(Dated: June 16, 2015)

We study the dependence on the quark mass of the compositeness of the lowest-lying odd parity hyperon states. Thus, we pay attention to Λ−like states in the strange, charm and beauty, sectors which are dynamically generated using a unitarized meson-baryon model. In the strange sector we use an SU(6) extension of the Weinberg-Tomozawa meson-baryon interaction, and we further implement the heavy-quark spin symmetry to construct the meson-baryon interaction when charmed or beauty hadrons are involved. In the three examined flavor sectors, we obtain two \( J^P = 1/2^- \) and one \( J^P = 3/2^- \) Λ states. We find that the Λ states which are bound states (the three Λ_b) or narrow resonances (one Λ(1405) and one Λ_c(2595)) are well described as molecular states composed of s-wave meson-baryon pairs. The \( \frac{1}{2}^- \) wide Λ(1405) and Λ_c(2595) as well as the \( \frac{3}{2}^- \) Λ(1520) and Λ_c(2625) states display smaller compositeness and so they would require new mechanisms, such as \( d \)-wave interactions.
I. INTRODUCTION

One of the chief theoretical efforts in hadron physics is to understand the nature of hadrons, whether they can be primarily explained within the quark-model picture as multiquark states or mainly qualify as dynamically generated states via hadron-hadron scattering processes. In particular, in the last years there has been a growing interest in the properties of strange and charmed baryons in connection with many experiments such as the on-going CLEO [1], Belle [2], BES [3], BaBar [4] as well as the planned PANDA [5] or the J-PARC upgrade [6]. Also, the LHCb Collaboration at CERN has been exploring in the recent years an almost terra incognita in the spectroscopy of baryons with the beauty degree of freedom. Results on beauty baryonic states, such as the $\Lambda_b$ excited states [7], have been reported, stimulating the theoretical work to understand the properties of the newly-discovered states.

Recent approaches based on unitarized coupled-channels methods have proven to be very successful in describing the existing experimental data in the charmed [8-25] and beauty baryonic sectors [26-27]. Most of these models emerge as the theoretical effort extends from the strange to charmed and beauty sectors, partially motivated by the parallelism between the $\Lambda(1405)$ and the $\Lambda_c(2595)$ as well as the $\Lambda_b(5912)$ states. Of special importance are the symmetries that are implemented in the hadronic models. While chiral symmetry should be implemented in the strangeness sector, heavy-quark spin symmetry (HQSS) [28-30] appears naturally as we deal with systems that include charmed and beauty degrees of freedom [31-41].

The use of the effective models combined with unitarity constraints in coupled channels allows to explain many baryons in terms of meson-baryon interactions, interpreting them as composite or dynamically-generated states. The ultimate goal is to determine the degree of “compositeness” and the “genuine” contributions of the given state. The formalism was developed by Weinberg in Ref. [42], and later applied to the deuteron in [43], showing that the deuteron can be fully understood as a proton-neutron bound state. More recent works have extended this analysis from bound states to resonances and from s-wave to higher partial waves [44-51]. The theoretical aspects have been further discussed in [52, 53].

The present paper is focused on the analysis of the compositeness of the lowest-lying $J^P = 1/2^−$ and $J^P = 3/2^− \Lambda$ states going from the strange to the beauty sectors 1. The aim is to shed some light on the nature of newly discovered excited $\Lambda_c$ and $\Lambda_b$ by exploiting the similarities with the strange $\Lambda$ states. We also address any existing regularity in the quark mass dependence of the compositeness of these excited baryons.

There exist previous studies in the strange sector. The $\Lambda(1520)$ has been recently discussed in Ref. [54], while the compositeness and elementariness of the two $\Lambda(1405)$ states have been evaluated within the chiral unitarity model (Goldstone boson-baryon chiral perturbation potential used as a kernel of a Bethe-Salpeter equation) at leading order (Weinberg-Tomozawa interaction) in Ref. [55] and incorporating next-to-leading chiral corrections [56]. While the results reported in Refs. [55, 56] are in qualitative agreement with those obtained in this work, there are some appreciable differences between our approach and that followed in [54] for the $\Lambda(1520)$ resonance, namely the consideration of d-wave interactions, which effects will be further investigated.

The structure of this work is as follows. In Section II we summarize the model we are using to describe meson-baryon interactions and present the dynamically-generated $\Lambda$ resonances in the strange, charm and beauty sectors. In Sect. III we use the generalized Weinberg’s sum rule to estimate the importance of the different channels in the generated $\Lambda$ states. With this analysis, we give an educated guess of the compositeness of these states. Finally, some conclusions are addressed in Sect. IV. In Appendix A we present the analytical expression of compositeness on the first and second Riemann sheets, whereas in Appendix B the compositeness rule is derived.

II. DYNAMICALLY-GENERATED STRANGE, CHARM AND BEAUTY $\Lambda$ STATES

In order to analyze the compositeness of the $\Lambda$ (isoscalar) states in the strange, charm or beauty sectors, we start by summarizing the meson-baryon model used in the different sectors.

