Relative stable categories and birationality

Paul Balmer and Greg Stevenson

Abstract
We propose a general method to construct new triangulated categories, relative stable categories, as additive quotients of a given one. This construction enhances results of Beligiannis, particularly in the tensor-triangular setting. We prove a birationality result, showing that the original category and its relative stable quotient are equivalent on some open piece of their spectrum.

1. Introduction
Traditionally, given a triangulated category $\mathcal{K}$, it is difficult to generate new triangulated categories from it. One can, of course, take Verdier quotients or pass to thick subcategories. However, this is quite restrictive and many properties of $\mathcal{K}$ will be inherited by any thick subcategory or quotient, which can be a curse as much as a blessing.

In recent years there have been breakthroughs which allow us to produce new triangulated categories from a given one — without recourse to an enhancement. In [7] the first-named author showed how to produce triangulated categories of modules over separable monads. Even more recently, Neeman has shown that one can complete a triangulated category with respect to a metric (see [25] for a survey of Neeman’s results). This host of new examples has already had profound implications for our understanding of geometry and representation theory.

This article is built upon a similarly profound construction, due to Beligiannis [8], which also yields new triangulated categories. Despite seeming relatively unknown, it predates the two constructions mentioned above. Beligiannis’ insight is that by treating a triangulated category equipped with a well-behaved class of triangles as if it were a Frobenius exact category, one can stabilize to produce a new triangulated category.

It is not hard to produce such well-behaved classes of triangles: We show in Theorem 4.23 that any sufficiently nice triple of adjoints gives rise to one. There are many examples of such
triples, and hence of such stabilizations. For instance, any spherical functor gives rise to a stable
category measuring how far away the spherical functor is from being faithful (Remark 4.24).

** For the rest of the introduction, and for most of the article, we focus on the tensor-triangulated case. Let $B$ be a rigid (a. k. a. strongly dualizable) object in a tensor-triangulated
category $\mathcal{K}$. The stable category of $\mathcal{K}$ relatively to $B$ is the additive quotient

$$\mathcal{K}_B = \mathcal{K}/B \otimes \mathcal{K},$$

that is, the category obtained by keeping the same objects as $\mathcal{K}$ and by modding out the
morphisms that factor via a tensor multiple of $B$, that is, via an object of $B \otimes \mathcal{K}$. The name
comes from the fact that objects $X, Y$ of $\mathcal{K}$ become isomorphic in $\mathcal{K}_B$ if and only if they become “stably” isomorphic $X \oplus P \simeq Y \oplus Q$ in $\mathcal{K}$ after adding direct summands $P, Q$ of objects in $B \otimes \mathcal{K}$. (See Lemma 5.2.)

This quotient $\mathcal{K}_B$ should not be confused with the more standard Verdier quotient
(localization) of $\mathcal{K}$ by the thick subcategory generated by $B$: We quantify in Lemma 4.13
the extent to which these constructions disagree. Nonetheless, the category $\mathcal{K}_B$ remains a
tensor-triangulated category, with triangulated structure first constructed by Beligiannis [8],
as discussed above.

Before analyzing $\mathcal{K}_B$, let us emphasize the warm generality in which our discussion is
basking. Among a much longer list of examples, here are three classics:

- $B$ could be a perfect complex in the derived category of a scheme;
- $B$ could be a finite genuine $\Gamma$-spectrum in the equivariant stable homotopy category of a
  compact Lie group $\Gamma$ (even $\Gamma = 1$ is interesting);
- $B$ could be a finite-dimensional representation in the stable module category of a finite
  group.

Historically, it seems that relative stable categories first appeared in the third setting, that
is, in modular representation theory, for instance, in [14]. In recent years, those categories have
generated renewed interest, in connection with cluster algebras [19], around Broué’s conjecture
[26] or even closer to tensor-triangular geometry in [2, 3, 13].

So what do we know about the tt-category $\mathcal{K}_B$ in general? Well, very little. In the recent
[13, Section 5], Carlson shows that $\mathcal{K}_B$ behaves in a “non-noetherian” fashion already in
modular representation theory; for instance, $\mathcal{K}_B$ can contain infinite towers of thick tensor-ideals. In other words, the methods that were successful for the ordinary stable category [11],
where cohomology is noetherian, have to give way to abstract tensor-triangular geometry: Thick tensor-ideals are classified by the spectrum $\text{Spc}(\mathcal{K}_B)$ of [4] and one should try to understand
that space.

It is natural to ask how this spectrum $\text{Spc}(\mathcal{K}_B)$ relates to the spectrum $\text{Spc}(\mathcal{K})$ of the
tt-category we start from. To understand the difficulty, note that the natural quotient functor
$\pi: \mathcal{K} \to \mathcal{K}_B$ is a tensor-functor but not a triangulated functor. In fact, the suspensions in $\mathcal{K}$
and $\mathcal{K}_B$ differ by twisting with an invertible object $F_B$ in $\mathcal{K}_B$. So it does not even make sense
to ask whether the image of a distinguished triangle in $\mathcal{K}$ remains distinguished in $\mathcal{K}_B$, for it is
not even a triangle! Consequently, we cannot produce a continuous map $\text{Spc}(\mathcal{K}_B) \to \text{Spc}(\mathcal{K})$
by using functoriality of $\text{Spc}(\cdot)$ and we do not know whether such a map exists in general.
(Compare Remark 8.11 though.) Inspired by [3], we can, however, prove a birationality result
relating $\mathcal{K}$ and $\mathcal{K}_B$.

** Theorem 1.1 (Birationality Theorem 8.7). There exists an object $C \in \mathcal{K}_B$ with the
following property. Consider the open subsets $U = \text{Spc}(\mathcal{K}) \setminus \text{supp}(B)$ and $V = \text{Spc}(\mathcal{K}_B) \setminus
supp(C) and the respective localizations $\mathcal{K} \rightarrow \mathcal{K}(U)$ and $\mathcal{K}_B \rightarrow \mathcal{K}_B(V)$. Then there exists a commutative diagram

$$
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{\pi} & \mathcal{K}_B \\
\text{res}_U \downarrow & & \downarrow \text{res}_V \\
\mathcal{K}(U) & \xrightarrow{\simeq} & \mathcal{K}_B(V)
\end{array}
$$

in which the lower functor is a tensor-triangulated equivalence $\mathcal{K}(U) \cong \mathcal{K}_B(V)$. In particular, these open subspaces $U$ and $V$ are homeomorphic.

In other words, although the functor $\pi: \mathcal{K} \rightarrow \mathcal{K}_B$ is not even triangulated, let alone an equivalence, there is a “common” open piece of the spectra $\text{Spc}(\mathcal{K})$ and $\text{Spc}(\mathcal{K}_B)$ on which $\pi$ becomes a triangulated equivalence.

Let us quickly outline the content of this work. After recalling basic terminology and notation in Section 2, we spend a few pages discussing the general framework of stable categories, without assuming the existence of a tensor product. We hope that our condensed presentation of the general theory will be useful to some readers beyond the above tt-geometric preoccupations. Specifically, Section 3 recalls the notion of proper class of exact triangles and Section 4 discusses the triangulation.

We also provide a pre-tensor version of the above birationality result in Section 5, see Corollary 5.10, after an analysis of the thick triangulated subcategories of the stable category in terms of the corresponding (non-triangulated) subcategories of $\mathcal{K}$.

Section 6 is an interlude. We prove that if we start with an algebraic triangulated category $\mathcal{K}$, then all stable categories built out of $\mathcal{K}$ remain algebraic. Recall that a triangulated category $\mathcal{K}$ is algebraic, in the sense of Keller [20], if it can be presented as the stable category of a Frobenius exact category; an equivalent definition is that $\mathcal{K}$ can be presented as the homotopy category of a differential-graded category. Knowing that $\mathcal{K}$ is algebraic allows, for instance, the invocation of results from tilting theory.

**Theorem 1.2** (Theorem 6.1). The relative stable category of an algebraic triangulated category remains algebraic.

This has been proved by Beligiannis in [9, Corollary 3.18] under a strong Ext-vanishing condition. We give a proof in complete generality.

The tensor enters the paper only in Section 7, where we discuss how the relative stable category inherits a tensor and we make other preparations. We are then ready for Section 8 where we wrap everything up and give the proof of Theorem 1.1.

## 2. Preliminaries

We begin by setting some conventions and introducing some basic notation which will be used throughout. We do not recall details of the ever-expanding yoga of tt-geometry here; in fact, tensor products do not appear until Section 7 and we utilize only fairly minimal machinery. Nonetheless, for a gentle introduction the interested reader should consult [6].

Our conventions for the various notions of equivalence and isomorphism, and our standing closure conditions on subcategories, are relatively standard.

**Convention 2.1.** We write $\cong$ for canonical (or natural) isomorphisms. We write $\simeq$ for a mere isomorphism for which we do not claim any naturality/uniqueness. We write $=$ for strict equalities, unique isomorphisms, or when we are lying desperately.
Convention 2.2. Throughout all subcategories are assumed to be full and replete, that is, closed under isomorphisms, unless explicitly mentioned otherwise.

Convention 2.3. Let \( \mathcal{K} \) be a triangulated category and consider an exact triangle 
\[ X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} \Sigma X \]
in \( \mathcal{K} \). We will call \( Z = \text{cone}(f) \) the cone of \( f \) (really the cone is the map \( g \) but this is a standard abuse). We sometimes also say that \( g \) (or just \( Z \)) is the cofiber of \( f \), or that \( f \) (or just \( X \)) is the fiber of \( g \).

Now we come to some notation that will be important throughout. The first piece is again standard.

Notation 2.4. Given a set \( \mathcal{A} \) of objects in \( \mathcal{K} \) we denote by \( \text{add}(\mathcal{A}) \) the closure of \( \mathcal{A} \) under finite sums and summands.

Next comes some more specialized notation. We will have cause to deal with both thick subcategories, that is, kernels of exact functors on objects, and certain ideals of morphisms, that is, kernels of additive functors on maps. We thus need notation to distinguish these two types of kernel.

Notation 2.5. Given an additive functor \( F: \mathcal{K} \to \mathcal{L} \) we set 
\[ \ker F = \{ f \in \mathcal{K} \mid F(f) = 0 \}, \]
to be the kernel of \( F \) on morphisms (that is, the ideal of \( F \)-phantoms). We will use 
\[ \text{Ker} F = \{ X \in \mathcal{K} \mid F(X) \cong 0 \}, \]
note the uppercase “K,” for the kernel on objects. We denote by \( \text{Im}(F) \) the essential image of \( F \).

We thus have two flavors of quotient at our disposal: the additive quotient by an ideal of maps and the Verdier quotient by a thick subcategory of objects (which is really a localization). We introduce notation to distinguish between these two operations.

Notation 2.6. If \( \mathcal{K} \) is a small additive category and \( \mathcal{N} \) is a full subcategory closed under sums and summands, we can form the ideal \( \mathcal{I} \) of maps which factor via \( \mathcal{N} \). We will often write \( \mathcal{K} / \mathcal{N} \) for the additive quotient \( \mathcal{K} / \mathcal{I} \).

Notation 2.7. We denote the Verdier quotient of a triangulated category \( \mathcal{K} \) by a thick subcategory \( \mathcal{J} \subseteq \mathcal{K} \) (that is, the localization of \( \mathcal{K} \) with respect to the morphisms whose cone belongs to \( \mathcal{J} \)) by \( \mathcal{K} \parallel \mathcal{J} \). This non-standard notation replaces the usual “\( \mathcal{K} / \mathcal{J} \)” in order to prevent confusion with the additive quotient. Note that the Verdier quotient factors via the additive quotient:

\[ \mathcal{K} \xrightarrow{\text{additive quotient}} \mathcal{K} / \mathcal{J} \xrightarrow{\exists!} \mathcal{K} \parallel \mathcal{J} \]

thus justifying the \( \parallel \) notation.

Recollection 2.8. We recall some basic facts concerning exact categories; we refer the reader to [12] for a thorough treatment. An exact category \( \mathcal{F} \) is an additive category together
with a chosen class \( \mathcal{S} \) of so-called \textit{admissible} short exact sequences \( M' \xrightarrow{i} M \xrightarrow{p} M'' \), consisting of admissible monomorphisms \( i \) and admissible epimorphisms \( p \), and satisfying the following axioms: \( \mathcal{S} \) is closed under isomorphism, contains the split exact sequences, and consists only of kernel–cokernel sequences; admissible monomorphisms (epimorphisms) are closed under composition; finally, the pushouts of admissible monomorphisms along any morphism exist and remain admissible monomorphisms, and dually for pullbacks of admissible epimorphisms.

\textbf{Recollection 2.9.} The notions of projective and injective objects in an exact category \( \mathcal{F} \) are defined as usual but with respect to the sequences in \( \mathcal{S} \). Projective precovers are admissible epimorphisms with projective source, and dually for injective preenvelopes. An exact category \( \mathcal{F} \) is \textit{Frobenius} if every object has a projective precover and an injective preenvelope and if injectives and projectives coincide. In that case, the additive quotient of \( \mathcal{F} \) by the projective-injectives, usually denoted by \( \mathcal{F}^{\perp} \), has a natural triangulated structure. The suspension of \( X \in \mathcal{F} \) is given by the cokernel of an injective preenvelope, which can be shown to be well defined and functorial in \( \mathcal{F} \). Given an exact sequence \( M' \xrightarrow{i} M \xrightarrow{p} M'' \) there is a commutative diagram

\[
\begin{array}{ccc}
M' & \xrightarrow{i} & M \\
\downarrow & & \downarrow \\
M' & \xrightarrow{E(M')} & \Sigma M',
\end{array}
\]

where \( M' \xrightarrow{E(M')} \) is an injective preenvelope. Going along the top row and then down we get \( M' \to M \to M'' \to \Sigma M' \) and the distinguished triangles in \( \mathcal{F} \) are precisely those isomorphic to sequences of this form. Further details can be found, for instance, in [17, Chapter I.2].

3. \textit{Proper classes of triangles}

There has been a proliferation of terminology, notation, and approaches in relative homological algebra dating from the infancy of the subject. Our reference is Beligiannis [8].† As the latter is rather long, we give a brief overview of some of the nomenclature for the reader’s convenience. This section is a preparation for Beligiannis’s Theorem 4.9 on the triangulation of relative stable categories. We discuss examples at the end of the section, starting with Definition 3.11.

\textbf{Remark 3.1.} Relative homological algebra in our triangulated category \( \mathcal{K} \) is indeed \textit{relative} to a given family of distinguished triangles \( \mathcal{E} \), whose precise properties we enunciate after this short conceptual warm-up. Most importantly, the family \( \mathcal{E} \) is not required to be closed under rotation of triangles: We do care very much about the order of the maps in the triangles of \( \mathcal{E} \). One could think of triangles in \( \mathcal{E} \)

\[
X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} \Sigma X
\]

as “generalized exact sequences,” in which \( f \) is a “generalized monomorphism,” \( g \) a “generalized epimorphism” and \( h \) a “generalized zero.” We call them, respectively \( \mathcal{E} \)-\textit{monomorphisms} (the \( f \)’s), \( \mathcal{E} \)-\textit{epimorphisms} (the \( g \)’s) and \( \mathcal{E} \)-\textit{phantoms} (the \( h \)’s).

