \infty} \lim_{t \to 0} \int_r^R \frac{\cos(\lambda^{1/2}|x-y|)e^{-it\lambda}}{2\pi \lambda^{1/2}}d\lambda = \frac{\exp(-|x-y|^2/4it)}{(4\pi it)^{1/2}}. \quad (B4)
\]
Therefore, by the dominated convergence theorem, we have from (B2), (B3), and (B4)
\[
\sup_{\psi \in L^{2,s}(\mathbb{R}), \psi \neq 0} \left\| \exp(-itH_0)\psi - \int_r^R E'(\lambda)e^{-it\lambda}d\lambda \psi \right\|_{-s'}^2 \left\| \psi \right\|^{-2} \to 0
\]
as $r \to 0$ and $R \to \infty$, and we finally obtain the formula (3.2).

Appendix C

In order to prove Theorem 3.1, we first summarize the several property of $E'(\lambda)$. By Lemma 2.3, we see that for $n \geq 0$ the remainder $F_n(\lambda)$ in (3.1) is $(n + 1)$-times differentiable, in $B(s,-s')$ for $s, s' > 2n + (n + 1) + 1/2 = 3n + 3/2$, and satisfies that $(d/d\lambda)^r F_n(\lambda) = o(\lambda^{n-r-1/2})$ as $\lambda \downarrow 0$ ($r = 0, 1, \ldots, n + 1$). On the other hand, we see from Lemma 2.4 that $(d/d\lambda)^r E'(\lambda) = O(\lambda^{-(r+1)/2})$ as $\lambda \to \infty$, in $B(s,-s')$ for $s, s' > (m + 1) + 1/2 = m + 3/2$ ($r = 0, 1, \ldots, m + 1$). In particular, if $m \geq 1$, $(d/d\lambda)^{m+1} E'(\lambda)$ is integrable on $[\delta, \infty)$ for an arbitrary $\delta > 0$.

Let us now split the integral in (3.2) into two parts by writing
\[
E'(\lambda) = \phi(\lambda) E'(\lambda) + (1-\phi(\lambda)) E'(\lambda),
\]
where $\phi \in C_0^\infty([0,\infty))$ and satisfies $\phi(\lambda) = 1$ in a neighbourhood of $\lambda = 0$. Such a function is realized by $f(\lambda) = 1 - \int_0^\lambda g(x)dx$, where $g(x) = h(x)/\int_R h(x)dx$ and $h(x) = \exp(-1/[1 - (x - d)^2])$ if $|x - d| < 1$ or 0 if $|x - d| \geq 1$ with $d > 1$.

From Lemma 10.1 in [14] and the discussion as mentioned above, we see that $(1 - \phi(\lambda))E'(\lambda)$ has a contributions of $o(t^{-m-1})$ to $\exp(-itH_0)$ in $B(s, -s')$, where $m \geq 1$ and $s, s' > m + 3/2$.

On the other hand, the contribution of $\phi(\lambda)E'(\lambda)$ to $\exp(-itH_0)$ gives the main part of the asymptotic expansion. Then, the coefficient of $G_{2j}$ is given by

$$
\int_0^\infty \phi(\lambda) \lambda^j e^{-it\lambda} d\lambda = i^j \frac{d^j}{dt^j} \left[ \int_0^\infty \lambda^{-1/2} e^{-it\lambda} d\lambda + \int_0^\infty (\phi(\lambda) - 1) \lambda^{-1/2} e^{-it\lambda} d\lambda \right]
$$

$$
= \Gamma(j + 1/2) (it)^{-j-1/2} i^j \frac{d^j}{dt^j} \int_0^\infty (\phi(\lambda) - 1) \lambda^{-1/2} e^{-it\lambda} d\lambda. \quad (C1)
$$

Note that since $\phi(\lambda) - 1$ and all its derivatives vanish in the neighbourhood of $\lambda = 0$ and $\phi \in C_0^\infty([0,\infty))$, the last term in (C1) decays faster than any negative-power of $t$. Furthermore, we understand, from Lemma 10.2 in [14] and the discussion in the first of the appendix, that if $s, s' > 3n + 3/2$, any contribution of the Fourier transform of the remainder $\phi(\lambda)F_n(\lambda)$ to $\exp(-itH_0)$ is of $o(t^{-n-1/2})$ in the norm of $B(s, -s')$. Summarizing the above arguments, we finally obtain, under the condition $s, s' > \max\{3n + 3/2, 5/2\}$,

$$
\left\| \exp(-itH_0) - \pi^{-1} \sum_{j=0}^n (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} G_{2j} \right\|_{s, -s'}
$$

$$
\leq \left\| \exp(-itH_0) - \int_R E'(\lambda)e^{-it\lambda} d\lambda \right\|_{s, -s'}
$$

$$
+ \left\| \int_R E'(\lambda)e^{-it\lambda} d\lambda - \sum_{j=0}^n (-1)^{j-1} \Gamma(j + 1/2)(it)^{-j-1/2} G_{2j} \right\|_{s, -s'} 
\rightarrow 0 + o(t^{-n-1/2}),
$$

as $r \downarrow 0$ and $R \rightarrow \infty$. This is just the asymptotic expansion of $\exp(-itH_0)$ in (3.3).