On one hand, for meson-baryon interactions involving strange hadrons, we consider the extension of the Weinberg-Tomozawa (WT) interaction to SU(6) of Refs. [55, 56]. This is an s-wave contact interaction. This model assumes that the light quark–light quark interaction is approximately spin independent as well as SU(3) flavor symmetric, thus, treating the six states of a light quark as equivalent. This approach has shown a reasonable semi-qualitative outcome for different excited baryonic states as compared to the experimental data [52].

On the other hand, in the heavy sectors of charm and beauty, we extend the model by making use of the HQSS to construct meson-baryon interactions involving heavy hadrons. Whereas HQSS connects vector and pseudoscalar
TABLE I. Baryon masses, \( M_i \), meson masses, \( m_i \), and meson decay constants, \( f_i \), (in MeV) used throughout this work. The widths in MeV units, \( \Gamma \), used in the convolutions (Eq. (1)) are also provided. The masses and decay constants are taken from Refs. \[31\]–[35]. The SU(6) × SU(2) × U(1) and SU(3) × SU(2) labels are displayed as well (for simplicity we do not explicitly give the spin of the heavy quark sector, since it is trivially 0 or 1/2.) The last column indicates the HQSS multiplets. Members of a doublet are placed in consecutive rows.

| Meson | mass width | decay constant | SU(6)_{U(1)} | SU(3)_{J+1} | HQSS | Baryon | mass width | SU(6)_{U(1)} | SU(3)_{J+1} | HQSS |

mesons containing heavy quarks as all type of spin interactions vanish for infinitely massive quarks, chiral symmetry fixes the lowest order interaction between Goldstone bosons and other hadrons in a model independent way via the WT interaction. Then, it is appealing to construct a model for four flavors including all basic hadrons (pseudoscalar and vector mesons, and 1/2+ and 3/2+ baryons) which reduces to the WT interaction in the sector where Goldstone bosons are involved and which incorporates HQSS in the sector where heavy quarks participate \[31\]–[35]. This SU(6) × HQSS model is justified in view of the reasonable semi-qualitative outcome of the SU(6) extension \[62\] and on a formal plausibly on how the SU(4) WT interaction in the heavy pseudoscalar meson-baryon sectors comes out in the vector-meson exchange picture.

The extended WT meson-baryon interaction, in the coupled meson-baryon basis with total heavy content (charm \( C \) /beauty \( B \) / H), strangeness \( S \), isospin \( I \) and spin \( J \), is given by

\[
V^{HSIJ}_{ij} = D^{HSIJ}_{ij} \frac{2\sqrt{s} - M_i - M_j}{4f_i f_j} \left( \frac{E_i + M_i}{2M_i} \right) \left( \frac{E_j + M_j}{2M_j} \right),
\]

(1)

where \( \sqrt{s} \) is the center of mass (C.M.) energy of the system; \( E_i \) and \( M_i \) are, respectively, the C.M. on-shell energy and mass of the baryon in the channel \( i \); and \( f_i \) is the decay constant of the meson in the \( i \)-channel. Symmetry breaking effects are introduced by using physical masses and decay constants. The masses and decay constants used in this work are shown in Table I. The masses shown correspond to the arithmetic mean of the different isospin partners.

The \( D^{HSIJ}_{ij} \) are the matrix elements coming from the group structure of the extended WT interaction \[35\]. The matrix elements required for the \( \Lambda(1520) \) sector, with quantum numbers \( C = 0 \), \( B = 0 \), \( S = -1 \), \( I = 0 \), \( J^P = 3/2^- \), can be found in Eq. (45) of Ref. \[60\]. Those for the \( \Lambda_c(2595) \), with \( C = 1 \), \( B = 0 \), \( S = 0 \), \( I = 0 \), \( J^P = 1/2^- \) and \( \Lambda_c(2625) \), with \( J^P = 3/2^- \), can be found in Tables XV and XVIII of Ref. \[61\], respectively. The same coefficients apply to the bottom case. Finally, the matrix elements for the \( \Lambda(1405) \) sector, with quantum numbers \( C = 0 \), \( B = 0 \), \( S = -1 \), \( I = 0 \), \( J^P = 1/2^- \), can be extracted following the directions of Appendix A of Ref. \[62\] and the conventions in \[64\]. For convenience these matrix elements are explicitly displayed in Table I.

In order to obtain the unitarized \( T \)-matrix, we solve the on-shell factorized form of the Bethe-Salpeter equation using the matrix \( V^{HSIJ} \) as kernel

\[
T^{HSIJ} = (1 - V^{HSIJ} G^{HSIJ})^{-1} V^{HSIJ},
\]

(2)
where $G^{HSIJ}$ is a diagonal matrix containing the meson-baryon propagator in each channel. Explicitly,

$$G^{HSIJ}_{\mu}(\sqrt{s}, m_i, M_i) = i 2M_i \int \frac{d^4 q}{(2\pi)^4} \frac{1}{q^2 - m_i^2} \frac{1}{(P - q)^2 - M_i^2},$$  

being $M_i(m_i)$ the baryon (meson) mass of the channel $i$ and $P^\mu$ the total four-momentum, which in the CM frame is given by $P^\mu_{CM} = (\sqrt{s}, 0)$. The loop function is explicitly given in Ref. [65] and in Appendix A.