We denote the ideal of \( \mathcal{E} \)-phantoms by \( \text{Ph}_{\mathcal{E}} = \{ h | \text{there is a triangle (3.2) in } \mathcal{E} \} \).

---

†Beware that, in [8], composition of morphisms \( fg \) means \( g \) \textit{after} \( f \), although the rule is the usual (reversed) one for functors. At the risk of stunning the reader with consistency, we here write both composition of morphisms and composition of functors in the usual right-to-left order.
HYPOTHESIS 3.3. We assume that $\mathcal{E}$ is a family of distinguished triangles in $\mathcal{K}$ closed under isomorphisms, suspension (that is, triple rotation), sums, and retracts, and that it contains the trivial triangles $X \xrightarrow{id} X \to 0 \to \Sigma X$ and $0 \to Y \xrightarrow{id} Y \to 0$; we further assume that $\mathcal{E}$-monomorphisms are closed under homotopy pushouts and $\mathcal{E}$-epimorphisms are closed under homotopy pullbacks. Finally we assume $\mathcal{E}$ to be saturated (see [8, Section 2.2]) in the sense that if the homotopy pull-back of a map $g$ along an $\mathcal{E}$-epimorphism is an $\mathcal{E}$-epimorphism, then $g$ is already an $\mathcal{E}$-epimorphism. (The dual statement with $\mathcal{E}$-monomorphisms is equivalent.) Explicitly, given a commutative diagram with distinguished rows and columns

\[
\begin{array}{ccc}
0 & \to & X \xrightarrow{f} X \xrightarrow{k} 0 \\
\downarrow & & \downarrow \\
W & \to & Y \xrightarrow{g} Y' \xrightarrow{g'} \Sigma W \\
\downarrow & & \downarrow \\
W & \to & Z \xrightarrow{\varphi} Z' \xrightarrow{g''} \Sigma W \\
\downarrow & & \downarrow \\
0 & \to & \Sigma X \xrightarrow{\varphi'} \Sigma X \xrightarrow{\varphi''} 0 \\
\end{array}
\]

if the third column $X \to Y' \to Z' \to$ and the second row $W \to Y \to Y'$ belong to $\mathcal{E}$, then the third row $W \to Z \to Z'$ also lies in $\mathcal{E}$.

In the language of [8] one says that $\mathcal{E}$ is a proper class of triangles.

REMARK 3.4. An ideal of morphisms $\mathcal{I}$ in $\mathcal{K}$ is called saturated (with respect to $\mathcal{E}$) if $\mathcal{I}$ contains every morphism $k$ such that $kg$ belongs to $\mathcal{I}$ for some $\mathcal{E}$-epimorphism $g$; equivalently, if $\mathcal{I}$ contains every morphism $k$ such that $fk$ belongs to $\mathcal{I}$ for $f$ an $\mathcal{E}$-monomorphism. For instance, the saturation property for $\mathcal{E}$ expressed in Hypothesis 3.3 is precisely asking the ideal $\mathcal{I} = \text{Ph}_\mathcal{E}$ of $\mathcal{E}$-phantoms to be a saturated ideal. Furthermore, this ideal $\mathcal{I}$ determines the proper class of triangles $\mathcal{E}$, as those distinguished triangles whose third map belongs to $\mathcal{I}$ (cf. [8, Section 2]).

EXAMPLES 3.5. There are many examples of proper classes of triangles $\mathcal{E}$.

1. The largest proper class $\mathcal{E}_{\text{dist}}$ and the smallest proper class $\mathcal{E}_{\text{split}}$

\[
\mathcal{E}_{\text{dist}} = \{\text{all distinguished triangles}\} \quad \text{and} \quad \mathcal{E}_{\text{split}} = \{\text{all split triangles } X \to Y \to Z \xrightarrow{0} \Sigma X\}
\]

have phantoms all morphisms and the zero morphisms, respectively.

2. Let $H : \mathcal{K}^{\text{op}} \to \mathcal{A}$ be a (co)homological functor to an abelian category and write $H^i = H \circ \Sigma^i$ as usual for $i \in \mathbb{Z}$. The class $\mathcal{E}_H$ consisting of the triangles (3.2) such that $H^i(h) = 0$ for all $i \in \mathbb{Z}$, that is, such that for all $i \in \mathbb{Z}$ the sequence $0 \to H^i(X) \xrightarrow{H^i(h)} H^i(Y) \xrightarrow{H^i(g)} H^i(Z) \to 0$ is exact in $\mathcal{A}$ (or $\mathcal{A}^{\text{op}}$ for cohomological) is a proper class of triangles. The ideal of $\mathcal{E}_H$-phantoms is precisely $\text{ker}(\bigoplus_i H^i)$. The trivial classes $\mathcal{E}_{\text{split}}$ and $\mathcal{E}_{\text{dist}}$ are special cases, for $H : \mathcal{K} \to \mathcal{A}(\mathcal{K})$ the embedding into its Freyd envelope $\mathcal{A}(\mathcal{K})$, and for $H = 0$ respectively. More generally, any Serre subcategory $\mathcal{B} \subseteq \mathcal{A}(\mathcal{K})$ yields a homological functor $H : \mathcal{K} \to \mathcal{A}(\mathcal{K}) \to \mathcal{A}(\mathcal{K})/\mathcal{B}$ and all proper classes appear as $\mathcal{E}_H$ in this way, for a suitable $\mathcal{B}$ (the subcategory of $\mathcal{A}(\mathcal{K})$ made up of images of $\mathcal{E}$-phantoms). See [8, Section 3].

3. Let $F : \mathcal{K} \to \mathcal{K}'$ be an exact functor of triangulated categories and $\mathcal{E}'$ be a proper class in $\mathcal{K}'$. Then $F^{-1}(\mathcal{E}')$ is a proper class in $\mathcal{K}$. For instance, if $\mathcal{E}' = \mathcal{E}_H'$ for a homological functor $H' : \mathcal{K} \to \mathcal{A}$, then $F^{-1}(\mathcal{E}') = \mathcal{E}_H$ where $H = H' \circ F$. The special case of $\mathcal{E}' = \mathcal{E}_{\text{dist}}(\mathcal{K}')$, consisting of all distinguished triangles, is boring since $F^{-1}(\mathcal{E}_{\text{dist}}(\mathcal{K}')) = \mathcal{E}_{\text{dist}}(\mathcal{K})$. The case
of split triangles $\mathcal{E}' = \mathcal{E}_{\text{split}}(\mathcal{X}')$ will be a much better source of examples. In particular, its ideal of phantoms is the ideal $\ker(F) = \{ h \mid F(h) = 0 \}$.

**Definitions 3.6.** Following the intuition of Remark 3.1 we adapt standard notions.

1. We say an object $P \in \mathcal{X}$ is $\mathcal{E}$-projective if for any triangle (3.2) in $\mathcal{E}$ the associated sequence of abelian groups

$$0 \to \mathcal{K}(P, X) \xrightarrow{\mathcal{K}(P,f)} \mathcal{K}(P, Y) \xrightarrow{\mathcal{K}(P,g)} \mathcal{K}(P, Z) \to 0$$

is exact. Dually we say $I$ is $\mathcal{E}$-injective if for any triangle (3.2) in $\mathcal{E}$ the sequence

$$0 \to \mathcal{K}(Z, I) \xrightarrow{\mathcal{K}(g,I)} \mathcal{K}(Y, I) \xrightarrow{\mathcal{K}(f,I)} \mathcal{K}(X, I) \to 0$$

is exact. (In both cases, exactness in the middle is clear and exactness on the left for all triangles in $\mathcal{E}$ is equivalent to exactness on the right.) We denote by

$$\text{proj}(\mathcal{E})$$

and

$$\text{inj}(\mathcal{E})$$

the classes of $\mathcal{E}$-projective and $\mathcal{E}$-injective objects, respectively. We note that they are closed under sums, summands, suspensions, and isomorphisms.

2. We say that $\mathcal{X}$ has enough $\mathcal{E}$-projectives (or sometimes that $\mathcal{E}$ has enough projectives) if every object $X \in \mathcal{X}$ admits a proj($\mathcal{E}$)-precover ($\mathcal{E}$-projective precover), that is, an $\mathcal{E}$-projective $P$ and an $\mathcal{E}$-epimorphism $P \to X$. Dually, we say that $\mathcal{X}$ has enough $\mathcal{E}$-injectives if every $X$ admits an inj($\mathcal{E}$)-preenvelope ($\mathcal{E}$-injective preenvelope) $X \to I$, that is, an $\mathcal{E}$-monomorphism to an $\mathcal{E}$-injective $I$.

**Example 3.7.** In the trivial cases of Examples 3.5(1), every object is $\mathcal{E}_{\text{split}}$-projective and $\mathcal{E}_{\text{split}}$-injective; only zero is $\mathcal{E}_{\text{dist}}$-projective or $\mathcal{E}_{\text{dist}}$-injective.

Here are some standard facts, mostly with standard proofs.

**Proposition 3.8.** Let $\mathcal{E}$ be a proper class of triangles in $\mathcal{X}$.

(a) An $\mathcal{E}$-epimorphism with $\mathcal{E}$-projective target is a split epimorphism. An $\mathcal{E}$-monomorphism with $\mathcal{E}$-injective source is a split monomorphism.

(b) For every $\mathcal{E}$-phantom $h$, we have $\mathcal{K}(P, h) = 0$ for every $\mathcal{E}$-projective $P$ and $\mathcal{K}(h, I) = 0$ for every $\mathcal{E}$-injective $I$.

(c) An object $X$ such that $\mathcal{K}(X, h) = 0$ (respectively, $\mathcal{K}(h, X) = 0$) for every $\mathcal{E}$-phantom $h$ must be $\mathcal{E}$-projective (respectively, $\mathcal{E}$-injective).

Suppose now that $\mathcal{X}$ has enough $\mathcal{E}$-projectives (respectively, enough $\mathcal{E}$-injectives). Then the following converses to the above hold true.

(d) An object $X$ such that every $\mathcal{E}$-epimorphism $Y \to X$ (respectively, every $\mathcal{E}$-monomorphism $X \to Y$) splits must be $\mathcal{E}$-projective (respectively, $\mathcal{E}$-injective).

(e) A morphism $h$ such that $\mathcal{K}(P, h) = 0$ for every $\mathcal{E}$-projective $P$ (respectively, $\mathcal{K}(h, I) = 0$ for every $\mathcal{E}$-injective $I$) must be an $\mathcal{E}$-phantom.

**Proof.** Parts (a), (b), (c) and (d) are easy exercises from the definition and the long exact sequences associated to distinguished triangles under $\mathcal{K}(X, -)$ and $\mathcal{K}(-, X)$. Let us prove (e) when $\mathcal{X}$ has enough projectives, say. Choose an $\mathcal{E}$-projective precover $g: P \to Z$ of the source of the given morphism $h: Z \to W$. Then in $\mathcal{K}(P, W)$, we have $hg = \mathcal{K}(P, h)(g) = 0$. Since $\mathcal{E}$-phantoms are saturated (Remark 3.4), we deduce from $hg = 0 \in \text{Ph}_\mathcal{E}$ with $g$ an $\mathcal{E}$-epimorphism that $h$ is an $\mathcal{E}$-phantom. □
In particular, there are enough $L \in L$ such that

This is our starting point.

We encounter an old friend.

**Proposition 3.10.** Let $F: \mathcal{K} \to \mathcal{K}'$ be relative-exact with respect to $\mathcal{E}$ in $\mathcal{K}$ and $\mathcal{E}'$ in $\mathcal{K}'$. A right adjoint $U: \mathcal{K}' \to \mathcal{K}$ of $F$, if it exists, must preserve injectives: $U(\text{inj}(\mathcal{E}')) \subseteq \text{inj}(\mathcal{E})$. Dually, a left adjoint $V: \mathcal{K}' \to \mathcal{K}$ of $F$, if it exists, must preserve projectives: $V(\text{proj}(\mathcal{E}')) \subseteq \text{proj}(\mathcal{E})$.

Proof. For $I \in \text{inj}(\mathcal{E}')$, the object $U(I)$ satisfies Definitions 3.6(1) since $\mathcal{K}(\cdot, U(I)) \cong \mathcal{K}'(F(\cdot), I) = \mathcal{K}'(\cdot, I) \circ F$ and $F$ is relative-exact and $I$ is injective. □

* * *

We conclude this section by discussing a method to produce proper classes of triangles by returning to the “$F$-split” triangles $\mathcal{E} = F^{-1}(\mathcal{E}_{\text{split}})$ of Examples 3.5(3). We begin by lightening the terminology in the natural way.

**Definition 3.11.** Let $F: \mathcal{K} \to \mathcal{L}$ be an exact functor of triangulated categories. We say that a triangle

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} \Sigma X \quad (3.12)$$

is $F$-split if $F(h) = 0$, in which case we say that $f$ is an $F$-monomorphism (that is, $F(f)$ is a split monomorphism), that $g$ is an $F$-epimorphism (that is, $F(g)$ is a split epimorphism) and that $h$ is an $F$-phantom. By Examples 3.5(3), the class $\mathcal{E}_F = F^{-1}(\mathcal{E}_{\text{split}})$ of $F$-split triangles is a proper class of triangles. The corresponding ideal $\text{Ph}_{\mathcal{E}_F}$ of $F$-phantoms is simply the kernel $\ker(F)$ of $F$ on morphisms. The $\mathcal{E}_F$-projective objects and $\mathcal{E}_F$-injective objects will simply be called $F$-projective and $F$-injective, respectively.

The definitions of $F$-split triangles, $F$-monomorphisms, $F$-epimorphisms, and $F$-phantoms are clear and transparently controlled by $F$. On the other hand, $F$-injectives and $F$-projectives are more mysterious, and it is not so obvious how to guarantee the existence of enough of them. This is our starting point.

