Knowledge, attitude, and practice regarding the screening of cervical cancer among women in New Delhi, India

Neha Dahiya*, Kavita Aggarwal†, Megha Chandra Singh‡, Suneela Garg§, Rajesh Kumar¶

ABSTRACT

Objective: Cervical cancer is one of the major concerns of public health importance in today’s world. It is a leading cause of mortality in women of reproductive age group worldwide, mainly in developing countries. Reduction in mortality and morbidity due to cervical cancer is possible through early detection and treatment. The major factors influencing the early detection of cervical cancer are knowledge regarding risk factors, screening, Pap smear, and symptoms among women. Materials and Methods: The present cross-sectional study was carried out to assess the knowledge, attitude, and practice of women about the risk factors, symptoms, and prevention of cervical cancer. Data were obtained from 220 women who visited international trade fair using a pretested self-administered questionnaire. Results: Only 75 study women (50.0%) had ever heard of cervical cancer. The knowledge regarding cervical cancer and its various domains was significantly higher in students and unmarried women. The foul-smelling vaginal discharge was the most common early symptom of cervical cancer according to most of the study women (26, 17.3%). Most of the study women (19, 12.7%) reported tobacco and smoking as the most common risk factor associated with cervical cancer. Only 39 women (26%) had ever heard of cervical cancer screening. Only 27 women (18.0%) ever had Pap smear done in the past and 87 women (58.0%) were willing to undergo cervical cancer screening is offered free of cost. Conclusion: The study demonstrates the lack of awareness in women regarding cervical cancer and its screening modalities. This necessitates spreading awareness regarding early symptoms and risk factors associated with cervical cancer for early detection and treatment initiation.

KEYWORDS: Attitude, Cervical cancer, Knowledge, Screening

INTRODUCTION

In the modern era, the world is heading toward the rising epidemic of noncommunicable diseases (NCDs). Out of these NCDs, cancer is the second leading cause of death globally. There were approximately 14.1 million new cancer cases and 8.2 million cancer deaths worldwide in 2012. Out of which, 8 million new cancer cases and 5.3 million cancer deaths occurred in economically developing countries [1]. The number of new cases is expected to rise by 70% over the next two decades [2]. At present, India is facing health transition. In addition to the unfinished agenda to control communicable diseases, nutritional deficiencies, there is an escalating epidemic of NCDs. In India, NCDs are estimated to account for 60% of total deaths including cancers accounting for 7% deaths [3].

Cervical cancer is the fourth most common cancer in women worldwide leading to the death of which 85% occur in low- and middle-income countries. In 2012, 528,000 new cervical cancer cases were diagnosed worldwide, of which 123,000 were diagnosed in India. Approximately 266,000 women died from this disease in 2012 worldwide, of which 67,000 died in India [4]. Most of the cervical cancer cases are found to be associated with carcinogenic human papillomavirus (HPV) infection. The other factors involved in the occurrence of cervical cancer include promiscuous sexual habits, reproductive factors such as genital hygiene, early menarche, the interval between menarche and first sexual intercourse, early age at marriage, high parity, other sexually-transmitted infection, and smoking. The peak age of infection with HPV infection is in women after initiation of sexual activity in their 20s. Early invasive cervical cancer typically occurs after 10 years of persistent HPV infection.
Women remain asymptomatic for many years after acquiring HPV infection, but the pathological changes during this long interval can be detected by various screening methods, i.e., Pap smear. Thus, it is possible to decrease morbidity and mortality associated with cervical cancer by diagnosing and treating it at precancerous stages.

Knowledge regarding various signs, symptoms, and risk factors associated with cervical cancer influences health-seeking behavior. Moreover, with their knowledge and positive attitude toward cervical cancer vaccine, the risk of getting HPV infection may be further reduced. This study was done with the objectives to study the knowledge of women about the symptoms, risk factors, prevention, and early diagnosis of cervical cancer and to assess the attitude and practice of women toward cervical cancer.

MATERIALS AND METHODS

This cross-sectional study was conducted at an international health fair in New Delhi. The general public attending the fair were provided health-promoting services in the form of free health check-up, feasible-free laboratory investigations, and health education in addition to various cultural programs for school children, college students, and the general public. The study was conducted in accordance with the Declaration of Helsinki and was approved by the Local Ethics Committee of the institute. Informed written consent was waived because the study was a retrospective data analysis.

Women aged 18 years or more who consented were included in the study through consecutive sampling. Women with diagnosis or having a history of cervical cancer in the past were excluded from the study. A predesigned pretested self-administered questionnaire was used to assess the knowledge of cervical cancer regarding symptoms, risk factors, screening methods, and vaccination; and attitude toward cervical cancer patients and screening tests. The questionnaire was developed in English and later on translated in Hindi (national language) understandable by the participants. It was pretested in 30 adult women in Delhi Gate urban health center in New Delhi.