When the meson and/or the baryon in the intermediate state is not a stable particle, we convolute the meson-baryon propagator (loop) with the corresponding hadronic spectral function, as done in Refs. [32, 66, 67]. Thus, in this case, the loop function $G$ is substituted by $\hat{G}$, which is defined as the convolution of the loop function $G$ with the spectral function of this intermediate resonant state ($R$),

$$\hat{G}^{HSIJ}(\sqrt{s}, m, M, \Gamma_R) = \frac{1}{N} \int_{(M_R - 2\Gamma_R)^2}^{(M_R + 2\Gamma_R)^2} d\hat{M}^2 \left(-\frac{1}{\pi}\right) \text{Im} \left( \frac{1}{M^2 - M_R^2 + iM_R\Gamma_R} \right) G^{HSIJ}(\sqrt{s}, m, \hat{M}),$$  

being $N$ a normalization factor that reads,

$$N = \int_{(M_R - 2\Gamma_R)^2}^{(M_R + 2\Gamma_R)^2} d\hat{M}^2 \left(-\frac{1}{\pi}\right) \text{Im} \left( \frac{1}{M^2 - M_R^2 + iM_R\Gamma_R} \right).$$  

The meson-baryon propagator is logarithmically ultraviolet divergent, thus, it needs to be renormalized. This has been done by a subtraction point regularization such that

$$G_{ii}^{HSIJ}(\sqrt{s}) = 0 \quad \text{at} \quad \sqrt{s} = \mu^{HSI},$$  

with

$$\mu^{HSI} = \sqrt{\alpha} \sqrt{m_{th}^2 + M_{th}^2},$$  

where $m_{th}$ and $M_{th}$ are, respectively, the masses of the meson and baryon producing the lowest threshold (minimal value of $m_{th} + M_{th}$) for each $HSI$ sector, independent of the angular momentum $J$, and $\alpha = 1$. A recent discussion on the regularization method can be found in Ref. [69]. The overall results obtained by the above choice of subtraction point is similar to the observed spectrum of low-lying hadronic resonances. A more precise agreement can be achieved by suitably shifting the subtraction point. To do so one can choose a value of the parameter $\alpha$ different from unity [31, 44]. Note that, other than this, the model has no free parameters.

The dynamically-generated baryon states appear as poles of the scattering amplitudes on the complex energy $\sqrt{s}$ plane. The poles of the scattering amplitude on the first Riemann sheet that appear on the real axis below threshold

| $\Sigma\pi$ | $N\bar{K}$ | $\Lambda\eta$ | $\Xi K$ | $N\bar{K}^*$ | $\Lambda\omega$ | $\Sigma\rho$ | $\Lambda\phi$ | $\Sigma K^*$ | $\Xi^* K^*$ |

are interpreted as \textit{bound states}. The poles that are found on the second Riemann sheet below the real axis and above threshold are identified with \textit{resonances}.\footnote{For convenience we will often use the word resonance for all molecular states discussed in this work, whether they are bound states or proper resonances.} The mass and the width of the state can be found from the position of the pole on the complex energy plane. Close to the pole, the scattering amplitude behaves as
\begin{equation}
T_{ij}^{HSIJ}(s) \approx \frac{g_i g_j}{\sqrt{s} - \sqrt{s_R}}.
\end{equation}

The mass $M_R$ and width $\Gamma_R$ of the state result from $\sqrt{s_R} = M_R - i \Gamma_R/2$, while $g_j$ (complex in general) is the coupling of the state to the $j$-channel.

The calculated positions and widths of the lowest-lying \Lambda states in the strange, charm and beauty sectors together with their couplings, $g_i$, to the different meson-baryon channels are shown in Tables III, IV and V. In the case we want to refer to a specific flavor we will write $\Lambda_s$, $\Lambda_c$ or $\Lambda_b$. For each flavor $f = s, c, b$, the resonances $\Lambda_f$ are ordered by closeness to the $\tau \Sigma_f$ threshold, and they are displayed in this sequence in the Tables.

We use the convoluted meson-baryon propagator for the non-stable intermediate particles (namely, $\rho$, $K^*$ and $\bar{K}^*$ mesons and $\Sigma^*$ baryon) in the study of the strange sector for the $\Lambda(1405)$ and $\Lambda(1520)$ resonances, in a similar manner as done in Ref. \cite{02}. In Ref. \cite{33}, it was reported that the convolution did not affect the dynamically generated $\Lambda_c$ states in a substantial manner as the dominant convoluted meson-baryon channels were far from the position of the heavy $\Lambda_c$ states.

In view of their mass position and dominant couplings, we assign these states to the experimental strange [\Lambda(1405), $\Lambda(1520)$], charmed [$\Lambda_c(2595)$, $\Lambda_c(2625)$] and beauty [$\Lambda_b(5912)$, $\Lambda_b(5920)$] states, similarly to Refs. \cite{31, 33, 34, 62}. Note, however, that in Refs. \cite{31, 34} the subtraction point was slightly modified in order to fix the position of the dynamically-generated states to the experimental predictions of the $\Lambda_c(2595)$ and $\Lambda_b(5912)$, respectively.