**Lemma 3.13.** Let $F: \mathcal{K} \to \mathcal{L}$ be an exact functor.

(a) Suppose that $F$ admits a right adjoint $U: \mathcal{L} \to \mathcal{K}$. Then $U(L)$ is $F$-injective for every $L \in \mathcal{L}$ and the unit of adjunction $\eta: X \to UF(X)$ is an $F$-monomorphism for every $X \in \mathcal{K}$. In particular, there are enough $F$-injectives and

$$F\text{-inj} = \text{add}(U(L) \mid L \in \mathcal{L}).$$

(b) Suppose that $F$ admits a left adjoint $V: \mathcal{L} \to \mathcal{K}$. Then $V(L)$ is $F$-projective for every $L \in \mathcal{L}$ and the counit of adjunction $\varepsilon: VF(X) \to X$ is an $F$-epimorphism for every $X \in \mathcal{K}$. In particular, there are enough $F$-projectives and

$$F\text{-proj} = \text{add}(V(L) \mid L \in \mathcal{L}).$$

Proof. This is standard. By construction of $\mathcal{E}_F = F^{-1}(\mathcal{E}_{\text{split}})$, the exact functor $F$ is relative-exact (Definition 3.9) with respect to $\mathcal{E}_F$ in $\mathcal{K}$ and $\mathcal{E}_{\text{split}}$ in $\mathcal{L}$. By Proposition 3.10, $U$ and
V preserve injectives and projectives, respectively. But every object of $\mathcal{L}$ is $\mathcal{E}_{\text{split}}$-projective-injective (Example 3.7). The claims about the (co)units of adjunction are immediate from the unit-count unit relations. □

**Remark 3.14.** One can develop relative homological algebra via resolutions, derived functors, etc., as in [8, Section 4] or Christensen [15]. See also [22, 23] for an illustration of these ideas in $KK$-theory. We bifurcate instead toward “singularity categories,” where projective and injective objects vanish.

4. Beligiannis’ construction

In usual homological algebra, the most convenient setting for constructing a stable category is a Frobenius exact category (see Recollection 2.8). The transposition of these ideas to relative homological algebra is the subject of this section.

Let $\mathcal{K}$ be an essentially small triangulated category and $\mathcal{E}$ be a proper class of triangles as in Section 3. We further assume the following strong symmetry in $\mathcal{E}$.

**Definition 4.1.** We say that a proper class of triangles $\mathcal{E}$ as in Hypothesis 3.3 is Frobenius if it has enough projectives and enough injectives and if they coincide

$$\text{proj}(\mathcal{E}) = \text{inj}(\mathcal{E}).$$

We refer to these as the $\mathcal{E}$-projective-injective objects, when we want to stress Frobeniusity. Otherwise, we simply speak of $\mathcal{E}$-projectives or $\mathcal{E}$-injectives, as needed.

**Definition 4.2.** For $\mathcal{E}$ Frobenius, we consider the $\mathcal{E}$-relative stable category, that is, the corresponding additive quotient of $\mathcal{K}$ by the $\mathcal{E}$-projective-injective objects

$$\mathcal{K}_\mathcal{E} = \frac{\mathcal{K}}{\text{proj}(\mathcal{E})} = \frac{\mathcal{K}}{\text{inj}(\mathcal{E})}.$$

This quotient comes equipped with the universal additive functor

$$\pi: \mathcal{K} \to \mathcal{K}_\mathcal{E}$$

mapping $\text{proj}(\mathcal{E}) = \text{inj}(\mathcal{E})$ to zero. Recall that the category $\mathcal{K}_\mathcal{E}$ can be realized by keeping the same objects as $\mathcal{K}$ (so that $\pi$ is the identity on objects) and by defining the hom groups as the quotients of abelian groups

$$\mathcal{K}_\mathcal{E}(X,Y) = \frac{\mathcal{K}(X,Y)}{\mathcal{N}_\mathcal{E}(X,Y)},$$

where the ideal of morphisms $\mathcal{N}_\mathcal{E}$ is defined for every pair of objects $X,Y$ as

$$\mathcal{N}_\mathcal{E}(X,Y) = \{ f: X \to Y \mid f \text{ factors via an } \mathcal{E}\text{-projective-injective object} \}.$$

We shall call a morphism $\mathcal{E}$-contractible if it belongs to $\mathcal{N}_\mathcal{E}$.

**Warning 4.3.** It is important not to confuse the two ideals we discuss here: The ideal $\mathcal{N}_\mathcal{E}$ of $\mathcal{E}$-contractible morphisms (those factoring via $\mathcal{E}$-projectives-injectives) and the ideal $\text{Ph}_\mathcal{E}$ of $\mathcal{E}$-phantoms (those appearing as the third map in an $\mathcal{E}$-triangle).

**Construction 4.4.** The idea is to put a triangulated structure on $\mathcal{K}_\mathcal{E}$ by working in $\mathcal{K}$ but relative to $\mathcal{E}$, in the same way that one triangulates the stable category of a Frobenius exact category; suspension and cones in $\mathcal{K}_\mathcal{E}$ will be given by the “same” homotopy pushouts/pullbacks as usual but where we think of $\text{proj}(\mathcal{E})$-precovers and $\text{inj}(\mathcal{E})$-preenvelopes.
as being the correct maps from or to a contractible object. Note for peace of mind that \( \pi(X) \cong 0 \) if and only if \( X \) is projective-injective (Lemma 5.2).

Given an object \( X \in \mathcal{K}_E \) we define \( \Sigma_E X \) to be the image under \( \pi \) of the cofiber in \( \mathcal{K} \) of a chosen \( \text{inj}(E) \)-preenvelope \( X \to X_E \). One can show that the result is independent of the choice of the preenvelope, up to a canonical isomorphism in \( \mathcal{K} \). Similarly \( \Sigma_E^{-1} \) is defined to be \( \pi \) applied to the fiber of any chosen \( \text{proj}(E) \)-precover \( X \to X_E \). Both of these constructions are well defined and functorial in \( \mathcal{K}_E \) and they are quasi-inverse to one another. This, as the notation suggests, defines the suspension on \( \mathcal{K}_E \). Further details can be found in Construction 4.20.

Given a morphism \( f \in \mathcal{K}_E(X,Y) \) we now construct its cofiber in \( \mathcal{K}_E \). Let \( \hat{f} \in \mathcal{K}(X,Y) \) be a lift of \( f \) to \( \mathcal{K} \), choose an \( \text{inj}(E) \)-preenvelope \( X \to X_E \) of \( X \), and consider the homotopy pushout in \( \mathcal{K} \), as in the leftmost square of

\[
\begin{array}{ccc}
X & \to & X_E \\
\downarrow \hat{f} & & \downarrow \downarrow \\
Y & \to & Z \\
\end{array}
\]

We define the cofiber of \( f \) to be \( \pi(Y \to Z) \). To obtain the distinguished triangle in \( \mathcal{K}_E \) these maps fit into, we complete the homotopy bicartesian square by taking cones (in \( \mathcal{K} \)) to get the rest of (4.5) above and we declare the diagram

\[
\begin{array}{ccc}
X & \to & Y \to Z \to \Sigma_E X
\end{array}
\]

to be a “basic” distinguished triangle in \( \mathcal{K}_E \). More generally, any triangle isomorphic in \( \mathcal{K}_E \) to a basic one is distinguished. We can define the fiber of \( f \) by taking the analogous homotopy pullback along a \( \text{proj}(E) \)-precover of \( Y \). And we can construct distinguished triangles in an apparently dual fashion, which actually coincides with the first one.

**Example 4.6.** Let us discuss the cofiber in \( \mathcal{K}_E \) of the class of an \( E \)-monomorphism. Since every morphism in \( \mathcal{K}_E \) is isomorphic to the class of an \( E \)-monomorphism (by replacing \( f : X \to Y \) with \( \langle i, f \rangle : X \to X_E \oplus Y \) where \( i : X \to X_E \) is an \( \text{inj}(E) \)-preenvelope), this example is actually generic. Consider a triangle in \( \mathcal{K} \)

\[
\begin{array}{ccc}
X & \to & Y \to Z \to \Sigma X
\end{array}
\]

and the homotopy pushout \( W \) of \( X \to Y \) along an \( \text{inj}(E) \)-preenvelope \( X \to X_E \). Since the morphism \( X_E \to W \) is an \( E \)-monomorphism (homotopy pushout of the \( E \)-monomorphism \( f \)) and since \( X_E \) is chosen to be \( E \)-injective, the morphism \( X_E \to W \) splits by Proposition 3.8(a). We therefore obtain a commutative diagram with exact rows and columns in \( \mathcal{K} \):

\[
\begin{array}{ccc}
X & \to & X_E \to \Sigma_E X \\
\downarrow f & & \downarrow (1) \\
Y & \to & X_E \oplus Z \to \Sigma_E X \\
\downarrow \hat{g} \cong \begin{pmatrix} \hat{g}_1 \\ \hat{g}_2 \end{pmatrix} & & \downarrow \hat{h} = (\hat{h}_1, \hat{h}_2) \\
Z & \to & Z
\end{array}
\]
As the morphism \((0,1): X_\mathcal{E} \oplus Z \to Z\) becomes an isomorphism in \(\mathcal{K}_\mathcal{E}\), with explicit inverse \((0,1): Z \to X_\mathcal{E} \oplus Z\), we see that the distinguished triangle of Construction 4.4 over the image \(\pi(f): X \to Y\) in \(\mathcal{K}_\mathcal{E}\) is isomorphic to the triangle:

\[
\begin{array}{ccc}
X & \xrightarrow{\pi_f} & Y & \xrightarrow{\pi_g} & Z & \xrightarrow{\pi_h} & \Sigma_\mathcal{E}X \\
\end{array}
\]

which is almost the image of the initial triangle (4.7). Only the third morphism differs, for the simple reason that its target is not the same as that of \(\pi h\), since the suspensions differ in \(\mathcal{K}\) and \(\mathcal{K}_\mathcal{E}\). We shall nevertheless call (4.8) the image-triangle of the \(\mathcal{E}\)-triangle (4.7). Again, we shall give further details in Construction 4.20.

The first stepping stone for our study is the following very general result.

**Theorem 4.9** (Beligiannis). Let \(\mathcal{E}\) be a Frobenius class of triangles in \(\mathcal{K}\), as in Definition 4.1. Construction 4.4 makes the \(\mathcal{E}\)-relative stable category \(\mathcal{K}_\mathcal{E}\) into a triangulated category. Moreover, for every triangle in \(\mathcal{E}\) of the form (4.7), the image-triangle (4.8) is a distinguished triangle in \(\mathcal{K}_\mathcal{E}\) and every distinguished triangle in \(\mathcal{K}_\mathcal{E}\) is isomorphic, in \(\mathcal{K}_\mathcal{E}\), to a triangle of this form.

**Remark 4.10.** The above result is given in [8, Theorem 7.2], with further reference to [10, Theorem 2.12]. Note that the latter makes a drastic assumption at some point, which works fine in models but not in full generality, in that kernels of some maps should exist. This assumption is not formally needed, as the careful reader will verify.

**Example 4.11.** The trivial classes of triangles \(\mathcal{E}_{\text{split}}\) and \(\mathcal{E}_{\text{dist}}\) of Examples 3.5(1) give us the trivial quotients \(\mathcal{K}_{\mathcal{E}_{\text{split}}} = 0\) and \(\mathcal{K}_{\mathcal{E}_{\text{dist}}} = \mathcal{K}\) respectively.

**Warning 4.12.** The quotient \(\pi: \mathcal{K} \to \mathcal{K}_\mathcal{E}\) is not necessarily exact, and in fact it will usually not be, as it does not even respect the suspension. We can say more as follows.

**Lemma 4.13.** For \(\mathcal{E}\) Frobenius, the additive quotient functor \(\pi: \mathcal{K} \to \mathcal{K}_\mathcal{E}\) is exact if and only if it is a localization. In that case, and if \(\mathcal{K}\) is idempotent-complete, then \(\pi\) is the projection of \(\mathcal{K}\) onto a direct summand, that is, \(\mathcal{K} = \mathcal{J} \oplus \mathcal{J}'\) where \(\mathcal{J} = \text{proj}(\mathcal{E})\) and \(\mathcal{J}' \cong \mathcal{K}_\mathcal{E}\) are orthogonal subcategories of \(\mathcal{K}\), both ways: \(\mathcal{K}(\mathcal{J}, \mathcal{J}') = 0 = \mathcal{K}(\mathcal{J}', \mathcal{J})\).

**Proof.** Localizations are exact so the sufficiency is clear. Conversely, suppose that \(\pi\) is exact. Then \(\mathcal{J} := \text{Ker} \pi = \text{proj}(\mathcal{E})\) is thick, and we get a commutative diagram

\[
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{\pi} & \mathcal{K}_\mathcal{E} \\
\end{array}
\]

where the dashed arrows exist by the respective universal properties and are both exact (one by the universal property and one by inspection). It follows from the uniqueness attached to the universal properties that these functors give an exact equivalence \(\mathcal{K} / \text{proj}(\mathcal{E}) \cong \mathcal{K}_\mathcal{E}\), identifying \(\mathcal{K}_\mathcal{E}\) with the Verdier quotient.

Now, suppose that this holds and furthermore that \(\mathcal{K}\) is idempotent-complete. Then for every \(X \in \mathcal{K}\), the distinguished triangle \(Z \xrightarrow{i} X \xrightarrow{\pi} \mathcal{K}_\mathcal{E}\) maps to \(\pi(Z) \xrightarrow{i} \pi(X) \to 0\) in \(\mathcal{K}_\mathcal{E}\) and it follows by fullness of \(\pi\) that there exists a morphism \(g: X \to Z\) in \(\mathcal{K}\) such that \(\pi(fg) = \pi(id_X)\). Hence there exists \(h: X_\mathcal{E} \to X\) such that \(id_X = fg + hi\). Applying \(i\) to this relation and using \(if = 0\), we see that \(i = ihi\). It follows
that $hi : X \to X$ and $ih : X_\ell \to X_\ell$ are idempotents. Since $\mathcal{E}$ is idempotent-complete, the

triangle is split, namely, $X \cong I_0 \oplus Z_0$, $X_\ell = I_0 \oplus I_1$, and $Z = \Sigma^{-1}I_1 \oplus Z_0$ so that the triangle becomes

$$Z = \Sigma^{-1}I_1 \oplus Z_0 \xrightarrow{i = (0, 0, 1)} X - I_0 \oplus Z_0 \xrightarrow{i = (1, 0, 0)} X_\ell = I_0 \oplus I_1 \oplus Z_0 \cong I_0 \oplus I_1 \oplus Z_0.$$ 

Since $i : X \to X_\ell$ is a pre-envelope, and yet is zero on $Z_0$, so it is zero on $Z_0$.

Dually, one can show that $K = J \oplus J'$. From this, it follows easily that $J' = J$ and that this subcategory is equivalent to $\mathcal{K}/\mathcal{E}$ under $\pi$. \hfill $\Box$

The assumption that $K$ is idempotent-complete is necessary in Lemma 4.13.

Example 4.14. Suppose that $L$ is a triangulated category with non-zero Grothendieck group $K_0(L) \neq 0$. Let $\mathcal{K} \subset L \oplus L'$ be the triangulated subcategory on the following objects $\mathcal{K} = \{(X,Y) \in L \times L' \mid [X] = [Y] \}$. Let $\pi : \mathcal{K} \to L$ be the projection onto the first summand. It is clearly exact and full. Let $J = \text{Ker}(\pi) = \{(0, Y) \mid [Y] = 0\}$. It is easy to check that $\pi : \mathcal{K} \to L$ realizes the additive quotient of $\mathcal{K}$ by $J$, using that for every $Y \in L$ the object $(0, Y \oplus \Sigma Y)$ belongs to $J$. The same trick proves that the conclusion of Lemma 4.13 does not hold. Indeed, it shows that $J' = \{ (X, 0) \mid [X] = 0 \}$. Therefore $J \oplus J' = \{ (X, Y) \mid [X] = [Y] = 0 \}$ is strictly smaller than $\mathcal{K}$ since we assume $K_0(L) \neq 0$.