The study participants reply to each questionnaire item related to knowledge about cervical cancer was allocated a score of 1 for every correct response. The cumulative scores were calculated for every study participant for cervical cancer knowledge. The knowledge score was ranging from 0 to 19. Women had ever heard of cervical cancer. The mean knowledge score of the study participants was 3.21 ± 3.75. The knowledge score was significantly higher in students and unmarried women [Table 1].

Knowledge about cervical cancer among study participants is shown in Table 2. Knowledge of cervical cancer was measured under the domains of symptoms, risk factors, and prevention.

| Table 1: Distribution of cervical cancer knowledge scores in subjects |
| --- |
| **Sociodemographic factor** | Number of subjects, n (%) | Average knowledge score (0-19) | P |
| --- | --- | --- | --- |
| Age (years) | 56 (37.3) | 4.30±4.771 | 0.111<sup>a</sup> |
| =30 | 94 (62.7) | 2.55±2.819 | |
| Religion | 130 (86.7) | 3.24±3.803 | 0.108<sup>b</sup> |
| Hindu | 7 (4.7) | 2.50±2.687 | 0.005<sup>b</sup> |
| Muslim | 5 (3.3) | 6.80±5.167 | 0.530<sup>a</sup> |
| Sikh | 8 (5.3) | 1.50±0.577 | 0.874<sup>a</sup> |
| Occupation | 102 (68.0) | 3.19±3.807 | 0.001<sup>b</sup> |
| Homemaker | 72 (48.0) | 2.10±1.594 | 0.008<sup>b</sup> |
| Student | 56 (37.3) | 3.13±3.537 | |
| Skilled professional | 22 (14.7) | 7.05±6.237 | |
| Marital status | 31 (20.7) | 5.94±5.645 | 0.001<sup>b</sup> |
| Unmarried | 119 (79.3) | 2.50±2.687 | |
| Married | 40 (26.7) | 2.47±2.935 | 0.874<sup>a</sup> |
| Age at marriage (years) | 79 (52.7) | 2.51±2.571 | |
| ≤20 | 4 (2.7) | 1.50±0.577 | 0.530<sup>a</sup> |
| >20 | 146 (97.3) | 3.25±3.793 | |

<sup>a</sup>Mann-Whitney test, <sup>b</sup>Kruskal–Wallis test
and cervical cancer screening. The most common symptom answered by the study participants was foul-smelling vaginal discharge (26, 17.3%), followed by bleeding in between periods and periods heavier and of longer duration (25, 16.7%), bleeding after intercourse (13, 8.7%), and postmenopausal bleeding (11, 7.3%). The most common risk factor was tobacco and smoking (19, 12.7%), followed by HPV infection (17, 11.3%), multiple sexual partners (16, 10.7%), prolonged use of birth control (15, 10.0%), history of sexually-transmitted diseases (14, 9.3%), poor menstrual hygiene (12, 8.0%), coitus at early age (10, 6.7%), and multiple (>5) pregnancy (7, 4.7%). Only 35 women (23.3%) ever heard of cervical cancer screening, and 39 women (26.0%) ever heard of Pap smear, but not all of them knew that Pap smear is a tool for cervical cancer screening. According to 13 (8.7%) women, Pap smear should be started at the age of <21 years, >21 years (17, 11.3%) and after 3 years of sexual exposure (9, 6.0%). When asked about frequency of Pap smear 21 (14.0%) said that Pap smear should be done in 1 year, 2 years (2, 1.3%), and 3 years (1, 0.7%). Out of a total of 150 participants, only 27 women (18.0%) ever had Pap smear done in the past. Only 18 women (12.0%) were aware of cervical cancer vaccination, but only 6 women (4.0%) knew the correct age for HPV vaccination.

The attitude of participants toward cervical cancer is shown in Table 3. According to 88 (58.7%) women, intermenstrual bleeding should not be considered as normal. 83 (55.3%) women said that a woman should not bear her first child by the age of 20 years. 91 (60.7%) women were in favor of women not bearing 5 or more children to increase family strength. 76 women (50.7%) realized the importance of gynecological examination at least every 3 years. Eighty (53.3%) women would not keep a distance from a neighborhood female suffering from cervical cancer. Eighty-seven women (58.0%) were willing to be screened for cervical cancer if offered a free cervical cancer screening.