Three \Lambda states are obtained in each of the flavor sectors, two of them with $J^P = 1/2^-$ and one with $J^P = 3/2^-$. The well-known two-pole pattern of the $\Lambda(1405)$ \cite{68, 70, 71} is reproduced for the $\Lambda_c(2595)$ and $\Lambda_b(5912)$. Indeed, for $J^P = 1/2^-$ we found a state that strongly couples to $NM$ and $NM^*$ channels, with $(M, M^*) = (\bar{K}, K^*)$, $(D, D^*)$ or $(\bar{B}, B^*)$ for strange, charm or beauty sectors, respectively. The $\bar{K}N$ dominance in the $\Lambda(1405)$ has been got some support from lattice QCD calculations \cite{72}. In addition, a second state $1/2^-$ coupling to $B\Sigma$, with $B = \Sigma$, $\Sigma_c$ or $\Sigma_b$ is also seen for strangeness, charm or beauty, respectively. (In what follows we simply refer to these two $\Lambda(\frac{1}{2}^-)$ states as “first” and “second” state, respectively). On the other hand, the $J^P = 3/2^-$ states $\Lambda_c(2625)$ and $\Lambda_b(5920)$ are the counterparts in the charm and beauty sectors of the $\Lambda(1520)$.

In Refs. \cite{31, 33, 34, 62}, the \textit{coupling constants} were interpreted as a measure of the importance of a channel in order to determine the molecular nature of the state. For instance, the $\Lambda(1405)$ state close to the scattering line would be a mixture of $\bar{K}N$ and $\bar{K}^*N$ states, while the second $\Lambda(1405)$ state, with a very large decay width, would be mainly a $\tau \Sigma$ state. In the next section, we argue that the coupling constants, though useful, are not sufficient to describe the nature of a resonance. Thus, further analyses of the nature and, hence, of the \textit{compositeness} of the \Lambda states are required.

\section{Compositeness of the \Lambda States}

In Ref. \cite{43} Weinberg analyzed the nature of the deuteron and found that this particle is best described as composed of a proton and a neutron, rather than a genuine dibaryon. More recently, the issue of compositeness was addressed in Ref. \cite{44,10} for $s$-waves and small binding energies. An extension to larger binding energies in coupled-channel dynamics was undertaken in Ref. \cite{47} for bound states and in Refs. \cite{48,51} for resonances. In this section we summarize the formalism and the conclusions derived in Ref. \cite{51} for the interpretation of the Weinberg’s sum rule and its generalization to resonances.

In the unitarized setting the sum rule follows from the identity \cite{52,55,57}:
\begin{equation}
-1 = \sum_{i,j} g_i g_j \left( \delta_{ij} \frac{\partial G_i(\sqrt{s})}{\partial \sqrt{s}} + G_i(\sqrt{s}) \frac{\partial V_{ij}(\sqrt{s})}{\partial \sqrt{s}} G_j(\sqrt{s}) \right) \bigg|_{\sqrt{s} = \sqrt{s_R}}.
\end{equation}

This relation is derived in Appendix \cite{13} It holds for bound states and resonances, as well as energy dependent or energy independent interactions.
The use of the definitions

\[ X_i = -\text{Re} \left( g_i^2 \frac{dG_i}{d\sqrt{s}} \bigg|_{\sqrt{s} = \Re} \right), \quad Z = -\text{Re} \sum_{i,j} g_i g_j \left( G_i \frac{\partial V_{ij}}{\partial \sqrt{s}} G_j \bigg|_{\sqrt{s} = \Re} \right) \]

provides the sum rule

\[ 1 = Z + \sum_i X_i. \]  

For bound states the extraction of the real part in Eq. (10) is redundant since the quantities involved are already real. The expression of \( X_i \) involves the derivative of the loop function. The analytical expression of this function on the first and second Riemann sheets is made explicit in Appendix A.

As follows from the analysis in [51], for bound states, the quantity \( X_i \) is related to the probability of finding the state in the channel \( i \). For resonances, \( X_i \) is still related to the squared wave function of the channel \( i \), in a phase prescription that automatically renders the wave function real for bound states, and so it can be used as a measure of the weight of that meson-baryon channel in the composition of the resonant state.

The quantity \( \sum_i X_i = 1 - Z \) represents the compositeness of the hadronic state in terms of all the considered channels, and \( Z \) is referred to as its elementariness. A non vanishing \( Z \) takes into account that ultimately the model is an effective one. The energy dependent interaction effectively accounts for other possible interaction mechanisms not explicitly included in the s-wave meson-baryon description. These could be other hadron-hadron interactions, or even genuine negative-parity baryonic components not of the molecular type (hence the appellative elementariness).

Thus, a small value of \( Z \) indicates that the state is well described by the contributions explicitly considered, namely, s-wave meson-baryon channels. Conversely, a larger value of \( Z \) indicates that, for that state, significant pieces of information are missing in the model, and this information is being included through an effective interaction, to the extent that the experimental hadronic properties are reproduced by the model.