Let us say a word on the naturality of the construction $(\mathcal{K}/\mathcal{E}) \mapsto \mathcal{K}/\mathcal{E}$. 

Proposition 4.15. Let $F : \mathcal{K} \to \mathcal{K}'$ be an exact functor and suppose that $\mathcal{E}$ and $\mathcal{E}'$ are Frobenius classes of triangles in $\mathcal{K}$ and $\mathcal{K}'$, with corresponding additive quotients $\mathcal{K}/\mathcal{E}$ and $\mathcal{K}'/\mathcal{E}'$, respectively. Provided that we have

(1) $F$ is relative-exact (Definition 3.9), that is, $F(\mathcal{E}) \subseteq \mathcal{E}'$,

(2) $F$ preserves projective-injectives, that is, $F(\text{proj} \mathcal{E}) \subseteq \text{proj} \mathcal{E}'$,

then there is a unique exact functor $F : \mathcal{K}/\mathcal{E} \to \mathcal{K}'/\mathcal{E}'$, such that the square

$\begin{array}{ccc}
\mathcal{K} & \xrightarrow{F} & \mathcal{K}' \\
\downarrow & & \downarrow \\
\mathcal{K}/\mathcal{E} & \xrightarrow{F} & \mathcal{K}'/\mathcal{E}'
\end{array}$

commutes. This construction is natural in $F$ in the obvious sense (without restriction on the allowed natural transformations).

Proof. This is an easy familiarizing exercise. By (2) the functor $F$ induces a unique functor $F$ making the desired square commute. Exactness is direct from Construction 4.4 (or Example 4.6) using (1). \hfill $\Box$

Remark 4.16. By Proposition 3.10, if $F$ admits a left (or right) adjoint which is relative-exact, then $F$ automatically preserves projectives (injectives).

Remark 4.17. If two functors $F : \mathcal{K} \to \mathcal{K}'$ and $G : \mathcal{K}' \to \mathcal{K}''$ satisfy the assumptions of Proposition 4.15, then so does $G \circ F$ and we have $G \circ F = G \circ F$. 

An easy but useful consequence of this functoriality is that one can very cheaply obtain exact autoequivalences of the additive quotient.
Corollary 4.18. Let $\mathcal{E}$ be a Frobenius class of triangles in $\mathcal{K}$. If $F$ is an exact autoequivalence of $\mathcal{K}$ such that $F(\mathcal{E}) = \mathcal{E}$ (or equivalently $F(\text{proj } \mathcal{E}) = \text{proj } \mathcal{E}$), then $F$ induces a unique exact autoequivalence $\tilde{F}$ of $\mathcal{K}_\mathcal{E}$ such that $\tilde{F}\pi = \pi F$.

Proof. Use that $F$ has an adjoint quasi-inverse $F^{-1}$ and the above two remarks. \hfill $\square$

Example 4.19. Any proper class of triangles $\mathcal{E}$ is closed under suspension $\Sigma$ and hence $\Sigma : \mathcal{K} \rightarrow \mathcal{K}$ induces a (skew-) exact autoequivalence $\Sigma : \mathcal{K}_\mathcal{E} \rightarrow \mathcal{K}_\mathcal{E}$. However, this induced autoequivalence is, in general, not the suspension $\Sigma_{\mathcal{E}}$ on $\mathcal{K}_\mathcal{E}$. Although $\Sigma_{\mathcal{E}}$ and $\Sigma$ need not agree, there is a natural comparison map between the two.

Construction 4.20. In order to define $\Sigma_{\mathcal{E}}$ we have fixed for each $X \in \mathcal{K}$ a triangle

$$X \xrightarrow{i_X} X_{\mathcal{E}} \xrightarrow{p_X} X' \xrightarrow{\alpha_X} \Sigma X,$$

with $i_X$ an inj($\mathcal{E}$)-preenvelope, and declared $\Sigma_{\mathcal{E}}(\pi(X)) = \pi(X')$. On the other hand, $\Sigma(\pi(X))$ is simply $\pi(\Sigma(X))$. We can thus define a transformation $\alpha : \Sigma_{\mathcal{E}} \rightarrow \Sigma$ by taking its component at each object $\pi(X)$ to be

$$\Sigma_{\mathcal{E}}\pi(X) = \pi(X') \xrightarrow{\pi(\alpha_X)} \pi(\Sigma X) = \Sigma\pi(X).$$

Of course $\alpha$ depends on the choices we have made in producing $\Sigma_{\mathcal{E}}$, but making different choices gives a natural transformation which is object-wise conjugate, by canonical isomorphisms, to $\alpha$.

Lemma 4.21. The transformation $\alpha : \Sigma_{\mathcal{E}} \rightarrow \Sigma$ constructed above is natural and graded, in the sense that the natural map $t : \Sigma_{\mathcal{E}} \circ \Sigma \rightarrow \Sigma \circ \Sigma_{\mathcal{E}}$, which is part of the structure of $\Sigma$ being an exact functor, makes the square

$$\begin{array}{ccc}
\Sigma_{\mathcal{E}} \circ \Sigma & \xrightarrow{t} & \Sigma \circ \Sigma_{\mathcal{E}} \\
\alpha_{\mathcal{E}} \downarrow & & \downarrow \Sigma(\alpha) \\
\Sigma^2 & \rightarrow & \Sigma^2 \\
i -1
\end{array}$$

commute.

Proof. Let $f : X \rightarrow Y$ be a map in $\mathcal{K}$ representing a class $\pi(f) : \pi(X) \rightarrow \pi(Y)$ in $\mathcal{K}_\mathcal{E}$. In $\mathcal{K}$ we have a commutative diagram

$$\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X_{\mathcal{E}} & \xrightarrow{f_{\mathcal{E}}} & Y_{\mathcal{E}} \\
\downarrow & & \downarrow \\
X' & \xrightarrow{\Sigma f} & Y' \\
\downarrow & & \downarrow \\
\Sigma X & \xrightarrow{\Sigma \pi f} & \Sigma Y
\end{array}$$

with $\pi(f') = \Sigma_{\mathcal{E}}\pi(f)$ by definition. Applying $\pi$ to the righthand square we deduce a commutative diagram exhibiting the naturality of $\alpha$:

$$\begin{array}{ccc}
\Sigma_{\mathcal{E}}\pi(X) & \xrightarrow{\alpha_{\mathcal{E}}(X)} & \pi(\Sigma X) \\
\downarrow \Sigma_{\mathcal{E}}\pi(f) & & \downarrow \pi(\Sigma f) \\
\Sigma_{\mathcal{E}}\pi(Y) & \xrightarrow{\alpha_{\mathcal{E}}(Y)} & \pi(\Sigma Y) \\
\downarrow \Sigma_{\mathcal{E}}\pi(f) & & \downarrow \pi(\Sigma f) \\
\Sigma_{\mathcal{E}}\pi(X) & \xrightarrow{\alpha_{\mathcal{E}}(X)} & \pi(\Sigma X) \\
\downarrow \Sigma_{\mathcal{E}}\pi(f) & & \downarrow \pi(\Sigma f) \\
\Sigma_{\mathcal{E}}\pi(Y) & \xrightarrow{\alpha_{\mathcal{E}}(Y)} & \pi(\Sigma Y) \\
\downarrow \Sigma_{\mathcal{E}}\pi(f) & & \downarrow \pi(\Sigma f) \\
\Sigma_{\mathcal{E}}\pi(Y) & \xrightarrow{\alpha_{\mathcal{E}}(Y)} & \pi(\Sigma Y).\end{array}$$
For the statement that $\alpha$ is graded we construct $t : \Sigma_{E} \circ \Sigma \to \Sigma \circ \Sigma_{E}$. Consider the diagram in $\mathcal{K}$:

$$
\begin{array}{ccc}
\Sigma X & \xrightarrow{\Sigma \pi_{X}} & (\Sigma X)_{E} \\
\downarrow & & \downarrow \\
\Sigma X & \xrightarrow{\Sigma \pi_{X}} & \Sigma^{2}X
\end{array}
$$

where we have produced the dashed and then dotted arrow via the fact that $-\Sigma_{i_{X}}$ is an inj $E$ preenvelope and then the usual axiom. The component of the natural transformation $t : \Sigma_{E} \circ \Sigma \to \Sigma \circ \Sigma_{E}$ at $\pi(X)$ is given by $\pi(\tilde{t}_{X})$. Applying $\pi$ to the rightmost square gives a commutative diagram in $\mathcal{K}$:

$$
\begin{array}{ccc}
\Sigma_{E}\Sigma\pi(X) & \xrightarrow{\Sigma\pi(X)} & \Sigma^{2}\pi(X) \\
\downarrow_{t_{\pi(X)}} & & \downarrow \\
\Sigma\Sigma_{E}\pi(X) & \xrightarrow{-\Sigma\pi(X)} & \Sigma^{2}\pi(X)
\end{array}
$$

as required. \hfill \Box

Here is a naturality statement for adjoint pairs, based on Proposition 4.15, with a somewhat slicker formulation.

**Lemma 4.22.** Let $F : \mathcal{K} \to \mathcal{K}'$ be an exact functor with right adjoint $G : \mathcal{K}' \to \mathcal{K}$. Suppose that $E$ and $E'$ are Frobenius classes of triangles on $\mathcal{K}$ and $\mathcal{K}'$, respectively, and that $F$ and $G$ are relative-exact with respect to those. Then necessarily

$F(\text{proj}(E)) \subseteq \text{proj}(E')$ and $G(\text{proj}(E')) \subseteq \text{proj}(E)$

and $F$ and $G$ descend to an adjoint pair of (exact) functors $F : \mathcal{K}_{E} \rightleftharpoons \mathcal{K}'_{E'} : G$.

**Proof.** The conservation of projective-injectives follows from Proposition 3.10. By Proposition 4.15, $F$ and $G$ induce exact functors on $\mathcal{K}_{E}$ and $\mathcal{K}'_{E'}$, and the unit and counits of the adjunction descend as well by naturality. The unit-counit relations are then simply the images of the unit-counit relations in $\mathcal{K}$ and $\mathcal{K}'$ under $\pi$ and $\pi'$.

We finish the section by discussing when the proper class $E_{F}$ of $F$-split triangles (Definition 3.11) is Frobenius.

**Theorem 4.23.** Suppose that we are given an exact functor $F : \mathcal{K} \to \mathcal{L}$ with both a left and a right adjoint

$$
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{F} & \mathcal{L} \\
V & \downarrow & U \\
\mathcal{L}
\end{array}
$$

satisfying the following generalized Wirthmüller condition: There exists an equivalence $W : \mathcal{L} \to \mathcal{L}$ such that $V \circ W \simeq U$. Then the $F$-injectives and $F$-projectives coincide in $\mathcal{K}$ and are given by

$$\text{add}(\text{Im}(U)) = \text{add}(\text{Im}(V))$$.  

In other words, the class $E_F = F^{-1}(E_{\text{split}})$ of $F$-split triangles is Frobenius. In particular, there is an induced triangulated structure on $\mathcal{K}_E := \mathcal{K}_{E_F}$ via Theorem 4.9.

Proof. Since $U \simeq V \circ W$ we have, for $X \in \mathcal{K}$, that $X \simeq U(L)$ for some $L \in \mathcal{L}$ if and only if $X \simeq VW(L)$ (for the same $L$) and so the essential images of $U$ and $V$ coincide. Hence $\mathrm{add} (\mathrm{Im}(U)) = \mathrm{add} (\mathrm{Im}(V))$, and we conclude by Lemma 3.13. □

Remark 4.24. The “Wirthmüller” condition in the theorem is reminiscent of the various generalizations of Frobenius functor and plays a similar role in producing situations well adapted to relative homological algebra (cf., for instance, [16, Section 3]). It also generalizes the notion of spherical functor (we direct the uninitiated but curious reader to [1, Section 2]), and so, we immediately obtain many examples from algebraic geometry.

Another important case in which the theorem applies is when the two adjoints are equal: $V = U$. This situation is often referred to as a Frobenius adjunction $V + F + V$, see [24]. This occurs when one considers induction, restriction, and coinduction along the inclusion of a subgroup of a finite group, or when one considers tensoring with a rigid object.

5. Thick subcategories and proto-birationality

We discuss the thick subcategories of the relative stable category $\mathcal{K}_E$.

Hypothesis 5.1. Let $\mathcal{K}$ be triangulated, $E$ a Frobenius class of triangles and

$$\pi: \mathcal{K} \to \mathcal{K}_E$$

the associated relative stable category as in Section 4.

Let us begin with the question of stable isomorphisms.

Lemma 5.2. Under Hypothesis 5.1, two objects $X, Y \in \mathcal{K}$ have isomorphic images $\pi(X) \simeq \pi(Y)$ in $\mathcal{K}_E$ if and only if there are $E$-projective-injective objects $C_1$ and $C_2$ and an isomorphism $X \oplus C_1 \simeq Y \oplus C_2$ in $\mathcal{K}$.

Proof. Pick an isomorphism $\pi f: \pi X \to \pi Y$ and pick a proj($E$)-precover $p: C_1 \to Y$. Complete the morphism $(f, p): X \oplus C_1 \to Y$ into a distinguished triangle in $\mathcal{K}$

$$W \xrightarrow{w} X \oplus C_1 \xrightarrow{(f, p)} Y \to \Sigma W.$$

Since the second map is an $E$-epimorphism, this is an $E$-triangle. By Example 4.6, its image triangle is distinguished in $\mathcal{K}_E$ and since $\pi(f, p) \cong \pi(f)$ is an isomorphism, we have $\pi(W) = 0$. So $W$ is $E$-injective and the $E$-monomorphism $w$ splits by Proposition 3.8(a), yielding the desired relation $Y \oplus W \simeq X \oplus C_1$ in $\mathcal{K}$. □

Remark 5.3. The above Lemma 5.2 justifies the name “stable category relative to $E$”: It is the place where objects become isomorphic if they are isomorphic in $\mathcal{K}$ up to adding summands in the subcategory $\text{proj}(E) = \text{inj}(E)$.

We now express the thick subcategories of $\mathcal{K}_E$ in terms of subcategories of $\mathcal{K}$.

Proposition 5.4. Under Hypothesis 5.1, there is an order-preserving bijection $J \mapsto \pi^{-1}(J)$, with inverse $\mathcal{C} \mapsto \pi(\mathcal{C})$, between the thick subcategories $J \subseteq \mathcal{K}_E$ and the additive subcategories $\mathcal{C} \subseteq \mathcal{K}$ containing $\text{proj}(E) = \text{inj}(E)$, closed under direct summands and
satisfying the following $\mathcal{E}$-two-out-of-three property: For every $\mathcal{E}$-triangle $X \to Y \to Z \to \Sigma X$ in $\mathcal{X}$, if two out of $X$, $Y$, $Z$ belong to $\mathcal{C}$, then so does the third.

