1. Introduction

The main purpose of this paper is to describe the (equivariant) intersection cohomology of certain moduli spaces ("framed Uhlenbeck spaces") together with some structures on them (such as e.g. the Poincaré pairing) in terms of representation theory of some vertex operator algebras ("W-algebras"). In this introduction we first briefly introduce the relevant geometric and algebraic objects (cf. Subsections 1(i) and 1(iii)) and then state our main result (in a somewhat weak form) in Subsection 1(iv) (a more precise version is discussed in 1(ix)). In Subsection 1(v) we discuss the motivation for our results and relate them to some previous works. In §1(viii) we mention earlier works from which we obtain strategy and techniques of the proof.

2000 Mathematics Subject Classification. Primary 17B69; Secondary 14D21, 14J60.
1(i). **Uhlenbeck spaces.** Let $G$ be an almost simple simply-connected algebraic group over $\mathbb{C}$ with Lie algebra $\mathfrak{g}$. Let also $\mathfrak{h}$ be a Cartan sub-algebra of $\mathfrak{g}$.

Let $\text{Bun}^d G$ be the moduli space of algebraic $G$-bundles over the projective plane $\mathbb{P}^2$ (over $\mathbb{C}$) with the instanton number $d$ and with trivialization at the line at infinity $\ell_{\infty}$. It is a non-empty smooth quasi-affine algebraic variety of dimension $2dh^\vee$ for $d \in \mathbb{Z}_{\geq 0}$, where $h^\vee$ is the dual Coxeter number of $G$.

By results of Donaldson [23] (when $G$ is classical) and Bando [4] (when $G$ is arbitrary) $\text{Bun}^d G$ is homeomorphic to the moduli space of anti-self-dual connections (instantons) on $S^4$ modulo gauge transformations $\gamma$ with $\gamma(\infty) = 1$ where the structure group is the maximal compact subgroup of $G$. We will use an algebro-geometric framework, as we can use various tools.

It is well-known that $\text{Bun}^d G$ has a natural partial compactification $\mathcal{U}^d G$, called the Uhlenbeck space. Set-theoretically, $\mathcal{U}^d G$ can be described as follows:

$$\mathcal{U}^d G = \bigsqcup_{0 \leq d' \leq d} \text{Bun}^{d'} G \times S^{d-d'}(\mathbb{A}^2),$$

where $S^{d-d'}(\mathbb{A}^2)$ denotes the corresponding symmetric power of the affine plane $\mathbb{A}^2$.

The variety $\mathcal{U}^d G$ is affine and it is always singular unless $d = 0$. It has a natural action of the group $G \times GL(2)$, where $G$ acts by changing the trivialization at $\ell_{\infty}$ and $GL(2)$ just acts on $\mathbb{P}^2$ (preserving $\ell_{\infty}$). In what follows, it will be convenient for us to restrict ourselves to the action of $G = G \times \mathbb{C}^* \times \mathbb{C}^*$ where $\mathbb{C}^* \times \mathbb{C}^*$ is the diagonal subgroup of $GL(2)$.

1(ii). **Main geometric object.** The main object of our study on the geometric side is the $G$-equivariant intersection cohomology $\text{IH}^*_G(\mathcal{U}^d G)$. By the definition, it is endowed with the following structures:

1) It is a module over $H^*_G(\text{pt})$. The latter algebra can be canonically identified with the algebra of polynomial functions on $\mathfrak{h} \times \mathbb{C}^2$ which are invariant under $W$, where $W$ is the Weyl group of $G$. In what follows we shall denote this ring by $A_G$; let also $F_G$ denote its field of fractions. We shall typically denote an element of $\mathfrak{h} \times \mathbb{C}^2$ by $(a, \varepsilon_1, \varepsilon_2)$.

2) There exists a natural symmetric (Poincaré) pairing $\text{IH}^*_G(\mathcal{U}^d G) \otimes_{A_G} \text{IH}^*_G(\mathcal{U}^d G) \rightarrow F_G$ (this follows from the fact that $(\mathcal{U}^d G)^{\mathbb{Z} \times \mathbb{C}^2}$ consists of one point).

3) For every $d \geq 0$ we have a canonical unit cohomology class $|1^d \rangle \in \text{IH}^*_G(\mathcal{U}^d G)$. 

The main purpose of this paper is to describe the above structures in terms of representation theory. To formulate our results, we need to introduce the main algebraic player – the $W$-algebra.

1(iii). **Main algebraic object:** $W$-algebras. In this subsection we recall some basic facts and constructions from the theory of $W$-algebras (cf. [28] and references therein). First, we need to recall the notion of Kostant-Whittaker reduction for finite-dimensional Lie algebras.

Let $\mathfrak{g}$ be as before a simple Lie algebra over $\mathbb{C}$ with the universal enveloping algebra $U(\mathfrak{g})$. Let us choose a triangular decomposition $\mathfrak{g} = \mathfrak{n}_+ \oplus \mathfrak{h} \oplus \mathfrak{n}_-$ for $\mathfrak{g}$. Let $\chi: \mathfrak{n}_+ \to \mathbb{C}$ be a non-degenerate character of $\mathfrak{n}_+$, i.e. a Lie algebra homomorphism such that $\chi|_{\mathfrak{n}_+, i} \neq 0$ for every vertex $i$ of the Dynkin diagram of $\mathfrak{g}$ (here $\mathfrak{n}_+, i$ denotes the corresponding simple root subspace). Then we can define the finite $W$-algebra of $\mathfrak{g}$ (to be denoted by $W_{\text{fin}}(\mathfrak{g})$) as the quantum Hamiltonian reduction of $U(\mathfrak{g})$ with respect to $(\mathfrak{n}_+, \chi)$. In other words, we have

$$W_{\text{fin}}(\mathfrak{g}) = \text{Hom}_{U(\mathfrak{g})}(U(\mathfrak{g}) \otimes \mathbb{C}, U(\mathfrak{g}) \otimes \mathbb{C}).$$

A well-known theorem of Kostant asserts that

1(f) $W_{\text{fin}}(\mathfrak{g})$ is naturally isomorphic to the center $Z(\mathfrak{g})$ of $U(\mathfrak{g})$.

In particular, we have

2(f) The algebra $W_{\text{fin}}(\mathfrak{g})$ has a natural embedding into $S(\mathfrak{h})$, whose image coincides with the algebra $S(\mathfrak{h})^W$.

3(f) The algebra $W_{\text{fin}}(\mathfrak{g})$ is a polynomial algebra in some variables $F^{(1)}, \ldots, F^{(\ell)}$, where $\ell = \text{rank}(\mathfrak{g})$. Each $F^{(\kappa)}$ is homogeneous as an element of $S(\mathfrak{h})^W$ of some degree $d+1 \geq 2$.

4(f) The algebra $W_{\text{fin}}(\mathfrak{g})$ is isomorphic to the algebra $W_{\text{fin}}(\mathfrak{g}^\vee)$.

Feigin and Frenkel (cf. [28] and references therein) have generalized the above results to the case of affine Lie algebras. Namely, let $\mathfrak{g}(\!(t)\!)$ denote the Lie algebra of $\mathfrak{g}$-valued formal loops. It has a natural central extension

$$0 \to \mathbb{C} \to \hat{\mathfrak{g}} \to \mathfrak{g}(\!(t)\!) \to 0$$

(this extension depends on a choice of an invariant form on $\mathfrak{g}$ which we choose so that the the squared length of every short coroot is equal to 2). The group $\mathbb{C}^*$ acts naturally on $\hat{\mathfrak{g}}$ by “loop rotation” and the same is true for its Lie algebra $\mathbb{C}$. We let $\mathfrak{g}_{\text{aff}}$ be the semi-direct product of $\hat{\mathfrak{g}}$ and $\mathbb{C}$ (for the above action).

For every $k \in \mathbb{C}$ one can consider the algebra $U_k(\hat{\mathfrak{g}}) —$ this is the quotient of $U(\hat{\mathfrak{g}})$ by the ideal generated by $1 - k$ where 1 denotes the generator of the central $\mathbb{C} \subset \mathfrak{g}_{\text{aff}}$. Let us also extend $\chi$ to $\mathfrak{n}_+(\!(t)\!)$ by taking the composition of the residue map $\mathfrak{n}_+(\!(t)\!) \to \mathfrak{n}_+$ with $\chi: \mathfrak{n}_+ \to \mathbb{C}$. Abusing slightly the notation, we shall denote this map again by $\chi$. 
The $\mathcal{W}$-algebra $\mathcal{W}_k(\mathfrak{g})$ is roughly speaking the Hamiltonian reduction of $U'_k(\hat{\mathfrak{g}})$ with respect to $(\mathfrak{n}_+(t),\chi)$. However, the reader must be warned that rigorously this reduction must be performed in the language of vertex operator algebras; in particular, $\mathcal{W}_k(\mathfrak{g})$ is a vertex operator algebra (cf. again [28] for the relevant definitions).

Unlike in the finite case, the algebra $\mathcal{W}_k(\mathfrak{g})$ is usually non-commutative (unless $k = -h^\vee$). The main results of Feigin and Frenkel about $\mathcal{W}_k(\mathfrak{g})$ can be summarized as follows (notice the similarities between (1f)-(4f) and (1)- (4)):

**Theorem 1.1.**

1. The algebra $\mathcal{W}_{-h^\vee}(\mathfrak{g})$ can be naturally identified with the center of the (vertex operator algebra version of) $U_{-h^\vee}(\hat{\mathfrak{g}})$.

2. Let $\mathcal{Heis}(\mathfrak{h})$ denote the central extension of $\mathfrak{h}((t))$ corresponding to the bilinear form on $\mathfrak{h}$ chosen above. Abusing the notation we shall use the same symbol for the corresponding vertex operator algebra. Also for any $k \in \mathbb{C}$ we can consider the corresponding algebra $\mathcal{Heis}_k(\mathfrak{h})$ (“Heisenberg algebra of level $k$”).

3. Then for generic $k$ there exists a canonical embedding $\mathcal{W}_k(\mathfrak{g}) \hookrightarrow \mathcal{Heis}_{k+h^\vee}(\mathfrak{h})$.

4. Suppose $k$ is generic. There is a natural isomorphism $\mathcal{W}_k(\mathfrak{g}) \cong \mathcal{W}_k(\mathfrak{g}^\vee)$ where $(k + h^\vee)(k^\vee + h^\vee_{\mathfrak{g}^\vee}) = r^\vee$ where $r^\vee$ is the “lacing number of $\mathfrak{g}$” (i.e. the maximal number of edges between two vertices of the Dynkin diagram of $\mathfrak{g}$). We shall call this isomorphism “the Feigin-Frenkel duality”.

The representation theory of $\mathcal{W}_k(\mathfrak{g})$ has been extensively studied (cf. for example [2]). In particular, to any $\lambda \in \mathfrak{h}^*$ one can attach a Verma module $M(\lambda)$ over $\mathcal{W}_k(\mathfrak{g})$ and $M(\lambda_1)$ is isomorphic to $M(\lambda_2)$ if $\lambda_1 + \rho$ and $\lambda_2 + \rho$ are on the same orbit of the Weyl group. This module carries a natural (Kac-Shapovalov) bilinear form, with respect to which the operator $W_n^{(\kappa)}$ is conjugate to $W_{-n}^{(\kappa)}$ (up to sign). This module can be obtained as the Hamiltonian reduction of the corresponding Verma module for $\mathfrak{g}$.

---

1. Note that for all $k \neq 0$ these algebras are isomorphic.
1(iv). **The main result: localized form.** Let us set

\[ M^d_{FG}(a) = IH^{*}_{G}(U^d_{G}) \otimes F_G; \quad M_{FG}(a) = \bigoplus_{d=0}^{\infty} M^d_{FG}(a). \]

It is easy to see that \( M^d_{FG}(a) \) is also naturally isomorphic to \( IH^{*}_{G,c}(U^d_{G}) \otimes F_G \) where the subscript \( c \) stands for cohomology with compact support.

Let us also set

\[ k = -h^\vee - \frac{\varepsilon_2}{\varepsilon_1}. \]

Then (a somewhat weakened) form of our main result is the following:

**Theorem 1.2.** Assume that \( G \) is simply laced and let us identify \( \mathfrak{h} \) with \( b^* \) by means of the invariant form such that \( (\alpha, \alpha) = 2 \) for every root of \( g \). Then there exists an action of the algebra \( W_k(g) \) on \( M_{FG}(a) \) such that

1) The resulting module is isomorphic to the Verma module \( M(\lambda) \) over \( W_k(g) \) where

\[ \lambda = \frac{a}{\varepsilon_1} - \rho \]

(here we take \( F_T = \text{Frac}(H_T^{*}(\text{pt})) \) as our field of scalars).

2) Under the above identification the Poincaré pairing on \( M_{FG}(a) \) goes over to the Kac-Shapovalov form on \( M(\lambda) \).

3) Under the above identification the grading by \( d \) corresponds to the grading by eigenvalues of \( L_0 \).

4) Let \( d \geq 1, n > 0 \). We have

\[ W^{(\kappa)}_n|1^d\rangle = \begin{cases} \pm \varepsilon^{-1}_1 \varepsilon^{-h^\vee+1}_2 |1^{d-1}\rangle & \text{if } \kappa = \ell \text{ and } n = 1, \\ 0 & \text{otherwise.} \end{cases} \]  

**Remarks.**

1) We believe that the sign in (1.3) is actually always “+”, however, currently we don’t know how to eliminate the sign issue. Note, however, that (1.3) still defines the scalar product \( \langle 1^d|1^d\rangle \) unambiguously. Also (assuming that the above sign issue can be settled) it follows from (1.3) that if we formally set \( w = \sum_d |1^d\rangle \) then we have

\[ W^{(\kappa)}_n(w) = \begin{cases} \varepsilon^{-1}_1 \varepsilon^{-h^\vee+1}_2 w & \text{if } \kappa = \ell \text{ and } n = 1, \\ 0 & \text{otherwise.} \end{cases} \]

Sometimes we shall write \( w_{a,\varepsilon_1,\varepsilon_2} \) to emphasize the dependence on the corresponding parameters.

2) The assumption that \( G \) is simply laced is essential for Theorem 1.2 to hold as stated. However, we believe that a certain modified version...
of Theorem 1.2 holds in the non-simply laced case as well, although at the moment we don’t have a proof of this modified statement (cf. subsection 1(x) for a brief discussion of the non-simply laced case).

3) Since $U_d\mathcal{G}$ is acted on by the full $GL(2)$ and not just by $\mathbb{C}^* \times \mathbb{C}^*$, it follows that the vector space $M_{\mathcal{G}}(a)$ has a natural automorphism which induces the involution $\varepsilon_1 \leftrightarrow \varepsilon_2$ on $\mathcal{F}$ (and leaves $a$ untouched). Note that changing $\varepsilon_1$ to $\varepsilon_2$ amounts to changing $k = -h^\vee - \frac{a}{\varepsilon_1}$ to $k^\vee = -h^\vee - \frac{a}{\varepsilon_2}$ and we have $(k + h^\vee)(k^\vee + h^\vee) = 1$. Note also that we are assuming that $\mathfrak{g}$ is simply laced, so $\mathfrak{g}$ is isomorphic to $\mathfrak{g}^\vee$ and the above geometrically defined automorphism is in fact a corollary of the Feigin-Frenkel duality (cf. Theorem 1.1).

1(v). Relation to previous works. We discuss previous works related to the above result here and later in §1(viii). This subsection is devoted for those works related to statements themselves, and §1(viii) is for those which give us a strategy and techniques of the proof.

First we discuss the statements (1),(2),(3). There are many previous works in almost the same pattern: We consider moduli spaces of instantons or variants on complex surfaces, and their homology groups or similar theory. Then some algebras similar to affine Lie algebras act on direct sums of homology groups, where we sum over various Chern classes.

The first example of such a result was given by the third-named author [44, 46]. The 4-manifold is $\mathbb{C}^2/\Gamma$ for a nontrivial finite subgroup $\Gamma \subset SU(2)$, and the gauge group is $U(r)$. The direct sum of homology groups of symplectic resolutions of Uhlenbeck spaces, called *quiver varieties* in more general context, is an integrable representation of the affine Lie algebra $\mathfrak{g}^\Gamma_{r,\text{aff}}$ of level $r$. Here $\mathfrak{g}^\Gamma$ is a simple Lie algebra of type $ADE$ corresponding to $\Gamma$ via the McKay correspondence, and $\mathfrak{g}^\Gamma_{r,\text{aff}}$ is its affine Lie algebra.

This result nicely fitted with the S-duality conjecture on the modular invariance of the partition function of $4d \, N = 4$ supersymmetric gauge theory by Vafa-Witten [63], as characters of integrable representations are modular forms. It was understood that the correspondence [44, 46] should be understood in the framework of a duality in string theories [61]. There are lots of subsequent developments in physics literature since then.

In mathematics, the case $\Gamma = \{e\}$ was subsequently treated by [45] and Grojnowski [32] for $r = 1$, and by Baranovsky [5] for general $r$. The corresponding $\mathfrak{g}^\Gamma_{r,\text{aff}}$ is the Heisenberg algebra, i.e., the affine Lie algebra associated with the trivial Lie algebra $\mathfrak{gl}_1$, in this case.
For $\Gamma = \{ e \}$, the symplectic resolution $\tilde{U}_d^r \to U_G^d$ of the Uhlenbeck space $U_G^d$ is given by the moduli space of torsion-free sheaves on $\mathbb{P}^2$ together with a trivialization at $\ell_\infty$ of generic rank $r$ and of second Chern class $d$. We call it the Gieseker space in this paper. For general $\Gamma$, we have its variant. All have description in terms of representations of quivers by variants of the ADHM description, and hence are examples of quiver varieties.

This result was extended to an action of the quantum toroidal algebra $U_q(L_{\mathfrak{g}_\Gamma, \text{aff}})$ on the equivariant K-theory of the moduli spaces when $\Gamma \neq \{ e \}$ [48, 50]. A variant for equivariant homology groups was given by Varagnolo [65].

In all these works, the action was given by introducing correspondences in products of moduli spaces, which give generators of the algebra. In particular, the constructions depend on good presentations of algebras. The case $\Gamma = \{ e \}$ was studied much later, as we explain below, as the corresponding algebra, which would be $U_q(L(\mathfrak{gl}_1, \text{aff}))$, was considerably more difficult.

Let us also mention that the second-named author with Kuznetsov [26] constructed an action of the affine Lie algebra $\widehat{\mathfrak{gl}}_r$ on the homology group of moduli spaces of parabolic sheaves on a surface, called flag Gieseker spaces or affine Laumon spaces when the surface is $\mathbb{P}^2$, the parabolic structure is put on a line and the framing is added. (Strictly speaking, the action was constructed on the homology group of the fibers of morphisms from flag Gieseker spaces to flag Uhlenbeck spaces. The action for the whole variety is constructed much later by Negut [56] in the equivariant K-theory framework.)

Let us turn to works on the inner product $\langle 1^d | 1^d \rangle$, which motivate the statement (4). It is given by the equivariant integration of 1 over $U_G^d$, and their generating function

\begin{equation}
Z(Q, a, \varepsilon_1, \varepsilon_2) = \sum_{d=0}^{\infty} Q^d \langle 1^d | 1^d \rangle
\end{equation}

is called “the instanton part of the Nekrasov partition function for pure $N = 2$ supersymmetric gauge theory” [57]. This partition function has been studied intensively in both mathematical and physical literature. In particular, a result, which is very similar to Theorem 1.2(1)~(4) (but technically much simpler) was proved by the first-named author [14]. Namely, in the situation of [14] on the representation theory side one deals with the affine Lie algebra $\mathfrak{g}_{\text{aff}}$ instead of the corresponding $W$-algebra, and on the geometric side one needs to replace the Uhlenbeck spaces $U_G^d$ by flag Uhlenbeck spaces $Z_G^\alpha$. In fact, it is important to
note that when the original group $G$ is not simply laced, the main result of [14] relates the equivariant intersection cohomology of the flag Uhlenbeck spaces for the group $G$ with the representation theory of the affine Lie algebra $\mathfrak{g}_\text{aff}^\vee$, whose root system is dual to that of $\mathfrak{g}_\text{aff}$.

A somewhat simpler construction exists also for the finite-dimensional Lie algebra $\mathfrak{g}^\vee$ – in that case on the geometric side one has to work with the so called space of based quasi-maps into the flag variety of $\mathfrak{g}$, also known as Zastava spaces (cf. [15] for a survey on these spaces).

The Nekrasov partition functions are equal for $U^d_G$ and for flag Uhlenbeck spaces at $\varepsilon_2 = 0$, and it is enough for some purposes, say to determine Seiberg-Witten curves, but they are different in general. Therefore it was clear that we must replace $\mathfrak{g}_\text{aff}^\vee$ by something else, but we did not know what it is.

A breakthrough was given in a physics context by Alday-Gaiotto-Tachikawa [1] (AGT for short). They conjectured that the partition functions for $G = SL(2)$ with four fundamental matters and adjoint matters are conformal blocks of the Virasoro algebra. They provided enough mathematically rigorous evidences, say numerical checks for small instanton numbers, and also physical intuition that this correspondence is coming from an observation that $N = 2$ 4d gauge theories are obtained by compactifying the underlying 6d theory on a Riemann surface. They also guessed that the Virasoro algebra is replaced by the $\mathcal{W}$-algebra for a group $G$ of type $ADE$.

There is a large literature in physics after AGT, especially for type $A$. We do not give the list, though those works are implicitly related to ours. We mention only one which was most relevant for us, it is [36] by Keller et al, where the statement (4) was written down for the first time for general $G$. (There is an earlier work by Gaiotto for $G = SL(2)$ [30], and various others for classical groups.)

Around the same time when [1] appeared in a physics context, there was an independent advance on the understanding of the algebra $U_q(L(\mathfrak{gl}_1)_{\text{aff}})$ acting on the K-theory of resolutions of Uhlenbeck spaces of type $A$ by Feigin-Tsymbaliuk [25] and Schiffmann-Vasserot [60]. They noticed that that $U_q(L(\mathfrak{gl}_1)_{\text{aff}})$ is isomorphic to various algebras, which had been studied in different contexts: a Ding-Iohara algebra, a shuffle algebra with the wheel conditions, the Hall algebra for elliptic curves, and an algebra studied by Miki [41]. Combined with the AGT picture, we understand that $U_q(L(\mathfrak{gl}_1)_{\text{aff}})$ is the limit of the deformed $\mathcal{W}(\mathfrak{gl}_r)$, or $\mathcal{W}(\mathfrak{gl}_r)$ by the reason explained below, when $r \to \infty$.

In [16] a similar result is conjectured (and proved in type A) for finite $\mathcal{W}$-algebras associated with a nilpotent element $e \in \mathfrak{g}^\vee$, which is principal in some Levi subalgebra (in that case on the geometric side
one works with the so called parabolic Zastava spaces - cf. [15] for the relevant definitions).

Finally Maulik-Okounkov [40] and Schiffman-Vasserot [59] proved Theorem 1.2 in the case when $G = SL(r)$. More precisely, they work with the equivariant cohomology of $\tilde{U}_d^G$ rather than with equivariant intersection cohomology of $U_d^G$, which is slightly bigger. As a result on the representation theory side they get a Verma module over $\mathcal{W}(\mathfrak{gl}_r)$ (this algebra is isomorphic to the tensor product of $\mathcal{W}(\mathfrak{sl}_r)$ with a (rank 1) Heisenberg algebra). We should also mention that we use the construction of [40] for $r = 2$ in a crucial way for the proof of Theorem 1.2.

1(vi). **Hyperbolic restriction.** One of the main technical tools used in the proof of Theorem 1.2 is the notion of hyperbolic restriction. Let us recall the general definition of this notion.

Let $X$ be an algebraic variety endowed with an action of $C^*$. Then $X^{C^*}$ is a closed subvariety of $X$. Let $A_X$ denote the corresponding attracting set. Let $i: X^{C^*} \to A_X$ and $j: A_X \to X$ be the natural embeddings. Then we have the functor $\Phi = i^*j_!$ from the derived category of constructible sheaves on $X$ to the derived category of constructible sheaves on $X^{C^*}$. This functor has been extensively studied by Braden in [12]. In particular, the main result of [12] says that $\Phi$ preserves the semi-simplicities of complexes.

Assume that we have a symplectic resolution $\pi: Y \to X$ in the sense of [40] and assume in addition that the above $C^*$-action lifts to $Y$ preserving the symplectic structure. Let $\mathcal{F} = \pi_*\mathcal{C}_Y[\dim X]$ (where $\mathcal{C}_Y$ denotes the constant sheaf on $Y$). Then we have

**Theorem 1.5.**

1. $[64]$ $\Phi(\mathcal{F})$ is isomorphic to $\pi_*\mathcal{C}_{Y^{C^*}}[\dim X^{C^*}]$.

2. Maulik-Okounkov’s stable envelop [40] gives us a choice of an isomorphism in (1).

See [53] for the proof. Though both $\Phi(\mathcal{F})$ and $\pi_*\mathcal{C}_{Y^{C^*}}[\dim X^{C^*}]$ are isomorphic semi-simple perverse sheaves, the proof of [64] only gives us a canonical filtration on the former whose associated graded is canonically isomorphic to the latter. Then the stable envelop [40] gives us a choice of a splitting.

Now we specialize the above discussion to the following situation. Let $P \subset G$ be a parabolic subgroup of $G$ with Levi subgroup $L$. Let us choose a subgroup $C^* \subset Z(L)$ (here $Z(L)$ stands for the center of $L$) such that the fixed point set of its adjoint action on $P$ is $L$ and the attracting set is equal to all of $P$. Let now $X = U_d^G$. We denote by $U_d^L$ the fixed point set of the above $C^*$ on $U_d^G$ and by $U_d^P$ the
corresponding attracting set. It is easy to see that if $L$ is not a torus, then $U_L^d$ is just homeomorphic to $U_{[L,L]}^d$ (and if $L$ is a torus, then $U_L^d$ is just $S^d(C^2)$). Often we are going to drop the instanton number $d$ from the notation, when there is no fear of confusion. We let $i$ and $p$ denote the corresponding maps from $U_L$ to $U_P$ and from $U_P$ to $U_L$. Also we denote by $j$ the embedding of $U_P$ to $U_G$. We have the diagram

$$U_L \xrightarrow{p} U_P \xrightarrow{j} U_G,$$

Thus we can consider the corresponding hyperbolic restriction functor $\Phi_{L,G} = i^*j^!$ (note that the functor actually depends on $P$ and not just on $L$, but it is easy to see that it doesn’t depend on the choice of $\mathbb{C}^* \subset Z(L)$ made above).

The following is one of the main technical results used in the proof of Theorem 1.2:

**Theorem 1.7.**

(1) Let $P_1 \subset P_2$ be two parabolic subgroups and let $L_1 \subset L_2$ be the corresponding Levi subgroups. Then we have a natural isomorphism of functors $\Phi_{L_1,G} \simeq \Phi_{L_1,L_2} \circ \Phi_{L_2,G}$.