The results we obtain for the compositeness weights, \( X_i \), and aggregated compositeness \( 1 - Z \) of the various \( \Lambda \) states are displayed in Tables [III] [IV] and [V] for the default value \( \alpha = 1 \) and also for another phenomenological choice of the subtraction point, so that the experimental masses are better reproduced. As mentioned in the introduction, the results reported in Refs. [55, 56] are in qualitative agreement with those presented in Table III for the \( \Lambda(1405) \) states. In what follows we draw some conclusions with regards to the nature of the \( \Lambda \) states and its variation with the quark mass can be extracted from the numbers.

First, the contribution of each meson-baryon channel to the dynamical generation of a state is determined not only by the value of the coupling constant but also depends on the closeness of meson-baryon channel to the state. For instance, the \( \bar{K}N \) and \( \bar{K}^*N \) channels have similar couplings to the first pole of \( \Lambda(1405) \) but their contribution to the compositeness is quite different due to their different thresholds, relative to the mass of the state.

Second, the neglected contributions can be measured by means of the elementariness. Indeed, we observe that those \( \Lambda \) poles close to the scattering line are well described as molecular states through the s-wave meson-baryon channels considered, while wider states need the consideration of other contributions, such as multi-hadron scattering. This is clearly manifest for the \( J^P = 3/2^- \) states \( \Lambda(1520) \) and \( \Lambda_c(2625) \). There is, however, not a strict correlation between the value of the width and the elementariness. The \( 1/2^- \) states have a larger compositeness than their \( 3/2^- \) counterparts.

Third, taking the natural identification between different \( \Lambda \) states for different flavors, one observes that as a rule, the heavier the flavor the larger the compositeness of the resonance. For instance, the \( \Lambda(1520) \), \( \Lambda_c(2625) \) and \( \Lambda_b(5920) \) states have \( 1 - Z = 0.27, 0.37, \) and \( 0.82 \), respectively (for \( \alpha = 1 \)).

In the tables we primarily display results for the default value \( \alpha = 1 \), even though this choice of subtraction point does not reproduce the empirical masses of the resonances in detail. We also display results with \( \alpha \) suitably fitted in each case so that empirical masses of the resonances are reproduced. For the sake of definiteness, an equal mass for the two \( 1/2^- \) \( \Lambda \) states of each flavor has been adopted. The purpose of doing this is not to achieve a precise description of the resonance, but rather to see to what extent the subtraction point and the resonance position are relevant for the compositeness discussion. We can see that no substantial modifications in the weights \( X_i \) take place in the charm and beauty cases, and the same holds for the first \( \Lambda(1405) \) state. The change is somewhat larger for the second \( \Lambda(1405) \) state and for the \( \Lambda(1520) \) resonance. For these two resonances, the change required in the subtraction points is also sizable.

In order to understand these features, one can observe that the three first \( \Lambda \) states, namely, \( \Lambda(1405) \), \( \Lambda_c(2595) \) and \( \Lambda_b(5912) \), have sizable weights \( (X_i) \) in the nucleon-pseudoscalar channel, \( \bar{K}N \), \( DN \) and \( \bar{B}N \), respectively, while the weights of the \( \Sigma \)-pseudoscalar lightest channels, \( \pi \Sigma, \pi \Sigma_c \) and \( \pi \Sigma_b \), are much smaller or even negligible in the bottom case. The couplings \( (g_i) \) to these two types of channels follow a similar trend, and this explains the small widths of these resonances. In fact, for the \( \Lambda(1405) \), the \( \bar{K}N \) channel is dominant as regards to compositeness (although the
coupling to $\bar{K}^*N$ is also large). For the $\Lambda_c(2595)$ and $\Lambda_b(5912)$, the weight of $DN$ and $\bar{B}N$ is important but competes with $D^*N$ and $B^*N$. For the charm (bottom) sector this was also found in [34] and in [25]. Likely, this is a consequence of the similar roles played by vector and pseudoscalar heavy mesons ($D$ and $D^*$ or $\bar{B}$ and $B^*$) due to heavy quark symmetry. The fact that these first $\Lambda(1405)$, $\Lambda_c(2595)$ and $\Lambda_b(5912)$ poles have compositeness $1 - Z$ close to unity indicates that the present model, with $s$-wave meson-baryon including pseudoscalar and vector mesons, gives a fair description of these resonances.

Likewise, the compositeness is large in the case of the second $\Lambda_b(5912)$ and the $\Lambda_b(5920)$, suggesting that the model is also fairly complete for these two resonances.

Small values of $1 - Z$, below 0.5, are found for the second $\Lambda(1405)$ and the second $\Lambda_c(2595)$ in the $1/2^-$ sector, as well as the $\Lambda(1520)$ and $\Lambda_c(2625)$ in the $3/2^-$ sector. A conspicuous difference between the first and second $\Lambda(1/2^-)$ resonances is that the latter states strongly couple to the lightest channel $\pi\Sigma$ or $\pi\Sigma_c$, and these channel largely saturate their compositeness $1 - Z$. The same applies to the $3/2^-$ $\Lambda$ states, this time with $\pi\Sigma^*$ or $\pi\Sigma^*_c$ channels. As a consequence, these four resonances have a sizable width. Related to this, the available phase-space of the meson-baryon pair allows mechanisms involving higher partial waves (beyond $s$-wave) to play a role in the composition of the resonance. These missing mechanisms would be accounted for by the larger values of $Z$ displayed by these four resonances.