Proof. The standard description of additive subcategories of the additive quotient $\mathcal{K}_\mathcal{E} = \mathcal{K} / \text{proj}(\mathcal{E})$ tells us that $\mathcal{J} \mapsto \pi^{-1}(\mathcal{J})$ identifies the lattice of thick subcategories of $\mathcal{K}_\mathcal{E}$ with a sublattice of additive subcategories of $\mathcal{K}$ containing proj$(\mathcal{E})$. We need to identify the image of this bijection, that is, express what it means for $\mathcal{J}$ to be thick in $\mathcal{K}_\mathcal{E}$ in terms of $\mathcal{C} = \pi^{-1}(\mathcal{J})$ in $\mathcal{K}$. Being thick certainly entails being closed under direct summands. (Note that $\mathcal{C}$ is then automatically stable under “$\mathcal{E}$-stable isomorphisms” by Lemma 5.2.) For $\mathcal{J}$ triangulated, we need to check the two-out-of-three property for triangles in $\mathcal{K}_\mathcal{E}$, which amounts to the $\mathcal{E}$-two-out-of-three property of the statement by the fact that every distinguished triangle in $\mathcal{K}_\mathcal{E}$ is the image triangle of an $\mathcal{E}$-triangle by Theorem 4.9. □

Remark 5.5. In particular, the subcategory $\mathcal{C} = \pi^{-1}(\mathcal{J})$ in Proposition 5.4 is not necessarily stable under suspension $\Sigma: \mathcal{K} \to \mathcal{K}$. (It is “stable under $\Sigma$” so to speak.)

Theorem 5.6. Under Hypothesis 5.1, let $\mathcal{C}$ be an additive subcategory of $\mathcal{K}$, containing proj$(\mathcal{E})$, closed under direct summands and satisfying the $\mathcal{E}$-two-out-of-three property of Proposition 5.4 (that is, its image $\pi(\mathcal{C})$ is a thick subcategory of $\mathcal{K}_\mathcal{E}$). Then the following are equivalent.

(i) $\mathcal{C}$ is itself a thick subcategory (that is, it is a triangulated subcategory) of $\mathcal{K}$.
(ii) $\mathcal{C}$ contains the thick subcategory thick(proj$(\mathcal{E})$).

In that case, that is, for every thick triangulated subcategory $\mathcal{C} \subseteq \mathcal{K}$ containing proj$(\mathcal{E})$, we have a natural equivalence induced by $\pi$

$$\mathcal{K} / \mathcal{C} \sim \mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$$

between the respective Verdier quotients, which is moreover exact.

Proof. Clearly (i)$\Rightarrow$(ii) since $\mathcal{C}$ contains proj$(\mathcal{E})$. Conversely, suppose that $\mathcal{C}$ contains thick(proj$(\mathcal{E})$) and let us show that $\mathcal{C}$ is a triangulated subcategory of $\mathcal{K}$.

Let us start with a general construction. Let $X \to Y \to Z \to \Sigma X$ be a distinguished triangle in $\mathcal{K}$. Choose an inj$(\mathcal{E})$-preenvelope $X \to I$ and consider the homotopy pushout (marked $\Box$) and the isomorphic cofibers $Z$ in $\mathcal{K}$:

$$\begin{array}{ccc}
X & \to & Y \\
\downarrow & & \downarrow \\
I & \to & V \\
\Box & & \Box \\
\downarrow & & \downarrow \\
I & \to & W.
\end{array} \quad (5.7)$$

Let now $V \to J$ be another inj$(\mathcal{E})$-preenvelope and consider the “next” homotopy pushout (marked $\Box$) and the isomorphic fibers $I$ in $\mathcal{K}$:

$$\begin{array}{ccc}
I & \to & V \\
\downarrow & & \downarrow \\
I & \to & J \\
\Box & & \Box \\
\downarrow & & \downarrow \\
W. \quad (5.8)
\end{array}$$

The bottom triangle tells us that $W \in \text{thick}(\text{inj}(\mathcal{E}))$ and our assumption about $\mathcal{C} \supseteq \text{thick}(\text{proj}(\mathcal{E}))$ implies that $W$ belongs to $\mathcal{C}$. Now the second homotopy pushout involves an $\mathcal{E}$-triangle (since $V \to J$ is an $\mathcal{E}$-monomorphism)

$$V \to J \oplus Z \to W \to \Sigma V. \quad (5.9)$$

This finishes the general construction.
Suppose now that $X$ and $Y$ are in $\mathcal{C}$ and let us prove that $Z \in \mathcal{C}$. By the $\mathcal{E}$-two-out-of-three property applied to (5.7), the object $V$ (which is the cone of $\pi(X \to Y)$ in $\mathcal{K}_\mathcal{E}$) belongs to $\mathcal{C}$. It now follows from the $\mathcal{E}$-two-out-of-three property applied to (5.9), that $J \oplus Z$, and therefore $Z$, belong to $\mathcal{C}$ as claimed. This proves (ii) $\Rightarrow$ (i).

Consider now the composite of the additive quotient and the Verdier quotient

$$Q : \mathcal{K} \xrightarrow{\pi} \mathcal{K}_\mathcal{E} \xrightarrow{q} \mathcal{K}_\mathcal{E} / \pi(\mathcal{C}).$$

We claim that this functor is exact. So let $X \to Y \to Z \to \Sigma X$ be a distinguished triangle in $\mathcal{K}$ and produce the diagrams (5.7), (5.8), and (5.9) as above. Since (5.9) is an $\mathcal{E}$-triangle, we know that it induces an exact triangle $V \to J \oplus Z \to W \to \Sigma \mathcal{E} V$ in $\mathcal{K}_\mathcal{E}$. Since $J,W \in \mathcal{C}$, the image of this triangle under the exact $q : \mathcal{K}_\mathcal{E} \to \mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$ reduces to an isomorphism $V \xrightarrow{\sim} Z$ in $\mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$. More precisely, the map $V \to Z$ in (5.7) becomes an isomorphism in $\mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$. But (5.7) provides us an exact triangle $X \to Y \to V \to \Sigma \mathcal{E} X$ in $\mathcal{K}_\mathcal{E}$, and therefore in $\mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$, which is an isomorphism in $\mathcal{K}_\mathcal{E} / \pi(\mathcal{C})$, to obtain exactly the image under $Q$ of our original triangle (cf. (4.8) and the discussion that follows). In other words, $Q$ is exact. Along the way (or in the special case of $Y = 0$) we have shown that $Q$ commutes with suspension, via the natural transformation $\alpha$ induces.

It is easy to see that the object-kernel $\text{Ker}(Q)$ of the above functor $Q$ is exactly $\mathcal{C}$, via Lemma 5.2 and $\mathcal{C} \supset \text{proj}(\mathcal{E})$.

The following corollary recovers our original inspiration [3, Theorem 3.4]. Compare also [13, Proposition 6.3] in modular representation theory.

**Corollary 5.10.** Let $\mathcal{K}$ be a triangulated category, $\mathcal{E}$ a Frobenius class of triangles, and $\pi : \mathcal{K} \to \mathcal{K}_\mathcal{E}$ be the corresponding quotient functor. Let

$$\mathcal{M} = \text{thick}_{\mathcal{K}}(\text{proj}(\mathcal{E}))$$

be the thick subcategory of $\mathcal{K}$ generated by the $\mathcal{E}$-projective-injectives. Then:

(a) the full subcategory $\pi(\mathcal{M})$ is thick in $\mathcal{K}_\mathcal{E}$;

(b) the functor $\pi$ induces an equivalence of the Verdier quotients

$$\bar{\pi} : \mathcal{K} / \mathcal{M} \xrightarrow{\sim} \mathcal{K}_\mathcal{E} / \pi(\mathcal{M});$$

(c) the functor $\bar{\pi}$ is exact.
Remark 5.11. Let us emphasize the content of Theorem 5.6 and Corollary 5.10. We have seen, in Lemma 4.13, that \( \pi: \mathcal{K} \to \mathcal{K}_E \) is not exact outside of degenerate situations. Yet, Theorem 5.6 shows that one can compare some Verdier quotients of \( \mathcal{K} \) with the corresponding Verdier quotients of \( \mathcal{K}_E \), via exact functors. The class of permissible quotients is defined by the thick subcategories containing a minimal one: \( \mathcal{M} = \text{thick}(\text{proj}(\mathcal{E})) \). In fact, if there exists a functor \( \mathcal{F}: \mathcal{K}_E \to \mathcal{L} \) such that the composite \( \mathcal{F} \circ \pi: \mathcal{K} \to \mathcal{L} \) is exact, then \( \mathcal{F} \circ \pi \) vanishes on \( \mathcal{M} \) (since it is exact and vanishes on proj(\( \mathcal{E} \))) and therefore induces an exact functor \( \mathcal{K}/\mathcal{M} \to \mathcal{L} \). This shows that \( \mathcal{K}/\mathcal{M} \) is the largest quotient of \( \mathcal{K} \) on which \( \pi \) (or anything factoring via \( \pi \)) is exact.” Corollary 5.10 tells us that this Verdier quotient of \( \mathcal{K} \) is indeed also a Verdier quotient of \( \mathcal{K}_E \), with respect to the corresponding thick subcategory \( \pi_\mathcal{M} \).

The existence of the exact equivalence \( \mathcal{K} \to \mathcal{K}_E \) defined only on suitable quotients modulo thick subcategories reminds us of birationality in algebraic geometry, that is, of a morphism which is only defined on certain open subschemes, “away” from \( \mathcal{M} = \text{thick}(\text{proj}(\mathcal{E})) \). We shall return to this “birationality” result in Section 8, when we have the conceptual force of tt-geometry behind us.

Remark 5.12. It can happen that \( \mathcal{M} = \mathcal{K} \) in Corollary 5.10, that is, that proj(\( \mathcal{E} \)) generates \( \mathcal{K} \), in which case, Theorem 5.6 is largely devoid of content.

* * *

Let us continue on in the setting of Hypothesis 5.1. It is natural to wonder what we can say about the lattice of thick subcategories of \( \mathcal{K}_E \) in terms of the lattice for \( \mathcal{K} \). We learned in Proposition 5.4 that there is a bijective correspondence between the thick subcategories of \( \mathcal{K}_E \) and certain additive subcategories of \( \mathcal{K} \), namely, those containing \( \text{proj}(\mathcal{E}) = \text{inj}(\mathcal{E}) \), closed under direct summands and satisfying the \( \mathcal{E} \)-two-out-of-three property. But, these are not necessarily triangulated; the ones which are triangulated are precisely those containing thick(\( \text{proj}(\mathcal{E}) \)) by Theorem 5.6. It turns out that there can be many of the former, non-\( \mathcal{K} \)-triangulated, variety and that the lattices can exhibit starkly divergent behaviors. The following construction hints at this and was discovered by Jon Carlson in representation theory, see [13].

Proposition 5.13. Let \( G: \mathcal{K} \to \mathcal{N} \) be an exact functor between triangulated categories such that every triangle in \( \mathcal{E} \) is \( G \)-split, that is, the \( \mathcal{E} \)-phantoms are contained in ker \( G \). Let \( \mathcal{A} \subseteq \mathcal{N} \) be an additive subcategory of \( \mathcal{N} \) which contains \( G(\text{proj}(\mathcal{E})) \) and is closed under direct summands. Then

\[
\pi(G^{-1}(\mathcal{A})) = \{ X \in \mathcal{K}_E \mid X \cong \pi Y \text{ with } Y \in \mathcal{K} \text{ and } GY \in \mathcal{A} \},
\]

is thick in \( \mathcal{K}_E \).

Proof. By assumption the additive subcategory \( \mathcal{C} := G^{-1}(\mathcal{A}) \) of \( \mathcal{K} \) contains proj(\( \mathcal{E} \)) and is closed under direct summands. We claim that \( \mathcal{C} \) satisfies the \( \mathcal{E} \)-two-out-of-three property of Proposition 5.4. This is easy since any \( \mathcal{E} \)-triangle becomes split under \( G \) and \( \mathcal{A} \) is closed under sums and summands. Then Proposition 5.4 tells us that \( \pi \mathcal{C} \) is then a thick subcategory of \( \mathcal{K}_E \). \( \square \)

Remark 5.14. A simple example, which is already of interest, is given by supposing that we are in the Wirthmüllery situation of Theorem 4.23 and taking \( G = F \).

Remark 5.15. Of course, the above construction \( \Phi: \mathcal{A} \mapsto \pi(G^{-1}\mathcal{A}) \) preserves inclusions. Thus, we can start with a proper chain of suitable categories

\[
\mathcal{A}_1 \subseteq \cdots \subseteq \mathcal{A}_n \subseteq \mathcal{A}_{n+1} \subseteq \cdots
\]
in \( \mathcal{N} \) and obtain a chain of thick subcategories of \( \mathcal{K}_\mathcal{E} \)

\[
\Phi \mathcal{A}_1 \subseteq \cdots \subseteq \Phi \mathcal{A}_n \subseteq \Phi \mathcal{A}_{n+1} \subseteq \cdots
\]

The rub is that our chain may no longer be proper, which naturally leads to the following question. Under which conditions can we say that \( \mathcal{A}_1 \subsetneq \mathcal{A}_2 \) implies \( \Phi \mathcal{A}_1 \subsetneq \Phi \mathcal{A}_2 \)? For an example where this does happen, we refer to [13, proof of Theorem 5.1].

6. Algebraicity

In this section we will prove Theorem 1.2, showing that passing to the relative stable category preserves the property of being algebraic. For a refresher on exact categories, see Recollection 2.8.

**Theorem 6.1.** Let \( \mathcal{I} \) be a Frobenius exact category, with admissible exact sequences \( \mathcal{I} \), let \( \mathcal{K} = \mathcal{F} = \mathcal{F} / \text{proj(}\mathcal{I}\text{)} \) be its stable category and let \( \varpi : \mathcal{I} \to \mathcal{K} \) be the quotient functor. Suppose that \( \mathcal{E} \) is a Frobenius class of triangles in \( \mathcal{K} \). Define \( \mathcal{I}_\mathcal{E} \subseteq \mathcal{I} \) to be the following class of admissible sequences in \( \mathcal{F} \):

\[
\mathcal{I}_\mathcal{E} := \{ E = \left( M' \xrightarrow{i} M \xrightarrow{p} M'' \right) \in \mathcal{I} \mid \text{the image triangle } \varpi E \text{ belongs to } \mathcal{E} \text{ in } \mathcal{K} \}
\]

Then \( \mathcal{I}_\mathcal{E} \) defines a Frobenius exact structure on \( \mathcal{F} \) whose projective-injective objects \( \varpi^{-1}(\text{proj(}\mathcal{E}\text{)}) \) are those objects of \( \mathcal{F} \) which are \( \mathcal{E} \)-projective-injective in \( \mathcal{K} \). Moreover, the stable category of this new Frobenius category is equivalent to \( \mathcal{K}_\mathcal{E} \) as a triangulated category in such a way that the canonical diagram commutes:

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\varpi} & \mathcal{F} / \text{proj(}\mathcal{I}\text{)} = \mathcal{K} \\
\downarrow{\varpi'} & & \downarrow{\pi} \\
\mathcal{F} / \text{proj(}\mathcal{I}_\mathcal{E}\text{)} & \xrightarrow{\varpi} & \mathcal{K}_\mathcal{E}.
\end{array}
\]

**Proof.** It is easy, as we outline below, to check that \( \mathcal{I}_\mathcal{E} \) is indeed an exact structure: Some of the axioms are inherited from \( \mathcal{I} \) and the rest are verified by applying \( \varpi : \mathcal{I} \to \mathcal{K} \) and using the axioms of a proper class of triangles for \( \mathcal{E} \). By definition (admissible) \( \mathcal{I}_\mathcal{E} \)-monomorphisms are precisely the (admissible) \( \mathcal{I} \)-monomorphisms whose image under \( \varpi \) are \( \mathcal{E} \)-monomorphisms. And similarly with epimorphisms.