(2) For $P$ and $L$ as above the complex $\Phi_{L,G}(IC(U_G^d))$ is perverse and semi-simple. Moreover, the same is true for any semi-simple perverse sheaf on $U_G^d$ which is constructible with respect to the natural stratification.

Note that when $G = SL(r)$, it is easy to deduce Theorem 1.7 from Theorem 1.5(1), since in this case the scheme $U_G^d$ has a symplectic resolution $\tilde{U}_r^d$.

1(vii). **Sketch of the proof.** The proof of Theorem 1.2 will follow the following plan:

1) Replace $G = G \times \mathbb{C}^* \times \mathbb{C}^*$-equivariant cohomology with $T = T \times \mathbb{C}^* \times \mathbb{C}^*$-equivariant cohomology. Note that the former is just equal to the space of $W$-invariants in the latter, so if we define an action of $W_k(g)$ on $\bigoplus_d IH^*_T(U_G^d) \otimes F_T$ (where $A_T = H^*_{T \times \mathbb{C}^* \times \mathbb{C}^*}(pt)$ and $F_T$ is its field of fractions) and check that if commutes with the action of $W$, we get an action of $W_k(g)$ on $\bigoplus_d IH^*_T(U_G^d) \otimes F_T$.

2) We are going to construct an action of $\mathfrak{heis}_{k+h^*}(h)$ on $\bigoplus_d IH^*_T(U_G^d) \otimes F_T$ and then get the action of $W_k(g)$ by using the embedding $W_k(g) \hookrightarrow \mathfrak{heis}_{k+h^*}(h)$. It should be noted that the above $\mathfrak{heis}_{k+h^*}(h)$-action will have several “disadvantages” that will disappear when we restrict ourselves to $W_k(g)$. For example, this action will depend on a certain auxiliary choice (a choice of a Weyl chamber).
3) The action of the Heisenberg algebra on \( \oplus_d \mathcal{H}_T(U_G^d) \otimes F_T \) will be constructed in the following way. Let us choose a Borel subgroup \( B \) containing the chosen maximal torus \( T \). We can identify \( \oplus_d \mathcal{H}_T(U_G^d) \otimes A_T F_T \) with \( \oplus_d \mathcal{H}_T(\mathcal{IC}(U_G^d)) \otimes F_T \), so it is enough to define an action of the Heisenberg algebra on the latter. For this it is enough to define the action of \( \text{Heis}(C\alpha^\vee_i) \) for every simple coroot \( \alpha^\vee_i \) of \( G \) (and then check the corresponding relations). Let \( P_i \) denote the corresponding sub-minimal parabolic subgroup containing \( B \). Let also \( L_i \) be its Levi subgroup (it is canonical after the choice of \( T \)). Note that \( [L_i, L_i] \simeq SL(2) \). Using the isomorphism \( \Phi_{T,G}(\mathcal{IC}(U_G^d)) \simeq \Phi_{T,L_i} \circ \Phi_{L_i,G}(\mathcal{IC}(U_G^d)) \) and Theorem 1.5, we define the action of \( \text{Heis}(C\alpha^\vee_i) \) on \( \oplus_d \mathcal{H}_T(\mathcal{IC}(U_G^d)) \otimes F_T \) using the results of [40] for \( G = SL(2) \).

Here it is important for us to write down \( \Phi_{L_i,G}(\mathcal{IC}(U_G^d)) \) in terms of \( \mathcal{IC}(U_{L_i}^{d'}) \) (\( d' \leq d \)) and local systems on symmetric products in a ‘canonical’ way. In particular, we need to construct a base in the multiplicity space of \( \mathcal{IC}(U_{L_i}^{d'}) \) in \( \Phi_{L_i,G}(\mathcal{IC}(U_G^d)) \). For \( G = SL(r) \), this follows from the stable envelop, thanks to Theorem 1.5(2). For general \( G \), this argument does not work, and we use the factorization property of Uhlenbeck spaces together with the special case \( G = SL(2) \). A further detail is too complicated to be explained in Introduction, so we ask an interested reader to proceed to the main text.

4) We now need to check the relations between various \( \mathfrak{Heis}(C\alpha^\vee_i) \). For this we have two proofs. One reduces it again to the results of [40] for \( G = SL(3) \) (note that since we assume that \( G \) is simply laced, any connected rank 2 subdiagram of the Dynkin diagram of \( G \) is of type \( A_2 \)). The other goes through the theory of certain “geometric” \( R \)-matrices (cf. Section 7). The proof of assertions (2) and (3) of Theorem 1.2 is more or less straightforward. The proof of assertion (4) is more technical and we are not going to discuss it in the Introduction. Let us just mention that for that proof we need a stronger form of the first 3 statements of Theorem 1.2 which is briefly discussed below.

1(viii). Relation to previous works – technical parts. Let us mention previous works which give us a strategy and techniques of the proof.

First of all, we should mention that the overall framework of the proof is the same as those in [40, 59]. We realize the Feigin-Frenkel embedding of \( W_k(g) \) into \( \mathfrak{Heis}_{k+h^\vee}(h) \) in a geometric way via the fixed point \( (U_G^d)^c = U_{L_i}^{d'} \), as is explained the geometric realization in 3),4) in §1(vii). This was first used in [40, 59] for type \( A \).
What we do here is to replace the equivariant homology of Gieseker spaces \( \tilde{U}_r^d \) by intersection cohomology of \( U_r^d \) as the former exists only in type A. Various foundational issues were discussed in the joint work of the first and second-named authors with Gaitsgory [20]. In particular, the fact that the character of \( M_{F,G}(a) \) is equal to the character of a Verma module over \( \mathcal{W}_k(\mathfrak{g}) \) follows from the main result of [20]. (For type A, it was done earlier in the joint work of the third-named author with Yoshioka. See [47, Exercise 5.15] and its solution in [54].)

A search of a replacement of Maulik-Okounkov’s stable envelop [40] was initiated by the third-named author [53]. In particular, the relevance of the hyperbolic restriction functor \( \Phi \) and the statement Theorem 1.5(2) were found. Therefore our technical aim is to find a ‘canonical’ isomorphism between \( \Phi_{L,G}(\text{IC}(U_r^d)) \) and a certain perverse sheaf on \( U_r^d \).

Let us also mention that Theorem 1.5(1) was proved much earlier by Varagnolo-Vasserot [64] in their study of quiver varieties. The functor \( \Phi \) realized tensor products of representations of \( \mathfrak{g}_{\text{aff}} \). (Strictly speaking, only quiver varieties of finite types were considered in [64]. A slight complication occurs for quiver varieties of affine types which give \( \mathfrak{g}_{\text{aff}} \). See [53, Remark 1] for detail.)

When we do not have a symplectic resolution like \( \tilde{U}_r^d \), we need another tool to analyze \( \Phi \). Fortunately the hyperbolic restriction functor was studied by Mirković-Vilonen [43, 42] in the context of the geometric Satake isomorphism, which asserts the category of \( G(\mathbb{C}[[t]]) \)-equivariant perverse sheaves on the affine Grassmannian \( \text{Gr}_G = G(\mathbb{C}((t)))/G(\mathbb{C}[[t]]) \) is equivalent to the category of finite dimensional representations of the Langlands dual \( G^\vee \) of \( G \) as tensor categories. The hyperbolic restriction functor realizes the restriction from \( G^\vee \) to its Levi subgroup.

In particular, it was proved that \( \Phi \) sends perverse sheaves to perverse sheaves. This was proved by estimating dimension of certain subvarieties of \( \text{Gr}_G \), now called Mirković-Vilonen cycles. The proof of Theorem 1.7 is given in the same manner, replacing Mirković-Vilonen cycles by attracting sets of the \( \mathbb{C}^* \)-action.

It is clear that we should mimic the geometric Satake isomorphism from the conjecture of the first and second-named authors [17] which roughly says the following: it is difficult to make sense of perverse sheaves on the double affine Grassmannian, i.e., the affine Grassmannian \( \text{Gr}_{G_{\text{aff}}} \) for the affine Kac-Moody group \( G_{\text{aff}} \). But perverse sheaves on \( U_r^d \) (and more generally instanton moduli spaces on \( \mathbb{C}^2/\Gamma \) with \( \Gamma = \mathbb{Z}/k\mathbb{Z} \)) serve as their substitute. Then they control the representation theory of \( G_{\text{aff}}^\vee \) at level \( k \).
This conjecture nicely fits with the third-named author’s works [44, 46] on quiver varieties via I. Frenkel’s level-rank duality for the affine Lie algebra of type A [29]. Namely in the correspondence between moduli spaces and representation theory, the gauge group determines the rank, and \( \Gamma \) the level respectively in the double affine Grassmannian. And the role is reversed in quiver varieties.

In [19], the first and second-named authors proposed a functor, acting on perverse sheaves, which conjecturally gives tensor products of \( G_{\text{aff}}^{\vee} \). This proposal was checked in [51] for type A, by observing that the same functor gives the branching from \( \mathfrak{g}_{\Gamma, \text{aff}} \) to the affine Lie algebra of a Levi subalgebra. The interchange of tensor products and branching is again compatible with the level-rank duality.

Here in this paper, tensor products and branching appear in the opposite side: The hyperbolic restriction functor \( \Phi \) realizes the tensor product in the quiver variety side, as we mentioned above. Therefore it should correspond to branching in the dual affine Grassmannian side. This is a philosophical explanation why the study of analog of Mirković-Vilonen cycles is relevant here.

1(ix). The main result: integral form. The formulation of Theorem 1.2 has an obvious drawback: it is only formulated in terms of localized equivariant cohomology. First of all, it is clear that as stated Theorem 1.2 only has a chance to work over the the localized field \( F = \mathbb{C}(\varepsilon_1, \varepsilon_2) \) rather than over \( A = \mathbb{C}[\varepsilon_1, \varepsilon_2] \). The reason is that our formula for the level \( k = -h^\vee - \frac{\varepsilon_2}{\varepsilon_1} \) and the highest weight \( \lambda = \frac{a}{\varepsilon_1} - \rho \) are not elements of \( A \). For many purposes, it is convenient to have an \( A \)-version of Theorem 1.2. In fact, technically in order to prove the last assertion of Theorem 1.2 we need such a refinement of the first 3 assertions (the reason is that we need to use the cohomological grading which is lost after localization). In earlier works [40, 59] for type A, the \( A \)-version appears only implicitly, as operators \( W_n^{(\kappa)} \) are given by cup products on Gieseker spaces. But in our case, Uhlenbeck spaces are singular, and we need to work with intersection cohomology groups. Hence \( W_n^{(\kappa)} \) do not have such descriptions.

So, in order to formulate a non-localized version of Theorem 1.2 one needs to define an \( A \)-version \( W_A(g) \) of the \( W \)-algebra (such that after tensoring with \( F \) we get the algebra \( W_k(g) \) with \( k = -h^\vee - \frac{\varepsilon_2}{\varepsilon_1} \)). We also want this algebra to be graded (such that the degrees of \( \varepsilon_1 \) and \( \varepsilon_2 \) are equal to 2); in addition we need analogs of statements (2) and (3) of Theorem 1.1. This is performed in the Appendix B. Let us note, that although this \( A \)-form is motivated by geometry, it can be defined purely in an algebraic way, following the work of Feigin and Frenkel. As far
as we know, this \( A \)-form does not appear in the literature before. As a purely algebraic application, we can remove the genericity assumption in Theorem 1.1(4). The third named author learns from Arakawa that this was known to him before, but the proof is not written. After this we prove an \( A \)-version of Theorem 1.2 in Section 8.

The non-localized equivariant cohomology groups also give us a refined structure in our construction. We construct \( \mathcal{W}_A(g) \)-module structures on four modules

\[
\bigoplus_d IH^*_{G,c}(U^d_G), \quad \bigoplus_d H^*_{T,c}(\Phi_{T,G}(\text{IC}(U^d_G)))
\]

\[
\bigoplus_d H^*_T(\Phi_{T,G}(\text{IC}(U^d_G))), \quad \bigoplus_d IH^*_G(U^d_G),
\]

where the subscript \( c \) stands for cohomology with compact support. They become isomorphic if we take tensor products with \( F_T \), i.e., in the localized equivariant cohomology. But they are different over \( A_G \) and \( A_T \). We show that they are universal Verma, Wakimoto modules \( M_A(a) \), \( N_A(a) \), and their duals respectively. Here by a Wakimoto module, we mean the pull-back of a Fock space via the embedding of \( \mathcal{W}(g) \) in \( \text{Heis}(h) \). They are universal in the sense that we can specialize to Verma/Wakimoto and their duals at any evaluation \( A_G \rightarrow \mathbb{C}, A_T \rightarrow \mathbb{C} \). This will be important for us to derive character formulas for simple modules, which will be discussed in a separate publication.

The importance of the integral form and the application to character formulas were first noticed in the context of the equivariant K-theory of the Steinberg variety and the affine Hecke algebra (see [22]), and then in quiver varieties [48] and parabolic Laumon spaces (= handsaw quiver varieties) [52].

1(x). Remarks about non-simply laced case. We have already mentioned above that verbatim Theorem 1.2 doesn’t hold for non-simply laced \( G \). However, we expect that the following modification of Theorem 1.2 should hold.

First, let \( G \) be any affine Lie algebra in the sense of [35] with connected Dynkin diagram. For example, \( G \) can be untwisted, and in this case it is isomorphic to a Lie algebra of the form \( g_{\text{aff}} \) for some simple finite-dimensional Lie algebra. But in addition there exist twisted affine Lie algebras. We refer the reader to [35] for the relevant definitions; let us just mention that every twisted \( G \) comes from a pair \((G', \sigma)\) where \( G' = g_{\text{aff}} \) for some simply laced simple finite-dimensional Lie algebra \( g \) and \( \sigma \) is a certain automorphism of \( g \) of finite order.
The Dynkin diagram of \( \mathcal{G} \) comes equipped with a special “affine” vertex. We let \( G_\mathcal{G} \) denote the semi-simple and simply connected group whose Dynkin diagram is obtained from that of \( \mathcal{G} \) by removing that vertex.

To such an algebra one can attach another affine Lie algebra \( \mathcal{G}^\vee \) — “the Langlands dual Lie algebra”. By definition, this is just the Lie algebra whose generalized Cartan matrix is transposed to that of \( \mathcal{G} \).

It turns out that one can define the Uhlenbeck spaces \( U^d_\mathcal{G} \) for any affine Lie algebra \( \mathcal{G} \) in such a way that \( U^d_\mathcal{G} = U^d_\mathcal{G} \) when \( \mathcal{G} = \mathfrak{g}_{aff} \) and \( \mathfrak{g} = \text{Lie}(G) \) (the definition uses the corresponding simply laced algebra \( \mathfrak{g} \) and its automorphism \( \sigma \) mentioned above). We are not going to explain the definition here (we shall postpone it for a later publication). This scheme is endowed with an action of the group \( G_\mathcal{G} \times \mathbb{C}^* \times \mathbb{C}^* \).

In addition to \( \mathcal{G} \) as above one can also attach a \( W \)-algebra \( \mathcal{W}(\mathcal{G}) \). Then we expect the following to be true:

**Conjecture 1.8.** There exists an action of \( \mathcal{W}(\mathcal{G}) \) on \( \bigoplus \text{IH}^*_\mathcal{G}(\mathcal{G}^\vee) \times \mathbb{C}^* \times \mathbb{C}^* \times (U^d_\mathcal{G}^\vee) \) satisfying properties similar to those of Theorem 1.2.

Let us discuss one curious corollary of the above conjecture. Let \( \mathfrak{g} \) be a finite-dimensional simple Lie algebra. Set \( \mathcal{G}_1 = \mathfrak{g}_{aff}^\vee, \mathcal{G}_2 = (\mathfrak{g}^\vee)_{aff} \). Then Conjecture 1.8 together with Feigin-Frenkel duality imply that there should be an isomorphism between \( \text{IH}^*_{\mathcal{G}_1} \times \mathbb{C}^* \times \mathbb{C}^* \times (U^d_\mathcal{G}_1) \) and \( \text{IH}^*_{\mathcal{G}_2 \times \mathbb{C}^* \times \mathbb{C}^*} \times (U^d_\mathcal{G}_2) \) which sends \( \xi_1 \) and to \( r_{\mathcal{G}_1} \xi_1 \). It would be interesting to see whether this isomorphism can be constructed geometrically (let us note that the naive guess that there exists an isomorphism between \( U^d_\mathcal{G}_1 \) and \( U^d_\mathcal{G}_2 \) giving rise to the above isomorphism between \( \text{IH}^*_{\mathcal{G}_1} \times \mathbb{C}^* \times \mathbb{C}^* \times (U^d_\mathcal{G}_1) \) and \( \text{IH}^*_{\mathcal{G}_2 \times \mathbb{C}^* \times \mathbb{C}^*} \times (U^d_\mathcal{G}_2) \) is probably wrong). This question might be related to the work [62] where the author explains how to derive the 4-dimensional Montonen-Olive duality for non-simply laced groups from 6-dimensional (2,0) theory.

1(xi). **Further questions and open problems.** In this subsection we indicate some possible directions for future research on the subject (apart from generalizing everything to the non-simply laced case, which was discussed before).
1(xi).1. **VOA structure and CFT.** Our results imply that the space $M_{F,G}(a)$ has a natural vertex operator algebra structure. It would be extremely interesting to construct this structure geometrically.

The AGT conjecture predicts a duality between $N = 2$ 4d gauge theories and 2d conformal field theories (CFT). The equivariant intersection cohomology group $M_{F,G}(a)$ is just the quantum Hilbert space associated with $S^1$, appeared as a boundary of a Riemann surface. We should further explore the 4d gauge theory from CFT perspective, as almost nothing is known so far.

1(xi).2. **Gauge theories with matter.** Our results give a representation-theoretic interpretation of the Nekrasov partition function of the pure $N = 2$ super-symmetric gauge theory on $\mathbb{R}^4$. For physical reasons it is also interesting to study gauge theories with matter. Mathematically it usually means that in the definition of the partition function (1.4) one should replace the equivariant integral of 1 by the equivariant integral of some other (intersection) cohomology class. However, when $G$ is not of type $A$ even the definition of the partition function is not clear to us. Namely, for $G = SL(r)$ one usually works with the Gieseker space $\tilde{U}_G^d$ instead of $U_G^d$. In this case the cohomology classes in question are usually defined as Chern classes of certain natural sheaves $\tilde{U}_G^d$ (such as, for example, the tangent sheaf). Since $U_G^d$ is singular and we work with intersection cohomology such constructions don’t literally make sense for $U_G^d$.

1(xi).3. **The case of $\mathbb{C}^2/\Gamma$.** It would be interesting to try and generalize our results to Uhlenbeck space of $\mathbb{C}^2/\Gamma$. Here we expect the case when $\Gamma$ is a cyclic group to be more accessible than the general case; in fact, in this case one should be able to see connections with $[17],[19]$ and on the other hand with $[9,8]$. On the other hand, the theory of quiver varieties deals with general $\Gamma$, but the group $G$ is of type $A$, as we mentioned in §1(v). The case when both $\Gamma$ and $G$ are not of type $A$ seems more difficult. Note that we must impose $\varepsilon_1 = \varepsilon_2$, therefore the level $k = -h^\vee - \varepsilon_2/\varepsilon_1$ cannot be deformed. In particular, the would-be $\mathcal{W}$-algebra does not have a classical limit.

1(xi).4. **Surface operators.** As we have already mentioned in §1(v), there are flag Uhlenbeck spaces parametrizing (generalized) $G$-bundles on $\mathbb{P}^2$ with parabolic structure on the line $\mathbb{P}^1$. A type of parabolic structure corresponds to a parabolic subgroup $P$ of $G$. Generalizing results in two extreme cases, $P = B$ in $[14]$ and $P = G$ in this paper, it is expected that the equivariant intersection cohomology group admits
a representation of the $W$-algebra associated with the principal nilpotent element in the Lie algebra $l$ of the Levi part of $P$. (We assume $G$ is of type $ADE$, and the issue of Langlands duality does not occur, for brevity.) This is an affine version of the conjecture in [16] mentioned before. Moduli of $G$-bundles with parabolic structure of type $P$ is called a surface operator of Levi type $l$ in the context of $N = 4$ supersymmetric gauge theory [33]. However there is a surface operator corresponding to arbitrary nilpotent element $e$ in Lie $G$ proposed in [21], which is supposed to have the symmetry of $W(g, e)$, the $W$-algebra associated with $e$. We do not understand what kind of parabolic structures nor equivariant intersection cohomology groups we should consider if $e$ is not regular in Levi.

1(xii). **Organization of the paper.** In Section 2 we discuss some generalities about Uhlenbeck spaces. Section 3 is devoted to the general discussion of hyperbolic restriction and Section 4 — to hyperbolic restriction on Uhlenbeck spaces. In Section 5 we relate the constructions and results of Section 4 to certain constructions of [40] in the case when $G$ is of type $A$. Section 6 is devoted to the construction of the action of the algebra $W_k(g)$ on $M_{G_c}(a)$ along the lines presented above. Section 7 is devoted to the discussion of “geometric $R$-matrices”.

1(xiii). **Some notational conventions.**

(i) A partition $\lambda$ is a nonincreasing sequence $\lambda_1 \geq \lambda_2 \geq \cdots$ of nonnegative integers with $\lambda_N = 0$ for sufficiently large $N$. We set $|\lambda| = \sum \lambda_i$, $l(\lambda) = \#\{i \mid \lambda_i \neq 0\}$. We also write $\lambda = (1^{n_1}2^{n_2} \cdots)$ with $n_k = \#\{i \mid \lambda_i = k\}$.

(ii) The equivariant cohomology group $H^*_G(pt)$ of a point is canonically identified with the ring of invariant polynomials on the Lie algebra $\text{Lie} G$ of $G$. The coordinate functions for the two factors $\mathbb{C}^*$ are denoted by $\varepsilon_1, \varepsilon_2$ respectively. We identify the ring of invariant polynomials on $g = \text{Lie} G$ with the ring of the Weyl group invariant polynomials on the Cartan subalgebra $h$ of $g$. When we consider the simple root $\alpha_i$ as a polynomial on $h$, we denote it by $a^i$.

(iii) For a variety $X$, let $D^b(X)$ denote the bounded derived category of complexes of constructible $\mathbb{C}$-sheaves on $X$. When $X$ is smooth and irreducible, $\mathcal{C}_X$ denotes the constant sheaf on $X$ shifted by $\dim X$. If $X$ is a disjoint union of irreducible smooth varieties $X_\alpha$, we understand $\mathcal{C}_X$ as the direct sum of $\mathcal{C}_{X_\alpha}$.

(iv) We make a preferred degree shift for the Borel-Moore homology group (with complex coefficients), and denote it by $H_{[s]}(X)$. 
The shift is coming from a related perverse sheaf, which is clear from the context. For example, if \( X \) is smooth, \( C_X \) is a perverse sheaf. Hence \( H_{[s]}(X) = H_{+\dim X}(X) \) is a natural degree shift, as it is isomorphic to \( H^{-*}(X, C_X) \). More generally, if \( L \) is a closed subvariety in a smooth variety \( X \), we consider \( H_{[s]}(L) = H_{+\dim X}(L) = H^{-*}(L, j^! C_X) \), where \( j: L \to X \) is the inclusion.

(v) We use the ADHM description of framed torsion free sheaves on \( \mathbb{P}^2 \) at several places. We change the notation \((B_1, B_2, i, j)\) in [47, Ch. 2] to \((B_1, B_2, I, J)\) as \( i, j \) are used for different things.

1(xiv). **Acknowledgments.** We dedicate this paper to the memory of Kentaro Nagao, who passed away on Oct. 22, 2013. His enthusiasm to mathematics did not stop until the end, even under a very difficult health condition. H.N. enjoyed discussions on results in this paper, and other mathematics with him last summer.

It is clear that this paper owes a lot to earlier works by D. Maulik, A. Okounkov, O. Schiffmann and E. Vasserot. The authors thank them for their patient explanation on the works.

A.B. is grateful to D. Gaitsgory for very helpful discussions related to Appendix A as well as with the proof of Theorem 3.22.

H.N. thanks to Y. Tachikawa who explained physical intuition to him, and to T. Arakawa and R. Kodera who taught him various things on \( W \)-algebras.

This work was started at 2012 fall, while H.N. was visiting the Simons Center for Geometry and Physics, and he wishes to thank the Center for warm hospitality. We thank the Abdus Salam International Centre for Theoretical Physics, the Euler International Mathematical Institute, the Higher School of Economics, Independent University of Moscow, where we continued the discussion.

A.B. was partially supported by the NSF grant DMS-1200807 and by the Simons foundation. Also this work was completed when A.B. was visiting the New Economic School of Russia and the Mathematics Department of the Higher School of Economics and he would like to thank those institutions for their hospitality.

M.F. was supported by The National Research University Higher School of Economics Academic Fund Program in 2014/2015 (research grant No. 14-01-0047).

The research of H.N. was supported in part by JSPS Kakenhi Grant Numbers 00201666, 25220701, 30165261, 70191062.

2. Preliminaries
2(i). **Instanton number.** We define an instanton number of a $G$-bundle $\mathcal{F}$ over $\mathbb{P}^2$. It is explained in, for example, [3]. Since it is related to our assumption that $G$ is simply-laced, we briefly recall the definition.

The instanton number is the characteristic class associated with an invariant bilinear form $(\ , \ )$ on the Lie algebra $\mathfrak{g}$ of $G$. Since we assume $G$ is simple, the bilinear form is unique up to scalar. We normalize it so that the square length of the highest root $\theta$ is 2.

When $G = SL(r)$, it is nothing but the second Chern class of the associated complex vector bundle.

For an embedding $SL(2) \to G$ corresponding to a root $\alpha$, we can induce a $G$-bundle $\mathcal{F}$ from an $SL(2)$-bundle $\mathcal{F}_{SL(2)}$. Then the corresponding instanton numbers are related by

\[(2.1) \quad d(\mathcal{F}) = d(\mathcal{F}_{SL(2)}) \times \frac{2}{(\alpha, \alpha)}.\]

Since we assume $G$ is simply-laced, we have $(\alpha, \alpha) = 2$ for any root $\alpha$. Thus the instanton number is preserved under the induction.

2(ii). **Moduli of framed $G$-bundles.** Let $\text{Bun}_d^G$ be the moduli space of $G$-bundles with trivialization at $\ell_\infty$ of instanton number $d$ as before. We often call them framed $G$-bundles.

The tangent space of $\text{Bun}_d^G$ at $\mathcal{F}$ is equal to the cohomology group $H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}(\ell_\infty))$, where $\mathfrak{g}_\mathcal{F}$ is the vector bundle associated with $\mathcal{F}$ by the adjoint representation $G \to GL(\mathfrak{g})$ ([20, 3.5]). Other degree cohomology groups vanish, and hence the dimension of $H^1$ is given by the Riemann-Roch formula. It is equal to $2dh^\vee$. Here $h^\vee$ is the dual Coxeter number of $G$, appearing as the ratio of the Killing form and our normalized inner product $(\ , \ )$.