Within the molecular approach, the first missing interaction mechanism is expected to come from $d$-wave interactions. These type of interactions have been considered in Ref. [25] for the $\Lambda(1520)$. The specific channels considered there are $\pi\Sigma^*$ and $K\Sigma^*$ in $s$-wave, and $KN$ and $\pi\Sigma$ in $d$-wave. Further, the interaction is modeled as to reproduce $\bar{K}N$ scattering data, and several fits consistent with the experimental mass of the $\Lambda(1520)$ are presented. That calculation suggests that $d$-wave components play an important role in the structure of the $\Lambda(1520)$. In Fig. 1 we display a comparison between our results and those in [25] for the weights of each channel. The vertical lines interpolate between the different values given in that work for different fits. While we have not included higher partial waves in our interaction, we find that the weights of the $s$-wave channels included in [25] are qualitatively similar in both calculations and the agreement improves as the position of the pole is moved to its experimental value by a change of subtraction point. It can also be seen that other $s$-wave channels are more relevant than $K\Sigma^*$, namely, $K^*N$, $\rho\Sigma$ and $\rho\Sigma^*$, although $\pi\Sigma^*$ is the dominant one in our model.

FIG. 1. Weights $X_i$ of the main channels contributing to the composition of the $\Lambda(1520)$. Our results (in blue) are represented by stars for $\alpha = 1$, and by squares when the subtraction point is modified to bring the mass of the resonance to its experimental value. The vertical lines in red indicate the weights obtained in [25] for the two $s$-wave and two $d$-wave channels considered there using various sets of fitting parameters.
IV. SUMMARY AND CONCLUSIONS

In this work we have studied the nature of the lowest-lying negative-parity Λ resonances with strange, charm or bottom flavors, with $J^P = \frac{1}{2}^-$ and $\frac{3}{2}^-$. To this end we have adopted a description based on pseudoscalar and vector mesons interacting in s-wave with $\frac{1}{2}^+$ and $\frac{3}{2}^+$ baryons. The model, spelled out in [55], is based on spin-flavor and heavy-quark extensions of the WT interaction, thereby embodying the correct symmetries in the appropriate limits, such as chiral symmetry and HQSS. (The symmetries are explicitly broken at the level of masses and decay constants of the basic hadrons.) The interaction is then used as an input of the Bethe-Salpeter equation in coupled-channels. The model has no free parameters, barring the choice of subtraction point in the renormalization of the loop function. This is fixed by a prescription, or occasionally used to modify the positions of the resonances to fulfill phenomenological constraints.

As already uncovered by previous studies, we find a double pole structure for the states with $J^P = \frac{1}{2}^-$ and a single pole for the states with $\frac{3}{2}^-$ for each of the three flavors. The novelty comes from the systematic study of the composition of these resonances, as a function of the heavy quark mass, addressing the question of to what extent the structure of the resonances is fully saturated by the available s-wave meson-baryon channels.

Regarding the overall compositeness of the nine Λ resonances studied, we find that for a given flavor sector, the closer to threshold (on the complex plane) the better the resonance is described as an s-wave meson-baryon molecule.

Also, the heavier the flavor the higher the compositeness $1 - Z$. More explicitly, we find that $1 - Z$ is large for the first $\Lambda(\frac{1}{2}^-)$ of each flavor and the compositeness decreases as we move to the second $\Lambda(\frac{1}{2}^-)$ states and then to the $\Lambda(\frac{3}{2}^-)$ ones. Also, the compositeness is large for all bottom $\Lambda$ states. This would indicate that the three first $\Lambda(\frac{1}{2}^-)$ and all the rest of the bottom resonances considered are largely saturated, regarding their composition, by $s$-wave meson-baryon channels. This would not be so for the strange and charmed second $\Lambda(\frac{1}{2}^-)$ and strange and charmed $\Lambda(\frac{3}{2}^-)$ resonances, which would require further components to achieve the saturation of the sum rule.

With respect to the detailed composition of the states, we find that the first $\Lambda(\frac{1}{2}^-)$ states of each flavor couple strongly to pseudoscalar-$N$ and vector-$N$ channels. This is a manifestation of spin-flavor symmetry between pseudoscalar and vector partners, and in particular HQSS in the charm and bottom cases. For the $\Lambda(1405)$ this implies that the pseudoscalar-$N$ channel, being lighter than the vector-$N$ one, almost saturates the compositeness of the state.

### TABLE IV. Same as Table III for the charm sector.

It is noteworthy that a large weight of $\bar{K}N$ in the $\Lambda(1405)$ has been recently reported from lattice QCD calculations [2]. The situation changes for charm and bottom flavors where the two channels ($DN$ and $D^*N$ or $BN$ and $B^*N$) are relatively closer due to HQSS. In this case, the weights of the channels follows more closely the trend of the couplings. (Although with smaller weights, a similar pattern appears for the strange partners of the mesons, $D_s\Lambda$, $D_s^*\Lambda$, etc., due to SU(3)–light flavor symmetry.) These two channels almost saturate the composition of the first $\Lambda_c(2595)$ and $\Lambda_b(5912)$ states.