So, it is straightforward that \( \mathcal{I}_\mathcal{E} \) is closed under isomorphisms and contains the split exact sequences by additivity of \( \varpi \) and since \( \mathcal{E} \) has these properties. We also inherit from \( \mathcal{I} \) that sequences in \( \mathcal{I}_\mathcal{E} \) are kernel–cokernel pairs. Similarly, \( \mathcal{I}_\mathcal{E} \)-monomorphisms and \( \mathcal{I}_\mathcal{E} \)-epimorphisms are closed under composition, since this holds for \( \mathcal{I} \), and is true of \( \mathcal{E} \)-monomorphisms and \( \mathcal{E} \)-epimorphisms. Finally, let us prove that pushouts of \( \mathcal{I}_\mathcal{E} \)-monomorphisms exist and are \( \mathcal{I}_\mathcal{E} \)-monomorphisms, the pullbacks of \( \mathcal{I}_\mathcal{E} \)-epimorphisms being dual. Again, existence is inherited from \( \mathcal{I} \) and provides \( \mathcal{I} \)-monomorphisms that still need to be shown to be \( \mathcal{I}_\mathcal{E} \)-admissible. We want to test this under \( \varpi \) by using the analogous property for \( \mathcal{E} \)-monomorphisms. To this end, it suffices to know that a pushout square along an \( \mathcal{I} \)-monomorphism yields a homotopy pushout square in \( \mathcal{K} \), which is immediate from the formulation of those squares in terms of \( \mathcal{I} \)-exact sequences and distinguished triangles, respectively, and the fact that \( \varpi \) maps \( \mathcal{I} \)-exact sequences to distinguished triangles.

Let us now see why \( \mathcal{I}_\mathcal{E} \)-projectives coincide with \( \varpi^{-1}(\text{proj(}\mathcal{E}\text{)}) \). Let \( Q \in \mathcal{F} \) be an object and consider an \( \mathcal{I} \)-exact sequence \( E = (M' \xrightarrow{i} M \xrightarrow{p} M'') \) and its image distinguished triangle...
in $\mathcal{K}$, for some morphism $h$

$$\varpi \mathbb{I} = \begin{pmatrix} \varpi M' & \varpi (i) \varpi M & \varpi (p) \varpi M'' & h \Sigma \varpi M' \end{pmatrix}.$$  

The connecting map $\partial$ in the $\operatorname{Ext}^*_{\mathcal{F}}(Q, -)$ long exact sequence induced by $\mathbb{E}$

$$\partial : \mathcal{F}(Q, M'') \to \operatorname{Ext}^1_{\mathcal{F}}(Q, M')$$

factors as the following composite:

$$\mathcal{F}(Q, M'') \xrightarrow{\varpi} \mathcal{K}(\varpi Q, \varpi M'') \xrightarrow{\mathcal{K}(\varpi Q, h)} \mathcal{K}(\varpi Q, \Sigma \varpi M') \cong \operatorname{Ext}^1_{\mathcal{F}}(Q, M').$$

As the first map is surjective, we see that the following two properties are equivalent.

(A) The homomorphism $\mathcal{K}(\varpi Q, h)$ is zero.

(B) The connecting map $\partial$ is zero, that is, the following short sequence is exact:

$$0 \to \mathcal{F}(Q, M') \to \mathcal{F}(Q, M) \to \mathcal{F}(Q, M'') \to 0.$$

We now vary the quantifiers: We fix $Q$ but we let $\mathcal{E}$ vary among all $\mathcal{I}_\mathcal{E}$-exact sequences, which is equivalent to $\varpi \mathcal{E}$ varying among all $\mathcal{I}_\mathcal{E}$-triangles since any triangle in the stable category is isomorphic to the image of some $\mathcal{I}$-exact sequence. Property (A) for all such $\mathcal{E}$ (that is, for all $\mathcal{I}_\mathcal{E}$-phantoms $h$) says that $\varpi Q$ is $\mathcal{I}_\mathcal{E}$-projective; see Proposition 3.8. Property (B) for all such $\mathcal{E}$ says that $Q$ is $\mathcal{I}_\mathcal{E}$-projective. This proves that the class of $\mathcal{I}_\mathcal{E}$-projectives coincides with $\varpi^{-1}(\text{proj}(\mathcal{E}))$.

A dual argument proves that the class of $\mathcal{I}_\mathcal{E}$-injectives coincides with $\varpi^{-1}(\text{inj}(\mathcal{E}))$. Since $\mathcal{E}$ is Frobenius, it also follows that $\mathcal{I}_\mathcal{E}$-projectives and $\mathcal{I}_\mathcal{E}$-injectives coincide. We now need to show that there are enough of them.

Let $X$ be an object of $\mathcal{F}$. We can find a $\text{proj}(\mathcal{E})$-precover of $\varpi X$ in $\mathcal{K}$, which can be written $\varpi(q) : \varpi Q \to \varpi X$ for some $Q \in \varpi^{-1}(\text{proj}(\mathcal{E}))$ and some morphism $q : Q \to X$ in $\mathcal{F}$. By the above discussion, we already know that $Q$ is $\mathcal{I}_\mathcal{E}$-projective. Replacing $q : Q \to X$ by $(q p) : Q \oplus P \to X$ where $p : P \to X$ is an $\mathcal{I}$-projective cover, we can assume that $q : Q \to X$ is an $\mathcal{I}$-epimorphism in $\mathcal{F}$, without changing the image $\varpi(q)$ since $\varpi(P) = 0$. Consider the associated $\mathcal{F}$-exact sequence in $\mathcal{F}$

$$\mathbb{E} = \begin{pmatrix} Y & Q & X \end{pmatrix}.$$  

Its image under $\varpi$ is a distinguished triangle

$$\varpi \mathbb{E} = \begin{pmatrix} \varpi Y & \varpi Q & \varpi X & k \Sigma \varpi Y \end{pmatrix}$$

for some morphism $k$. Since $\varpi(q)$ was chosen to be a $\text{proj}(\mathcal{E})$-precover, it is an $\mathcal{E}$-epimorphism and this triangle belongs to $\mathcal{E}$. By definition of $\mathcal{I}_\mathcal{E}$, the sequence $\mathbb{E}$ then belongs to $\mathcal{I}_\mathcal{E}$. In short, $q : Q \to X$ is an $\mathcal{I}_\mathcal{E}$-precover. Dually, $\mathcal{F}$ admits enough $\mathcal{I}_\mathcal{E}$-injectives. So $\mathcal{F}$ is also Frobenius with the (smaller) class of exact sequences $\mathcal{I}_\mathcal{E}$.

It only remains to verify that the $\mathcal{I}_\mathcal{E}$-stable category of $\mathcal{F}$ is equivalent to $\mathcal{K}_\mathcal{E}$ as triangulated categories. But this is clear from the fact that the $\mathcal{I}_\mathcal{E}$-projective-injective objects are precisely those in $\mathcal{D} = \varpi^{-1}(\text{proj}(\mathcal{E}))$, and a standard “third isomorphism theorem” for additive quotients:

$$\mathcal{K} / \text{proj}(\mathcal{E}) = (\mathcal{F} / \text{proj}(\mathcal{F}))/ (\mathcal{D} / \text{proj}(\mathcal{F})) \cong \mathcal{F} / \mathcal{D}.$$  

Exactness of this equivalence is left as an easy exercise. □
7. Tensor-triangulated stable categories

From now on, we assume that $\mathcal{K}$ is not only triangulated but tensor-triangulated. We discuss what to assume on $\mathcal{K}$ and $\mathcal{E}$ to make sure that the relative stable category $\mathcal{K}_E$ becomes tensor-triangulated. We also discuss how the tensor on $\mathcal{K}$ naturally produces some interesting Frobenius classes $\mathcal{E}$. We then discuss the impact on the triangular spectra $\text{Spc}(\mathcal{K})$ and $\text{Spc}(\mathcal{K}_E)$.

Our assumption that $\mathcal{K}$ is a tensor-triangulated category (tt-category for short) means that $\mathcal{K}$ admits a symmetric monoidal structure $\otimes: \mathcal{K} \times \mathcal{K} \to \mathcal{K}$ which is exact in each variable, that is, $X \otimes ?: \mathcal{K} \to \mathcal{K}$ is exact for every $X \in \mathcal{K}$, and such that the two induced isomorphisms $\Sigma ? \otimes \Sigma ?? \sim \Sigma^2 (? \otimes ??)$ commute up to sign. See details in [18, Appendix A]. We denote the $\otimes$-unit by $1$.

**Definition 7.1.** An object $X \in \mathcal{K}$ is called rigid (a. k. a. strongly dualizable) if there exists an object $X^\vee \in \mathcal{K}$, called its dual, and an adjunction

$$X \otimes ? \dashv X^\vee \otimes ?$$

(7.2)

Of interest to us will be the unit and counit of this adjunction (at 1), denoted by

$$\text{coev}: 1 \to X^\vee \otimes X \quad \text{and} \quad \text{ev}: X \otimes X^\vee \to 1.$$

We say that $\mathcal{K}$ is rigid if every object $X \in \mathcal{K}$ is rigid and the functor $(-)^\vee$ is exact; rigidity implies that $\mathcal{K}$ is closed monoidal and exactness of $(-)^\vee$ is equivalent to the internal hom being exact in both variables. Standard monoidal adjunction theory gives canonical isomorphisms $(X \otimes Y)^\vee \cong X^\vee \otimes Y^\vee$ and $X^{\vee \vee} \cong X$, etc.

**Remark 7.3.** It is well known that if $F: \mathcal{K} \to \mathcal{L}$ is monoidal and $X$ is rigid in $\mathcal{K}$, then $F(X)$ is rigid in $\mathcal{L}$, with dual $F(X)^\vee = F(X^\vee)$. Indeed, it suffices to transport the unit and counit of the adjunction (and their relations) under $F$.

The compatibility of proper classes of triangles with tensor is the obvious one.

**Definition 7.4.** We say that a proper class of triangles $\mathcal{E}$ as in Hypothesis 3.3 is a $\otimes$-class if it is closed under tensoring in the sense that if

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} \Sigma X$$

belongs to $\mathcal{E}$ and $W \in \mathcal{K}$ then the triangle

$$X \otimes W \xrightarrow{f \otimes W} Y \otimes W \xrightarrow{g \otimes W} Z \otimes W \xrightarrow{h \otimes W} \Sigma X \otimes W$$

also lies in $\mathcal{E}$. This is equivalent to asking that the class of $\mathcal{E}$-monomorphisms (or the class of $\mathcal{E}$-epimorphisms or the ideal of phantoms $\text{Ph}_\mathcal{E}$) is closed under tensoring. Since $\text{Ph}_\mathcal{E}$ is an ideal, it follows from being closed under tensoring with objects (that is, identity morphisms) that it is $\otimes$-closed, that is, closed under tensoring with all maps.

**Remark 7.5.** It is, however, not immediate from $\mathcal{E}$ being a Frobenius $\otimes$-class that $\mathcal{K}_E$ becomes a tt-category. Indeed, we still need to show that $\text{proj}(\mathcal{E})$ is tensor-closed.
Definition 7.6. If $\mathcal{K}$ has an internal hom, which we denote $\text{hom}: \mathcal{K}^{\text{op}} \times \mathcal{K} \to \mathcal{K}$, it also makes sense to ask for $\mathcal{E}$ to be closed under $\text{hom}(W, -)$ for all $W \in \mathcal{K}$. In this case we say $\mathcal{E}$ is hom-closed and evidently this corresponds to hom-closure of $\text{Ph}_{\mathcal{E}}$.

Lemma 7.7. If $\mathcal{E}$ is a proper hom-closed class of triangles, then $\text{proj}(\mathcal{E})$ is closed under tensoring. In particular, the ideal $\mathcal{N}$ of maps factoring via $\text{proj}(\mathcal{E})$ is a $\otimes$-closed. Dually, if $\mathcal{E}$ is a proper $\otimes$-class of triangles, then $\text{inj}(\mathcal{E})$ is hom-closed. In particular, the ideal $\mathcal{N}'$ of maps factoring via $\text{inj}(\mathcal{E})$ is hom-closed.

If moreover $\mathcal{E}$ has enough projectives (injectives), then the above implications are equivalences.

Proof. This is an immediate consequence of the tensor-hom adjunction.

In the situation of Lemma 7.7, provided that $\mathcal{E}$ is Frobenius, the stable category $\mathcal{K}_{\mathcal{E}}$ is again symmetric monoidal as is the quotient functor $\pi$; this is a general fact about additive quotients by tensor-closed ideals of morphisms. Moreover, rigid objects of $\mathcal{K}$ get sent to rigid objects in $\mathcal{K}_{\mathcal{E}}$; this is a consequence of the fact that $\pi$ is monoidal (Remark 7.3).

Proposition 7.8. If $\mathcal{E}$ is a Frobenius class of triangles closed under hom and tensoring, then the category $\mathcal{K}_{\mathcal{E}}$, equipped with the induced triangulation, is closed symmetric monoidal in such a way that both hom and tensor are exact in each variable. If, moreover, $\mathcal{K}$ is rigid then so is $\mathcal{K}_{\mathcal{E}}$.

Proof. It is, as mentioned above, well known that $\mathcal{K}_{\mathcal{E}}$ is again symmetric monoidal and the quotient functor is symmetric monoidal. By Lemma 7.7 we know that $\text{proj}(\mathcal{E})$ is closed under tensoring and, by assumption, so is $\mathcal{E}$. Thus Proposition 4.15 tells us that the induced tensor product on $\mathcal{K}_{\mathcal{E}}$ is exact in both variables.

As we have noted that, by Lemma 7.7, $\text{proj}(\mathcal{E})$ is closed under tensoring. Since $\mathcal{E}$ is Frobenius, said lemma also tells us that $\text{proj}(\mathcal{E})$ is closed under the internal hom. We can thus apply Lemma 4.22 to see that the internal hom descends to an internal hom on $\mathcal{K}_{\mathcal{E}}$. It is immediate that $\pi$ is closed in this situation.