It is known that $\text{Bun}_d^G$ is connected, and hence irreducible ([20, Prop. 2.25]).

It is also known that $\text{Bun}_d^G$ is a holomorphic symplectic manifold. Here the symplectic form is given by the isomorphism

\[(2.2) \quad H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}(-2\ell_\infty)) \cong H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}^*(-\ell_\infty)),\]

where $\mathfrak{g} \cong \mathfrak{g}^*$ is induced by the invariant bilinear form, and $\mathcal{O}_{\mathbb{P}^2}(-\ell_\infty) \to \mathcal{O}_{\mathbb{P}^2}(-2\ell_\infty)$ is given by the multiplication by the coordinate $z_0$ corresponding to $\ell_\infty$. The tangent space $T_\mathcal{F} \text{Bun}_d^G \cong H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}(\ell_\infty))$ is isomorphic also to $H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}(-2\ell_\infty))$ and the above isomorphism can be regarded as $T_\mathcal{F} \text{Bun}_d^G \to T_\mathcal{F}^* \text{Bun}_d^G$. It is nondegenerate and closed. (See [47, Ch. 2, 3] for $G = SL(r)$. General cases can be deduced from the $SL(r)$-case by a faithful embedding $G \to SL(r)$.)
Stratification. Let $\mathcal{U}_G^d$ be the Uhlenbeck space for $G$. It has a stratification
\begin{equation}
\mathcal{U}_G^d = \bigsqcup \text{Bun}_{G,\lambda}^{d_1} \times \text{Bun}_{G,\lambda}^{d_2} \times S_\lambda \mathbb{A}^2,
\end{equation}
where the sum runs over pairs of integers $d_1$ and partitions $\lambda$ with $d_1 + |\lambda| = d$. Here $S_\lambda \mathbb{A}^2$ is a stratum of the symmetric product $S^{|\lambda|} \mathbb{A}^2$, consisting of configurations of points whose multiplicities are given by $\lambda$, that is
\begin{equation}
S_\lambda \mathbb{A}^2 = \left\{ \sum \lambda_i x_i \in S^{|\lambda|} \mathbb{A}^2 \mid x_i \neq x_j \text{ for } i \neq j \right\}
\end{equation}
for $\lambda = (\lambda_1 \geq \lambda_2 \geq \cdots)$. We have
\begin{equation}
\dim \text{Bun}_{G,\lambda}^{d_1} = 2(d_1 h^\vee + l(\lambda)).
\end{equation}

Let $\mathcal{U}_{G,\lambda}^{d_1}$ be the closure of $\text{Bun}_{G,\lambda}^{d_1}$. We have a finite morphism
\begin{equation}
\mathcal{U}_G^{d_1} \times S_\lambda \mathbb{A}^2 \rightarrow \mathcal{U}_{G,\lambda}^{d_1},
\end{equation}
extending the identification $\text{Bun}_{G,\lambda}^{d_1} \times S_\lambda \mathbb{A}^2 = \text{Bun}_{G,\lambda}^{d_1}$, where $S_\lambda \mathbb{A}^2$ is the closure of $S_\lambda \mathbb{A}^2$ in $S^{|\lambda|} \mathbb{A}^2$.

Factorization. For any projection $a: \mathbb{A}^2 \rightarrow \mathbb{A}^1$ we have a natural map $\pi_{a,G}^d: \mathcal{U}_G^d \rightarrow S^d \mathbb{A}^1$. See [20, §6.4]. It is equivariant under $G = G \times \mathbb{C}^* \times \mathbb{C}^*$; it is purely invariant under $G$. We also change the projection $a$ according to the $\mathbb{C}^* \times \mathbb{C}^*$-action.

Let us explain a few properties. Let $\mathcal{F} \in \text{Bun}_G^d$. It is a principal $G$-bundle over $\mathbb{P}^2$ trivialized at $\ell_{\infty}$, but can be also considered as a $G$-bundle over $\mathbb{P}^1 \times \mathbb{P}^1$ trivialized at the union of two lines $\{\infty\} \times \mathbb{P}^1$ and $\mathbb{P}^1 \times \{\infty\}$. We extend $a$ to $\mathbb{P}^1 \times \mathbb{P}^1 \rightarrow \mathbb{P}^1$. Then $\pi_{a,G}^d(\mathcal{F})$ measures how the restriction of $\mathcal{F}$ to a projective line $a^{-1}(x)$ differs from the trivial $G$-bundle for $x \in \mathbb{P}^1$. If $x$ is disjoint from $\pi_{a,G}^d(\mathcal{F})$, then $\mathcal{F}|_{a^{-1}(x)}$ is a trivial $G$-bundle. If not, the coefficient of $x$ in $\pi_{a,G}^d(\mathcal{F})$ counts non-triviality with an appropriate multiplicity. (See [20, §4].)

On the stratum $\text{Bun}_{G}^{d_1} \times S_\lambda \mathbb{A}^2$, $\pi_{a,G}^d$ is given as the sum of $\pi_{a,G}^{d_1}$ and the natural morphism $S_\lambda \mathbb{A}^2 \rightarrow S^{|\lambda|} \mathbb{A}^1$ induced from $a$. This property comes from the definition of the Uhlenbeck as a space of quasi-maps. (See [20, §§1,2].)

For type $A$, it is given as follows in terms of the ADHM description $(B_1, B_2, I, J)$ (see [47, Ch. 2]): let $B_a$ be the linear combination of $B_1, B_2$ corresponding to the projection $a: \mathbb{A}^2 \rightarrow \mathbb{A}^1$. Then $\pi_{a,G}^d$ is the characteristic polynomial of $B_a$. (See [20, Lem. 5.9].)

Moreover, most importantly, this map enjoys the factorization property, which says the following. Let us write $d = d_1 + d_2$ with $d_1, d_2 > 0$. 

Let \((S^{d_1}A^1 \times S^{d_2}A^1)_0\) be the open subset of \(S^{d_1}A^1 \times S^{d_2}A^1\) where the first divisor is disjoint from the second divisor. Then we have a natural isomorphism

\[
(2.7) \quad \mathcal{U}_G^d \times_{S^dA^1} (S^{d_1}A^1 \times S^{d_2}A^1)_0 \cong (\pi_{a,G}^d \times \pi_{a,G}^{d_2})^{-1}((S^{d_1}A^1 \times S^{d_2}A^1)_0).
\]

See [20, Prop. 6.5]. We call \(\pi_{a,G}^d\) the factorization morphism. Often we are going to make statements about \(\mathcal{U}_G^d\) and we are going to prove them by induction on \(d\); (2.7) will usually allow us to say that the inductive step is trivial away from the preimage under \(\pi_{a,G}^d\) of the main diagonal in \(S^dA^1\). In this case we are going to say that (the generic part of) the induction step “follows by the factorization argument”.

3. Localization

3(i). General Statement. Let \(T\) be a torus acting on \(X\) and \(Y\) be a closed invariant subset containing \(X_T\). Let \(\varphi: Y \to X\) be the inclusion. Let \(U \overset{\text{def}}{=} X \setminus Y\) and \(\psi: U \to X\) be the inclusion. Let \(F \in D^b_T(X)\). We consider distinguished triangles

\[
(3.1) \quad \varphi_! \varphi^! F \to F \to \psi_* \psi^* F \overset{+1}{\to}, \quad \psi_! \psi^! F \to F \to \varphi_* \varphi^* F \overset{+1}{\to}.
\]

Denote the Lie algebra of \(T\) by \(t\). Natural homomorphisms

\[
(3.2) \quad H^*_T(X, F) \to H^*_T(X, \varphi_* \varphi^* F) \cong H^*_T(Y, \varphi_* F),
\]

\[
(3.3) \quad H^*_T(Y, \varphi^! F) \cong H^*_T(X, \varphi_* \varphi^! F) \cong H^*_T(X, \varphi_! \varphi^! F) \to H^*_T(X, F)
\]

become isomorphisms after inverting an element \(f \in \mathbb{C}[t]\) such that

\[
(3.4) \quad \{x \in t \mid f(x) = 0\} \supset \bigcup_{x \in X \setminus Y} \text{Lie}(\text{Stab}_x).
\]

See [31, (6.2)]. These assertions follow by observing \(H^*_T(X; \psi_* \psi^! F) = H^*_T(X, Y; F)\) and \(H^*_T(X; \psi_* \psi^* F) = H^*_T(U; F)\) are torsion in \(\mathbb{C}[t]\). The same is true also for cohomology groups with compact supports. We call these statements the localization theorem.

We now suppose that we have an action of \(\mathbb{C}^* \times \mathbb{C}^*\) commuting with the \(T\)-action such that

\[
(3.5) \quad \begin{align*}
& X^{\mathbb{C}^* \times \mathbb{C}^*} \text{ is a single point, denoted by } 0. \\
& \text{If } n_1, n_2 > 0, (t^{n_1}, t^{n_2}) \cdot x \text{ goes to } 0 \text{ when } t \to 0.
\end{align*}
\]

In fact, it is enough to have a \(\mathbb{C}^*\)-action for the result below, but we consider a \(\mathbb{C}^* \times \mathbb{C}^*\)-action, as the Uhlenbeck space has natural \(\mathbb{C}^* \times \mathbb{C}^*\)-action.

Let \(T = T \times \mathbb{C}^* \times \mathbb{C}^*\).
Lemma 3.6. The natural homomorphisms $H^*_T(X, \mathcal{F}) \to H^*_T(Y, \varphi^*\mathcal{F})$, $H^*_{T,c}(X, \varphi^!\mathcal{F}) \to H^*_{T,c}(Y, \varphi^!\mathcal{F})$ are isomorphisms for $\mathcal{F} \in D^b_T(X)$.

Proof. Let $b^X_0 : \{0\} \to X$, $b^Y_0 : \{0\} \to Y$ be inclusions, and $a_X : X \to \{0\}$, $a_Y : Y \to \{0\}$ be the obvious morphisms. Since 0 is the unique fixed point of an attracting action of $\mathbb{C}^* \times \mathbb{C}^*$ by our assumption, adjunction gives us isomorphisms $(a_X)_* \cong (b^X_0)^*$, $(a_Y)_* \cong (b^Y_0)^*$ on equivariant objects by [12, Lemma 6]. Therefore we have a diagram

$$
\begin{array}{ccc}
H^*_T(X, \mathcal{F}) & \longrightarrow & H^*_T(Y, \varphi^*\mathcal{F}) \\
\cong & & \cong \\
H^*_T((b^X_0)^*\mathcal{F}) & \longrightarrow & H^*_T((b^Y_0)^*\varphi^*\mathcal{F}),
\end{array}
$$

where the lower horizontal equality follows from $\varphi b^Y_0 = b^X_0$. If $\mathcal{F}$ is a sheaf, other three homomorphisms are given by restrictions, therefore the diagram is commutative. Hence it is also so for $\mathcal{F} \in D^b_T(X)$ by a standard argument. Taking the dual spaces, we obtain the second assertion. \hfill \Box

3(ii). The case of Ext algebras. Let $\mathcal{F}, \mathcal{G} \in D^b_T(X)$. We claim that

$$
\begin{align*}
(3.8) & \quad \text{Ext}_{D^b_T(X)}(\mathcal{F}, \mathcal{G}) \to \text{Ext}_{D^b_T(Y)}((\varphi^!\mathcal{F}), (\varphi^!\mathcal{G})) , \\
(3.9) & \quad \text{Ext}_{D^b_T(X)}(\mathcal{F}, \mathcal{G}) \to \text{Ext}_{D^b_T(Y)}((\varphi^*\mathcal{F}), (\varphi^*\mathcal{G}))
\end{align*}
$$

are isomorphisms after inverting an appropriate element $f$. Taking adjoint and considering (3.1), we see that it is enough to show that

$$
(3.10) \quad \text{Ext}_{D^b_T(X)}(\psi_*\psi^*\mathcal{F}, \mathcal{G}) , \quad \text{Ext}_{D^b_T(X)}(\mathcal{F}, \psi^!\psi^!\mathcal{G})
$$

are torsion. Let us observe that

$$
(3.11) \quad \text{Ext}_{D^b_T(X)}(\psi_*\psi^*\mathcal{F}, \psi_*\psi^*\mathcal{F}) \cong \text{Ext}_{D^b_T(U)}(\psi^*\psi_*\psi^*\mathcal{F}, \psi^*\mathcal{F})
$$

is torsion, as it is an equivariant cohomology group over $U$. Then multiplying the identity endomorphism of $\psi_*\psi^*\mathcal{F}$ to $\text{Ext}_{D^b_T(X)}(\psi_*\psi^*\mathcal{F}, \mathcal{G})$, we conclude that $\text{Ext}_{D^b_T(X)}(\psi_*\psi^*\mathcal{F}, \mathcal{G})$ is torsion. The same argument applies also to $\text{Ext}_{D^b_T(X)}(\mathcal{F}, \psi^!\psi^!\mathcal{G})$.

3(iii). Attractors and repellents. Let $X$ be a $T$-invariant closed subvariety in an affine space with a linear $T$-action. Let $A \subset T$ be a subtorus and $X^A$ denote the fixed point set.

Let $X_*(A)$ be the space of cocharacters of $A$. It is a free $\mathbb{Z}$-module. Let

$$
(3.12) \quad a_{\mathbb{R}} = X_*(A) \otimes_{\mathbb{Z}} \mathbb{R}.
$$
Let \( \text{Stab}_x \) be the stabilizer subgroup of a point \( x \in X \). A chamber \( \mathfrak{C} \) is a connected component of
\[
\mathfrak{a}_\mathbb{R} \setminus \bigcup_{x \in X \setminus X^A} X_*(\text{Stab}_x) \otimes \mathbb{Z} \mathbb{R}.
\]

We fix a chamber \( \mathfrak{C} \). Choose a cocharacter \( \lambda \) in \( \mathfrak{C} \). Let \( x \in X^A \). We introduce attracting and repelling sets:
\[
(3.13) \quad \mathcal{A}_x = \left\{ y \in X \mid \text{the map } t \mapsto \lambda(t)(y) \text{ extends to a map } A^1 \to X \text{ sending } 0 \text{ to } x \right\},
\]
\[
(3.14) \quad \mathcal{R}_x = \left\{ y \in X \mid \text{the map } t \mapsto \lambda(t^{-1})(y) \text{ extends to a map } A^1 \to X \text{ sending } 0 \text{ to } x \right\}.
\]
These are closed subvarieties of \( X \), and independent of the choice of \( \lambda \in \mathfrak{C} \). Similarly we can define \( \mathcal{A}_X, \mathcal{R}_X \) if we do not fix the point \( x \) as above. Note that \( X^A \) is a closed subvariety of both \( \mathcal{A}_X \) and \( \mathcal{R}_X \); in addition we have the natural morphisms \( \mathcal{A}_X \to X^A \) and \( \mathcal{R}_X \to X^A \).

3(iv). **Hyperbolic restriction.** We continue the setting in the previous subsection. We choose a chamber in \( \mathfrak{a}_\mathbb{R} \), and consider the diagram
\[
(3.15) \quad X^A \xrightarrow{p} \mathcal{A}_X \xrightarrow{j} X,
\]
where \( i, j \) are embeddings, and \( p \) is defined by \( p(y) = \lim_{t \to 0} \lambda(t)y \).

We consider Braden’s hyperbolic restriction functor \([12]\) defined by \( \Phi = i^*j! \). (See also a recent paper \([24]\).) Braden’s theorem says that we have a canonical isomorphism
\[
(3.16) \quad i^*j! \cong i_-^*j_-^!
\]
on weakly \( A \)-equivariant objects, where \( i_-, j_- \) are defined as in (3.15) for \( \mathcal{R}_X \) instead of \( \mathcal{A}_X \).

Note also that \( i^* \) and \( p_* \) are isomorphic on weakly equivariant objects, we have \( \Phi = p_*j_! \). (See \([12, (1)]\).)

Let \( \mathcal{F} \in D^b_T(X) \). A homomorphism
\[
(3.17) \quad H^*_T(X^A, i^*j^!\mathcal{F}) \cong H^*_T(X^A, p_*j^!\mathcal{F}) = H^*_T(\mathcal{A}_X, j^!\mathcal{F}) \to H^*_T(X, \mathcal{F})
\]
becomes an isomorphism after inverting a certain element by the localization theorem in the previous subsection, applied to the pair \( \mathcal{A}_X \subset X \).

We also have two naive restrictions
\[
(3.18) \quad H^*_T(X^A, (j \circ i)^!\mathcal{F}), \quad H^*_T(X^A, (j \circ i)^*\mathcal{F}).
\]
For the first one, we have a homomorphism to the hyperbolic restriction
\[
(3.19) \quad H^*_T(X^A, (j \circ i)^!\mathcal{F}) \to H^*_T(X^A, i^*j^!\mathcal{F}),
\]
which factors through $H^*(A_X, j^*\mathcal{F})$. Then it also becomes an isomorphism after inverting an element.

The second one in (3.18) fits into a commutative diagram

$$
\begin{array}{c}
H^*_T(X^A, i^* j^! \mathcal{F}) \\ \uparrow \\
H^*_T(A_X, j^! \mathcal{F}) \\
\end{array} \quad \text{---} \quad \begin{array}{c}
H^*_T(X^A, (j \circ i)^* \mathcal{F}) \\
\uparrow \\
H^*_T(A_X, j^* \mathcal{F}).
\end{array}
$$

(3.20)

Two vertical arrows are isomorphisms after inverting an element $f$. The lower horizontal homomorphism factors through $H^*_T(X, \mathcal{F})$ and the resulting two homomorphisms are isomorphisms after inverting an element, which we may assume equal to $f$. Therefore the upper arrow is also an isomorphism after inverting an element.

3(v). Recovering the integral form. We assume (3.5) and also that $X$ is affine. We consider the hyperbolic restriction with respect to $T$.

Let $A_T = \mathbb{C}[\text{Lie}(T)] = \mathbb{C}[\epsilon_1, \epsilon_2, a]$ and $F_T$ be its quotient field.

We further assume that $H^*_{T,c}(X, \mathcal{F})$ is torsion free over $H^*_T(\text{pt}) = A_T$, i.e., $H^*_{T,c}(X, \mathcal{F}) \to H^*_{T,c}(X, \mathcal{F}) \otimes_{A_T} F_T$ is injective. This property for the Uhlenbeck space will be proved in Lemma 6.5.

We consider a homomorphism

$$H^*_T(X, \mathcal{F}) \cong H^*_T(X^T, i^* j^! \mathcal{F}) \to H^*_T(X^T, i^* j^! \mathcal{F})$$

(3.21)

for $\mathcal{F} \in D^b_T(X)$. The first isomorphism is given in Lemma 3.6. By the localization theorem, the second homomorphism becomes an isomorphism after inverting an element $f \in \mathbb{C}[\text{Lie} T]$ which vanishes on the union of the Lie algebras of the stabilizers of the points $x \in A_X \setminus X^T$.

Theorem 3.22. Consider the intersection $H^*_T(X, \mathcal{F}) \cap H^*_T(X, i^* j^! \mathcal{F})$ in $H^*_T(X, \mathcal{F}) \otimes_{A_T} F_T$. It coincides with $H^*_T(X, \mathcal{F})$.

The proof occupies the rest of this subsection. We first give a key lemma studying stabilizers of points in $A_X \setminus X^T$.

Lemma 3.23. Suppose that $(\lambda^\vee, n_1, n_2)$ is a cocharacter of $T$ such that either of the followings holds

1. $\lambda^\vee$ is dominant and $n_1, n_2 > 0$.
2. $\lambda^\vee$ is regular dominant and $n_1, n_2 \geq 0$.

Then there is no point in $A_X \setminus X^T$ whose stabilizer contains $(\lambda^\vee, n_1, n_2)(\mathbb{C}^*)$.

Proof. Assume $\lambda$ is dominant and $n_1, n_2 \geq 0$.

Suppose that $x \in A_X$ is fixed by $(\lambda^\vee, n_1, n_2)(\mathbb{C}^*)$. Then we have

$$\lambda^\vee(t^{-1}) \cdot x = (t^{n_1}, t^{n_2}) \cdot x.$$  

(3.24)
Since $\lambda^\vee$ is dominant, its attracting set contains $A_X$. Therefore the left hand side has a limit when $t \to \infty$. On the other hand, the right hand side has a limit when $t \to 0$. Therefore $C^* \ni t \mapsto \lambda^\vee(t^{-1}) \cdot x \in X$ extends to a morphism $\mathbb{P}^1 \to X$. As $X$ is affine, such a morphism must be constant, i.e., (3.24) must be equal to $x$.

If $n_1, n_2 > 0$, $x$ must be the unique $C^* \times C^*$ fixed point. It is contained in $X^T$.

If $\lambda^\vee$ is regular, $x$ is fixed by $T$, that is $x \in X^T$. \hfill \Box

Proof of Theorem 3.22. Let $\alpha$ be an element in $H^*_{T,c}(X, \mathcal{F})$ which is not divisible by any non-constant element of $A_T$. Let $J_+^\alpha$ be two fractional ideals of $A_T$ consisting of those rational functions $f$ such that $f\alpha \in H^*_{T,c}(X^T, i^*j^! \mathcal{F})$ and $f\alpha \in H^*_{T,c}(X^T, i^*j^! - \mathcal{F})$ respectively. We need to show that $J_+^\alpha \cap J_-^\alpha = A_T$. Note that a priori the right hand side is embedded in the left hand side.

Let $f \in J_+^\alpha$. Then $f = g/h$ where $g, h \in A_T$ and $h$ is a product of linear factors of the form $(\mu, m_1, m_2)$ such that

- $\langle \lambda^\vee, \mu \rangle > 0$ for a regular dominant coweight $\lambda^\vee$, and
- $m_1, m_2 \geq 0$ with at least one of them nonzero.

In fact, we have $\langle (\lambda^\vee, n_1, n_2), (\mu, m_1, m_2) \rangle \neq 0$ for any $(\lambda^\vee, n_1, n_2)$ as in Lemma 3.23. Taking a regular dominant coweight $\lambda^\vee$ and $n_1, n_2 = 0$, we get the first condition. Next we take $\lambda = 0$ and $n_1, n_2 > 0$ and get the second condition.

Similarly for $f = g/h \in J_-^\alpha$, $h$ is a product of $(\mu, m_1, m_2)$ with $\langle \lambda^\vee, \mu \rangle < 0$ for a regular dominant coweight $\lambda^\vee$, and the same conditions for $(m_1, m_2)$ as above. Then there are no linear factors satisfying both conditions, hence we have $J_+^\alpha \cap J_-^\alpha = A_T$. \hfill \Box

4. Hyperbolic restriction on Uhlenbeck spaces

This section is of technical nature, but will play a quite important role later. Feigin-Frenkel realized the $\mathcal{W}$-algebra $\mathcal{W}_k(g)$ in the Heisenberg algebra $\mathfrak{Heis}(h)$ associated with the Cartan subalgebra $h$ of $g$. (See [28, Ch. 15].)

We will realize this picture in a geometric way. In [40] Maulik-Okounkov achieved it by stable envelopes which relate the cohomology group of Gieseker space to that of the fixed point set with respect to a torus. The former is a module over $\mathcal{W}_k(g)$ and the latter is a Heisenberg module. In [59] Schiffmann-Vasserot also related two cohomology groups by a different method.
We will take a similar approach, but we need to use a sheaf theoretic language, as Uhlenbeck space is singular. We use the \textit{hyperbolic restriction functor}, introduced by Braden \cite{Braden}, and combine it with the theory of stable envelops. This study was initiated by the third author \cite{Nakajima}. A new and main result here is Theorem 4.20, which says that perversity is preserved under the hyperbolic restriction in our situation.

We fix a pair $T \subset B$ of a maximal torus $T$ and a Borel subgroup $B$, and consider only parabolic subgroups $P$ containing $B$, except we occasionally use opposite parabolic subgroups $P_-$ until \S 4(xiii). In \S 4(xiii), we consider other parabolic subgroups also.

4(i). \textbf{A category of semisimple perverse sheaves.} Let $\text{IC}(\text{Bun}^d_{G,\lambda}, \rho)$ denote the intersection cohomology (IC) complexes, where $\rho$ is a simple local system on $\text{Bun}^d_{G,\lambda} = \text{Bun}^d_G \times S_{\lambda} \mathbb{A}^2$ corresponding to an irreducible representation of $S_{n_1} \times S_{n_2} \times \cdots$ via the covering
\begin{equation}
(\mathbb{A}^2)^{n_1} \times (\mathbb{A}^2)^{n_2} \times \cdots \setminus \text{diagonal} \rightarrow S_{\lambda} \mathbb{A}^2,
\end{equation}
where $\lambda = (1^{n_1}2^{n_2} \cdots)$. (Recall $S_{\lambda} \mathbb{A}^2$ is a stratum of $S^{\lambda} \mathbb{A}^2$, see (2.4).)

\textbf{Definition 4.2.} Let $\text{Perv}(\mathcal{U}_d^G)$ be the additive subcategory of the abelian category of semisimple perverse sheaves on $\mathcal{U}_d^G$, consisting of finite direct sum of $\text{IC}(\text{Bun}^d_{G,\lambda}, \rho)$.

By abuse of notation, we use the same notation $\text{IC}(\text{Bun}^d_{G,\lambda}, \rho)$ even if $\rho$ is a reducible representation of $S_{n_1} \times S_{n_2} \times \cdots$. It is the direct sum of the corresponding simple IC sheaves.

If $\rho$ is the trivial rank 1 local system, we omit $\rho$ from the notation and denote the corresponding IC complex by $\text{IC}(\text{Bun}^d_{G,\lambda})$, or $\text{IC}(\mathcal{U}_d^G, \lambda)$. Furthermore, we omit $\lambda$ from the notation when it is the empty partition $\emptyset$. Therefore $\text{IC}(\mathcal{U}_d^G)$ means $\text{IC}(\text{Bun}^d_{G,\emptyset})$.

Objects in $\text{Perv}(\mathcal{U}_d^G)$ naturally have structures of equivariant perverse sheaves in the sense of \cite{BFG} with respect to the group action $G = G \times \mathbb{C}^* \times \mathbb{C}^*$ on $\mathcal{U}_d^G$. We often view $\text{Perv}(\mathcal{U}_d^G)$ as the subcategory of equivariant perverse sheaves.

4(ii). \textbf{Fixed points.} Let $P$ be a parabolic subgroup of $G$ with a Levi subgroup $L$. Let $A = Z(L)^0$ denote the connected center of $L$. Let $\text{Bun}_d^L$ denote the moduli space of $L$-bundles on $\mathbb{P}^2$ with trivialization at $\ell_\infty$ of ‘instanton number $d'$'. The latter expression makes sense, since the notion of instanton number, defined as in \S 2(i), corresponds to a choice of a bilinear form on the coweight lattice, which is the same for $G$ and for $L$.