For the second $\Lambda(\frac{1}{2}^-)$ states, the main observation is its sizable coupling to the lightest channels $\pi\Sigma$, $\pi\Sigma_c$ and $\pi\Sigma_b$. As a consequence these states are effectively more excited than the first $\Lambda(\frac{1}{2}^-)$ states and for the strange and charm flavor this explains their larger widths, as compared to the first states. The larger phase space also implies that higher partial waves could play a role, consistently with the fact that they are much less saturated by the s-wave

meson-baryon channels considered here.

Another observation is the similar structure of the second $\Lambda(\frac{1}{2}^{-})$ and $\Lambda(\frac{3}{2}^{-})$ states, which appear as HQSS or spin-flavor partners. This is particularly clear in the bottom case, where HQSS works better. The couplings of $\pi\Sigma_b$ in the second $\Lambda_b(5912)$ and $\pi\Sigma_b^{*}$ in $\Lambda_b(5920)$ are similar and, the same pattern is seen for $BN$ and $B^{*}N$. This translates to the corresponding composition weights, although distorted by the effect of different excitation energy of the channels. The spin-flavor symmetry between $\Sigma_c$ and $\Sigma_c^{*}$, and $\Sigma$ and $\Sigma^{*}$ still acts for charm and strange flavors.

Although beyond the scope of the present work, it would be interesting to consider also quark models and try to compare to hadronic results in order to see whether the composition of a given resonance can be termed as molecular, made of quarks or hybrid, and if possible to quantify the hybrid mixture.

**Appendix A: Derivative of the loop function**

In order to compute analytically the derivative of the (s-wave) loop function required in Eq. (10), we recall its definition in Eq. (A3): 

\[ G = i \, 2M \int \frac{d^{4}q}{(2\pi)^{4}} \frac{1}{q^2 - m^2 + i\epsilon} \frac{1}{(P - q)^2 - M^2 + i\epsilon}, \quad M, m > 0. \]  

(A1)

Choosing the C.M. frame, $P^\mu = (\sqrt{s}, 0)$, its partial derivative with respect to the energy can be written as 

\[ G'(\sqrt{s}) = \frac{\partial G}{\partial \sqrt{s}} = -i4M \int \frac{d^{4}q}{(2\pi)^{4}} \frac{1}{q^2 - m^2 + i\epsilon} \frac{P^0 - q^0}{((P - q)^2 - M^2 + i\epsilon)^2}. \]  

(A2)

Unlike the loop function, $G'(\sqrt{s})$ is ultraviolet convergent. The use of a standard Feynman’s parameterization (see e.g. Eq. (10.13) of [74]) gives 

\[ G' = -i8M \int \frac{d^{4}q}{(2\pi)^{4}} \int_{0}^{1} dx \frac{x(P^0 - q^0)}{((q - xP)^2 - x^2P^2 - m^2 + (P^2 - M^2 + m^2)x + i\epsilon)^3}, \]  

(A3)

and after a translation in the integration variable:

\[ G' = -i8M\sqrt{s} \int_{0}^{1} dx \int \frac{d^{4}q}{(2\pi)^{4}} \frac{x(1 - x)}{(q^2 + x(1 - x)s - (1 - x)m^2 - xM^2 + i\epsilon)^3}. \]  

(A4)

The integral over $q^\mu$ is now straightforward (using e.g. Eq. (A.44) of [75]) to obtain

\[ G' = \frac{M\sqrt{s}}{4\pi^2} \int_{0}^{1} dx \frac{1}{s - m^2 + M^2/(1 - x) + i\epsilon}. \]  

(A5)

It follows that $G'$ is purely real for $s < (M + m)^2$, while $\text{Im}G' < 0$ for $s > (M + m)^2$.

The integral Eq. (A5) is well defined for $\sqrt{s}$ on the complex plane, excluding $s = (M + m)^2$, and it yields

\[ G' = \frac{M}{4\pi^2 s\sqrt{s}} \left( s - (M^2 - m^2) \log \frac{M}{m} - s(M^2 + m^2) - (M^2 - m^2)^2 \log \sqrt{s - s_+ - \sqrt{s - s_-}} - \sqrt{s - s_+} \right) \]  

(A6)

with

\[ s_\pm = (M \pm m)^2, \quad \text{Arg} \sqrt{s - s_+} \in [0, \pi), \quad \text{Arg} \sqrt{s - s_-} \in \left[ -\frac{\pi}{2}, \frac{\pi}{2} \right], \quad \text{Im log} \in [0, \pi] \quad \text{(FRS)}. \]  

(A7)

The function $G'(\sqrt{s})$ inherits the branching points and Riemann sheet structure of the loop function $G$. The expression in Eqs. (A6) and (A7) corresponds to the so-called First Riemann Sheet (FRS) with respect to the $s_+$ branching point and the branch cut is along $s \geq s_+$. For the FRS, the point $s = s_-$ is a regular point. $s_+$ is a branching point of order one (by circling twice around $s_+$ the function returns to its original value) hence there is a Second Riemann Sheet (SRS) with respect to $s_+$ that continues the FRS at the two borders of the selected cut. The SRS is obtained by analytic continuation. The point $s = s_-$ is a branching point of order one in the SRS. However,
for the physical phase space of interest the new Riemann sheets introduced by the branching at $s_-$ are not relevant. The expression of $G' (\sqrt{s})$ on the SRS takes the same form as in Eq. (A7) but taking

$$\text{Arg} \, \sqrt{s - s_+} \in [0, \pi), \quad \text{Arg} \, \sqrt{s - s_-} \in [\pi, 2\pi), \quad \text{Im} \log \in [\pi, 2\pi]$$

(SRS).

