Abstract

**Background:** Bronchopulmonary dysplasia (BPD) is a serious and lifelong pulmonary disease in premature neonates, which has an influence on a quarter of premature newborns. Wingless/integrated(Wnt)/β-catenin signaling pathway affects lung cell differentiation and lung tissue structure, and is abnormal activation in the lungs of rats with pulmonary fibrosis. **Method:** Newborn rats were subjected to hyperoxia-exposure, histopathological changes in lung tissues were evaluated through Immunohistochemistry (IHC), Dishevelled (DVL-1) and signaling pathways were detected through western blotting and real-time PCR. **Results:** Contrasting with the normoxic lungs, hyperoxia-exposed lungs demonstrated larger alveoli, less alveoli and thicker alveolar septa, and the number of alveoli reduced obviously, alveoli enlarged seriously in hyperoxia group. SOD activity was decreased (7th day: $P < 0.05$; 14th day: $P < 0.01$), and MDA was increased (7th day: $P < 0.05$; 14th day: $P < 0.01$) after hyperoxia exposure. Protein and mRNA expression levels of β-catenin, DVL-1, Ctnnb1 and Cyclin D1 were upregulated by hyperoxia exposure on 7th day ($P < 0.01$) and 14th day ($P < 0.01$). **Conclusion:** We confirmed the positive role of DVL-1 and Wnt/β-catenin signaling pathway in promoting BPD under hyperoxia conditions, and provided promising therapeutic targets in the future.

**Keywords:** Hyperoxia-induced lung injury; DVL-1; Wnt/β-catenin signaling pathway; Bronchopulmonary dysplasia (BPD)

Introduction
Bronchopulmonary dysplasia (BPD) is a serious and lifelong pulmonary disease in premature neonates, which has an influence on a quarter of premature newborns [1-3]. Preterm newborn is related to an increased risk of long-term pulmonary problems. The pathogenesis of BPD involves a complex interaction between genetic and environmental factors. A variety of endogenous and exogenous stimulus, such as ventilator volume injury, barotrauma, hyperoxia injury, patent ductus arteriosus, result in inflammatory cascade reaction, immature lung tissue, uncontrolled pulmonary vascular development and abnormal repair of lung tissue after injury[4,5].

Dishevelled (DVL-1) had been reported to mediate three signaling pathways, including canonical Wingless/integrated(Wnt)/β-catenin pathway, non-canonical Wnt/β-catenin pathway and Wnt/Ca\(^{2+}\) pathway[6]. In the classic canonical Wnt signaling pathway, the upregulation of DVL-1 expression leads to the overexpression of β-CATENIN protein. The accumulation of β-CATENIN protein in the cytoplasm and then promotes the transcription of Wnt/β-catenin pathway downstream genes in the nucleus[7]. Recent studies showed that abnormal activation of Wnt/β-catenin pathway caused the occurrence of pulmonary diseases [8,9]. In newborn lung tissue, Wnt/β-catenin signaling pathway affects lung cell differentiation and lung tissue structure, and is abnormal activation in the lungs of rats with pulmonary fibrosis [10]. Wnt/β-catenin pathway was activated in lung tissue in animal models of BPD and idiopathic pulmonary fibrosis, which suggested that Wnt/β-catenin pathway had potential as a therapeutic target for the treatment and prevention of BPD[11,12].

We speculated that DVL-1 played a significant role in promoting the occurrence and development of BPD. The present study aimed to determine the role of DVL-1 and the involvement of Wnt/β-catenin pathway in the occurrence and development of BPD. It was demonstrated that DVL-1 protein expression was increased and played a key role in activating Wnt/β-catenin signaling pathway in hyperoxia-exposed newborn rat lung.

Materials and methods

Reagents
Sheep anti-rabbit horseradish peroxidase-conjugated(HRP)-conjugated secondary antibody(Cell Signaling Technology, MA, USA); RIPA lysis buffer(Cell Signaling Technology, MA, USA), BCA Protein Assay Kit, StarSignal Chemiluminescent Assay Kit (Vazyme, Nanjing, China), StarScript II First-strand cDNA Synthesis Mix With
gDNA Remover, 2×RealStar Green Fast Mixture (with ROXII), TRIgene (TaKaRa, Dalian, China), polyvinylidene difluoride (PVDF) membranes (Millipore, Burlington, USA); DVL-1, β-CATENIN and Cyclin D1 primary antibodies (ZENBIO biotech, Chengdu, China); GAPDH primary antibody (Goodhere biotech, Hangzhou, China); PCR primers (genscript biotech, Nanjing, China); malondialdehyde (MDA) and superoxide dismutase (SOD) assay kits (Solarbio life sciences, Beijing, China); immunohistochemistry kit (MXB, Fujian, China).