Suppose that $F \in \text{Bun}_d^G$ is fixed by the $A$-action. It means that bundle automorphisms at $\ell_\infty$ parametrized by $A$ extend to the whole
space $\mathbb{P}^2$. The extensions are unique. Therefore the structure group $G$ of $\mathcal{F}$ reduces to the centralizer of $A$, which is $L$. Hence $(\text{Bun}_G^d)^A = \text{Bun}_L^d$.

Let us consider the fixed point subvariety

$$(4.3) \quad U_L^d = (U_G^d)^A$$

in the Uhlenbeck space. Then we have an induced stratification

$$(4.4) \quad U_L^d = \bigsqcup_{d_1 + d_2 = d, \lambda | d_2} \text{Bun}_{L,\lambda}^{d_1}, \quad \text{Bun}_{L,\lambda}^{d_1} = \text{Bun}_L^{d_1} \times S_\lambda \mathbb{A}^2.$$  

Strictly speaking, our $U_L^d$ depends on the choice of the embedding $L \to G$, therefore should be denoted, say by $U_{L,G}^d$. We think that there is no fear of confusion.

Note that $[L, L]$ is again semi-simple and simply-connected. (See [11, Cor. 4.4].) Suppose that we have only one simple factor. Since we assume $G$ is simply-laced, $[L, L]$ is also. The instanton number is the same for $G$ and $[L, L]$. Otherwise we define the instanton number for $[L, L]$ by the invariant form on $\text{Lie}([L, L])$ induced from one on $\mathfrak{g}$.

Since we only have trivial framed $L/[L, L]$-bundles as $\mathbb{P}^2$ is simply-connected, we have

$$(4.5) \quad \text{Bun}_L^{d_1} = \text{Bun}_{[L, L]}^{d_1}.$$  

Since $[L, L]$ is a subgroup of $G$, we have the induced closed embedding $U_{[L,L]}^d \to U_G^d$ (see [20, Lem. 6.2]), which clearly factors as

$$(4.6) \quad U_{[L,L]}^d \to U_L^d.$$  

By (4.5), this map is bijective. Since both spaces are closed subschemes of $U_G^d$, we have

**Proposition 4.7.** The morphism $U_{[L,L]}^d \to U_L^d = (U_G^d)^A$ is a homeomorphism between the underlying topological spaces.

We are interested in perverse sheaves on $U_L^d$, hence we only need underlying topological spaces. Hence we may identify $U_L^d$ and $U_{[L,L]}^d$. We define the category $\text{Perv}(U_L^d)$ in the same way as $\text{Perv}(U_G^d)$.

**Example 4.8.** The case when $L$ is a maximal torus $T$ is most important. We have

$$(4.9) \quad U_T^d = S^d \mathbb{A}^2 = \bigsqcup_{\lambda | d} S_\lambda \mathbb{A}^2,$$  

as we do not have nontrivial framed $T$-bundles.
4(iii). **Polarization.** Following [40, §3.3.2], we introduce the notion of a polarization of a normal bundle of the smooth part of a fixed point component.

Let us give a definition in a general situation. Suppose a torus $A$ acts on a holomorphic symplectic manifold $X$, preserving the symplectic structure. Let $Z$ be a connected component of $X^A$ and $N_Z$ be its normal bundle in $X$. Consider $A$-weights of a fiber of $N_Z$. Let $e(N_Z)|_{H^*_A(\text{pt})}$ be the $H^*_A(\text{pt})$-part of the Euler class of the normal bundle, namely the product of all $A$-weights of a fiber of $N_Z$. Since $A$ preserves the symplectic form, $Z$ is a symplectic submanifold, and weights of $N_Z$ appear in the pairs $(\alpha_i, -\alpha_i)$. Hence

\[
(4.10) \quad (-1)^{\text{(codim} Z)/2} e(N_Z)|_{H^*_A(\text{pt})} = \prod \alpha_i^2
\]

is a perfect square. A choice of a square root $\delta$ of (4.10) is called a polarization of $Z$ in $X$.

In the next subsection we consider attractors and repellents. We have a polarization $\delta_{\text{rep}}$ given by product of weights in repellent directions. However this will not be a right choice to save signs. Our choice of the polarization $\delta$, which follows [40, Ex. 3.3.3], will be explained in §5(iii) for Gieseker spaces, and in §6(ii) for Uhlenbeck spaces. Then we understand $\delta = \pm 1$, depending on whether it is the same as or the opposite to $\delta_{\text{rep}}$, in other words we identify $\delta$ with $\delta/\delta_{\text{rep}}$, as $\delta_{\text{rep}}$ is clear from the context.

Note that a polarization does not make sense unless the variety $X$ is smooth. Therefore we restrict the normal bundle to $Z \cap \text{Bun}^d_G = Z \cap \text{Bun}^d_L$ and consider a polarization there for Uhlenbeck spaces.

However a fixed point component $Z$, in general, does not intersect with $\text{Bun}^d_G$. Say $Z \cap \text{Bun}^d_G = \emptyset$ if $L = T$. We do not consider a polarization of $Z$ in this case, and smooth cases are enough for our purpose.

4(iv). **Definition of hyperbolic restriction functor.** We now return to the situation when $X = \mathcal{U}^d_G$. We choose a parabolic subgroup $P$ with a Levi subgroup $L$ as before.

We consider the setting in §§3(iii), 3(iv) with $A = Z(L)^0$. Then (3.13) is the hyperplane arrangements induced by roots:

\[
(4.11) \quad a_\mathbb{R} \setminus \bigcup_{\alpha} \{ \alpha |_{a_\mathbb{R}} = 0 \},
\]

where the union runs over all positive roots $\alpha$ which do not vanish on $a_\mathbb{R}$. The chambers are in one to one correspondence to the parabolic
subgroups containing $L$ as their Levi (associated parabolics). Therefore the fixed $P$ determines a ‘positive’ chamber.

We denote the corresponding attracting and repelling sets $\mathcal{A}_X$, $\mathcal{R}_X$ by $\mathcal{U}_P^a$ and $\mathcal{U}_P^r$. Often we are going to drop the instanton number $d$ from the notation, when there is no fear of confusion. We let $i$ and $p$ denote the corresponding maps from $\mathcal{U}_L$ to $\mathcal{U}_P$ and from $\mathcal{U}_P$ to $\mathcal{U}_L$. Also we denote by $j$ the embedding of $\mathcal{U}_P$ to $\mathcal{U}_G$. We shall sometimes also use similar maps $i_-$, $j_-$ and $p_-$ where $\mathcal{U}_P$ is replaced with $\mathcal{U}_{P_-}$. We have diagrams

\begin{equation}
(4.12) \quad \mathcal{U}_L \xrightarrow{i} \mathcal{U}_P \xrightarrow{j} \mathcal{U}_G, \quad \mathcal{U}_L \xrightarrow{i_-} \mathcal{U}_{P_-} \xrightarrow{j_-} \mathcal{U}_G.
\end{equation}

**Definition 4.13.** We define the functor $\Phi_{L,G}$ by $i^* j^! = p_* j^!$.

We apply it to weakly $A$-equivariant objects, in particular on $\text{Perv}(\mathcal{U}_G^d)$. **Warning.** Of course, the functor $\Phi_{L,G}$ depends on $P$ and not just on $L$. When we want to emphasize $P$, we write $\Phi_{p,L,G}$. Otherwise $P$ is always chosen so that $P \supset B$ for the fixed Borel subgroup $B$.

Let us justify our notation $\mathcal{U}_P$ for the attracting set. We have a one parameter subgroup $\lambda: \mathbb{G}_m \to G$ such that

\begin{equation}
(4.14) \quad P = \left\{ g \in G \left| \lim_{t \to 0} \lambda(t) g \lambda(t)^{-1} \text{ exists} \right. \right\},
\end{equation}

\begin{equation}
L = G^{\lambda(\mathbb{G}_m)} = \left\{ g \in G \left| \lambda(t) g = g \lambda(t) \right. \text{ for any } t \in \mathbb{G}_m \right\}.
\end{equation}

Then we have

\begin{equation}
(4.15) \quad \mathcal{U}_P \overset{\text{def.}}{=} \left\{ x \in \mathcal{U}_G \left| \lim_{t \to 0} \lambda(t) \cdot x \text{ exists} \right. \right\},
\end{equation}

\begin{equation}
\mathcal{U}_L \overset{\text{def.}}{=} (\mathcal{U}_G)^{\lambda(\mathbb{G}_m)} = \left\{ x \in \mathcal{U}_G \left| \lambda(t) \cdot x = x \right. \text{ for any } t \in \mathbb{G}_m \right\}.
\end{equation}

We embed $G$ into $SL(N)$ and consider the corresponding space for $G = SL(N)$. We use the ADHM description for $\mathcal{U}_{SL(N)}$ to identify it with the affine GIT quotient as in [47, Ch. 3]. Then $SL(N) = SL(W)$, and $\mathcal{U}_P$ coincides with the variety $\pi(\mathfrak{z})$ studied in [49, §3]. Here $\pi$ is Gieseker-Uhlenbeck morphism, and $\mathfrak{z}$ is the attracting set in the Gieseker space, which will be denoted by $\tilde{U}_P$ later.

In [49, Rem. 3.16] it was remarked that $\mathfrak{z}$ parametrizes framed torsion free sheaves having a filtration $E = E^0 \supset E^1 \supset \cdots \supset E^k \supset E^{k+1} = 0$. If all $F^i = E^i/E^{i+1}$ are locally free, $E$ is a $P$-bundle. Thus $\mathcal{U}_P$ contains a possibly empty open subset $p^{-1}(\text{Bun}_L)$ consisting of $P$-bundles.

Let us, however, note that $\mathcal{U}_P \cap \text{Bun}_G$ is not entirely consisting of $P$-bundles, hence larger than $p^{-1}(\text{Bun}_L)$. Consider a short exact sequence

\[ 0 \to F^2 \to E \to F^1 = \mathcal{I}_x \to 0, \]
arising from the Koszul resolution of the skyscraper sheaf at a point \( x \in \mathbb{A}^2 \). Here \( \mathcal{I}_x \) is the ideal sheaf for \( x \). Then \( E \in \mathcal{U}_P \cap \text{Bun}_G \), but \( E \) is not a \( P \)-bundle as \( F^1 \) is not locally free. More detailed analysis will be given in the proof of Proposition 5.45.

4(v). Associativity.

**Proposition 4.16.** Let \( Q \) be another parabolic subgroup of \( G \), contained in \( P \) and let \( M \) denote its Levi subgroup. Let \( Q_L \) be the image of \( Q \) in \( L \) and we identify \( M \) with the corresponding Levi group. Then we have a natural isomorphism of functors

\[
\Phi_{M,L} \circ \Phi_{L,G} \cong \Phi_{M,G}.
\]

**Proof.** It is enough to show that

\[
\mathcal{U}_P \times_{\mathcal{U}_L} \mathcal{U}_{Q_L} = \mathcal{U}_Q,
\]
as

\[
p'_*j'^{\ast}p_\ast j^\ast = p'^\ast p''_\ast j''^\ast = (p' \circ p'')_\ast (j \circ j''^\ast)
\]
in the diagram

\[
\begin{array}{ccc}
\mathcal{U}_Q & \xrightarrow{j''} & \mathcal{U}_P & \xrightarrow{j} & \mathcal{U}_G \\
\downarrow{p''} & & \downarrow{p} & & \\
\mathcal{U}_{Q_L} & \xrightarrow{j'} & \mathcal{U}_L & & \\
\downarrow{p'} & & & & \\
\mathcal{U}_M & & & & \\
\end{array}
\]

The left hand side of (4.18) is just equal to \( p^{-1}(\mathcal{U}_{Q_L}) \). By embedding \( G \) into \( SL(N) \) we may assume that \( G = SL(N) \). In this case, we use the ADHM description to describe \( \mathcal{U}_P, \mathcal{U}_Q, \mathcal{U}_{Q_L} \). By [49, Proof of Lemma 3.6], they are consisting of data \((B_1, B_2, I, J)\) such that \( JF(B_1, B_2)I\) are in \( P, Q, Q_L \) respectively, i.e., upper triangular in appropriate sense, for any products \( F(B_1, B_2) \) of \( B_1, B_2 \) of arbitrary order. Now the assertion is clear. \( \square \)

4(vi). Preservation of perversity. The following is our first main result:

**Theorem 4.20.** \( \Phi_{L,G}(\text{IC}(\mathcal{U}_G)) \) is perverse (and semi-simple, according to [12, Theorem 2]). Moreover, the same is true for any perverse sheaf in \( \text{Perv}(\mathcal{U}_G) \).
The proof will be given in §A.
Let us remark that the result is easy to prove for type $A$, see [53, §4.4, Lemma 3]. The argument goes back to an earlier work by Varagnolo-Vasserot [64].

4(vii). **Hyperbolic restriction on** $\text{Bun}_L^d$. Let us consider the restriction of $\Phi_{L,G}(\text{IC}(\mathcal{U}_L^d))$ to the open subset $\text{Bun}_L^d$ in this subsection.

For simplicity, suppose that $[L, L]$ has one simple factor so that the instanton numbers of $L$-bundles are the same as those of $[L, L]$-bundles. In particular, $\text{Bun}_L^d$ is irreducible. Then $\text{IC}(\mathcal{U}_L^d)$ is a simple perverse sheaf, and we study

\begin{equation}
\text{Hom}_{\text{Perv}(\mathcal{U}_L^d)}(\text{IC}(\mathcal{U}_L^d), \Phi_{L,G}(\text{IC}(\mathcal{U}_G^d))).
\end{equation}

We restrict (4.12) to the open subsets consisting of genuine bundles:

\begin{equation}
\text{Bun}_L^d \xrightarrow{p} p^{-1}(\text{Bun}_L^d) \xrightarrow{i} \text{Bun}_G^d.
\end{equation}

Let us take $\mathcal{F} \in \text{Bun}_L^d$. Then the tangent space of $\text{Bun}_L^d$ at $\mathcal{F}$ is $H^1(\mathbb{P}^2, \mathfrak{g}_\mathcal{F}(\ell_\infty))$, where $\mathfrak{g}$ is the Lie algebra of $L$. This is the subspace of $H^1(\mathbb{P}^2, \mathfrak{g}(\ell_\infty)) = T_\mathcal{F} \text{Bun}_G^d$, consisting of $Z(L)^0$-fixed elements. The normal bundle of $\text{Bun}_L^d$ in $\text{Bun}_G^d$ splits into the sum of $H^1(\mathbb{P}^2, \mathfrak{n}_\mathcal{F}(\ell_\infty))$ and $H^1(\mathbb{P}^2, \mathfrak{n}_\mathcal{F}(\ell_\infty))$, where $\mathfrak{n}$ is the nil radical of $\mathfrak{p} = \text{Lie } P$, and $\mathfrak{n}^-$ is its opposite. They correspond to attracting and repellent directions respectively. Then $p^{-1}(\text{Bun}_L^d)$ is a vector bundle over $\text{Bun}_L^d$, whose fiber at $\mathcal{F}$ is $H^1(\mathbb{P}^2, \mathfrak{n}_\mathcal{F}(\ell_\infty))$. It parametrizes framed $P$-bundles. The morphism $p$ is the projection and $i$ is the inclusion of the zero section. Therefore we have the Thom isomorphism between $i^*j^!(\mathcal{C}_{\text{Bun}_G^d})$ and $\mathcal{C}_{\text{Bun}_L^d}$ up to shift.

Note further that $\dim p^{-1}(\text{Bun}_L^d)$ is the half of the sum of dimensions of $\text{Bun}_L^d$ and $\text{Bun}_G^d$, as $H^1(\mathbb{P}^2, \mathfrak{n}_\mathcal{F}(\ell_\infty))$ and $H^1(\mathbb{P}^2, \mathfrak{n}_\mathcal{F}(\ell_\infty))$ are dual to each other with respect to the symplectic form. Hence a shift is unnecessary, and the Thom isomorphism gives the canonical identification $i^*j^!(\mathcal{C}_{\text{Bun}_G^d}) \cong \mathcal{C}_{\text{Bun}_L^d}$. Therefore we normalize the canonical homomorphism

\begin{equation}
1_{L,G}^d \in \text{Hom}_{\text{Perv}(\mathcal{U}_L^d)}(\text{IC}(\mathcal{U}_L^d), \Phi_{L,G}(\text{IC}(\mathcal{U}_G^d)))
\end{equation}

so that it is equal to the Thom isomorphism on the open subset.

Note also that a homomorphism in (4.21) is determined by its restriction to $\text{Bun}_L^d$, hence (4.21) is 1-dimensional from the above observation. And $1_{L,G}^d$ is its base.

If $[L, L]$ has more than one simple factors $G_1, G_2, \ldots$, $\text{Bun}_L^d$ is not irreducible as it is isomorphic to $\bigcup_{d_1 + d_2 + \cdots = d} \text{Bun}_{G_1}^d \times \text{Bun}_{G_2}^d \times \cdots$. Then
IC(\mathcal{U}_L^d) must be understood as the direct sum
\begin{equation}
\bigoplus_{d_1 + d_2 + \cdots = d} IC(Bun_{G_1}^{d_1} \times Bun_{G_2}^{d_2} \times \cdots).
\end{equation}
In particular, (4.21) is not 1-dimensional. But it does not cause us any trouble. We have the canonical isomorphism for each summand, and $1^d_{L,G}$ is understood as their sum.

4(viii). Space $U^d$ and its base. We shall introduce the space $U^d$ of homomorphisms from $C_S(d)\otimes A^2$ to $\Phi_{L,G}(IC(U^d_G))$ and study its properties in this subsection. A part of computation is a byproduct of the proof of Theorem 4.20 (see Lemma 4.39). The study of $U^d$ will be continued in the remainder of this section, and also in the next section.

**Definition 4.25.** For $d > 0$, we define a vector space
\begin{equation}
U^d_{L,G} \equiv U^d \overset{\text{def}}{=} \text{Hom}_{Perv(U^d_L)}(C_S(d)\otimes A^2, \Phi_{L,G}(IC(U^d_G)))
= H^{-2}(S(d)\otimes A^2, \xi^!\Phi_{L,G}(IC(U^d_G))),
\end{equation}
where $(d)$ is the partition of $d$ consisting of a single entry $d$, and $\xi: S(d)\otimes A^2 \to U^d_L$ is the inclusion.

We use the notation $U^d$, when $L, G$ are clear from the context.

Since the hyperbolic restriction $\Phi_{L,G}$ depends on $P$, the space $U^d_{L,G}$ depends also on $P$. When we want to emphasize $P$, we denote it by $U^d_{L,G}^P$ or simply by $U^d_P$.

We have a natural evaluation homomorphism
\begin{equation}
U^d \otimes C_S(d)\otimes A^2 \to \Phi_{L,G}(IC(U^d_G)),
\end{equation}
which gives the isotypical component of $\Phi_{L,G}(IC(U^d_G))$ corresponding to the simple perverse sheaf $C_S(d)\otimes A^2$.

By the factorization §2(iv) together with the Thom isomorphism $i^*j_!(C_{Bun_{d_L}^1}) \cong C_{Bun_{d_L}^1}$, we get

**Proposition 4.28.** We have the canonical isomorphism
\begin{equation}
\Phi_{L,G}(IC(U^d_G)) \cong \bigoplus IC(Bun_{L,\lambda}^{d_1}, \rho).
\end{equation}
Here $\rho$ is the (semisimple) local system on $Bun_{L,\lambda}^{d_1} = Bun_L^{d_1} \times S_{\lambda}\otimes A^2$ with $\lambda = (1^{n_1}2^{n_2}\cdots)$ corresponding to the representation of $S_{n_1} \times S_{n_2} \times \cdots$ on $(U^1)^{\otimes n_1} \otimes (U^2)^{\otimes n_2} \otimes \cdots$ given by permutation of factors.

For example, the isotypical component for the intersection cohomology complex $IC(Bun_{L,\lambda}^{d_1})$ for the trivial simple local system is
\begin{equation}
\text{Sym}^{n_1} U^1 \otimes \text{Sym}^{n_2} U^2 \otimes \cdots,
\end{equation}
where Sym denotes the symmetric power.

**Lemma 4.31.** Suppose \( L = T \). We have

\[
H^*(S^d \mathbb{A}^2, \Phi_{T,G}(\text{IC}(U^d_G))) \cong \bigoplus_{|\lambda|=d} \text{Sym}^{n_1} U^1 \otimes \text{Sym}^{n_2} U^2 \otimes \cdots
\]

where \( \lambda = (1^{n_1}; 2^{n_2}; \ldots) \).

**Proof.** Since \( L = T \), we have \( U^d_T = S^d \mathbb{A}^2 \). See Example 4.8. Then the assertion means that only trivial representation of \( S_{n_1} \times S_{n_2} \times \cdots \) contribute to the global cohomology group.

Let \( U \) be an open subset of \((\mathbb{A}^2)^{n_1} \times (\mathbb{A}^2)^{n_2} \times \cdots\) consisting of pairwise disjoint \( n_1 \) ordered points, \( n_2 \) ordered points, and so on in \( \mathbb{A}^2 \). Forgetting orderings, we get an \((S_{n_1} \times S_{n_2} \times \cdots)\)-covering \( p: U \to S_3 \mathbb{A}^2 \). The pushforward of the trivial rank 1 system with respect to \( p \) is the regular representation \( \rho_{\text{reg}} \) of \( S_{n_1} \times S_{n_2} \times \cdots \).

Since \( p \) extends to a finite morphism \((\mathbb{A}^2)^{n_1} \times (\mathbb{A}^2)^{n_2} \times \cdots \to S_3 \mathbb{A}^2\), we have \( \text{IC}(S_3 \mathbb{A}^2, \rho_{\text{reg}}) = p_! (\mathcal{G}_x^{(\mathbb{A}^2)^{n_1} \times (\mathbb{A}^2)^{n_2} \times \cdots}) \). By the Künneth theorem, the global cohomology group \( H^*(\bullet) \) of the right hand side is \( H^*((\mathbb{A}^2)^{n_1}) \otimes H^*((\mathbb{A}^2)^{n_2}) \otimes \cdots \). This is 1-dimensional, and corresponds to the trivial isotypical component of \( \rho_{\text{reg}} \). Now the assertion follows. \( \square \)

Let us continue the study of \( U^d \). Let us note that all of our spaces \( U^d_G, U^d_L, U^d_P \) have trivial factors \( \mathbb{A}^2 \) given by the center of instantons, or the translation on the base space \( \mathbb{A}^2 \) except \( d = 0 \) where \( U^d_G = U^d_L = U^d_P = \text{pt} \). We assume \( d \neq 0 \) hereafter. Let \( U^d_G \) denote the centered Uhlenbeck space at the origin, thus we have \( U^d_G = U^d_G \times \mathbb{A}^2 \). Let us compose factorization morphisms \( \pi_{h,G}^d, \pi^d_{v,G} \) for the horizontal and vertical projections \( h: \mathbb{A}^2 \to \mathbb{A}^1, v: \mathbb{A}^2 \to \mathbb{A}^1 \) with the sum map \( \sigma: S^d \mathbb{A}^1 \to \mathbb{A}^1 \). Then \( U^d_G = (\sigma \pi_{h,G}^d \times \sigma \pi^d_{v,G})^{-1}(0,0) \). We use the notation \( U^d_G, U^d_L, U^d_P \) for the centered spaces, and the factorization is compatible with the hyperbolic restriction. Let us use the same notation for \( i, j, p \) for the centered spaces. Then we have

\[
U^d = H^0(\xi^1_0 p_* j^1_! \text{IC}(U^d_G)),
\]

where \( \xi_0 \) is the inclusion of the single point \( d \cdot 0 \) in \( U^d_G \). Here \( d \cdot 0 \) is the point in \( S(d) \mathbb{A}^2 \), the origin with multiplicity \( d \).

By base change we get

\[
U^d \cong H^0(p^{-1}(d \cdot 0), j^1_! \text{IC}(U^d_G)),
\]

where \( j: p^{-1}(d \cdot 0) \to U^d_G \) is the inclusion.
Note that the spaces of homomorphisms between objects in ${\text{Perv}}(\mathcal{U}_d^d)$ are canonically isomorphic for equivariant category with respect to $L \times \mathbb{C}^* \times \mathbb{C}^*$ and non-equivariant one. (See [39, 1.16(a)].) Therefore (4.29) is an isomorphism in the equivariant derived category, though we use the factorization, which is not equivariant with respect to $\mathbb{C}^* \times \mathbb{C}^*$.

We have

**Lemma 4.35.**

\[(4.36) \dim U^d = \text{rank } G - \text{rank}[L, L].\]

**Proof.** According to a theorem of Laumon [37] the Euler characteristic of the stalk of $\text{IC}(\mathcal{U}_d^d)$ at a point of $S_{(d)} \mathbb{A}^2$ is equal to the Euler characteristic of the stalk of $\Phi_{L,G}(\text{IC}(\mathcal{U}_d^d))$ at the same point; the former was computed in Theorem 7.10 in [20].

First, let us give a proof in the case $L = T$. Then it is easy to see that Proposition 4.28 implies that the stalk of $\Phi_{T,G}(\text{IC}(\mathcal{U}_d^d))$ at a point of $S_{(d)} \mathbb{A}^2$ is isomorphic to $\text{Sym}^d(\oplus_i U^i_{T,G})$, where we regard $\oplus_i U^i_{T,G}$ as a graded vector space (with the natural grading coming from $i$) and the super-script $d$ means degree $d$ with respect to that grading. Comparing it with Theorem 7.10 of [20] (and using induction on $d$), we get $\dim U^d_{T,G} = \text{rank}(G)$ for every $d$.

Let us now consider the case of arbitrary $L$. Again, it is easy to deduce from Proposition 4.28 that the stalk of $\Phi_{T,L}(\Phi_{L,G}(\text{IC}(\mathcal{U}_d^d))) \simeq \Phi_{T,G}(\text{IC}(\mathcal{U}_d^d))$ at a point of $S_{(d)} \mathbb{A}^2$ is isomorphic to

$$\bigoplus_{d_1 + d_2 = d} \text{Sym}^{d_1}(\oplus_i U^i_{T,L}) \otimes \text{Sym}^{d_2}(\oplus_j U^j_{L,G}),$$

where the meaning of the super-scripts $d_1$ and $d_2$ is as above. In view of the preceding paragraph, we get $\dim U^d_{T,G} = \text{rank}(G) - \text{rank}([L, L])$. \qed

The dimension estimate Corollary A.9 and the argument in [42, Prop. 3.10] implies that

\[(4.37) H^0(p^{-1}(d \cdot 0), \tilde{j}^! \text{IC}(\mathcal{U}_d^d)) \simeq H^0(p^{-1}(d \cdot 0) \cap \text{Bun}_G^d, \tilde{j}^! \text{IC}(\mathcal{U}_d^d)) = H_{0}(p^{-1}(d \cdot 0) \cap \text{Bun}_G^d, \mathbb{C}).\]

Here we use the degree shift convention of the Borel-Moore homology group (see Convention (iv)), which is shift by $\dim \mathcal{U}_d^d = 2dh^\vee - 2$ in this case.