The function $G' (\sqrt{s})$ is displayed in Fig. 2. In the plot $\sqrt{s}$ is on the FRS when $\text{Re}(s) < (M + m)^2$ or when $\text{Re}(s) > (M + m)^2$ and $\text{Im}(s) > 0$, and on the SRS when $\text{Re}(s) > (M + m)^2$ and $\text{Im}(s) < 0$. The bound states fall on the “negative” (with respect to $M + m$) real axis and the resonances fall below the “positive” real axis, for the relevant channel. This cut of the complex plane covers most cases. An exception is the $\Lambda(1520)$ with $\sqrt{s} = 0.780$, which falls slightly at the left of the branch cut, for $\pi \Sigma^*$.

For completeness we give here analytical form of the loop function, subtracted at $s = s_+$:

$$G = -\frac{M}{8\pi^2 s} \left( \frac{M - m}{M + m} \log \frac{M}{m} + \sqrt{s - s_+} \sqrt{s - s_-} \text{log} \frac{\sqrt{s - s_+} - \sqrt{s - s_-}}{\sqrt{s - s_+} + \sqrt{s - s_-}} \right).$$

The choices of branches for the FRS and the SRS are as in Eqs. (A7) and (A8), respectively.

**Appendix B: Compositeness sum rule**

In this appendix we prove the relation in Eq. (9).

We start from Eq. (2)

$$T(\sqrt{s}) = (V^{-1}(\sqrt{s}) - G(\sqrt{s}))^{-1}$$

(B1)

where $T$, $V$ and $G$ are matrices and $G$ is diagonal. Taking a derivative with respect to $\sqrt{s}$ (using the operator identity $\delta(A^{-1}) = -A^{-1} \delta AA^{-1}$)

$$T' = T \left( G' + V^{-1} V' V^{-1} \right) T.$$

(B2)

On the other hand, Eq. (A5) implies

$$T_{ij} = \frac{g_i g_j}{\Delta} + R_{ij}(\sqrt{s}), \quad \Delta = \sqrt{s - s_R},$$

(B3)

where the remainder $R_{ij}$ is regular at the pole. Taking a derivative with respect to $\Delta$, substituting $T$ in Eq. (B2) and multiplying by $\Delta^2$ gives, at $\Delta = 0$,

$$-g_i g_j = \sum_{k,l} g_k g_l \left( G_k' \delta_{kl} + \sum_{r,s} (V^{-1})_{kr} V'_{rs} (V^{-1})_{sl} \right)_{\Delta = 0} g_i g_j.$$  

(B4)

Since at least one of the couplings must be different from zero (to have a pole) it follows that

$$-1 = \sum_{k,l} g_k g_l \left( G_k' \delta_{kl} + \sum_{r,s} (V^{-1})_{kr} V'_{rs} (V^{-1})_{sl} \right)_{\Delta = 0}. $$

(B5)
To arrive to Eq. (9) it only remains to show that \((V^{-1})_{ll}\) can be replaced by \(\delta_{ll} G_l\) in Eq. (B5). This follows from \(V^{-1} = T^{-1} + G\) and \(\sum_l (T^{-1})_{jl} g_l |\Delta = 0 = 0\). The latter equality can be deduced from,

\[ \sum_l (T^{-1})_{jl} \left( \frac{g_l g_j}{\Delta} + R_{lj}(\sqrt{\Delta}) \right) = 1 \]  

without summing over the index \(j\), which trivially follows from Eq. (B3) and \(T^{-1} T = 1\). Thus, in the limit \(\Delta \to 0\), we find

\[ \lim_{\Delta \to 0} \sum_l (T^{-1})_{jl} g_l = \lim_{\Delta \to 0} \frac{\Delta}{\Delta} g_j = 0. \]  

(B7)

The statement is trivial if there is just one channel. More generally, the singular part of \(T\) in Eq. (B3) is a matrix of rank one, the corresponding one-dimensional subspace being spanned by the vector \(g_i\), in coupled-channels space. The combination \(\sum_l (T^{-1})_{jl} g_l\) selects that subspace, in which \(T^{-1}\) vanishes at the pole.

3 The argument assumes that, at the pole, \(T\) is a regular matrix on the complementary subspace. For instance, it would not work for \(T = \begin{pmatrix} \frac{\alpha^2}{\Delta} & 1 \\ 1 & 0 \end{pmatrix}\), however, such a singular complement requires \(V\) to be singular at the resonance pole. We assume that this is not the case since \(V^T\) would not exist at the pole.