### DISCUSSION

Awareness about cervical cancer screening can improve women’s approach leading to an increased rate of early diagnosis and treatment of cervical cancer. Treatment started at an early stage of cervical cancer is more cost-effective which can help in reducing the overall morbidity and mortality associated with cervical cancer. The deficit in awareness regarding screening leads to delayed reporting and high mortality. The present study was conducted in 150 adult women in New Delhi to assess the knowledge and attitude of cervical cancer screening among them. Out of 150 study participants, 75 (50%) women had heard of cervical cancer. This proportion was much higher as compared to the proportion found in previous studies [6-8]. This may be due to an increase in health promotion activities conducted by Government of India in the past few years, and the study population was residing in urban areas. In this regard, the National Program for Prevention and Control of Cancer, Diabetes, CVD, and Stroke has been launched in 2010 to decrease mortality associated with NCDs. Despite having knowledge about cervical cancer, the awareness regarding symptoms and risk factors was low in study participants.

| Knowledge about symptoms | n (%) |
|--------------------------|-------|
| Bleeding in between periods | 25 (16.7) |
| Foul smelling vaginal discharge | 26 (17.3) |
| Postmenopausal bleeding | 11 (7.3) |
| Periods heavier and of longer duration | 25 (16.7) |
| Bleeding after intercourse | 13 (8.7) |

| Knowledge about risk factors | n (%) |
|-----------------------------|-------|
| HPV infection | 17 (11.3) |
| Multiple sexual partners | 16 (10.7) |
| Coitus at early age | 10 (6.7) |
| Tobacco and smoking | 19 (12.7) |
| History of STD | 14 (9.3) |
| Poor menstrual hygiene | 12 (8.0) |
| Prolonged use of birth controlled (>5 years) | 15 (10.0) |
| Multiple pregnancy (>5) | 7 (4.7) |

| Knowledge about cervical cancer screening | n (%) |
|------------------------------------------|-------|
| Ever heard of Pap smear test | 39 (26.0) |
| Pap smear should be started at age <21 years | 13 (8.7) |
| >21 years | 17 (11.3) |
| After 3 years of sexual exposure | 9 (6.0) |

HPV: Human papilloma virus, STD: Sexually transmitted disease

| Pap smear frequency | n (%) |
|---------------------|-------|
| Every years | 21 (14.0) |
| Every 2 years | 2 (1.3) |
| Every 3 years | 1 (0.7) |
| Vaccine available for cervical cancer | 18 (12.0) |
| Age for HPV vaccination | n (%) |
| <5 years | 2 (1.3) |
| 5-10 years | 0 |
| 10-26 years | 6 (4.0) |
| Immediately after marriage | 7 (4.7) |

| Table 3: Attitude towards cervical cancer | n (%) |
|------------------------------------------|-------|
| Intermenstrual bleed should not be considered as normal | 88 (58.7) |
| A woman should not bear her first child by the age of 20 years | 83 (55.3) |
| Women should not bear 5 or more children to increase family strength | 91 (60.7) |
| Women should get an internal examination done by a gynecologist at least once in 3 years | 76 (50.7) |
| If any lady in the neighborhood is suffering from cervical cancer, you would not keep distance from her | 80 (53.3) |
| If you were offered a free cervical cancer screening you would be willing to be screened | 87 (58) |

In the present study, 35 women (23.3%) had heard of cervical cancer screening. Thirty-nine (26%) women knew about the Pap smear test. This is lower as compared to studies done in Kuwait [9], Singapore [10], Vietnamese-American women [11], the United Kingdom [12], and Kenya [13]. This difference may be due to different study population or differences in the level and method of health promotion to create awareness about Pap smear screening. In addition to similar studies done in India, the present study shows that despite being an effective tool
of cervical cancer control, Pap smear is underutilized [14-18]. Availability of Pap smear for early detection of cervical cancer is not sufficient for control of cervical cancer. The awareness and adequate utilization of screening services by target population determine the impact of health promotion in decreasing morbidity and mortality of cervical cancer. Promotion of Pap smear screening in the healthcare sector may provide an important opportunity for the intervention of cervical cancer.

In the cross-sectional study conducted by Varughese et al. in Ludhiana, India, of the 304 women interviewed 28.9% (88) had heard of cervical cancer and only 4.3% (13) of the women had heard about Pap smear [6]. This could be due to the increase in the use of Pap smear for cervical cancer screening in the recent past. Despite this increase of Pap smear usage, there is a need to spread awareness regarding Pap smear and cervical cancer screening among women. Dissemination of information through mass media campaigns and leaflets may help in increasing health-seeking behavior of the women for cervical cancer screening. In the present study, 87 women (58%) were willing to be screened if offered a free cervical cancer screening test, but only 27 (18%) women had ever had Pap smear done in the past. This difference can be minimized by providing Pap smear or other appropriate cervical cancer screening tests at the level of primary health care. The study findings suggest further need to create awareness regarding vaccination available and screening for cervical cancer among women.

**CONCLUSION**

The present study demonstrates that there is a lack of awareness among women regarding cervical cancer risk factors, symptoms, signs, screening methods in developing countries like India. There is need of appropriate interventions to create awareness among reproductive age group women for early diagnosis and treatment to reduce incidence and cost of late stage cervical cancer.