Let us set

\[(4.38) \mathcal{U}_{F,0}^d \overset{\text{def.}}{=} p^{-1}(d \cdot 0).\]
The subscript 0 stands for $d \cdot 0$, and this convention will be also used later. More generally, we denote $p^{-1}(x)$ by $U^{d}_{P,x}$ for $x \in U^{d}_{P}$.  

Then $H^{0}(U^{d}_{P,0} \cap \text{Bun}^{d}_{G}, \mathbb{C})$ has a base given by $(dh^{\vee} - 1)$-dimensional irreducible components of $U^{d}_{P,0} \cap \text{Bun}^{d}_{G}$. The dimension estimate Corollary A.9 implies that $U^{d}_{P,0} \cap \text{Bun}^{d'}_{G}$ $(d' < d)$ is lower-dimensional. Therefore

**Lemma 4.39.** We have

\[ U^{d} \cong H^{0}(U^{d}_{P,0}). \]

This space has a base given by $(dh^{\vee} - 1)$-dimensional irreducible components of $U^{d}_{P,0}$.

4(ix). **Irreducible components.** Let us describe $(dh^{\vee} - 1)$-dimensional irreducible components of $U^{d}_{B,0}$ for $P = B$ explicitly. We believe that there is no irreducible component of smaller dimension (see Remark A.7), but we do not have a proof.

First consider the case $G = SL(2)$. By Lemma 4.35 we have $\dim U^{d} = 1$, and hence $U^{d}_{B,0}$ has only one $(2d - 1)$-dimensional irreducible component. As we have observed in the previous subsection, it is the closure of $U^{d}_{B,0} \cap \text{Bun}^{d}_{G}$. In §5(viii), it will be shown that $U^{d}_{B,0} \cap \text{Bun}^{d}_{G}$ consists of rank 2 vector bundles $E$ arising from a short exact sequence

\[ 0 \to \mathcal{O} \to E \to \mathcal{I} \to 0 \]

compatible with framing, where $\mathcal{I}$ is an ideal sheaf of colength $d$.

For a general $G$, consider the diagram (4.19) with $M = T$, $L = L_{i}$ the Levi subgroup corresponding to a simple root $\alpha_{i}$. Note that $[L_{i}, L_{i}] \cong SL(2)$, and hence $U^{d}_{L_{i}}$ is homeomorphic to $U^{d}_{SL(2)}$. Therefore $U^{d}_{B_{L_{i}},0} \cap \text{Bun}^{d}_{L_{i}}$ is irreducible of dimension $2d - 1$ by the above consideration.

**Proposition 4.42.** The irreducible components of $U^{d}_{B,0}$ of dimension $dh^{\vee} - 1$ are the closures of $p^{-1}(U^{d}_{B_{L_{i}},0} \cap \text{Bun}^{d}_{L_{i}})$ for $i \in I$. Let us denote the closure by $Y_{i}$.

**Proof.** Consider the upper right part of (4.19), which is (4.12). Its restriction to the open subset $\text{Bun}^{d}_{L_{i}}$ has been described in §4(vii). As $p$ is a vector bundle whose rank is equal to the half of the codimension of $\text{Bun}^{d}_{L_{i}}$ in $\text{Bun}^{d}_{G}$, it follows that the inverse image $p^{-1}(U^{d}_{B_{L_{i}},0} \cap \text{Bun}^{d}_{L_{i}})$ is irreducible and has dimension $dh^{\vee} - 1$. Therefore the closure of $p^{-1}(U^{d}_{B_{L_{i}},0} \cap \text{Bun}^{d}_{L_{i}})$ is an irreducible component of $U^{d}_{B,0}$.

Since $\dim U^{d} = \text{rank } G$ by Lemma 4.35, it is enough to check that $p^{-1}(U^{d}_{B_{L_{i}},0} \cap \text{Bun}^{d}_{L_{i}}) \neq p^{-1}(U^{d}_{B_{L_{j}},0} \cap \text{Bun}^{d}_{L_{j}})$ if $i \neq j$. When $G = SL(r)$,
\( U^d_{B,0} \cap \text{Bun}^d \) consists of vector bundles \( E \) having a filtration \( 0 = E_0 \subset E_1 \subset \cdots \subset E_r = E \) compatible with framing. Moreover \( p^{-1}(U^d_{B,I_{L_i},0} \cap \text{Bun}^d_I) \) consists of those with \( c_2(E_i/E_{i-1}) = d \) and \( c_2(E_j/E_{j-1}) = 0 \) for \( j \neq i \). Therefore \( p^{-1}(U^d_{B,I_{L_i},0} \cap \text{Bun}^d_I) \neq p^{-1}(U^d_{B,I_{L_j},0} \cap \text{Bun}^d_I) \) for \( i \neq j \). (See §5(viii) for detail.) For a general \( G \), we embed \( G \) into \( SL(N) \). Then we need to replace \( B \) by a parabolic \( P \), but \( p^{-1}(U^d_{B,I_{L_i},0} \cap \text{Bun}^d_I) \) is embedded into a corresponding space, and the same argument still works. \( \square \)

4(x). A pairing on \( U^d \). Let us introduce a pairing between \( U^{d,P} \) and \( U^{d,P-} \) in this subsection.

We combine Braden’s isomorphism (3.16) with the natural homomorphism \( \xi_0^i \to \xi_0^* \) to get
\[
H^0(\xi_0^i j^* IC(\mathcal{U}^d_G)) \to H^0(\xi_0^* i^j IC(\mathcal{U}^d_G)).
\]
The right hand side is dual to
\[
U^{d,P-} = H^0(\xi_0^* i^j IC(\mathcal{U}^d_G)).
\]
Thus we have a pairing between \( U^{d,P} \) and \( U^{d,P-} \). Following the convention in [40, 3.1.3], we multiply the pairing by the sign \((-1)^{\dim \mathcal{U}^d_G/2} = (-1)^{d_{\text{rank}} - 1} \). Let us denote it by \( \langle , \rangle \). When we want to emphasize that it depends on the choice of the parabolic subgroup \( P \), we denote it by \( \langle , \rangle_P \).

Since \( \xi_0^* \mathcal{C}_{d,0} \to \xi_0^* \mathcal{C}_{d,0} \) is obviously an isomorphism, this pairing is nondegenerate.

The transpose of the homomorphism \( U^{d,P} \to (U^{d,P-})^\vee \) is a linear map \( U^{d,P-} \to (U^{d,P})^\vee \). It is
\[
H^0(\xi_0^i j^* IC(\mathcal{U}^d_G)) \to H^0(\xi_0^* i^j IC(\mathcal{U}^d_G)),
\]
given by the transpose of the composite of \( \xi_0^i \to \xi_0^* \) and Braden’s isomorphism \( i^* j^* \to i^j \). They are the same as original homomorphisms \( \xi_0^i \to \xi_0^* \) and \( i^* j^* \to i^j \) respectively. It means that
\[
\langle u, v \rangle_P = \langle v, u \rangle_P \quad \text{for } u \in U^{d,P}, \ v \in U^{d,P-},
\]
where \( \langle , \rangle_P \) is the pairing defined with respect to the opposite parabolic, i.e., one given after exchanging \( i, j \) and \( i^\vee, j^\vee \) respectively.

4(xi). Another base of \( U^d \). We next construct another base of \( U^d = U^d_{T,G} \) for \( L = T \), which is \((\text{rank } G)\)-dimensional by Lemma 4.35. This new base is better behaved under hyperbolic restrictions than the previous one given by irreducible components.
This subsection is preliminary, and the construction will be completed in §6(ii).

We study \( U^d_{T,L} \), using the associativity of the hyperbolic localization (Proposition 4.16) for \( M = T, L = L_i \) the Levi subgroup corresponding to a simple root \( \alpha_i \). Since various Levi subgroups appear, we use the notation \( U^d_{T,G} \) indicating groups we are considering.

Note that \([L_i, L_i] \cong SL(2)\), and hence \( U^d_{L_i} \) is homeomorphic to \( U^d_{SL(2)} \). We understand \( IC(U^d_{L_i}) \) as \( IC(U^d_{SL(2)}) \) and apply Lemma 4.35 to see that

\[
U^d_{T,L_i} = \text{Hom}_{\text{Perv}(U^d_{T})}(C_{S(d)A^2}, \Phi_{T,L_i}(IC(U^d_{L_i})))
\]

is 1-dimensional. In the next section, we shall introduce an element \( 1^d_{L_i} \) in \( U^d_{T,L_i} \) using the theory of the stable envelop in (40).

Taking \( L = L_i \) in the construction in §4(vii), we apply the functor \( \Phi_{T,L_i} \). By Proposition 4.16 we get an element

\[
\Phi_{T,L_i}(1^d_{L_i,G}) \in \text{Hom}_{\text{Perv}(U^d_{T})}(\Phi_{T,L_i}(IC(U^d_{L_i})), \Phi_{T,G}(IC(U^d_{G}))).
\]

Composing with the element \( 1^d_{L_i} \) in \( U^d_{T,L_i} \) mentioned just above, we get

\[
\Phi_{T,L_i}(1^d_{L_i,G}) \circ 1^d_{L_i} \in U^d_{T,G}.
\]

We have \((\text{rank}\ G)\)-choices of \( i \). Then we will show that

\[
\{ \tilde{\alpha}^d_i \text{ def.} = \Phi_{T,L_i}(\delta 1^d_{L_i,G}) \circ 1^d_{L_i} \}_i
\]

gives a basis of \( U^d_{T,G} \) in the next subsection. Here we will introduce an appropriate polarization \( \delta = \pm 1 \), using a consideration of rank 2 case. See (6.6). Moreover, this will gives us an identification \( U^d_{T,G} \) with the Cartan subalgebra \( \mathfrak{h} \) of \( \mathfrak{g} \) such that \( \tilde{\alpha}^d_i \) is sent to the \( i \)th simple coroot \( \alpha_i^\vee \). See a remark after Proposition 6.15.

We normalize the inclusion \( IC(U^d_{L_i}) \rightarrow \Phi_{L_i,G}(IC(U^d_{G})) \) by \( \delta 1^d_{L_i,G} \) as above. Then the projection \( \Phi_{L_i,G}(IC(U^d_{L_i})) \rightarrow IC(U^d_{L_i}) \) is also determined, as \( IC(U^d_{L_i}) \) has multiplicity 1 in \( \Phi_{L_i,G}(IC(U^d_{G})) \) (see §4(vii)). Therefore we have the canonical isomorphism

\[
\Phi_{L_i,G}(IC(U^d_{G})) \cong IC(U^d_{L_i}) \oplus IC(U^d_{L_i})^\perp,
\]

where \( IC(U^d_{L_i})^\perp \) is the sum of isotypical components for simple factors not isomorphic to \( IC(U^d_{L_i}) \). Applying \( \Phi_{T,L_i} \) and using \( \Phi_{T,L_i}, \Phi_{L_i,G} = \Phi_{T,G} \), we get an induced decomposition

\[
U^d_{T,G} = U^d_{T,L_i} \oplus (U^d_{T,L_i})^\perp.
\]

This decomposition is orthogonal with respect to the pairing in §4(x) in the following sense. We have the decomposition \( U^d_{T,G} = U^d_{T,L_i} \oplus \)}
\[(U^{d,B-\cap L_i})^\perp\] for the opposite Borel \(B_-,\) and
\[(4.53) \quad \langle U^d_{T,L_i},(U^{d,B-\cap L_i})^\perp\rangle = 0 = \langle (U^d_{T,L_i})^\perp,U^{d,B-\cap L_i}_{T,L_i}\rangle.\]

Moreover the restriction of the pairing to \(U^{d,B\cap L_i}_{T,L_i}, U^{d,B-\cap L_i}_{T,L_i}\) coincides with one defined via \(U^d_{L_i}.\)

4(xii). **Dual base.** Let \(\tilde{\alpha}_i^{d-}\) denote the element defined as \(\tilde{\alpha}_i^d\) for the opposite Borel. We shall prove
\[(4.54) \quad \langle [Y_j], \tilde{\alpha}_i^{d-}\rangle = \pm \delta_{ij} (-1)^{d-1} d\]
modulo the computation for \(G = SL(2),\) corresponding to the case \(i = j\) in this subsection. The computation for \(G = SL(2)\) will be given in Remark 5.95. This formula means that \(\tilde{\alpha}_i^{d-}\) is the dual base to the base given by irreducible components \(Y_j\) with respect to the pairing \(\langle \cdot, \cdot \rangle\)
up to sign.

Consider the diagram (4.19) for the centered version, where we take \(M = T, L = L_i\) as in §4(xi). Let us consider the open embedding of \(c \text{Bun}_{L_i}^d\) to \(\mathcal{U}_{L_i}^d.\) We have the corresponding restriction homomorphism
\[
U^d_{T,G} = H^0(\xi_0^d(p^0 \circ j^0)) = H^0(\xi_0^d j^0 \Phi_{L_i,G}(\text{IC}(\mathcal{U}_{L_i}^d)))
\]
\[
\cong H^0(\xi_0^d j^0 \Phi_{L_i,G}(\text{IC}(\mathcal{U}_{L_i}^d)))
\]
\[(4.55) \quad \cong H^0(p^0 \circ j^0) \mid_{\text{cBun}_{L_i}^d, j^0 \Phi_{L_i,G}(\text{IC}(\mathcal{U}_{L_i}^d)))}
\]

where \(j^0\) is the restriction of \(j^0\) to \(p^0 \cap (d \cdot 0)\). When we restrict \(\Phi_{L_i,G}(\text{IC}(\mathcal{U}_{L_i}^d))\)
to the open set \(\text{cBun}_{L_i}^d,\) the first summand \(\text{IC}(\mathcal{U}_{L_i}^d)\) in the decomposition (4.51) is replaced by the constant sheaf \(\mathcal{C}_{\text{cBun}_{L_i}^d}\), and the second summand is killed. Therefore we have an isomorphism
\[
H^0(p^0 \circ j^0) \mid_{\text{cBun}_{L_i}^d, j^0 \Phi_{L_i,G}(\text{IC}(\mathcal{U}_{L_i}^d)))}
\]
\[
\cong H^0(p^0 \circ j^0) \mid_{\text{cBun}_{L_i}^d, \mathcal{C}) \cong U^d_{T,L_i}
\]

where the second isomorphism is nothing but (4.37) for \(G\) replaced by \(\mathcal{L}_i.\)

Thus the projection \(U^d_{T,G} \rightarrow U^d_{T,L_i}\) to the first summand in (4.52) is nothing but the restriction homomorphism we have just constructed.

Let us further consider the restriction of the upper right corner of the diagram (4.19) to the open subset \(\text{cBun}_{L_i}^d.\) Then
\[
p^0 \circ j^0 \mid_{\text{cBun}_{L_i}^d} = p^0 \circ (U^d_{L_i,0} \cap \text{cBun}_{L_i}^d)
\]
has been studied in §4(ix): Its closure is an irreducible component of $\mathcal{U}^d_{B,0}$. By the base change the restriction to $c\text{Bun}^d_{L_i}$ is replaced by one to $p^{-1}(\mathcal{U}^d_{B_{L_i},0} \cap c\text{Bun}^d_{L_i})$, and we can replace relevant IC sheaves by constant sheaves. The Thom isomorphism gives us $p_*j'\mathcal{C}_{\text{Bun}^d_G} \cong \mathcal{C}_{\text{Bun}^d_{L_i}}$ as in §4(vii). Note that the intersection of an irreducible component $Y_j$ of Proposition 4.42 with the open subset $p^{-1}(\mathcal{U}^d_{B_{L_i},0} \cap c\text{Bun}^d_{L_i})$ is lower-dimensional if $i \neq j$, as $p^{-1}(\mathcal{U}^d_{B_{L_i},0} \cap c\text{Bun}^d_{L_i})$ is irreducible. Therefore the fundamental class of $Y_j$ goes to 0 under the restriction. Hence we have (4.54) for $i \neq j$ by (4.53). In fact, we will see that $Y_j \cap p^{-1}(\mathcal{U}^d_{B_{L_i},0} \cap c\text{Bun}^d_{L_i}) = \emptyset$ for type A in §5(viii), and the same is true for any $G$ thanks to an embedding $G \to SL(N)$.

The Thom isomorphism sends $[Y_j]$ to $[\mathcal{U}^d_{B_{L_i},0}]$ from the definition of $Y_j$. The sign in (4.54) appears as we multiply the Thom isomorphism by a polarization $\delta$ (see (6.6) below). Therefore the computation of (4.54) for $i = j$ is reduced to the case $G = SL(2)$. The relevant computation will be given in Remark 5.95 as we mentioned above.

4(xiii). Aut$(G)$ invariance. Let Aut$(G)$ be the group of automorphisms of $G$. Its natural action on $\text{Bun}^d_G$ extends to $\mathcal{U}^d_G$ ([20, §6.1]).

Let us fix a cocharacter $\lambda: \mathbb{G}_m \to G$, and consider our construction with respect to $\sigma \circ \lambda$ for $\sigma \in \text{Aut}(G)$. Here $L = G^{N(\mathbb{G}_m)}$ is considered as a fixed Levi subgroup. Substituting $\sigma \circ \lambda$ into $\lambda$ in the formula (4.14), we define a pair $(P^\sigma, L^\sigma)$ of a parabolic subgroup and its Levi part. The action $\varphi_\sigma: \mathcal{U}^d_G \to \mathcal{U}^d_G$ induces $\varphi_\sigma: \mathcal{U}^d_P \to \mathcal{U}^d_P, \varphi_\sigma: \mathcal{U}^d_L \to \mathcal{U}^d_L$, and we have a commutative diagram

\[
\begin{array}{ccc}
\mathcal{U}^d_L & \xrightarrow{i} & \mathcal{U}^d_P \\
| \varphi_\sigma | & | \varphi_\sigma | & | \varphi_\sigma |
\end{array}
\]

\[
\begin{array}{ccc}
\mathcal{U}^d_{L^\sigma} & \xrightarrow{i} & \mathcal{U}^d_P \\
| \varphi_\sigma | & | \varphi_\sigma | & | \varphi_\sigma |
\end{array}
\]

(4.56)

where the subscript $\sigma$ indicates morphisms between spaces for $\sigma \in \text{Aut}(G)$.

Since $\text{IC}(\mathcal{U}^d_G)$ is an Aut$(G)$-equivariant perverse sheaf, we have an isomorphism $\varphi_\sigma^* \text{IC}(\mathcal{U}^d_G) \cong \text{IC}(\mathcal{U}^d_G)$. Therefore we have an isomorphism

\[
i^*j^! \text{IC}(\mathcal{U}^d_G) \cong \varphi_\sigma^*i^*j^! \text{IC}(\mathcal{U}^d_G).
\]

(4.57)

The isomorphism (4.57) is equivariant in the following sense: The right hand side is a $T^\sigma = T^\times \mathbb{C}^* \times \mathbb{C}^*$-equivariant perverse sheaf, while the left hand side is $T$-equivariant. The isomorphism (4.57) respects equivariant structures under the group isomorphism $\sigma: T \xrightarrow{\cong} T^\sigma$. In
particular, we have an isomorphism
\begin{equation}
\varphi_\sigma : H^*_\mathbb{T}(U^d_L, i^*j^! \text{IC}(U^d_G)) \xrightarrow{\cong} H^*_\mathbb{T^\sigma}(U^d_{L^\sigma}, i^*_\sigma j^!_\sigma \text{IC}(U^d_{G^\sigma})),
\end{equation}
which respects the $H^*_\mathbb{T}(\text{pt})$ and $H^*_\mathbb{T^\sigma}(\text{pt})$ structures via $\mathbb{T} \cong \mathbb{T^\sigma}$.

In the same way, we obtain a canonical isomorphism
\begin{equation}
U^d_{L,G} \xrightarrow{\varphi^\sigma} U^d_{L^\sigma,G},
\end{equation}
which is denoted also by $\varphi_\sigma$ for brevity.

The pairing $\langle \ , \ \rangle$ in §4(x) is compatible with $\varphi_\sigma$: Let us denote by $\langle \ , \ \rangle_{P^\sigma}$ the pairing between $U^d_{L^\sigma,G}$ and $U^d_{L^\sigma,G}$. We have $\varphi_\sigma : U^d_{L,G} \xrightarrow{\cong} U^d_{L^\sigma,G}$ as above, and the following holds
\begin{equation}
\langle \varphi_\sigma(u), \varphi_\sigma(v) \rangle_{P^\sigma} = \langle u, v \rangle_P, \quad u \in U^d_{L,G}, v \in U^d_{L^\sigma,G}.
\end{equation}

The decomposition (4.51) is transferred under $\varphi_\sigma$ to
\begin{equation}
i^*_\sigma j^!_\sigma \text{IC}(U^d_G) \cong \pm \text{IC}(U^d_{L^\sigma}) \oplus \text{IC}(U^d_{L^\sigma})^\perp.
\end{equation}

Here the sign $\pm$ means that we multiply the projection to $\text{IC}(U^d_{L^\sigma})$ by $\pm$, according to whether $\sigma$ respects the polarization $\delta$ for $U^d_{L}$ and $U^d_{L^\sigma}$ or not. Our polarization will be invariant under inner automorphisms, so the sign depends on diagram automorphisms $\text{Aut}(G)/\text{Inn}(G)$. The decomposition (4.52) is mapped to
\begin{equation}
U^d_{L^\sigma,G} = U^d_{T^\sigma,G} \oplus (U^d_{T^\sigma,G})^\perp.
\end{equation}

Suppose $\sigma \in L$. We have $L^\sigma = L$, $P^\sigma = P$, $i^\sigma = i$, $j^\sigma = j$. Then $i^* j^! \text{IC}(U^d_G)$ is an $L$-equivariant perverse sheaf, and (4.57) is the isomorphism induced by the equivariant structure.

Let us further assume $L = T$. Then $T$ acts trivially on $U^d_{L} = S^d \mathbb{A}^2$, and $\varphi_\sigma|_{U^d_{L}} = \text{id}$. The equivariant structure of the $T$-equivariant perverse sheaf $i^* j^! \text{IC}(U^d_G)$ is trivial. In particular, the isomorphism (4.57) is the identity. Therefore (4.57) is well-defined for $\sigma \in \text{Aut}(G)/(T/Z(G))$, where $Z(G)$ is the center of $G$.

Note that chambers of hyperbolic restrictions for $L = T$ are Weyl chambers. They appear as a subfamily for $W = N_G(T)/T$ in $\text{Aut}(G)/(T/Z(G))$.

Let us take $\sigma = w_0$, the longest element of the Weyl group. Then $B^{w_0} = B_{-}$. We come back to $B$ via (4.46), and hence we get
\begin{equation}
\langle u, v \rangle_B = \langle \varphi_{w_0}(u), \varphi_{w_0}(v) \rangle_{B_{-}} = \langle \varphi_{w_0}(v), \varphi_{w_0}(u) \rangle_B
\end{equation}
for $u \in U^d_{T,G}, v \in U^d_{T,G}$.

We can take $\sigma \in \text{Aut}(G)$, which preserves $T$ and the set of positive roots, and induces a Dynkin diagram automorphism. Then $B^\sigma = B$. 

Hence \( U_{T,G}^{d,B} \) is a representation of the group of Dynkin diagram automorphisms. The inner product is preserved.

We have \( L_i^d = L_{\sigma(i)} \), where \( \sigma(i) \) is the vertex of the Dynkin diagram, the image of \( i \) under the corresponding Dynkin diagram automorphism. From (4.61) \( \varphi_{\sigma}(\tilde{\alpha}_d^i) \) is equal to \( \tilde{\alpha}_d^{\sigma(i)} \) up to scalar. We will prove the following in §5(xiv).

**Lemma 4.64.** We have

\[
\varphi_{\sigma}(\tilde{\alpha}_d^i) = \pm \tilde{\alpha}_d^{\sigma(i)},
\]

where \( \pm \) is the ratio of the polarizations for \( \text{Bun}_{d,L}^i \) and \( \text{Bun}_{d,L_{\sigma(i)}}^i \), compared under \( \varphi_{\sigma} \).

5. Hyperbolic restriction in type A

We shall study the case \( G = SL(r) \) in detail in this section.

We have the moduli space \( \tilde{U}_r^d \) of framed torsion free sheaves \( (E, \varphi) \) of rank \( r \), second Chern class \( d \) over \( \mathbb{P}^2 \). It is called the Gieseker space. We have a projective morphism \( \pi \) (the Gieseker-Uhlenbeck morphism) from \( \tilde{U}_r^d \) to the corresponding Uhlenbeck space \( U_r^d \). It is known that \( \tilde{U}_r^d \) is smooth and \( \pi \) is a semi-small resolution of singularities. Therefore we can study \( \text{IC}(U_r^d) \) via the constant sheaf \( C_{\tilde{U}_r^d} \) over \( \tilde{U}_r^d \). (See [47, Ch. 3,5,6], where \( \tilde{U}_r^d, U_r^d \) are denoted by \( \mathcal{M}(n,r), \mathcal{M}_0(n,r) \) respectively. See also [54, Ch.3] for further detail.)

If \( r = 1 \), we understand \( \tilde{U}_r^d \) as the Hilbert scheme \( \text{Hilb}^d(\mathbb{A}^2) \) of \( d \) points on \( \mathbb{A}^2 \), while \( U_r^d \) is the symmetric power \( S^d\mathbb{A}^2 \).

5(i). Gieseker-Uhlenbeck. Let us first explain the relation between \( \text{IC}(U_r^d) \) and \( C_{\tilde{U}_r^d} \) in more detail.

We have the Gieseker-Uhlenbeck morphism \( \pi : \tilde{U}_r^d \to U_r^d \). It is semi-small with respect to the standard stratification (2.3). All strata are relevant and fibers are irreducible. Therefore

\[
\pi_! C_{\tilde{U}_r^d} \cong \bigoplus_{d_i + |\lambda| = d} H_{\text{top}}(\pi^{-1}(x_{\lambda}^{d_i})) \otimes \text{IC}(\text{Bun}_{G,\lambda}^{d_i}),
\]

where \( x_{\lambda}^{d_i} \) is a point in the stratum \( \text{Bun}_{G,\lambda}^{d_i} \). See [5, §3].

We identify \( H_{\text{top}}(\pi^{-1}(x_{\lambda}^{d_i})) \cong \mathbb{C} \) by the fundamental class \( [\pi^{-1}(x_{\lambda}^{d_i})] \). And \( \text{IC}(U_r^d,\lambda) \) is isomorphic to the pushforward of \( \text{IC}(U_r^d) \otimes C_{\tilde{U}_r^d} \) under the finite morphism (2.6). Then we have

\[
H_{\pi}^*(\tilde{U}_r^d) \cong \bigoplus H_{\pi}^*(U_r^d) \otimes H_{\text{top}}(\pi^{-1}(x_{\lambda}^{d_i})) \otimes H_{\pi}^*(S_{\lambda,\mathbb{A}^2}).
\]
We also have the corresponding isomorphism for the cohomology with compact support.

5(ii). **Heisenberg operators.** For $r = 1$, the third author and Grojnowski independently constructed operators acting on the direct sum of homology groups of $\tilde{U}_r^d$ satisfying the Heisenberg relation (see [47, Ch. 8]). It was extended by Baranovsky to higher rank case [5]. Let us review his construction in this subsection.