Finally, the statement concerning rigidity follows from Remark 7.3.

Remark 7.9. Note that we do not assert that $\mathcal{K}_{\mathcal{E}}$ is quite a tt-category: We do not know that, in $\mathcal{K}_{\mathcal{E}}$, the tensor product satisfies the appropriate Koszul signs with respect to suspension. In certain general situations we can verify this, see Corollary 8.6.

Corollary 7.10. If $\mathcal{K}$ is rigid and $\mathcal{E}$ is a proper $\otimes$-class of triangles, the subcategories of projectives and of injectives, $\text{proj}(\mathcal{E})$ and $\text{inj}(\mathcal{E})$, are tensor-closed. In that case, $\mathcal{K}_{\mathcal{E}}$ is a rigid tt-category (up to Koszul signs).

* * *

Let us now turn to the other connection between the tensor structure of $\mathcal{K}$ and proper classes: The production of Frobenius classes of triangles using the tensor. In glorious generality, one can finesse a tensor-version of the Wirthmüller conditions of Theorem 4.23. Let us instead go straight for the jugular.

Corollary 7.11. Let $\mathcal{K}$ be a tt-category and let $B \in \mathcal{K}$ be a rigid object. Let $\mathcal{E}_B$ denote the class of $(B \otimes -)$-split triangles, that we shall simply call $B$-split triangles, that is, the proper class whose ideal of phantoms $\text{Ph}_B = \ker(B \otimes -)$, are the maps killed by tensoring.
with $B$. Then $\mathcal{E}_B$ is a Frobenius $\otimes$-class of triangles, whose class of projective-injectives is precisely $\text{add}(B \otimes \mathcal{K})$. The corresponding quotient
\[ \mathcal{K}_B = \mathcal{K} / \text{add}(B \otimes \mathcal{K}) \]
is a tt-category, and the quotient functor $\pi_B : \mathcal{K} \to \mathcal{K}_B$ is monoidal.

**Proof.** Since $B$ is rigid, we have adjoint functors and so Theorem 4.23 applies to give the first statement. We use here that the unit–counit relations for the adjunction tell us that $\text{add}(B \otimes K) = \text{add}(B \vee \otimes K)$ (cf. Proposition 7.13). For the statements regarding the monoidal structure, it is enough to note that if $f \in \ker(B \otimes -)$ is a $B$-phantom and $X \in \mathcal{K}$ is arbitrary then
\[ B \otimes (X \otimes f) \cong (B \otimes f) \otimes X = 0 \]
and
\[ B \otimes \text{hom}(X, f) \cong \text{hom}(B \vee, \text{hom}(X, f)) \cong \text{hom}(X \otimes B \vee, f) \cong \text{hom}(X, B \otimes f) = 0. \]

Thus Proposition 7.8 applies to give the remaining statements with the exception of the Koszul signs. This additional compatibility condition is satisfied, but we defer the proof to Corollary 8.6. \[ \square \]

**Example 7.12.** Let $p$ be a prime number and $k$ be a field of characteristic $p$. Let $G$ be a finite group (we assume that $p$ divides the order of $G$ to avoid dwelling too much on the zero category). Given a finite collection $\mathcal{K}$ of subgroups of $G$ one can consider $\text{mod}_{\mathcal{K}} kG$, the stable category of $G$ relative to $\mathcal{K}$ as defined in [14]. This is given by working relative to modules induced from subgroups in $\mathcal{K}$ or, equivalently, by considering $\text{mod} kG$ with the exact structure where the exact sequences are those that split when restricted to all subgroups in $\mathcal{K}$.

This construction can be phrased in terms of the additive quotients studied here. The sum, suspension, and summand closed subcategory of $\text{mod} kG$
\[ \mathcal{C}_{\mathcal{K}} = \text{add}(\text{Ind}_H^G M \mid H \in \mathcal{K}, M \in \text{mod} kH) \]
is preenveloping and precovering (this is proved in [14]), so the corresponding additive quotient is triangulated. One easily checks that it coincides with $\text{mod}_{\mathcal{K}} kG$.

More generally, one could take a finite-dimensional representation $V$ of $G$ and consider $((\text{mod} kG) \otimes V)\otimes$, which is again the projective-injectives for a Frobenius class of triangles and obtain a corresponding triangulated additive quotient. The interested reader is referred, for instance, to [21].

Let us return to our general discussion. We begin with some basic observations.

**Proposition 7.13.** Let $B \in \mathcal{K}$ be rigid.

(a) The rigid object $B$ is $\otimes$-faithful (that is, $B \otimes - : \mathcal{K} \to \mathcal{K}$ is faithful) if and only if $\text{coev} \colon 1 \to B \otimes B \vee$ is a split monomorphism, if and only if $\mathcal{K}_B = 0$.

(b) The objects $B$ and $B \vee$ and, more generally, the rigid objects $B \otimes m \otimes (B \vee) \otimes n$ for all $m, n > 0$ define the same relative category $\mathcal{K}_B$. 

Proof. Part (a) is an easy exercise using that the only monomorphisms in a triangulated
category are the split ones. Part (b) follows from the standard unit–counit relations that
guarantee $B \in \text{add}(B \otimes \mathcal{K})$, etc. \hfill \flushright \Box

Remark 7.14. If $B$ is only nil-faithful (a. k. a. solid), meaning that every $f \in \ker(B)$ is
$\otimes$-nilpotent, which is also equivalent to saying $\text{supp} B = \text{Spc} \mathcal{K}$, then $\mathcal{K}_B$ is not necessarily
trivial. In other words, even when $\text{thick}^\otimes(B) = \mathcal{K}$, if $\text{add}(B \otimes \mathcal{K}) \neq \mathcal{K}$, then $\mathcal{K}_B \neq 0$ is a
non-trivial tt-category.

Example 7.15. In the representation-theoretic setting of Example 7.12, consider a
collection $H_1, \ldots, H_n \leq G$ of subgroups and the object $B = \oplus_{i=1}^n \text{Ind}_{H_i}^G k$ in $\mathcal{K} = \text{mod}(kG)$. Then $B$ is $\otimes$-faithful if only if one of the indices $[G : H_i]$ is prime to $p$, whereas the property
$\text{supp}(B) = \text{Spc}(\mathcal{K})$ is much more flexible: It suffices that every elementary abelian subgroup
of $G$ is conjugate to a subgroup of one the $H_i$.

We can specialize much of what we have seen in the general triangular setting to the tt-
setting. For instance, we have the obvious analogue of naturality.

Corollary 7.16. Given a tt-functor $F : \mathcal{K} \to \mathcal{K}'$ and $B \in \mathcal{K}$ rigid, then there is a unique
(tt-)functor $\bar{F}$ making the following square commute

\[
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{F} & \mathcal{K}' \\
\pi \downarrow & & \downarrow \pi' \\
\mathcal{K}_B & \xrightarrow{\bar{F}} & \mathcal{K}'_{F(B)}.
\end{array}
\]

Proof. It is enough to check conditions (1) and (2) of Proposition 4.15 as the preservation of
the monoidal structure follows from the universal property of the monoidal additive quotients.
Let $B' = F(B)$ and let $\mathcal{E}_B$ and $\mathcal{E}_{B'}$ denote the Frobenius classes of triangles arising from $B$
and $B'$ in $\mathcal{K}$ and $\mathcal{K}'$, respectively. If $\delta$ is a $B$-phantom, that is, $B \otimes \delta = 0$, then since $F$ is
monoidal, we have $B' \otimes F(\delta) \cong F(B) \otimes F(\delta) \cong F(B \otimes \delta) \cong 0$. Thus $F(\mathcal{E}_B) \subseteq \mathcal{E}_{B'}$, showing
(1), by exactness of $F$. Similarly, if $Y$ is a summand of $X \otimes B$, then $F(Y)$ is a summand of
$F(B \otimes X) = B' \otimes F(X)$ so $F$ sends $\text{add}(B \otimes \mathcal{K})$ to $\text{add}(B' \otimes \mathcal{K}')$ showing that (2) holds. \hfill \flushright \Box

Remark 7.17. One might hope that Corollary 7.16 would provide a method for producing
 equivalences of relative stable categories, or facilitating their computation by finding a good $F : \mathcal{K} \to \mathcal{K}'$. However, asking that $\bar{F}$ be conservative is already a lot to hope for if $F$ is
not already conservative itself. Indeed, if $\ker F = 0$, then $\ker F \subseteq \text{add}(B \otimes \mathcal{K})$. In particular,
if $\ker F = 0$ but $\ker F \neq 0$, then $\text{add}(B \otimes \mathcal{K})$ contains a non-zero tt-ideal. This property
reminds us of Theorem 5.6 and offers a natural transition to the next section.

8. Thick tensor ideals and birationality

We now concentrate on what we can say concerning thick $\otimes$-ideals in the case that the relative
quotient is a tt-category with the induced tt-structure. We focus on the setup of Corollary 7.11
with the additional assumption that $\mathcal{K}$ is rigid: So $\mathcal{K}$ is a rigid tt-category, $B \in \mathcal{K}$ is an object,
which gives rise to the Frobenius class of $B$-split triangles $\mathcal{E}_B$ with $\text{proj}(\mathcal{E}_B) = \text{add}(B \otimes \mathcal{K})$, and the corresponding stable category $\mathcal{K}_B = \mathcal{K} / \text{add}(B \otimes \mathcal{K})$ is again a rigid tt-category.
We denote by $\pi : \mathcal{K} \to \mathcal{K}_B$ the (non-exact) monoidal quotient functor.
Remark 8.1. In this situation the thick subcategory of Corollary 5.10
\[ \mathcal{M} = \text{thick}_{\mathcal{X}}(\text{proj}(\mathcal{E}_B)) = \text{thick}_{\mathcal{X}}(B \otimes \mathcal{X}) = \text{thick}^{\otimes}_{\mathcal{X}}(B) \]
is automatically a \( \otimes \)-ideal. Thus the corresponding equivalence between the quotients can be idempotent completed to an equivalence
\[ \mathcal{X}(U) = (\mathcal{X}/\mathcal{X}Z)^\sim \cong (\mathcal{X}_B/\pi\mathcal{M})^\sim, \]
where \( \xi \) denotes idempotent completion, and \( \mathcal{X}(U) \) is the category associated to the open \( U = \text{Spc}\mathcal{X} \setminus Z \) for \( Z = \text{supp} \mathcal{X} B \).

This helps to make precise our comments about birationality in Remark 5.11: \( \mathcal{X}_B \) admits a Verdier quotient equivalent to the part of \( \mathcal{X} \) supported on \( U \). We want to show that the right-hand category \( (\mathcal{X}_B/\pi\mathcal{M})^\sim \) is also \( \mathcal{X}_B(V) \) for a natural quasi-compact open \( V \subseteq \text{Spc}(\mathcal{X}_B) \).

Now let us consider a construction which exploits the tensor structure in a way which is different to what we have seen so far and that will help us determine the open \( V \) of Remark 8.1.

Construction 8.2. Ponder the distinguished triangle on the coevaluation morphism
\[ F_B \xrightarrow{\xi_B} 1 \xrightarrow{\text{coev}} B \otimes B^\vee \xrightarrow{\Sigma F_B} \]
(8.3)
in \( \mathcal{X} \). By the unit–counit relations for an adjunction we know that \( \text{coev} \otimes B \) is a split monomorphism, and so its fiber \( \xi_B \) is \( B \)-phantom:
\[ \xi_B \otimes B = 0. \]
(8.4)
We already get a lot of mileage out of the morphism \( \xi_B \). This map controls the triangulated structure on \( \mathcal{X}_B \); in some sense one can view \( \mathcal{X}_B \) as being \( \mathcal{X} \) “twisted by \( \xi_B \).” This is made precise in the next theorem.

Recall from Example 4.19 that we denote by \( \Sigma \) the autoequivalence of \( \mathcal{X}_B \) induced by \( \Sigma \), the suspension of \( \mathcal{X} \), which is naturally isomorphic to \( \Sigma 1 \otimes (\cdot) \). We will also need to concept of \( (\otimes)\)-invertibility: an object \( X \in \mathcal{X} \) is invertible if there exists an \( X^{-1} \) such that \( X \otimes X^{-1} \cong 1 \).

We note that if \( X \) is invertible, then necessarily \( X^{-1} = X^\vee \).

Theorem 8.5. With the above notation, we have the following.

(a) The object \( \pi(F_B) \) is invertible in \( \mathcal{X}_B \).
(b) There is a natural isomorphism
\[ \Sigma_B(\cdot) \cong \pi(F_B) \otimes \Sigma(\cdot) \]
between the suspension in \( \mathcal{X}_B \) and the functor induced by suspension (Example 4.19) twisted by this invertible. Moreover, under this isomorphism, \( \pi(\xi_B) \otimes \Sigma : \Sigma_B \to \Sigma \) is the comparison morphism \( \alpha \) of Construction 4.20.

(c) Given a morphism \( f : X \to Y \) in \( \mathcal{X} \), the cone on its image \( \pi f \) in \( \mathcal{X}_B \) can be obtained as \( \pi(\text{cone}(\xi_B \otimes f)) \). In fact the whole triangle over \( \pi(f) \) can be obtained from the diagram
\[
\begin{align*}
X \\
\downarrow f \\
F_B \otimes X \\
\xi_B \otimes f \\
Y \\
\downarrow g \\
Z \\
\downarrow h \\
\Sigma(F_B \otimes X),
\end{align*}
\]
where the row is a distinguished triangle in \( \mathcal{X} \), by applying \( \pi \) to the triple \( (f, g, h) \) and using the identification \( \pi(F_B \otimes \Sigma) \cong \Sigma_B \) of part (a).
Proof. The map $\xi_B$ is a $B$-phantom and so coev is a $\text{inj}(E_B)$-preenvelope. It follows that in $K_B$ we have

$$\Sigma_B 1 \cong \pi(\Sigma F_B).$$

This generalizes to any object as coev gives functorial $\text{inj}(E_B)$-preenvelopes by Lemma 3.13, proving the second part of the statement. Let us emphasize that $\Sigma_B 1$ is generally not $\Sigma 1 = \pi(\Sigma 1)$, although both are $\otimes$-invertible in $K_B$. The former because it is the suspension of the unit, the latter because $\pi$ is monoidal.

To show $\pi(F_B)$ is invertible, it is enough to note that desuspending the triangle on coev gives an isomorphism

$$\pi(F_B) \cong \Sigma B \Sigma^{-1}$$

and then use that $\pi$ and suspension preserve invertibility.