Animal procedures and treatment

All animals’ experimental procedures were approved by the Ethics Committee of Animals, The Affiliated Wuxi Children's Hospital of Nanjing Medical University. The Sprague Dawley (SD) rats were obtained from the Nanjing Agriculture University. A total of 36 newborn SD rats were randomly selected into two groups, hyperoxia group (85% O2 from the beginning of birth) and control group (normoxia, 21% O2). Rats had free access to food and water. On 7th and 14th days after birth, nine newborn rats of two groups were anesthetized with 1% pentobarbitone by intraperitoneal injection to gather the entire lungs aseptically, respectively. The right lung was fixed with paraformaldehyde (PFA) for immunohistochemistry, the upper lobes of the left lung were used for real-time qPCR and oxidative stress index test, and the lower lobes of the left lung were used for western blotting.

Oxidative stress index test

The upper lobes of the left lung was homogenized with cold normal saline, centrifuged (4°C, 12500g, 10min), and the supernatant was collected for assays. Malondialdehyde (MDA) and superoxide dismutase (SOD) assays were performed using assay kits, according to manufacturers’ instructions.

Western blot analysis

Total protein was separated from lung tissues with RIPA, and quantified with a BCA protein assay kit. After dilution with loading buffer, the separated proteins were boiled for 5 min. Twenty micrograms of protein samples were separated using 12.5 SDS-PAGE, and electrotransferred onto polyvinylidene difluoride membranes. The membranes were probed overnight at 4°C with primary antibodies against DVL-
IHC

Immunohistochemistry (IHC)

A-fixed lung tissues were dehydrated, vitrified, embedded in paraffin, fixed, and cut into 5 μM thick sections, which were then fixed in a 60°C oven for 4 h. Sections were dewaxed with dimethylbenzene, hydrated with gradient alcohol according to the manufacturer’s instructions, and treated with 3% H₂O₂ to block endogenous peroxidase activity. Treated sections were placed into an EDTA-Tris buffer solution and microwaved for 20 min, blocked with serum, and incubated overnight at 4 °C with DVL-1 primary antibody(1:200 dilution), β-CATENIN primary antibody(1:200 dilution) and CYCLIN D1 primary antibody (1:200 dilution). After sequential incubation with a biotin-labeled secondary antibody and streptavidin-peroxidase, sections were developed using 3,3’-diaminobenzidine (DAB), dehydrated. IHC score was determined semi-quantitatively by multiplication of the positive fraction with the grayscale value according to the following system: a) positive fraction was categorized as 0, no staining; 1+, ≤10%; 2+, >10%, <50%; 3+, ≥50%. b) grayscale value was as 0, no staining; 1, weaker than, or the same as that in lung; 2, more intense than the staining in lung. IHC score of more than 2 which is, therefore, intensity score of more than 2, was defined as positive.

RT-PCR

Real-Time Polymerase Chain Reaction (RT-PCR)

Lung RNA was extracted using Trigene reagent according to the manufacturer’s instructions. The purified mRNA was reverse transcribed into cDNA using PrimeScript™ RT reagent Kit with gDNA Eraser, and real-time PCR was performed using TB Green® Premix Ex Taq™ II (Tli RNaseH Plus). Data were standardized to the endogenous expression of GAPDH. The sequences of the primers are listed in Table 1. Real-time PCR was performed according to the method provided by QuantStudio 3 (Applied Biosystems, USA) in a 20 μl volume using 1 μl cDNA, 1 μl forward primer, 1 μl reverse primer, and 10 μl 2 × RealStar Green Fast Mixture (with ROX II). The thermal cycling conditions were as follows: Stage 1 = 1 cycle, 30 s at 95°C; Stage 2 =
45 cycles, 10 s at 95°C, 30 s at 60°C; Stage 3 = 1 cycle, 15 s at 95°C, 1min at 60°C.

**Statistical Analysis**

The experimental data were expressed as mean ± standard deviation (SD) values. Statistical analysis was conducted by SPSS 21.0 software (SPSS Inc., Chicago, IL, USA). One-way analysis of variance for multiple-group comparisons were performed with GraphPad Prism 8 (GraphPad Software, San Diego, USA). *P* value of <0.05 was considered statistically significant.

**Results**

**Hyperoxia-induced pathological changes in the lung**

In the present study, rats exposed to 85% O$_2$ were inhibited alveolar development, which was correlated with the pulmonary morphological changes of BPD (Figure 1). On the 7th day, the alveoli of hyperoxia-induced rats were separated irregularly and the terminal air sacks were enlarged. Contrasting with the normoxic lungs, hyperoxia-exposed lungs demonstrated larger alveoli, less alveoli and thicker alveolar septa. As increasing duration of the hyperoxic exposure, the differences between the two groups increased significantly. On the 14th day, the number of alveoli reduced obviously, alveoli enlarged seriously in hyperoxia group.