We consider here both $H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^d)$ and $H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^d)$, the equivariant cohomology with arbitrary and compact support, which is Poincaré dual to Borel-Moore and the ordinary equivariant homology groups. To save the notation, we use the notation $H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^d)$ meaning either of cohomology groups.

For $n > 0$ we consider subvariety

$$P_n \subset \bigcup_d \tilde{U}_r^d \times \tilde{U}_r^{d+n} \times \mathbb{A}^2,$$

consisting of triples $(E_1, E_2, x)$ such that $E_1 \supset E_2$ and $E_1/E_2$ is supported at $x$. We have

**Proposition 5.4.** $P_n$ is half-dimensional in $\tilde{U}_r^d \times \tilde{U}_r^{d+n} \times \mathbb{A}^2$ for each $d$.

Let us denote the projection to the third factor by $\Pi$. For a cohomology class $\alpha \in H^{[s]}_{\mathbb{T},c}(\mathbb{A}^2)$, we consider $P^\Delta_n(\alpha) = [P_n] \cap \Pi^*(\alpha)$ as a correspondence in $\tilde{U}_r^d \times \tilde{U}_r^{d+k}$. Then we have the convolution product

$$P^\Delta_n(\alpha) : H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^d) \to H^{[s+\deg \alpha]}_{\mathbb{T},c}(\tilde{U}_r^{d+n}).$$

Thanks to the previous proposition, the shift of the degree is simple in our perverse degree convention. The reason why we put $\Delta$ in the notation will be clear later.

We define $P^{\Delta}_n(\alpha)$ as the adjoint operator

$$P^{\Delta}_n(\alpha) : H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^{d+n}) \to H^{[s+\deg \alpha]}_{\mathbb{T},c}(\tilde{U}_r^d).$$

Here we have two remarks. First we follow the sign convention in [40, 3.1.3] for the intersection pairing

$$\langle \bullet, \bullet \rangle = (-1)^{\dim X/2} \int_X \bullet \cup \bullet.$$

Second, we take $\alpha \in H^{[s]}_{\mathbb{T},c}(\mathbb{A}^2)$ for $H^{[s]}_{\mathbb{T}}(\tilde{U}_r^d)$ and $\alpha \in H^{[s]}_{\mathbb{T}}(\mathbb{A}^2)$ for $H^{[s]}_{\mathbb{T},c}(\tilde{U}_r^d)$. Then the operators are well-defined, though various projections are not proper. (See [47, §8.3].)
We have the commutator relation
\[(5.8) \quad [P^\Delta_m(\alpha), P^\Delta_n(\beta)] = \langle \alpha, \beta \rangle m\delta_{m+n,0}.\]

If \(m + n = 0\), one of \(\alpha\) or \(\beta\) is in \(H^*_{T^c}(\mathbb{A}^2)\) and another is in \(H^*_{T^c}(\mathbb{A}^2)\). Hence \(\langle \alpha, \beta \rangle\) is well-defined.

Since the construction is linear over \(H^*_{T^c}(\text{pt})\), and \(H^*_{T^c}(\mathbb{A}^2)\), \(H^*_c(\mathbb{A}^2)\) are free of rank 1, we can choose \(\alpha\) to be their generators, i.e., the Poincaré dual of [0] for \(H^*_{T^c}(\mathbb{A}^2)\), and 1 (dual of [\(\mathbb{A}^2\)]) for \(H^*_c(\mathbb{A}^2)\). We assume these choices hereafter until §6. Note also that \(\langle [0], 1 \rangle = -1\) in our sign convention.

We take the direct sum over \(d\) in (5.2):
\[(5.9) \quad \bigoplus_d H^*_{T^c}(\mathcal{U}_d^d) \cong \bigoplus_d H^*_{T^c}(\mathcal{U}_d^d) \otimes \bigoplus_\lambda H_{\text{top}}(\pi^{-1}(x^d_\lambda)) \otimes H^*_c(S_{\lambda}A^2).\]

Note that \(H^*_{T^c}(S_{\lambda}A^2) \cong H^*_{T^c}(\text{pt}) \cdot 1\), as \(S_{\lambda}A^2\) is equivariantly contractible. Here \(1 \in H^0_{T^c}(S_{\lambda}A^2) = H^*_{T^c}[2(\lambda)](S_{\lambda}A^2)\).

From the definition of the Heisenberg operators, it acts only on the second factor of (5.9): \(\lambda = 0\) are killed by \(P^\Delta_k([0])\) \((k > 0)\) and the summand for \(\lambda = (1^n_1 2^{n_2} \cdots)\) is spanned by the monomial in \(P_{-1}(1)^{n_1}/n_1! \cdot P_{-2}(1)^{n_2}/n_2! \cdots\). The second factor is isomorphic to the Fock space.

Let us give another representation of the Heisenberg algebra. Let 0 denote the point \(d \cdot 0 \in S(d)A^2\), and consider the inverse image \(\pi^{-1}(0) \subset \mathcal{U}_r^d\), and denote it by \(\mathcal{U}_r^d\). It is the Quot scheme parametrizing quotients of \(O_{\mathbb{P}^2}\) of length \(d\) whose support is 0.

The following is known, and was already used in (5.1).

**Proposition 5.10.** \(\mathcal{U}_r^d\) is an irreducible \((dr - 1)\)-dimensional subvariety in \(\mathcal{U}_r^d\), unless \(d = 0\).

It is needless to say that we have \(\mathcal{U}_{r,0}^d = \mathcal{U}_r^0 = \text{pt.}\)

The convolution product by \(P_{\pm k}^\Delta(\alpha)\) sends \(H^*_{[s]}(\mathcal{U}_{r,0}^d)\) to \(H^*_{[s-deg \alpha]}(\mathcal{U}_{r,0}^{d+k})\), where \(\alpha \in H^*_{T^c}(\mathbb{A}^2)\) for \(k < 0\), \(\alpha \in H^*_T(\mathbb{A}^2)\) for \(k > 0\). Therefore
\[(5.11) \quad \bigoplus_d H^*_{[s]}(\mathcal{U}_{r,0}^d)\]

is a representation of the Heisenberg algebra. It is known that \(\mathcal{U}_r^d\) is homotopy equivalent to \(\mathcal{U}_r^1\), hence \(H^*_{[s]}(\mathcal{U}_{r,0}^d)\) is isomorphic to the ordinary homology group of \(\mathcal{U}_r^d\), and hence to \(H^*_c(\mathcal{U}_r^d)\) by the Poincaré duality.
5(iii). **Fixed points and polarization.** Let us take a decomposition \( r = r_1 + r_2 + \cdots + r_N \). We have the corresponding \((N - 1)\)-dimensional torus, which is the connected center \( A = Z(L)^0 \) of the Levi subgroup \( L = S(GL(r_1) \times \cdots \times GL(r_N)) \subset SL(r) \). We have the corresponding parabolic subgroup \( P \) consisting of block upper triangular elements.

Let us consider the fixed point set \( \tilde{U}_L^d = (\tilde{U}_L^d)^A \). It consists of framed sheaves, which is a direct sum of sheaves of rank \( r_1, r_2, \ldots, r_N \). Thus we have

\[
(5.12) \quad \tilde{U}_L^d = \bigsqcup_{d = d_1 + \cdots + d_N} \tilde{U}_{r_1}^{d_1} \times \cdots \times \tilde{U}_{r_N}^{d_N}.
\]

We omit the superscript \( d \), when there is no fear of confusion.

Following [40, Ex.3.3.3], we choose a polarization \( \delta \) for each component of \( \tilde{U}_L \), as a quiver variety associated with the Jordan quiver.

Let us review the construction quickly. See the original paper for more detail: We represent \( \tilde{U}_L \) as the space of quadruples \((B_1, B_2, I, J)\) satisfying certain conditions. We decide to choose pairs, say \((B_1, I)\), from quadruples. The choice gives us a decomposition of the tangent bundle of \( \tilde{U}_L \) as

\[
(5.13) \quad T\tilde{U}_r = T^{1/2} + (T^{1/2})^\vee
\]

in the equivariant \( K \)-theory with respect to the \( A \)-action on \( \tilde{U}_r \). We also have the decomposition of \( T\tilde{U}_L \), and hence also of the normal bundle. Then we choose a polarization \( \delta \) of \( \tilde{U}_L \) in \( \tilde{U}_r \) as product of weights in the normal bundle part of \((T^{1/2})^\vee\).

Let us also explain another description of the polarization \( \delta \) given in [40, §12.1.5]. We consider the following Quot scheme

\[
(5.14) \quad Q_r = \{ (E, \varphi) \mid x_2 O^{\oplus r} \subset E \subset O^{\oplus r} \} \subset \tilde{U}_r,
\]

where \( x_2 \) is one of coordinates of \( \mathbb{A}^2 \). This is a fixed point component of a certain \( \mathbb{C}^* \)-action, and is a smooth lagrangian subvariety in \( \tilde{U}_r \). In the ADHM description, it is given by the equation \( B_2 = 0 = J \). Now \((T^{1/2})^\vee\) is the normal direction to \( Q_r \) at a point in \( Q_r \). Since any component of \( \tilde{U}_L \) intersects with \( Q_r \), and the intersection is again a smooth lagrangian subvariety, \( Q_r \) gives us the polarization.

Note that the polarization is invariant under the action of \( G = SL(r) \) on \( \tilde{U}_r \), as we promised in §4(xiii).

We calculate the sign \( \pm \) of the ratio of this polarization \( \delta \) and the repellent one \( \delta_{\text{rep}} \), of \( \tilde{U}_L^d \times \tilde{U}_L^0 \) and \( \tilde{U}_L^0 \times \tilde{U}_L^d \) in \( \tilde{U}_L^d \) for a later purpose. Here \( L = S(GL(2) \times GL(1)) \) in the first case and \( L = S(GL(1) \times GL(2)) \) for the latter case.
Lemma 5.15. We have $\delta_{\text{rep}}/\delta = 1$ for $\tilde{U}_2^d \times \tilde{U}_1^0$, $\delta_{\text{rep}}/\delta = (-1)^d$ for $\tilde{U}_1^0 \times \tilde{U}_2^d$.

Proof. Both components $\tilde{U}_2^d \times \tilde{U}_1^0$, $\tilde{U}_1^0 \times \tilde{U}_2^d$ intersect with the open set $\pi_{a,G}^{-1}(S(1^d)A^1)$, the inverse image of the open stratum under the factorization morphism. Since the normal bundle decomposes according to the factorization, the polarization is of the form $(\pm 1)^d$. Hence it is enough to determine the case $d = 1$.

We factor out $A^2$ in $\tilde{U}_1^1$ and consider the centered Gieseker spaces. We have

\begin{equation}
\tilde{U}_3^1 \cong T^*\mathbb{P}^2,
\end{equation}

\begin{equation}
\tilde{U}_2^1 \times \tilde{U}_1^0 \cong T^*(z_2 = 0), \quad \tilde{U}_1^0 \times \tilde{U}_1^2 \cong T^*(z_0 = 0),
\end{equation}

where $[z_0 : z_1 : z_2]$ is the homogeneous coordinate system of $\mathbb{P}^2$. The polarization $\delta$ above is given by the base direction of the cotangent bundle.

On the other hand, the repellent directions are base in the first case and fibers in the second case. Therefore we have $\delta_{\text{rep}}/\delta = 1$ in the first case and $-1$ in the second case. $\square$

5(iv). Stable envelop. Recall we considered the attracting set $\mathcal{U}_P$ in the Uhlenbeck space $\mathcal{U}_G$. Let us denote its inverse image $\pi^{-1}(\mathcal{U}_P)$ in $\tilde{U}_r$ by $\tilde{U}_P$. This is the tensor product variety, denoted by $\mathfrak{T}$ in [53], where $\mathcal{U}_P$ is denoted by $\mathfrak{T}_0$. (In [49] $\mathfrak{T}$ was denoted by $\mathfrak{Z}$.)

We have the following moduli theoretic description:

\begin{equation}
\tilde{U}_P = \left\{(E, \varphi) \in \tilde{U}_r \mid E \text{ admits a filtration } 0 = E_0 \subset E_1 \subset \cdots \subset E_N = E \text{ with rank } E_i/E_{i-1} = r_i, \text{ compatible with } \varphi.\right\}.
\end{equation}

See §4(iv).

We consider the fiber product $Z_P$ of $\tilde{U}_P$ and $\tilde{U}_L$ over $\mathcal{U}_L$:

\begin{equation}
Z_P = \tilde{U}_P \times_{\mathcal{U}_L} \tilde{U}_L,
\end{equation}

where the map from $\tilde{U}_L$ to $\mathcal{U}_L$ is the restriction of $\pi$, and the map from $\tilde{U}_P$ to $\mathcal{U}_L$ is the composition of the restriction $\tilde{U}_P \to \mathcal{U}_P$ of $\pi$ and the map $p$ in §4(iv). In the above description of $\tilde{U}_P$, it is just given as the direct sum $\bigoplus (E_i/E_{i-1})^{\vee \vee}$ plus the sum of singularities of $E_i/E_{i-1}$. One can show that $Z_P$ is a lagrangian subvariety in $\tilde{U}_r \times \tilde{U}_L$. See [53, Prop. 1]. (There are no lower dimensional irreducible components, as all strata are relevant for the semismall morphism $\pi: \tilde{U}_r \to \mathcal{U}_G$.)
Maulik-Okounkov stable envelop is a ‘canonical’ lagrangian cycle class \( \mathcal{L} \) in \( Z_P \):

\[
\mathcal{L} \in H_{[0]}(Z_P).
\]

See \cite[§3.5]{40}. Note that \( \mathcal{L} \) depends on the choice of the parabolic subgroup \( P \) as well as the polarization \( \delta \). Since they are canonically chosen, we suppress them in the notation \( \mathcal{L} \).

The convolution by \( \mathcal{L} \) defines a homomorphism

\[
\mathcal{L} * - = p_1^\ast(p_2^\ast(-) \cap \mathcal{L}) : H_{[\ast]}(\tilde{\mathcal{U}}_L) \to H_{[\ast]}(\tilde{\mathcal{U}}_P).
\]

It is known that \( \mathcal{L} * - \) is an isomorphism (see \cite[§4.2]{53}), and it does also make sense for equivariant homology groups, as \( H_{[0]}(Z_P) \cong H_T^0(Z_P) \).

We have \( H_{[\ast]}(\tilde{\mathcal{U}}_L) \cong H_{[\ast]}(\tilde{\mathcal{U}}_{P,x}) \) by the Poincaré duality. Then we have

\[
H_{[\ast]}^T(\tilde{\mathcal{U}}_L) \to H_{[\ast]}^T(\tilde{\mathcal{U}}_P)
\]

as the composite of \( \mathcal{L} * - \) and the pushforward with respect to the inclusion \( \tilde{\mathcal{U}}_P \subset \tilde{\mathcal{U}}_L \). This is the original formulation of stable envelop in \cite[Ch. 3]{40}, and properties of \( \mathcal{L} \) are often stated in terms of this homomorphism there.

Let \( x \in U_L \). Let \( \tilde{\mathcal{U}}_{L,x} \) denote the inverse image of \( x \) under the Gieseker-Uhlenbeck morphism \( \tilde{\mathcal{U}}_L \to U_L \). Similarly let \( \tilde{\mathcal{U}}_{P,x} \) denote the inverse image of \( x \) under the composition \( \tilde{\mathcal{U}}_P \to U_P \to U_L \). Then the convolution \( \mathcal{L} * - \) also defines

\[
\mathcal{L} * - : H_{[\ast]}^T(\tilde{\mathcal{U}}_{L,x}) \to H_{[\ast]}^T(\tilde{\mathcal{U}}_{P,x}),
\]

where \( T_x \) is the stabilizer of \( x \).

\textbf{5(v). Tensor product module.} Let \( 0 = d \cdot 0 \) as before and consider the inverse image \( \tilde{\mathcal{U}}_{P,0}^d \) of \( 0 \) under \( \tilde{\mathcal{U}}_P^d \to U_L^d \) as in the previous subsection.

We consider the direct sum

\[
\bigoplus_d H_{[\ast]}^T(\tilde{\mathcal{U}}_{P,0}^d).
\]

The Heisenberg algebra acts on the sum: This follows from a general theory of the convolution algebra: it is enough to check that \( \tilde{\mathcal{U}}_{P,0}^d \circ (P_n \cap \Pi^{-1}(0)) \subset \tilde{\mathcal{U}}_{P,0}^{d+n} \) (for \( k > 0 \)). If \((E_1, E_2, x) \in P_n \cap \Pi^{-1}(0)\), then \( \pi(E_2) = \pi(E_1) + n \cdot 0 \). Therefore the assertion follows.
The stable envelop $\mathcal{L} \ast -$ gives an isomorphism $\bigoplus_d H^*_d(U_{L,0}^d) \cong \bigoplus_d H^*_d(U_{r_1,0}^{d_1}) \otimes \cdots \otimes H^*_d(U_{r_N,0}^{d_N})$, where the left hand side is the tensor product

\[(5.25) \bigoplus_{d_1, \ldots, d_N} H^*_d(U_{r_1,0}^{d_1}) \otimes \cdots \otimes H^*_d(U_{r_N,0}^{d_N})\]

by (5.12). This is a representation of $N$ copies of Heisenberg algebras. Under the stable envelop, $P_{\Delta_k}([0])$ on (5.24) is mapped to

\[(5.26) \sum_{i=1}^N 1 \otimes \cdots \otimes P_{\Delta_k}([0]) \otimes \cdots \otimes 1.\]

This is [40, Th. 12.2.1]. Our Heisenberg generators are diagonal in this sense, and hence we put $\Delta$ in the notation. This result is compatible with the decomposition $W(sl_r) = W(sl_r) \otimes \text{Heis}$, where $W(sl_r)$ is contained in the tensor product of the remaining $(N - 1)$ copies of Heisenberg algebras, orthogonal to the diagonal one.

5(vi). Sheaf theoretic analysis. By [53, §4, Lem. 4] we have a natural isomorphism

\[(5.27) H^*_0(Z_P) \cong \text{Hom}_{\text{Perf}(U_L)} \left(p_! j^* \pi_* C_{\tilde{U}_L}, \pi_* C_{\tilde{U}_L} \right)\]

where $j$, $p$ are as in §4(iv) and we use the same symbol $\pi$ for Gieseker-Uhlenbeck morphisms for $\tilde{U}_r$ and $\tilde{U}_L$.

The Verdier duality gives us an isomorphism

\[(5.28) \text{Hom}(p_! j^* \pi_* C_{\tilde{U}_L}, \pi_* C_{\tilde{U}_L}) \cong \text{Hom}(\pi_* C_{\tilde{U}_L}, p_* j^! \pi_* C_{\tilde{U}_L}).\]

Therefore the stable envelop gives us the canonical isomorphism

\[(5.29) \pi_* C_{\tilde{U}_L} \xrightarrow{\cong} \Phi_{L,G}(\pi_* C_{\tilde{U}_L}) = p_* j^! \pi_* C_{\tilde{U}_L},\]

as $\pi_1 = \pi_*$. This is nothing but Theorem 1.5(2) in Introduction.

Let $x \in U_L$ and $i_x$ denote the inclusion of $x$ in $U_L$. Then $\mathcal{L} \in \text{Hom}(\pi_* C_{\tilde{U}_L}, p_* j^! \pi_* C_{\tilde{U}_L})$ defines an operator

\begin{align*}
H^*(i_x^! \pi_* C_{\tilde{U}_L}) & \longrightarrow H^*(i_x^! p_* j^! \pi_* C_{\tilde{U}_L}) \\
\| & \| \\
H_{[-\epsilon]}(\tilde{U}_{L,x}) & \longrightarrow H_{[-\epsilon]}(\tilde{U}_{P,x}).
\end{align*}

(5.30)

This is equal to $\mathcal{L} \ast -$ in (5.23) under the isomorphism (5.27). See [53, §4.4].
5(vii). **The associativity of stable envelops.** Let us take parabolic subgroups \( Q \subset P \subset G \) and the corresponding Levi subgroup \( M \subset L \) as in §4(v). \((G\) is still \( SL(r)\)). Let \( Q_L \) be the image of \( Q \) in \( L \).

Let us denote by \( \mathcal{L}_{L,G} \) the isomorphism given by the stable envelop in (5.29):

\[
\pi_! C_{\tilde{U}_L} \xrightarrow{\mathcal{L}_{L,G}} \Phi_{L,G}(\pi_! C_{\tilde{U}_L}).
\]

We similarly have isomorphisms

\[
\pi_! C_{\tilde{U}_M} \xrightarrow{\mathcal{L}_{M,G}} \Phi_{M,G}(\pi_! C_{\tilde{U}_M}), \quad \pi_! C_{\tilde{U}_L} \xrightarrow{\mathcal{L}_{M,L}} \Phi_{M,L}(\pi_! C_{\tilde{U}_L}).
\]

Then stable envelops are compatible with the associativity (4.17) of the hyperbolic restriction:

**Proposition 5.33.** We have a commutative diagram

\[
\begin{array}{ccc}
\pi_! C_{\tilde{U}_M} & \xrightarrow{\mathcal{L}_{M,G}} & \Phi_{M,G}(\pi_! C_{\tilde{U}_M}) \\
\xrightarrow{\mathcal{L}_{M,L}} & & \xrightarrow{\mathcal{L}_{M,L}(\mathcal{L}_{L,G})} \\
\Phi_{M,L}(\pi_! C_{\tilde{U}_L}) & \xrightarrow{\Phi_{M,L}(\mathcal{L}_{L,G})} & \Phi_{M,L}(\pi_! C_{\tilde{U}_L}).
\end{array}
\]

Let us check that this follows from the proof of [40, Lemma 3.6.1]. (To compare the following with the original paper, the reader should note that the tori \( A \supset A' \) were used in [40], which correspond to \( Z(M)^0 \supset Z(L)^0 \) respectively in our situation.)

We consider

\[
Z_P = \tilde{U}_P \times_{\tilde{U}_L} \tilde{U}_L, \quad Z_Q = \tilde{U}_Q \times_{\tilde{U}_M} \tilde{U}_M, \quad Z_{Q_L} = \tilde{U}_{Q_L} \times_{\tilde{U}_M} \tilde{U}_M.
\]

The stable envelops \( \mathcal{L}_{L,G}, \mathcal{L}_{M,G}, \mathcal{L}_{M,L} \) are classes in \( H[0](Z_P), H[0](Z_Q), H[0](Z_{Q_L}) \) respectively. We consider the convolution product

\[
\mathcal{L}_{L,G} \ast \mathcal{L}_{M,L} \in H[0](Z_P \circ Z_{Q_L}).
\]

Note that \( Z_P \circ Z_{Q_L} \) consists of \((x_1, x_3) \in \tilde{U}_P \times \tilde{U}_M \) such that there exists \( x_2 \in \tilde{U}_{Q_L} \subset \tilde{U}_L \) with \((x_1, x_2) \in Z_P, (x_2, x_3) \in Z_{Q_L}\) by definition. This is nothing but \( Z_Q \). Therefore \( \mathcal{L}_P \ast \mathcal{L}_{Q_L} \) is a class in \( H[0](Z_Q) \). The proof in [40, Lemma 3.6.1] actually gives \( \mathcal{L}_{L,G} \ast \mathcal{L}_{M,L} = \mathcal{L}_{M,G} \).

Therefore the commutativity of (5.34) follows, once we check that the convolution product corresponds to the composition of homomorphisms (Yoneda product) under the isomorphism (5.27). This is not covered by [22, Prop. 8.6.35], as the base spaces of fiber products are different: \( \mathcal{U}_L \) and \( \mathcal{U}_M \). But we can easily modify its proof to our situation.
5(viii). Space $V^d$ and its base given by irreducible components.

Let us write $d$ for the instanton number again. Similarly to (4.26) we define

$$V^d_{L,G} \equiv V^d \overset{\text{df.}}{=} \text{Hom}(C_{S(d)} \mathbb{A}^2, \Phi_{L,G}(\pi_! C_{\tilde{U}^d}))$$

$$= H^{-2}(S(d) \mathbb{A}^2, \xi_! \Phi_{L,G}(\pi_! C_{\tilde{U}^d})),$$

where $\xi: S(d) \mathbb{A}^2 \to \mathcal{U}^d_L$ is as before. We denote by $V^{d,P}_{L,G}$ or $V^{d,P}$ when we want to emphasize $P$.

As in Lemma 4.39 we have

$$V^d \cong H_{[0]}(\tilde{U}^d_{P,0}),$$

and $V^d$ has a base given by $(dh^\vee - 1)$-dimensional irreducible components of $\tilde{U}^d_{P,0}$.

On the other hand, $H_{[0]}(\tilde{U}^d_{P,0})$ is isomorphic to $H_{[0]}(\tilde{U}^d_{L,0})$ by the stable envelop. In the description (5.12), note that the fiber $\tilde{U}_{r,i,0}^{d_i}$ has $\dim = \dim \tilde{U}_{r,i}^{d_i}/2 - 1$ by Proposition 5.10 unless $d_i = 0$. Therefore we can achieve the degree $[0] = \dim \tilde{U}^d_L - 2 = \sum \dim \tilde{U}_{r,i}^{d_i} - 2$ only when all $d_i = 0$ except one. There are $N$ choices $i = 1, \ldots, N$. Therefore $\dim V^d = N$.

Let us study $V^d = H_{[0]}(\tilde{U}^d_{P,0})$ in more detail. This will give the detail left over from §4(ix). By [49, §3] we have a decomposition

$$\tilde{U}^d_{P,0} = \bigsqcup_{d_1 + \cdots + d_N = n} \Xi(d_1, \ldots, d_N)_0,$$

where

$$\Xi(d_1, \ldots, d_N)_0 = \left\{ (E, \varphi) \mid E \text{ admits a filtration } 0 = E_0 \subset E_1 \subset E_N = E \text{ with } E_i/E_{i-1} \subset \tilde{U}_{r,i,0}^{d_i}\right\}.$$

We have a projection

$$\Xi(d_1, \ldots, d_N)_0 \to \tilde{U}_{r,i,0}^{d_i} \times \cdots \times \tilde{U}_{r,N,0}^{d_N},$$

which is a vector bundle of rank $dr - \sum d_ir_i$. Note that

$$\dim \tilde{U}_{r,i,0}^{d_i} = \begin{cases} 0 & \text{if } d_i = 0, \\ d_ir_i - 1 & \text{if } d_i \neq 0. \end{cases}$$

(See Proposition 5.10.) Therefore

$$\dim \Xi(d_1, \ldots, d_N)_0 = dr - \# \{i \mid d_i \neq 0\} \leq dr - 1.$$
The equality holds if and only if there is only one \( i \) with \( d_i \neq 0 \). Therefore \( H_0(\mathcal{U}_{d,-0}) \) is spanned by fundamental cycles
\[(5.44) \quad [\Sigma(d,0,\ldots,0)_0], \quad \cdots, [\Sigma(0,\ldots,0,d)_0].\]
Thus it is \( N \)-dimensional, as expected.