It remains to prove (c). By what we have already seen, we may compute the cone of $\pi(f) : \pi X \to \pi Y$ via the central homotopy bicartesian square in the following map of triangles:

$$
\begin{align*}
F_B \otimes X & \xrightarrow{\xi_B \otimes X} X \xrightarrow{\text{coev}_X} B \otimes B^Y \otimes X \xrightarrow{\Sigma (F_B \otimes X)} \\
F_B \otimes X & \xrightarrow{\xi_B \otimes f} Y \xrightarrow{g} Z \xrightarrow{h} \Sigma (F_B \otimes X),
\end{align*}
$$

where the fibers agree by the octahedral axiom. It follows that $\pi(Y \xrightarrow{g} Z) = \pi(\text{cone}(\xi_B \otimes f))$ is the cone of $\pi(f)$ in $K_B$. \qed

Corollary 8.6. Let $\mathcal{K}$ be a rigid tt-category and $B \in \mathcal{K}$ an object. Then the tensor product and suspension are related by the usual Koszul signs in $K_B$.

Proof. By Theorem 8.5(b) there is an isomorphism $\Sigma_B (-) \cong \pi(F_B) \otimes \Sigma(-)$. It follows immediately from the fact that $\mathcal{K}$ is a tt-category that $\Sigma$ plays nicely with $\otimes$. Thus it is sufficient to verify that juggling $\pi(F_B)$, via associators and symmetry constraints which we denote by $a$ and $s$, respectively, does not introduce any signs, that is, that the following diagram commutes:

$$
\begin{align*}
(F_B^{\otimes r} \otimes X) \otimes (F_B^{\otimes s} \otimes Y) & \xrightarrow{s} (F_B^{\otimes r} \otimes X) \otimes (Y \otimes F_B^{\otimes s}) \\
& \xrightarrow{a} ((F_B^{\otimes r} \otimes X) \otimes Y) \otimes F_B^{\otimes s} \\
F_B^{\otimes r} \otimes (X \otimes (F_B^{\otimes s} \otimes Y)) & \xrightarrow{a} F_B^{\otimes s} \otimes ((F_B^{\otimes r} \otimes X) \otimes Y) \\
& \xrightarrow{s} (F_B^{\otimes s} \otimes (F_B^{\otimes r} \otimes X) \otimes Y) \\
F_B^{\otimes s} \otimes ((X \otimes F_B^{\otimes s}) \otimes Y) & \xrightarrow{a} F_B^{\otimes s} \otimes ((F_B^{\otimes r} \otimes (X \otimes Y)) \\
& \xrightarrow{s} (F_B^{\otimes s} \otimes F_B^{\otimes r}) \otimes (X \otimes Y) \\
F_B^{\otimes r} \otimes ((F_B^{\otimes s} \otimes X) \otimes Y) & \xrightarrow{a} F_B^{\otimes r+s} \otimes (X \otimes Y).
\end{align*}
$$
By the coherence theorem for symmetric monoidal categories, this boils down to checking the two permutations agree, which they do. □

**Theorem 8.7.** Let \( \pi : \mathcal{K} \to \mathcal{K}_B \) be the quotient with respect to \( B \) and consider \( \xi_B : F_B \to \mathfrak{1} \) the fiber of the coevaluation map \( \eta : 1 \to B' \otimes B \) as in Construction 8.2. Let \( C = \text{cone}(\xi_B^2) \) in \( \mathcal{K} \). Let \( U = U_\mathcal{K}(B) \) the open complement of \( \text{supp}_\mathcal{K}(B) \) and \( V = U_{\mathcal{K}_B}(\pi(C)) \) the open complement of \( \text{supp}_{\mathcal{K}_B}(\pi(C)) \). Then \( \pi \) restricts to a \( \otimes \)-triangulated equivalence

\[
\pi|_U : \mathcal{K}(U) \cong \mathcal{K}_B(V).
\]

In particular, \( \text{Spc}(\pi|_U) \) is a homeomorphism between \( V \) and \( U \).

We shall need a general \( \text{tt} \)-fact.

**Lemma 8.8** [5, § 2]. Let \( f : F \to \mathfrak{1} \) be a morphism in a rigid \( \text{tt} \)-category such that \( f^\otimes n \otimes \text{cone}(f) = 0 \) for some \( n \geq 1 \). Then the \( \text{tt} \)-ideal where \( f \) is nilpotent \( \mathcal{J} := \{ X \in \mathcal{K} \mid f^\otimes n \otimes X = 0 \text{ for } n \geq 0 \} \) coincides with \( \text{thick}(\text{cone}(f)) \).

**Proof.** By [5, Proposition 2.12], this \( \mathcal{J} \) is a \( \text{tt} \)-ideal, hence our assumption gives \( \text{thick}(\text{cone}(f)) \subseteq \mathcal{J} \). The reverse inclusion follows from [5, Proposition 2.14]. □

**Proof of Theorem 8.7.** We want to apply Corollary 5.10 to \( \mathcal{M} = \text{thick}(\text{proj}(E_B)) \) as announced in Remark 8.1, where we already saw that \( \mathcal{M} = \text{thick}(B) = \mathcal{K}_{\text{supp}(B)} \). So, we need to identify \( \pi(\mathcal{M}) = \{ Y \in \mathcal{K}_B \mid Y \simeq \pi(X) \text{ for } X \in \mathcal{M} \} \). The cone on \( f = \xi_B \) is \( B \otimes B' \) by (8.3), and \( f \otimes \text{cone}(f) = 0 \) by (8.4), so we may apply Lemma 8.8. Noting that \( B \) and \( B' \) generate the same \( \text{tt} \)-ideal of \( \mathcal{K} \), namely, \( \mathcal{M} \), we learn that \( \mathcal{M} \) is exactly the locus of nilpotence of \( \xi_B \):

\[
\mathcal{M} = \{ X \in \mathcal{K} \mid \xi_B^\otimes n \otimes X = 0 \text{ for } n \geq 0 \}.
\]

We claim that its image in \( \mathcal{K}_B \) is simply the locus of nilpotence of the image of \( \xi_B \):

\[
\pi(\mathcal{M}) = \{ Y \in \mathcal{K}_B \mid \pi(\xi_B)^\otimes n \otimes Y \text{ for } n \geq 0 \}.
\]

(8.9)

One inclusion is trivial: If \( \xi_B^\otimes n \otimes X = 0 \) then applying the tensor-functor \( \pi \) we have \( \pi(\xi_B)^\otimes n \otimes \pi(X) = 0 \). Conversely, suppose that \( \pi(\xi_B)^\otimes n \otimes \pi(X) = 0 \) for some \( n \geq 0 \) and let us show that \( \xi_B^{\otimes n+1} \otimes X = 0 \). The assumption is that the morphism \( \xi_B^\otimes n \otimes X \) vanishes under \( \pi \), hence factors via some object \( B \otimes Z \), say \( \xi_B^\otimes n \otimes X = \beta\alpha : F_B^\otimes n \otimes X \overset{\beta}{\to} B \otimes Z \overset{\alpha}{\to} X \). In that case, the following commutative diagram

\[
\begin{array}{ccccccc}
F_B^\otimes n+1 \otimes X & \overset{\xi_B^{\otimes n+1} \otimes X}{\longrightarrow} & F_B \otimes X & \overset{\pi}{\longrightarrow} & X \\
\downarrow F_B \otimes \beta & & \downarrow & & \downarrow \\
F_B \otimes B \otimes Z & \overset{\xi_B \otimes B \otimes Z}{\longrightarrow} & B \otimes Z & \overset{=} {\longrightarrow} & B \otimes Z \\
\end{array}
\]

proves the claim. Hence we have (8.9). We now want to use Lemma 8.8 “backwards,” for \( \pi(\xi_B) \) in the rigid category \( \mathcal{K}_B \). For that, we need to know the cone on \( \pi(\xi_B) \), which is \( \pi(\text{cone}(\xi_B^2)) = \pi(C) \) by Theorem 8.5(c) and we need to know that \( \pi(\xi_B) \) is nilpotent on its cone. In fact, one can prove directly that already in \( \mathcal{K} \) we have \( \xi_B^2 \otimes C = 0 \). In any case,
since \( C = \text{cone}(\xi^\otimes 2) \in \text{thick}^\otimes \text{(cone}(\xi_B)) \) by the octahedron on \( \xi^\otimes 2_B = \xi_B \circ (F_B \otimes \xi_B) \), we have \( C \in \mathcal{M} \) and therefore \( \xi_B \) is nilpotent on \( C \). The conclusion of Lemma 8.8 for \( \pi(\xi_B) \) is that

\[
\pi(\mathcal{M}) = \text{thick}^\otimes(C).
\]

Corollary 5.10 then tells us that \( \pi \) induces an equivalence of Verdier quotients

\[
\mathcal{K} // \text{thick}^\otimes(B) = \mathcal{K} // \mathcal{M} \cong \mathcal{K}_B // \pi \mathcal{M} = \mathcal{K}_B // \text{thick}^\otimes(C).
\]

Idempotent-completing both sides gives the equivalence

\[
\mathcal{K}(U) \cong \mathcal{K}_B(V) \text{ by definition of the open complements } U \text{ and } V.
\]

Finally we have \( U \cong \text{Spc}(\mathcal{K}(U)) \cong \text{Spc}(\mathcal{K}_B(V)) \cong V. \) \( \Box \)

There is a more general question of understanding the space \( \text{Spc}(\mathcal{K}_B) \) outside of the open \( V \) determined in Theorem 8.7. Note that we have a tt-version of Proposition 5.13, which indicates that \( \text{Spc}(\mathcal{K}_B) \) might be rather big, as there tends to be many more additive tensor-ideals than triangulated tensor-ideals.

**Corollary 8.10.** Let \( G : \mathcal{K} \to \mathcal{L} \) be a tt-functor such that every triangle in \( \mathcal{E}_B \) is \( G \)-split. Let \( \mathcal{A} \subseteq \mathcal{N} \) be a summand-closed additive subcategory which contains \( GB \) and is closed under tensoring in \( \mathcal{N} \). Then \( \pi(G^{-1}\mathcal{A}) \) is a thick \( \otimes \) ideal of \( \mathcal{K}_B \).

**Remark 8.11.** Given an invertible object \( u \in \mathcal{K} \) in a tt-category, we can define a graded commutative ring

\[
R_{\mathcal{K}}^\bullet = R_{\mathcal{K}, u}^\bullet = \text{Hom}_\mathcal{K}(1, u^\otimes \bullet),
\]

and a spectral (that is, quasi-compact) continuous map

\[
\rho_{\mathcal{K}}^\bullet : \text{Spc} \mathcal{K} \to \text{Spec}^\bullet(R_{\mathcal{K}, u}^\bullet),
\]

where \( \text{Spec}^\bullet \) denotes the homogeneous spectrum. This map is defined by sending a tt-prime \( \mathcal{P} \in \text{Spc} \mathcal{K} \) to the homogeneous prime ideal generated by the elements

\[
\{ f : 1 \to u^\otimes n \mid \text{cone}(f) \notin \mathcal{P} \},
\]

as \( n \) varies.

The prototypical non-trivial invertible object that exists in any tt-category is \( \Sigma \) \( \mathbb{1} \), and so, we get a comparison map

\[
\rho_{\mathcal{K}}^\bullet : \text{Spc} \mathcal{K} \to \text{Spec}^\bullet(R_{\mathcal{K}}^\bullet),
\]

where \( R_{\mathcal{K}}^\bullet = R_{\mathcal{K}, \Sigma \mathbb{1}}^\bullet \) is the graded endomorphism ring of the unit.

Of course, this construction is natural in the sense that every tt-functor \( F : \mathcal{K} \to \mathcal{L} \) induces a ring homomorphism \( F : R_{\mathcal{K}, u}^\bullet \to R_{\mathcal{L}, v}^\bullet \), where \( v = F(u) \), and thus a map on homogeneous spectra. The functor \( F \) also induces a spectral map \( F^\bullet : \text{Spec} \mathcal{L} \to \text{Spec} \mathcal{K} \) and all of this fits into a commutative square

\[
\begin{array}{ccc}
\text{Spec} \mathcal{L} & \xrightarrow{F^\bullet} & \text{Spec} \mathcal{K} \\
& \mathcal{P}_{\mathcal{L}, v} \downarrow & \mathcal{P}_{\mathcal{K}, u} \\
\text{Spec} R_{\mathcal{L}, v}^\bullet & \xrightarrow{\mathcal{P}_{\mathcal{F}}^\bullet} & \text{Spec} R_{\mathcal{K}, u}^\bullet.
\end{array}
\]

Now let \( B \) be any rigid object and \( \pi : \mathcal{K} \to \mathcal{K}_B = \mathcal{K} / \text{add}(B \otimes \mathcal{K}) \) be the corresponding relative category. Set \( v = \Sigma \mathbb{1} \). Note that this invertible is not \( \Sigma_B(1) \). However, the functor \( \pi \) yields a graded homomorphism \(\pi : R_{\mathcal{K}}^\bullet \to R_{\mathcal{K}_B, v}^\bullet\) and therefore a spectral continuous map

\[
\text{Spec}^\bullet(\pi) : \text{Spec}^\bullet(R_{\mathcal{K}_B, v}^\bullet) \to \text{Spec}^\bullet(R_{\mathcal{K}}^\bullet).
\]
If we suppose that $\rho_{\mathcal{K}}^\ast : \text{Spc} \mathcal{K} \to \text{Spec}^\ast \mathcal{R}_{\mathcal{K}}$ is a homeomorphism, then there exists a unique spectral map $\pi^1 : \text{Spc} \mathcal{K}_B \to \text{Spc} \mathcal{K}$ making the following square commute

$$
\begin{array}{ccc}
\text{Spc} \mathcal{K}_B & \xrightarrow{\pi^1} & \text{Spc} \mathcal{K} \\
\rho_{\mathcal{K}_B, v} & \circlearrowleft & \rho_{\mathcal{K}} \\
\text{Spec}^\ast \mathcal{R}_{\mathcal{K}_B, v} & \xrightarrow{\text{Spec}^\ast (\pi)} & \text{Spec}^\ast \mathcal{R}_{\mathcal{K}}
\end{array}
$$

simply defined to be the composite

$$\pi^1 := \rho_{\mathcal{K}}^{-1} \circ \text{Spec}^\ast (\pi) \circ \rho_{\mathcal{K}_B, v}.$$ 

Each map is spectral, so the composite is as well, and unicity is clear.

The assumption that the comparison map $\rho_{\mathcal{K}}^\ast : \text{Spc} \mathcal{K} \to \text{Spec}^\ast \mathcal{R}_{\mathcal{K}}$ is a homeomorphism is intrinsic to $\mathcal{K}$ and has really nothing to do with the relative stable category construction $\mathcal{K}_B$.

The above diagram therefore suggests that one could hope to define $\pi^1 : \text{Spc}(\mathcal{K}_B) \to \text{Spc}(\mathcal{K})$ in general. In other words, although $\pi : \mathcal{K} \to \mathcal{K}_B$ is not a tt-functor, its seems to induce some map on spectra, which extends the birational homeomorphism of Theorem 8.7.

Acknowledgements. We are thankful to Apostolos Beligiannis and Jon Carlson, for valuable discussions around relative categories and references.