In hyperoxia group, IHC scores of β-CATENIN, DVL-1 and CYCLIN D1 were significantly higher than those of control group on 7th day (*P* < 0.01), and were also significantly higher on 14th day than those on 7th day (*P* < 0.01) (Figure 1, Table 2). SOD is the main antioxidant enzyme, MDA is an end products of membrane lipid peroxidation, used as an indicator of cell oxidation. We found that SOD activity was decreased (7th day:*P* < 0.05; 14th day:*P* < 0.01), and MDA was increased (7th day:*P* < 0.05; 14th day:*P* < 0.01) after hyperoxia exposure, as shown in Table 3.

**Hyperoxia-exposure upregulated DVL-1 protein expression and activated Wnt/β-catenin signaling pathway in newborn rat lung**

As shown in Figure 2, compared to control group, the protein expression levels of DVL-1 were upregulated after hyperoxia exposure on 7th day and 14th day (*P* < 0.01), but there was no significant difference after hyperoxia exposure on 3rd day. The protein expression levels of β-CATENIN, CTNNBL1 and CYCLIN D1 were upregulated...
after hyperoxia exposure on 3\textsuperscript{rd} day ($P < 0.01$), 7\textsuperscript{th} day ($P < 0.01$) and 14\textsuperscript{th} day ($P < 0.01$).

The result of Real-time PCR analysis indicated that the mRNA expression levels of $\beta$-catenin, DVL-1, Ctnnb1 and Cyclin D1 were upregulated by hyperoxia exposure on 7\textsuperscript{th} day ($P < 0.01$) and 14\textsuperscript{th} day ($P < 0.01$).

**Discussion**

It is important to explore the mechanism of lung injury caused by hyperoxia for guiding clinical prevention and treatment of BPD. BPD is a chronic lung disease which is characterized by dysplasia of pulmonary alveoli and pulmonary microvascular. In the present study, we found that alveolar wall was ruptured after hyperoxia exposure continuously, and simplified structure became more obvious with the extension of hyperoxia exposure time. The evaluation of lung development results showed that the hyperoxia-exposure affected the development of the alveolar, angiogenesis and lung, ultimately induced BPD.

DVL-1 is the crucial regulator of Wnt/$\beta$-catenin signaling pathway, which associates diverse arrays of biologic processes such as organogenesis, tissue homeostasis, and pathogenesis of many human diseases. In the genomes of higher organism (including mammals), three genes encoding isoforms of Dishevelled (DVL-11, DVL-12, and DVL-13) are present. Canonical Wnt/$\beta$-catenin signaling pathway was most sensitive to changes in the abundance of either DVL-13 or DVL-11[13]. Previous studies have confirmed the role of DVL-1 family proteins in promoting the occurrence and development of lung tumors. Coexpression of DVL-1 and IQ-domain GTPase-activating protein 1 (IQGAP1) in the cytoplasm and nucleus was correlated with poor prognosis of non-small cell lung cancer, and coexpression in nucleus might play a critical role in the activation of canonical Wnt/$\beta$-catenin signaling Wnt pathway[14]. Phosphorylated Dishevelled-2 (DVL-1-2) protein were significantly higher in cisplatin resistant A549 cells compared with that in A549 cells[15]. However, there has been no research on the mechanism of DVL-1's involvement in hyperoxia-induced lung injury or BPD. Our study elucidates that increased DVL-1 expression was correlated with the development of BPD. DVL-1 protein is highly expressed in hyperoxia-induced lung injury, and not in the normal rat alveolar and bronchial epithelia.

Recent studies have shown that Wnt/$\beta$-catenin signaling pathway plays an extremely important role in lung development, the occurrence and development of lung
diseases [16-18]. Transforming growth factor-β upregulates canonical WNT signaling and inhibits the peroxysome proliferator activated receptor gamma (PPARγ). The absence or a decrease in Wnt/β-catenin signaling during the canalicular stage of pulmonary development, partly related to inflammatory processes, severely affects the developmental processes during the subsequent saccular and alveolar stages. PPARγ stimulates transdifferentiation of myofibroblasts into lipofibroblasts, which helps normal alveolarization. Importantly, hypoxia and hyperoxia promote upregulation of the canonical WNT/β-catenin system as well as TGF-β accompanied by downregulation of PPARγ [18]. The administration of PPARγ agonist, rosiglitazone, has been shown to prevent hyperoxia-induced molecular and morphological changes in a rat model [19]. In the present study, the protein expression levels of Wnt/β-catenin pathway members were increased in the hyperoxia group on 7th and 14th. Aberrant activation of Wnt/β-catenin signaling pathway induced to heterotopic differentiation of alveolar, increased alveolar volume, reduced alveolar number and resulted in simple pulmonary structure.

In the conclusion, our findings implicated that hyperoxia-exposure resulted that the number of alveoli reduced obviously, alveoli enlarged seriously in newborn rat lung tissues. Hyperoxia-exposure upregulated the protein expression levels of DVL-1 and activated Wnt/β-catenin signaling pathway. These findings demonstrated the positive role of DVL-1 and Wnt/β-catenin signaling pathway in promoting BPD under hyperoxia conditions, and provided promising therapeutic targets in the future.