In the remainder of this subsection, we study the corresponding space \( U^d = H_0(\mathcal{U}_{d,0}) \) for the Uhlenbeck space. Note that we have projective morphism \( \pi: \mathcal{U}_{P,0} \to \mathcal{U}_{P,0} \), and the Quot scheme \( \pi^{-1}(d \cdot 0) = \mathcal{U}_{r,0} \) is contained in \( \mathcal{U}_{r,0} \). The class of fiber \( \mathcal{U}_{r,0} \) is given by \( P_{-d([0])}(\mathcal{U}_{G}) \), and \( H_0(\mathcal{U}_{P,0}) \) is killed by Baranovsky’s Heisenberg operators by the construction.

**Proposition 5.45.** Among \( N \) cycles in (5.44), the first one \([\Sigma(d,0,\ldots,0)_0]\) is \([\mathcal{U}_{r,0}]\). The remaining cycles give a base of \( U^d = H_0(\mathcal{U}_{P,0}) \) under \( \pi_* \).

From the definition, this description of irreducible components of \( U_{P,0} \) is the same as one in Proposition 4.42 when \( G = SL(r) \), \( P = B \).

**Proof.** Suppose that \( E \in \Sigma(d,0,\ldots,0)_0 \). Then we have a short exact sequence
\[(5.46) \quad 0 \to E_1 \to E \to O^{\oplus r_2 + \cdots + r_N} \to 0 \]
with \( E_1 \in \mathcal{U}_{r,0} \). Consider
\[(5.47) \quad 0 \to O^{\oplus r_2 + \cdots + r_N} \to E^\vee \to E_1^\vee \to \mathcal{E}xt^1(O^{\oplus r_2 + \cdots + r_N}, O) \]
Since \( \mathcal{E}xt^1(O^{\oplus r_2 + \cdots + r_N}, O) = 0 \), the last homomorphism \( E^\vee \to E_1^\vee \) is surjective. Therefore this is a short exact sequence. Dualizing again, we get
\[(5.48) \quad 0 \to E_1^{\vee \vee} \to E^{\vee \vee} \to O^{\oplus r_2 + \cdots + r_N} \to 0. \]
The last homomorphism \( E^{\vee \vee} \to O^{\oplus r_2 + \cdots + r_N} \) is surjective as \( E \to O^{\oplus r_2 + \cdots + r_N} \) is so. (Or, we observe \( E_1^{\vee \vee} \cong O^{\oplus r_1} \) as \( E_1 \in \mathcal{U}_{r,0} \), and \( \mathcal{E}xt(\mathcal{O}^{\oplus r_1}, \mathcal{O}) = 0 \).) Therefore this is also exact. We have \( E_1^{\vee \vee} = O^{\oplus r_1} \) as \( E_1 \in \mathcal{U}_{r,0} \). Since the extension between the trivial sheaves is zero on \( \mathbb{P}^2 \), we have \( E^{\vee \vee} = O^{\oplus r} \). Therefore \( E \in \mathcal{U}_{r,0} \).

Thus we have \( \Sigma(d,0,\ldots,0)_0 \subset \mathcal{U}_{r,0} \). Since both are \((dr-1)\)-dimensional, and \( \mathcal{U}_{r,0} \) is irreducible, they must coincide. This shows the first claim.

For the second claim, we need to show that any of \( \Sigma(0,d,0,\ldots,0)_0 \), \( \ldots, \Sigma(0,\ldots,0,d)_0 \) contains a locally free sheaf. Then it is enough to consider the case \( N = 2 \) and check that \( \Sigma(0,d)_0 \) contains a locally free sheaf, as an extension of a locally free sheaf by a locally sheaf is again locally free. Furthermore we may assume \( r = 2 \) and \( r_1 = r_2 = 1 \).
We use the ADHM description. Let

\[
B_1 = \begin{pmatrix}
0 & 1 & 0 & \ldots & 0 \\
0 & 1 & \ldots & 0 \\
\vdots & \ddots & \ddots & \ddots \\
0 & \ldots & 0 & 1 \\
0 & 0 & 1 & \ldots & 0
\end{pmatrix},
B_2 = 0,
\]

\[
I = \begin{pmatrix}
0 & 0 \\
\vdots & \vdots \\
0 & 0 \\
1 & 0
\end{pmatrix},
J = \begin{pmatrix}
0 & 0 & \ldots & 0 \\
0 & 0 & \ldots & 0
\end{pmatrix}.
\]

We have \([B_1, B_2] + IJ = 0\). We see \((B_1, B_2, I, J)\) is stable, i.e., a subspace \(S \subset \mathbb{C}^d\) containing the image of \(I\) and invariant under \(B_1, B_2\) must be \(S = \mathbb{C}^d\). We also see that \((B_1, B_2, I, J)\) is costable, i.e., a subspace \(S \subset \mathbb{C}^d\) contained in the kernel of \(J\) and invariant under \(B_1, B_2\) must be \(S = 0\). Therefore \((B_1, B_2, I, J)\) defines a framed locally free sheaf \((E, \varphi)\), i.e., an element in \(\text{Bun}_d^{d, \text{SL}(2)}\). We consider a subspace \(\{(0,*)\} \subset \mathbb{C}^2\), which is the kernel of \(a\). Taking 0 as a subspace in \(\mathbb{C}^d\), we have a subrepresentation of a quiver. Therefore \(E\) contains the trivial rank 1 sheaf \(O_{\mathbb{P}^2}\) correspondingly. The quotient \(E/O_{\mathbb{P}^2}\) is given by the data

\[
I = \begin{pmatrix}
0 \\
\vdots \\
0
\end{pmatrix},
J = \begin{pmatrix}
0 & 0 & \ldots & 0
\end{pmatrix},
\]

and \(J = 0\), \(B_1\), \(B_2\) the same as above. This is the ideal sheaf \((x^d, y)\), and hence in \(\tilde{U}_{d, 0}^d\). Thus \(E\) is a point in \(\mathcal{X}(0, d)\).

5(ix). **A pairing on** \(V^d\). In the same way as §4(x), we can define a nondegenerate pairing between \(V^d, P\) and \(V^d, P_\perp\).

We have an isomorphism

\[
H^0(\xi_0^* i_\ast j_\ast \pi_\ast \mathcal{C}_{\tilde{U}_{d, 0}^d}) \xrightarrow{\sim} H^0(\xi_0^* i_\ast j_\ast \pi_\ast \mathcal{C}_{\tilde{U}_{d, 0}^d}),
\]

where we also used \(i_\ast = \pi_\ast\) as \(\pi\) is proper. By the base change and the replacement \(i_\ast, i_\ast^\perp\) to \(p_\ast, (p_\ast)\), we can identify this with

\[
H_0^0(\tilde{U}_{P, 0}^d) \rightarrow H_0^0(\tilde{U}_{P_\perp, 0}^d),
\]

and we have a pairing

\[
\langle , \rangle: H_0^0(\tilde{U}_{P, 0}^d) \otimes H_0^0(\tilde{U}_{P_\perp, 0}^d) \rightarrow \mathbb{C}.
\]
Note that we also have the intersection pairing in the centered Gieseker space \( \mathcal{U}_r^d \). As the intersection \( \mathcal{U}_{r_0}^d \cap \mathcal{U}_{r_{-\mathcal{L}}}^d \) consists of a compact space \( \mathcal{U}_r^d \), the pairing is well-defined, and takes values in \( \mathbb{C} \). We multiply the sign \((-1)^{\dim \mathcal{U}_r^d/2} = (-1)^{dr-1}\) as before.

**Lemma 5.52.** The pairing is equal to that on equivariant cohomology groups:

\[
\langle \ , \ \rangle : H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \otimes H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \to H_\pi^*(pt).
\]

By the localization theorem, natural homomorphisms

\[
H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \to H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}),
\]

\[
H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \to H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d})
\]

become isomorphisms over the fractional field of \( H_\pi^*(pt) \). Then the pairing between \( H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \) and \( H_\pi^*(\xi^i_0 j^j_\pi \mathcal{C}_{\mathcal{U}_r^d}) \) is equal to the intersection pairing by [22, §8.5]. Therefore we only need to show that the composition

\[
i^i_0 j^j_\pi \to i^i_0 j^j_\pi \to i^i_0 j^j_\pi
\]

is equal to \( i^i_0 j^j_\pi = i^i_0 j^j_\pi \to i^i_0 j^j_\pi \). This is a consequence of the following general statement: Let \( T \) be a torus action on \( X \) and \( Y = X^T \) (more generally, it can be a closed invariant subset containing \( X^T \)). Let \( a : Y \to X \) be the embedding. Let \( F \) be a functor from \( D_T(X) \) to \( D_T(Y) \). Assume that we have two morphisms of functors \( \alpha, \beta : a^! \to F \). Then \( \alpha = \beta \) if and only if it is so on the image of \( a_1 : D_T(Y) \to D_T(X) \).

We apply this claim to \( a = ji, \ F = i^i_0 j^j_\pi \). In our case, \( \alpha = \beta \) on \( a_1 D_T(Y) \) is evident, as all the involved morphisms are identities on the fixed point set \( Y \).

Let us give the proof of the claim. We consider a natural map \( a_1 F \to \mathcal{F} \) for \( \mathcal{F} \in D_T(X) \). It becomes an isomorphism if we apply \( a_1 \) by the base change. We set \( \mathcal{G} = a_1 F \). We have \( \alpha_{\mathcal{G}} = \beta_{\mathcal{G}} \), as homomorphisms \( a^! \mathcal{G} \to \mathcal{F}(\mathcal{G}) \), from the assumption. Then we have \( \alpha_{\mathcal{F}} = \beta_{\mathcal{F}} \) as the composition of \( \alpha_{\mathcal{G}} = \beta_{\mathcal{G}} \) and \( \mathcal{F}(\mathcal{F}) \to \mathcal{F}(\mathcal{G}) \).

**5(x).** Another base of \( V^d \). Recall we have the canonical isomorphism \( \pi^! \mathcal{C}_{\mathcal{U}_r^d} \cong \Phi_{L,G}(\pi^! \mathcal{C}_{\mathcal{U}_r^d}) \) in (5.29). Thanks to the decomposition (5.12), the morphism \( \pi : \mathcal{U}_r^d \to \mathcal{U}_r^d \) is the composite of

\[
\pi \times \cdots \times \pi : \mathcal{U}_{r_1}^d \times \cdots \times \mathcal{U}_{r_N}^d \to \mathcal{U}_{SL(r_1)}^d \times \cdots \times \mathcal{U}_{SL(r_N)}^d
\]
with the sum map
\[(5.58) \quad \kappa: U^d_{SL(r_1)} \times \cdots \times U^d_{SL(r_N)} \to U^d_L.\]
The latter is a finite birational morphism. Then \(\mathcal{C}_{U^d_L}\) decomposes under (5.57) as in (5.1):
\[(5.59) \quad \pi_l \mathcal{C}_{U^d_L} = \bigoplus \kappa_l IC(\text{Bun}_{U^d_{SL(r_1)}, \lambda_1}^d \times \cdots \times \text{Bun}_{U^d_{SL(r_N)}, \lambda_N}^d),\]
where \(\lambda_1, \ldots, \lambda_N\) are partitions with \(d = d_1 + |\lambda_1| + \cdots + d_N + |\lambda_N|\). (These \(d_1, \ldots, d_N\) are different from above.) The image of the closure of \(\text{Bun}_{U^d_{SL(r_1)}, \lambda_1}^d \times \cdots \times \text{Bun}_{U^d_{SL(r_N)}, \lambda_N}^d\) under \(\kappa\) is the closure of
\[(5.60) \quad \text{Bun}_{U^d_{SL(r_1)}}, \ldots, \text{Bun}_{U^d_{SL(r_N)}} \times S_{\mu} \mathbb{A}^2,\]
where \(\mu = \lambda_1 \sqcup \cdots \sqcup \lambda_N\). Let us denote this stratum by \(\text{Bun}_{L, \mu}^{d_1, \ldots, d_N}\).
Then as \(\kappa\) is a finite morphism, we have
\[(5.61) \quad \kappa_l IC(\text{Bun}_{U^d_{SL(r_1)}, \lambda_1}^d \times \cdots \times \text{Bun}_{U^d_{SL(r_N)}, \lambda_N}^d) \cong IC(Bun_{L, \mu}^{d_1, \ldots, d_N}, \rho),\]
where \(\rho\) is the local system corresponding to the covering
\[(5.62) \quad S_{\lambda_1} \mathbb{A}^2 \times \cdots \times S_{\lambda_N} \mathbb{A}^2 \setminus \text{diagonal} \to S_{\mu} \mathbb{A}^2\]
and \(\mu = \lambda_1 \sqcup \cdots \sqcup \lambda_N\). Taking sum over \(\lambda_1, \lambda_2, \ldots\) which give the same \(\mu\), we get
\[(5.63) \quad \bigoplus_{\lambda_1 \sqcup \cdots \sqcup \lambda_N = \mu} \kappa_l IC(\text{Bun}_{U^d_{SL(r_1)}, \lambda_1}^d \times \cdots \times \text{Bun}_{U^d_{SL(r_N)}, \lambda_N}^d)
\cong IC(Bun_{L, \mu}^{d_1, \ldots, d_N}, \rho),\]
where \(\rho\) is now given by the permutation representation
\[(5.64) \quad (V^1)^{\otimes n_1} \otimes (V^2)^{\otimes n_2} \otimes \cdots\]
of \(S_{n_1} \times S_{n_2} \times \cdots\) if \(\mu = (1^{n_1}2^{n_2} \cdots)\) with \(\dim V^d = N\). Let us understand that this \(V^d\) is temporarily different from the previous one (5.37). Here we define \(V^d\) as the cohomology of the union of the fibers of (5.62) for the special case when \(\mu\) is the partition \((d)\) with the single entry \(d\), where the union runs over \(\lambda_1, \ldots, \lambda_N\):
\[(5.65) \quad \sigma: \bigsqcup_{\lambda_1 \sqcup \cdots \sqcup \lambda_N = (d)} S_{\lambda_1} \mathbb{A}^2 \times \cdots \times S_{\lambda_N} \mathbb{A}^2 \setminus \text{diagonal} \to S_{(d)} \mathbb{A}^2,\]
and
\[(5.66) \quad V^d = H_0(\sigma^{-1}(d \cdot 0)).\]
If \(\mu = (d)\), one of \(\lambda_1, \ldots, \lambda_N\) is \((d)\) and others are the empty partition \(\emptyset\). Therefore we have \(\dim V^d = N\).
Moreover \( \text{Hom}_{\text{Perv}(\mathcal{U}^d_L)}(\mathcal{C}_{S(d), A^2}, \pi_! C_{\mathcal{U}^d_L}) \) is given by the component \( \text{IC}(\text{Bun}_{L,(d)}^0, \ldots, \text{Bun}_{L,(d)}^0, L, \rho) \), where \( \rho \) is the trivial representation of \( S_1 \) on \( V^d \). Therefore we have a canonical isomorphism

\[
V^d \cong \text{Hom}_{\text{Perv}(\mathcal{U}^d_L)}(\mathcal{C}_{S(d), A^2}, \pi_! C_{\mathcal{U}^d_L}) \cong \text{Hom}_{\text{Perv}(\mathcal{U}^d_L)}(\mathcal{C}_{S(d), A^2}, \Phi_{L,G}(\pi_! C_{\mathcal{U}^d_L})),
\]

(5.67)

where the second isomorphism is given by the stable envelop \( L \). Thus our \( V^d \) is canonically isomorphic to the previous one (5.37).

We have just shown

\[
\pi_! C_{\mathcal{U}^d_L} \cong \bigoplus \text{IC}(\text{Bun}_{L,(d)}^0, \ldots, \text{Bun}_{L,(d)}^0, L, \rho).
\]

This is similar to Proposition 4.28, where we used the factorization argument to construct an isomorphism. Our argument looks slightly different, as we have not used the projection \( a: A^2 \to A^1 \). But the isomorphism is the same as one given by the factorization argument from the above construction, together with the observation that \( a, i, j \) commute with the projection \( \pi_{a,i,j} \) (\( ? = G, P, L \)).

Note that we have \( e_i \in V^d = H_0(\sigma^{-1}(d \cdot 0)) \) corresponding to the component of \( \sigma^{-1}(d \cdot 0) \) in

\[
S_0 A^2 \times \cdots \times S_0 A^2 \times \cdots \times S_0 A^2.
\]

Then \( e_1, \ldots, e_N \) gives a base of \( V^d \).

If we view \( V^d \) as \( \text{Hom}_{\text{Perv}(\mathcal{U}^d_L)}(\mathcal{C}_{S(d), A^2}, \pi_! C_{\mathcal{U}^d_L}) \), \( e_i \) is the composite of homomorphisms

\[
\mathcal{C}_{S(d), A^2} \to \pi_! C_{\mathcal{U}^d_L} \to \pi_! C_{\mathcal{U}^d_L},
\]

where the left homomorphism is given by the fundamental class \( [\pi^{-1}(d \cdot 0)] \), and the right one is given by the inclusion of the component \( d_i = d, d_j = 0 \) (\( j \neq i \)) in the decomposition (5.12).

**Example 5.71.** For \( d = 1 \), \( \mathcal{U}^1_L \) (resp. \( \mathcal{U}^1_L \)) is isomorphic to the product of \( A^2 \) and the cotangent bundle of \( \mathbb{P}^{r-1} \) (resp. the closure of the minimal nilpotent orbit of \( \mathfrak{sl}_r \)). Further suppose \( N = r \) and \( r_1 = \cdots = r_N = 1 \). Then \([40, \text{Remark 3.5.3}]\) gives us the relation:

\[
\frac{1}{k!(k-1)!} \left[ \sum_{\text{all factors}} \right] = (-1)^{k-1}(e_k + e_{k+1} + \cdots + e_r).
\]

(5.72)

Here the sign \((-1)^{k-1}\) comes from the polarization, mentioned in §5(iii).
Example 5.73. We know that $\Xi(d, 0, \ldots, 0)_0 = [\tilde{U}^d_{r,0}]$ (Proposition 5.45), and hence

\[(5.74) \quad [\Xi(d, 0, \ldots, 0)_0] = e_1 + \cdots + e_N\]

by (5.26).

On the other hand, the opposite extreme $[\Xi(0, 0, \ldots, d)_0]$ is equal to $e_N$ up to sign by the support property of the stable envelop [40, Th. 3.3.4 (i)]. The polarization is opposite, therefore the sign is the half of the codimension of the corresponding fixed point component. We get

\[(5.75) \quad [\Xi(0, 0, \ldots, d)_0] = (-1)^{(d-r)N} e_N.\]

If $N = 2$, two elements exhaust the base.

The transition matrix between two bases for $d > 1$, $N > 2$ can be calculated from (4.54) together with (5.80) below. Though (4.54) determines $[\Xi(0, \ldots, 0, d, 0, \ldots, 0)_0]$ ($d$ is in the $k$th entry) up to $\mathbb{C}[\Xi(d, 0, \ldots, 0)_0]$, it is a linear span of $e_k, \ldots, e_N$ thanks to the support property of the stable envelop. Therefore we can fix the ambiguity.

5(xi). Computation of the pairing. Let us relate the pairing in §5(ix) to the pairing defined on $\tilde{U}_L^d$ using the stable envelop

\[(5.76) \quad \mathcal{L} : H[0](\tilde{U}_L^d) \xrightarrow{\sim} H[0](\tilde{U}_L^d).\]

Let us temporarily denote the stable envelop with respect to the opposite parabolic by $\mathcal{L}^-$. Then we want to compute

\[(5.77) \quad \langle \mathcal{L}(\alpha), \mathcal{L}^-(\beta) \rangle,
\]

which is equal to the intersection pairing times $(-1)^{\dim \tilde{U}_L^d}$ by Lemma 5.52.

Suppose that $\alpha, \beta$ are classes on a component $Z$ of $\tilde{U}_{L,0}^d$. Let us take equivariant lifts of $\alpha, \beta$ to $Z(L)^0$-equivariant cohomology. Since the supports of $\mathcal{L}(\alpha)$ and $\mathcal{L}^-(\beta)$ intersects along $Z$ by one of characterizing properties of the stable envelop [40, Th. 3.3.4(i)], we need to compute the restriction of the (Poincaré dual of) $\mathcal{L}(\alpha), \mathcal{L}^-(\beta)$ to the fixed point $Z$. Again by a property of the stable envelop [40, Th. 3.3.4(ii)], we have $\mathcal{L}(\alpha)|_Z = (\delta_{\text{rep}}/\delta) e(N^-) \cup \alpha$ and $\mathcal{L}^-(\beta)|_Z = (\delta_{\text{att}}/\delta) e(N^+) \cup \beta$, where $\delta_{\text{rep}}, \delta_{\text{att}}$ are the polarizations given by attracting and repelling directions. Then we have

\[(5.78) \quad \int_{\tilde{U}_L^d} \mathcal{L}(\alpha) \cup \mathcal{L}^-(\beta) = \frac{\delta_{\text{rep}}\delta_{\text{att}}}{\delta^2} \int_{\tilde{U}_L^d} e(N) \cup \alpha \cup \beta = (-1)^{\dim Z/2} \int_Z \alpha \cup \beta\]
by the fixed point formula. Therefore if we multiply \((-1)^{\dim \widetilde{\mathcal{U}}^d/2}\), we get
\((-1)^{\dim Z/2} \int_X \alpha \cup \beta = \langle \alpha, \beta \rangle\).

If \(\alpha, \beta\) are supported on different components \(Z, Z'\) of \(\widetilde{\mathcal{U}}^d\) respectively, we use a property [40, Th. 3.7.5], which says the restrictions of \(\mathcal{L}(\alpha), \mathcal{L}(\beta)\) to components other than \(Z, Z'\) are zero. Then it is clear that \(\langle \mathcal{L}(\alpha), \mathcal{L}^-(\beta) \rangle = 0\).

As an application of this formula, let us we compute \((e_i, e^-_j)\), where \(e_i \in V^d\) as in the previous subsection, and \(e^-_j \in V^{d,P}\) is defined in the same way using the opposite hyperbolic restriction \(\mathcal{L}^-\). This is reduced to the computation of the self-intersection number of the punctual Quot scheme \(\mathcal{U}_{\pi_i,0}^d\) in the centered Gieseker space \(\mathcal{U}_{\pi_i}^d\). This is given by \((-1)^{r_i,d-1} dr_i = (-1)^{\dim \mathcal{U}_{\pi_i,0}^d/2} dr_i\) ([5, §4]). Therefore we get

**Proposition 5.79.** We have

\[
\tag{5.80}
\langle e_i, e^-_j \rangle = dr_i \delta_{ij}.
\]

5(xii). **Relation between \(V^d\) and \(U^d\).** Let us apply the decomposition (5.1) to (5.67). We have

\[
V^d = \text{Hom}(\mathcal{C}_{S(d)^{\mathbb{A}^2}}, \Phi_{L,G}(\pi c_{\mathcal{U}^d})) = \bigoplus_{d_1 + |\lambda| = d} H_{\text{top}}(\pi^{-1}(x^d_{\lambda})) \otimes \text{Hom}(\mathcal{C}_{S(d)^{\mathbb{A}^2}}, \Phi_{L,G}(\text{IC}(\text{Bun}^d_{G,\lambda}))).
\]

Then \(\text{Hom}(\mathcal{C}_{S(d)^{\mathbb{A}^2}}, \Phi_{L,G}(\text{IC}(\text{Bun}^d_{G,\lambda})))\) is nonzero only in either of the following cases:

1. \(d_1 = d\) and \(\lambda = \emptyset\),
2. \(d_1 = 0\) and \(\lambda = (d)\).

In the first case, it is \(U^d\) by definition. And in the second case, it is

\[
\tag{5.82}
\text{Hom}(\mathcal{C}_{S(d)^{\mathbb{A}^2}}, \Phi_{L,G}(\mathcal{C}_{S(d)^{\mathbb{A}^2}})) = \text{Hom}(\mathcal{C}_{S(d)^{\mathbb{A}^2}, \mathcal{C}_{S(d)^{\mathbb{A}^2}}} \simeq \mathbb{C} \text{id}.
\]

Thus

\[
\tag{5.83}
V^d \cong (H_{\text{top}}(\pi^{-1}(x^d_{\emptyset})) \otimes U^d) \oplus H_{\text{top}}(\pi^{-1}(x^d_{(d)})).
\]

Note that \(\pi^{-1}(x^d_{\emptyset})\) is a single point. Therefore we have the canonical isomorphism \(H_{\text{top}}(\pi^{-1}(x^d_{\emptyset})) \cong \mathbb{C}\). Now the homomorphism \(\pi_*: V^d \cong H_{[0]}(\mathcal{U}_{P,0}^d) \to U^d \cong H_{[0]}(\mathcal{U}_{P,0}^d)\) is identified with the projection to the first component in (5.83). In particular, bases of \(U^d\) and \(V^d\) given by irreducible components (see Lemma 4.39 and Proposition 5.45) are related by the projection.
The subspace $H_{\text{top}}(\pi^{-1}(x_{(d)}^0))$ is 1-dimensional space spanned by the fundamental class $[\pi^{-1}(x_{(d)}^0)]$, or equivalently $P_{-d}([0]) \cdot [U_G^0]$ where $P_{-d}([0])$ is the Heisenberg operator, and $[U_G^0] = 1 \in H^0_G(U_G^0)$. Recall that the Baranovsky’s Heisenberg operator is mapped to the diagonal operator under the stable envelop, see §5(v). It means that $[\pi^{-1}(x_{(d)}^0)]$ is equal to

$$(5.84) \quad e_1 + \cdots + e_N,$$

where $\{e_i\}$ is the base of $V^d$ in the previous subsection.

And $U^d$ is the subspace killed by the Heisenberg operator $P_d(1)$. Therefore

$$(5.85) \quad U^d \cong \{ \lambda_1 e_1 + \cdots + \lambda_N e_N \mid \lambda_1 + \cdots + \lambda_N = 0 \}.$$ 

We have a base $\{e_i - e_{i+1}\}_{i=1,\ldots,N-1}$ of $U^d$.

It is also clear that the decomposition (5.83) is orthogonal with respect to the pairing in §5(ix). And the restriction of the pairing to $U^d$ is equal to one in §4(x). Therefore we can calculate the pairing between $U^d,P$ and $U^d,P^-$. Let us consider the case $P = B$ for brevity. We have

$$(5.86) \quad \langle e_i - e_{i+1}, e_j^- - e_{j+1}^- \rangle = \begin{cases} 2d & \text{if } i = j, \\ -d & \text{if } |i - j| = 1, \\ 0 & \text{otherwise} \end{cases}$$

by Proposition 5.79. Thus the pairing between $U^d,B$ and $U^d,B^-$ is identified with the natural pairing on the Cartan subalgebra $h$ of $\mathfrak{sl}_r$ multiplied by $d$, under the identification $e_i - e_{i+1}$ and $e_i^- - e_{i+1}^-$ with the simple coroot $\alpha_i^\vee$.

5(xiii). **Compatibility.** Let us take $L = T$. We shall show that the base $\{e_i - e_{i+1}\}_i$ of $U^d$ is compatible with the construction in §4(xi) in this subsection.

We fix the Borel subgroup $B$ consisting of upper triangular matrices, and let $P_i$ be the parabolic subgroup corresponding to a simple root $\alpha_i$ and $L_i$ be the Levi subgroup ($i = 1,\ldots,r - 1$). Recall that we have taken

$$(5.87) \quad 1_{L_i,G}^d \in \text{Hom}_{\text{Perv}(U_{L_i}^d)}(\text{IC}(U_{L_i}^d), \Phi_{L_i,G}(\text{IC}(U_G^d))).$$

(See (4.23).)

Let us consider the corresponding fixed point set $\tilde{U}_{L_i}^d = (\tilde{U}_r^d)^{Z(L_i)}$ in the Gieseker space. The decomposition (5.12) in our case is

$$(5.88) \quad \bigsqcup_{d_1 + \cdots + d_{i+1} + \cdots + d_r = d} \tilde{U}_{d_1}^1 \times \cdots \times \tilde{U}_{d_{i+1}}^1 \times \tilde{U}_{d_1}^2 \times \tilde{U}_{d_2}^1 \times \tilde{U}_{d_{i+2}}^1 \times \cdots \times \tilde{U}_{d_r}^1.$$
There is a distinguished connected component, isomorphic to $\tilde{U}_d^i$ with $d_i = d$, $d_j = 0$ for $j \neq i$. Let us denote it by $Z$.

Recall that $U_{d, L}^d$ is equal to $U_{SL(2)}^d$ as a topological space and the open subvariety $\text{Bun}_{d, L}^d$ is equal to $\text{Bun}_{SL(2)}^d$. The connected component $Z$ is characterized among all components of $\tilde{U}_d^i$, as it contains $\text{Bun}_{d, L}^d$.

We denote by $\delta$ the polarization of $Z$ in $U_{d, L}^d$ in §5(iii). We understand it is $\pm 1$, according to whether it is equal to the polarization given by attracting directions or not, as in §4(iii). We correct $1_{L, G}^d$ by $\delta 1_{L, G}^d$ so that it will be compatible with the stable envelop.

Let us consider the diagram

\begin{equation}
\begin{array}{ccc}
\text{IC}(U_{d, L}^d) & \delta 1_{L, G}^d & \Phi_{L, G}(\text{IC}(U_G^d)) \\
\uparrow & & \uparrow \\
\pi_! C_{\tilde{U}_d^i} & \cong \ & \Phi_{L, G}(\pi_! C_{\tilde{U}_d^i}).
\end{array}
\end{equation}

The upper arrow is given just above, and the bottom arrow is the stable envelop. The right vertical arrow comes from the natural projection to the direct summand $\pi_! (C_{\tilde{U}_d^i}) \to \text{IC}(U_G^d)$ in (5.1), which is the identity homomorphism on the open subset $\text{Bun}_G^d$ of $U_G^d$. The left vertical arrow is defined as follows. We have the distinguished component $Z$ of $\tilde{U}_d^i$ isomorphic to $\tilde{U}_d^i$. We have $\text{IC}(U_{d, L}^d) = \text{IC}(U_{SL(2), L}^d)$, and hence have a natural projection $\pi_! C_{\tilde{U}_d^i} \to \text{IC}(U_{L, G}^d)$, as for the right vertical arrow. Composing with the restriction to the distinguished component $\pi_! C_{\tilde{U}_d^i} \to \pi_! C_Z$, we define the left vertical arrow.

**Proposition 5.90.** The diagram (5.89) is commutative.

**Proof.** From the construction of the diagram, it is clear that we need to check the commutativity on the open subset $\text{Bun}_G^d$. Then the commutativity is clear, as two constructions $\delta 1_{L, G}^d$ and $\mathcal{L}_{L, G}^d$ are the same: Both are given by the Thom isomorphism corrected by polarization. See [40, Th. 3.3.4(ii)] for the stable envelop. □

Recall also that we have proposed that there exists a canonical element

\begin{equation}
1_{L, d}^d \in \text{Hom}(C_{S(d)^A}, \Phi_{T, L}(\text{IC}(U_{L, d}^d)))
\end{equation}

\begin{equation}
\cong \text{Hom}(C_{S(d)^A}, \Phi_{C^*, SL_2}(\text{IC}(U_{SL_2}^d)))
\end{equation}
in §4(xi). We define it so that the following diagram is commutative:

\[
\begin{array}{ccc}
\mathcal{C}_{S(d)A^2} & \xrightarrow{1^d_{\mathcal{L}_i}} & \Phi_{C^*,SL(2)}(\text{IC}(\mathcal{U}^d_{SL(2)})) \\
\downarrow & & \uparrow \\
\pi_1\mathcal{C}_{\mathcal{L}} & \xrightarrow{\cong} & \Phi_{C^*,SL(2)}(\pi_1\mathcal{C}_{\mathcal{L}}),
\end{array}
\]

where we choose the parabolic subgroup in $SL(2) \cong [L_i, L_i]$ corresponding to the chosen Borel subgroup $B$ to define the hyperbolic restriction $\mathcal{L}_{C^*,SL(2)}$. The right vertical arrow is the projection to the direct summand as before. The left vertical arrow is $e_i - e_{i+1}$, where \(\{e_i, e_{i+1}\}\) is the base of $V^d_{C^*,SL(2)} \cong \text{Hom}(\mathcal{C}_{S(d)A^2}, \pi_1\mathcal{C}_{\mathcal{L}})$, i.e., $e_i$ corresponds to $\tilde{\mathcal{U}}_1^d \times \tilde{\mathcal{U}}_1^0 \subset \tilde{\mathcal{U}}_1^d$, and $e_{i+1}$ corresponds to $\tilde{\mathcal{U}}_1^0 \times \tilde{\mathcal{U}}_1^d$.

We enlarge the bottom row as

\[
\begin{array}{ccc}
\mathcal{C}_{S(d)A^2} & \xrightarrow{1^d_{\mathcal{L}_i}} & \Phi_{T,L_i}(\text{IC}(\mathcal{U}^d_{L_i})) \\
\downarrow & & \uparrow \\
\pi_1\mathcal{C}_{\mathcal{L}} & \xrightarrow{\cong} & \Phi_{T,L_i}(\pi_1\mathcal{C}_{\mathcal{L}}).
\end{array}
\]

Here we identify $\tilde{\mathcal{U}}_2^d$ with the distinguished component $Z$. We similarly consider $\tilde{\mathcal{U}}_2^d$ as a union of components of $\tilde{\mathcal{U}}_i^d$, putting it in $i$ and $(i+1)$th components. The left vertical arrow is $e_i - e_{i+1}$, where \(\{e_1, \ldots, e_r\}\) is a base of $V^d_{T,G}$. Two bases are obviously compatible, so it is safe to use the same notation.

We apply $\Phi_{T,L_i}$ to the commutative diagram (5.89) and combine it with (5.93):

\[
\begin{array}{ccc}
\mathcal{C}_{S(d)A^2} & \xrightarrow{1^d_{\mathcal{L}_i}} & \Phi_{T,L_i}(\text{IC}(\mathcal{U}^d_{L_i})) \xrightarrow{\Phi_{T,L_i}(\delta_1_{L_i,G})} \Phi_{T,G}(\text{IC}(\mathcal{U}^d_{G})) \\
\downarrow & & \uparrow \\
\pi_1\mathcal{C}_{\mathcal{L}} & \xrightarrow{\cong} & \Phi_{T,L_i}(\pi_1\mathcal{C}_{\mathcal{L}}) \xrightarrow{\cong} \Phi_{T,G}(\pi_1\mathcal{C}_{\mathcal{L}}).
\end{array}
\]

The composite of lower horizontal arrows is $\mathcal{L}_{T,G}$ by the commutativity (5.34). Recall we made an identification of $V^d$ by $\mathcal{L}_{T,G}$ (see (5.67)). Therefore $e_i - e_{i+1} \in V^d$ considered as a homomorphism $\text{Hom}(\mathcal{C}_{S(d)A^2}, \Phi_{T,G}(\pi_1\mathcal{C}_{\mathcal{L}}))$ is the composition of arrows from the upper left corner to the lower right corner.
It is also clear that the homomorphism $V^d \to U^d$ given by the composition of the rightmost upper arrow coincides with the projection in (5.83).

We thus see that $\{\tilde{\alpha}_i^d = \Phi_{T,L_i}(\delta_1^{d}_{L_i,G}) \circ 1_{L_i}^{d}\}$ coincides with the base $\{e_i - e_{i+1}\}$ of $U^d$. This gives the construction promised in §4(xi) when $G$ is of type $A$.

Remark 5.95. Suppose $G = SL(2)$. Thanks to Example 5.73, we have $\langle \mathfrak{X}(0,d)_0 \rangle = (\mathfrak{X}(0,d)_0)^d$. (Here $r_1 = r_2 = 1$.) Therefore we have $\langle \mathfrak{X}(0,d)_0, \tilde{\alpha}_1^{d-\cdot} \rangle = (\mathfrak{X}(0,d)_0)^d \langle e_2^d, e_1^{d-\cdot} - e_2^{d-\cdot} \rangle = (\mathfrak{X}(0,d)_0)^d d$.

In particular, it does not extend to an action on the Gieseker space $\tilde{U}^d_{i}$, as the second Chern class may drop when we take a dual of a sheaf.

In the ADHM description, the diagram automorphism is given by

$$(5.96) \quad ([B_1, B_2, I, J]) \mapsto [(B_1', B_2', -J', I')] .$$

This does not preserve the stability condition. Therefore we must be careful when we study what happens under this automorphism.

Nevertheless we give

Proof of Lemma 4.64. Recall $\sigma \in Aut(G)$ preserves $T, B$, and corresponds to a Dynkin diagram automorphism. Recall also $\tilde{\alpha}_i^d = \Phi_{T,L_i}(\delta_1^{d}_{L_i,G}) \circ 1_{L_i}^{d}$.

It is clear that $\Phi_{T,L_i}(1_{L_i}^{d})$ is sent to $\Phi_{T,L_i}(\delta_1^{d}_{L_i,G}) \circ 1_{L_i}^{d}$. Next consider $1_{L_i}^{d} \in U_{T,L_i}^d$. In view of Lemma 4.39, $U_{T,L_i}^d$ is $H_{10}(U_{B \cap L_i, 0}^d)$, which is 1-dimensional space spanned by the irreducible component $[U_{B \cap L_i, 0}^d]$. The class $[U_{B \cap L_i, 0}^d]$ is sent to $[U_{B \cap L_i, 0}^d]$ under $\varphi_\sigma$, as it is induced from the isomorphism $U_{B \cap L_i, 0}^d \to U_{B \cap L_i, 0}^d$.

On the other hand, $[U_{B \cap L_i, 0}^d]$ is the image of $\langle \mathfrak{X}(0,d)_0 \rangle$ under $\pi_* : H_{10}(\tilde{U}_{B \cap L_i, 0}^d) \to H_{10}(U_{B \cap L_i, 0}^d)$. We have $\mathfrak{X}(0,d)_0 = (\mathfrak{X}(0,d)_0)^d$ by Example 5.73. Hence
[\mathcal{U}^d_{T\cap L,0}] = (-1)^{d+1}L_i/2. Combining with the above observation, we deduce the assertion. □

6. \textit{W}-ALGEBRA REPRESENTATION ON LOCALIZED EQUIVARIANT COHOMOLOGY

The goal of this section is to define a representation of the \( \mathcal{W} \)-algebra \( \mathcal{W}_k(\mathfrak{g}) \) on the direct sum of equivariant intersection cohomology groups \( IH^*_T(\mathcal{U}^d_G) \) over \( d \), isomorphic to the Verma module with the level and highest weight, given by the equivariant variables by

\[
(6.1) \quad k + h^\vee = -\frac{\varepsilon_2}{\varepsilon_1}, \quad \mathbf{a} = (a_1, \ldots, a^\ell)
\]

respectively. Here \( \mathbf{a} \) is a collection of variables, but will be regarded also as a variable in the Cartan subalgebra \( \mathfrak{h} \) so that \( a^i = \alpha_i(\mathbf{a}) \) for a simple root \( \alpha_i \).

Since the level is a rational function in \( \varepsilon_1, \varepsilon_2 \), we must be careful over which ring the representation is defined. In geometric terms, it corresponds to that we need to consider localized equivariant cohomology groups. The equivariant cohomology group \( H^*_T(\ ) \) is a module over \( H^*_T(pt) = \mathbb{C}[\text{Lie} \mathbb{T}] = \mathbb{C}[\varepsilon_1, \varepsilon_2, \mathbf{a}] \). Let us denote this polynomial ring by \( \mathbb{A}_T \) and its quotient field by \( \mathbb{F}_T \). In algebraic terms, it means that our \( \mathcal{W} \)-algebra is defined over \( \mathbb{C}(\varepsilon_1, \varepsilon_2) \). Then the level \( k \) is a generic point in \( \mathbb{A}^1 \). Moreover we consider a Verma module whose highest weight is in \( \mathfrak{h}^* \otimes \mathbb{F}_T \). This means that the highest weight is also generic. More precisely, we regard \( \mathbf{a} \) as a canonical element in \( \mathfrak{h}^* \otimes \mathbb{F}_T = \mathfrak{h}^* \otimes \text{Frac}(S(\mathfrak{h}^*)[\varepsilon_1, \varepsilon_2]) \) given by the inner product on \( \mathfrak{h} \).

Here we have used the Langlands duality implicitly : we first consider \( \mathbf{a} \) as an element in \( \mathfrak{h} \otimes \mathbb{F}_T \) via the identity \( \mathfrak{h} \otimes \mathfrak{h}^* \). Then we regard the first \( \mathfrak{h} \) as the dual of the Cartan subalgebra of the Langlands dual of \( \mathfrak{g} \). But the Langlands dual is \( \mathfrak{g} \) itself as we are considering ADE cases.

We will construct a representation on

\[
(6.2) \quad \bigoplus_d IH^*_T(\mathcal{U}^d_G) \otimes_{\mathbb{A}_T} \mathbf{F}_T = \bigoplus_d H^*_T(\mathcal{U}^d_G, \text{IC}(\mathcal{U}^d_G)) \otimes_{\mathbb{A}_T} \mathbf{F}_T.
\]

By the localization theorem and Lemma 3.6, natural homomorphisms

\[
(6.3) \quad \begin{align*}
& IH^*_{T,c}(\mathcal{U}^d_G) \cong H^*_T(\mathcal{U}^d_T, i^! j^!(\text{IC}(\mathcal{U}^d_G))) \\
& \rightarrow H^*_{T,c}(\mathcal{U}^d_T, \Phi_{T,G}(\text{IC}(\mathcal{U}^d_G))) \\
& \rightarrow H^*_T(\mathcal{U}^d_T, \Phi_{T,G}(\text{IC}(\mathcal{U}^d_G))) \\
& \rightarrow H^*_T(\mathcal{U}^d_T, i^* j^!(\text{IC}(\mathcal{U}^d_G))) \cong IH^*_T(\mathcal{U}^d_G)
\end{align*}
\]
all become isomorphisms over $F_T$. Thus over $F_T$, we could use any of these four spaces. Let us denote its direct sum by $M_F(a)$:

$$M_F(a) = \bigoplus_d IH^*_T,c(U^d_G) \otimes_{A_T} F_T.$$  

In fact, we will construct representations of integral forms (i.e., $A_T$-forms) of Heisenberg and Virasoro algebras on non-localized equivariant cohomology groups $\bigoplus_d H^*_T,c(U^d_G)$ of hyperbolic restrictions in this section. This construction will be the first step towards a construction of the $W$-algebra representation on non-localized equivariant cohomology groups. To follow the remaining argument, the reader needs to read our definition of an integral form of the $W$-algebra given in §B. Therefore the whole construction will be postponed to §8(i).

Let us denote the fundamental class $1 \in IH^0_T(U^0_G) = IH^0_T,c(U^0_G) = H^0_T(pt)$ by $|a\rangle$. It will be identified with the highest weight vector (or the vacuum vector) of the Verma module. See Proposition 6.42 below.

We also use the following notation:

$$A = \mathbb{C}[\varepsilon_1, \varepsilon_2], \quad F = \mathbb{C}(\varepsilon_1, \varepsilon_2).$$  

6(i). Freeness.

**Lemma 6.5.** Four modules appearing in (6.3) are free over $A_T$.

**Proof.** By Lemma 3.6 all four modules are pure, as $(U^d_G)^T$ is a single point, and they are stalks at the point. Now freeness follows as in [31, Th. 14.1(8)].

Or we have odd cohomology vanishing by [20, Th. 7.10]. So it also follows from [31, Th. 14.1(1)].  

In particular, homomorphisms in (6.3) are all injective.

6(ii). Another base of $U^d$, continued. Let $U^d = U^d_{T,G}$ be as in §4(viii). Let $L_i$ be the Levi subgroup corresponding to a simple root $\alpha_i$ and consider $U^d_{T,L_i}$ as in §4(xi). We identify $IC(U^d_{L_i})$ with $IC(U^d_{SL(2)})$ by the bijective morphism $U^d_{SL(2)} \to U^d_{L_i}$ (see Proposition 4.7). We have a maximal torus and a Borel subgroup induced from those of $G$. Then $U^d_{T,L_i}$ has the base in (5.85), where it consists of a single element as $N = 2$. Let us denote the element by $1^d_{L_i}$, as we promised in §4(xi).

Next consider $1^d_{L,G}$ given by the Thom isomorphism as in §4(vii). We have the repellent polarization $\delta_{rep}$ of $Bun^d_{L_i}$ in $Bun^d_G$. We modify it to $\delta$ according to Lemma 5.15. We choose and fix a bipartite coloring
of the vertices of the Dynkin diagram, i.e., \( o : I \to \{ \pm 1 \} \) such that \( o(i) = -o(j) \) if \( i \) and \( j \) are connected in the diagram. Then we set
\[
\delta = o(i)^d \delta_{\text{rep}}.
\]
This is our polarization, which was promised in (4.50). Let us write
\[
\tilde{\alpha}_i^d \overset{\text{def}}{=} \Phi_{T,L_i}(\delta_1^d \in G) \circ 1^d_{L_i}.
\]
This gives us a collection \( \{ \tilde{\alpha}_i^d \} \) of elements in \( U^d \) labeled by \( I \). Thanks to (4.54), it is a base of \( U^d \). This will follow also from Proposition 6.15.

6(iii). **Heisenberg algebra associated with the Cartan subalgebra.** We construct a representation of the Heisenberg algebra associated with the Cartan subalgebra \( h \) of \( g \) on the direct sum of (6.2) in this subsection. It will be the first step towards the \( W \)-algebra representation.

Let us first review the construction of the Heisenberg algebra representation in §5(v) for the case \( r = 2 \) and \( L = S(GL(1) \times GL(1)) = C^* \). We consider Heisenberg operators \( P_\Delta^\alpha \equiv P_\Delta^\alpha(1) \) associated with the cohomology class 1 \( \in H^{[\ast]}(A) \). We omit (1) hereafter. They are not well-defined on \( \bigoplus_{d} H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^d) \) if \( k > 0 \), but are well-defined on the localized equivariant homology group \( \bigoplus_{d} H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^d) \otimes A_T \), and satisfy the commutation relations
\[
[P_\Delta^\alpha, P_\Delta^\beta] = -2m \delta_{\mu,-\nu} \frac{1}{\varepsilon_1 \varepsilon_2}.
\]

Via the stable envelop, we have the isomorphism
\[
\bigoplus_{d} H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^d) \cong \bigoplus_{d} H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^d) \cong \bigoplus_{d_1,d_2} H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^{d_1} \otimes H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^{d_2})),
\]
and we have the representation of the tensor product of two copies of Heisenberg algebras, given by \( P_n^{(1)} = P_n \otimes 1 \) and \( P_n^{(2)} = 1 \otimes P_n \) on the localized equivariant homology group, where \( P_n \) is the Heisenberg generator for \( r = 1 \). The above Heisenberg generator \( P_n^\Delta \) is the diagonal \( P_n^{(1)} + P_n^{(2)} \). See §5(v).

We have
\[
H^{[\ast]}_{\bar{\pi}}(\tilde{U}_T^d) \cong H^{[\ast]}_{\bar{\pi}}(U_{\mathcal{C}}^d, \pi_* j_! \pi_! \mathcal{C}_{\bar{U}_T^d}) = H^{[\ast]}_{\bar{\pi}}(U_{\mathcal{C}}^d, \Phi_{\mathcal{C}^*, SL(2)}(\pi_* \mathcal{C}_{\bar{U}_T^d})),
\]
by §5(vi) and \( \pi_* = \pi_* \). This homology group contains
\[
H^{[\ast]}_{\bar{\pi}}(U_{\mathcal{C}}^d, \Phi_{\mathcal{C}^*, SL(2)}(\text{IC}(U_{\mathcal{S}L(2)}^d)))
\]
as a direct summand, and the anti-diagonal Heisenberg algebra generated by \( P_n^{(1)} - P_n^{(2)} \) acts on its direct sum over \( d \). (See §5(xii).)
Let us return back to general $G$. Let $L_i$ be the Levi subgroup as in the previous subsection. We identify $\text{IC}(U_{dL(2)}^d)$ with $\text{IC}(U_{L_i}^d)$ as before, and we have a(n anti-diagonal) Heisenberg algebra representation on

\begin{equation}
\bigoplus_d H^*_T(U_T, \Phi_{T,L}(\text{IC}(U_{L_i}^d))) \otimes_{A_T} F_T.
\end{equation}

Using the decomposition (4.51) and $\Phi_{T,L_i} \Phi_{L,G} = \Phi_{T,G}$, we have an induced Heisenberg algebra representation on $M_F(a)$ in (6.4). Let us denote the Heisenberg generator by $P_i^n$.

By Lemma 4.31, the space $M_F(a)$ is isomorphic to

\begin{equation}
\text{Sym}((U^1 \oplus U^2 \oplus \cdots) \otimes_C F_T)
\end{equation}

where Sym denotes the symmetric power. $(U^d = U_{T,G}^d$ as before.)

Let us describe $P_i^n$ in this space. Recall that we have the orthogonal decomposition $U^d = U_{T,L_i}^d \oplus (U_{T,L_i}^d)^\perp$ in (4.52). Then we have the factorization

\begin{equation}
\text{Sym}((U^1 \oplus U^2 \oplus \cdots) \otimes_C F_T) \cong \text{Sym}((U_{T,L_i}^d \oplus (U_{T,L_i}^d)^\perp \oplus \cdots) \otimes_C F_T)
\end{equation}

The first factor of the right hand side is the usual Fock space associated with the Cartan subalgebra $\mathfrak{h}_{sl_2}$ of $\mathfrak{sl}_2$. In fact, using $U_{dL_i}^d \cong \mathfrak{a}_{2d}$, we identify $U_{T,L_i}^d$ with $\mathfrak{h}_{sl_2}$. The pairing is multiplied by $-1/\varepsilon_1\varepsilon_2$ from the natural one. Then the factor is $\text{Sym}(\mathfrak{z}^{-1}\mathfrak{h}_{sl_2}[\mathfrak{z}^{-1}])$ and the Heisenberg algebra acts in the standard way. From its definition, our Heisenberg operator $P_i^n$ is given by the tensor product of the Heisenberg operator for $\text{Sym}(\mathfrak{z}^{-1}\mathfrak{h}_{sl_2}[\mathfrak{z}^{-1}])$, and the identity.

The following means that the operators $P_i^n$ define the Heisenberg algebra $\mathfrak{heis}(\mathfrak{h})$ associated with the Cartan subalgebra $\mathfrak{h}$ of $\mathfrak{g}$.

**Proposition 6.15.** Heisenberg generators satisfy commutation relations

\begin{equation}
[P_i^m, P_j^n] = -m\delta_{m,-n}(\alpha_i, \alpha_j)\frac{1}{\varepsilon_1\varepsilon_2}
\end{equation}

If we normalize the generator by $\hat{n}_i^n = \varepsilon_2 P_i^n$, the relations match with a standard convention with level $-\varepsilon_2/\varepsilon_1 = k + h'$. See (B.6).

From the construction, $P_{a,d}$ applied to the vacuum vector $|a\rangle \in H^0_T(U_T, \Phi_{T,G}(\text{IC}(U_G^0)))$ is equal to $\Phi_{T,L_i}(\delta^1_{L_i,G}) \circ 1_{L_i}^d \in U^d$ divided by $\varepsilon_1\varepsilon_2$, considered as an element in (6.13).

From the construction, (6.13) is the Fock space of the Heisenberg algebra associated with the Cartan subalgebra $\mathfrak{h}$. It is the space of
polynomials on $t \mathfrak{h}^*[t]$ with values in $F_T$. The element $\tilde{\alpha}_i^d$ is a linear function, living on $t^d \mathfrak{h}^*$.

Proof of Proposition 6.15. The case $(\alpha_i, \alpha_j) = 2$, i.e., $i = j$ is obvious from the construction.

Next consider the case $(\alpha_i, \alpha_j) = -1$. Then $i$ and $j$ are connected by an edge in the Dynkin diagram. Let us take the parabolic subgroup $P$ corresponding to the subset consisting of two vertices $i$ and $j$, and the corresponding Levi subgroup $L$. We have $[L, L] \cong SL(3)$. Then from our construction and the compatibility of the stable envelop with the hyperbolic restriction functor in §5(xiii), the assertion follows the $SL(3)$-case, which is clear as Heisenberg algebra generators are given by

$$P^n_i = P_n \otimes 1 \otimes 1 - 1 \otimes P_n \otimes 1, \quad P^n_j = 1 \otimes P_n \otimes 1 - 1 \otimes 1 \otimes P_n.$$  \hspace{1cm} (6.17)

Note also that our polarization $\delta$ in (6.6) was chosen so that it is the same as the polarization for $\tilde{U}^d_{SL(3)}$ via Lemma 5.15 up to overall sign independent of $d$.

Finally consider the case $(\alpha_i, \alpha_j) = 0$. We argue as above by taking the corresponding Levi subgroup $L$ with $[L, L] \cong SL(2) \times SL(2)$. Then it is clear that Heisenberg generators commute. If a reader would wonder that $SL(2) \times SL(2)$ is not considered in §5, we instead take a type $A_k$ subdiagram containing $i$, $j$ and take the corresponding Levi subgroup $L$ with $[L, L] \cong SL(k+1)$. Then it is clear that the Heisenberg generators $P^i_m$, $P^j_n$ commute for $SL(k+1)$. Therefore they commute also for $G$. \hfill $\square$

Let us consider Heisenberg operators $P^i_n([0]) = \varepsilon_1 \varepsilon_2 P^i_n$, coupled with the Poincaré dual of $[0] \in H^*_T(\mathbb{A}^2)$, and denote them by $\tilde{P}^i_n$. Then they are well-defined on non-localized equivariant cohomology groups

$$\bigoplus_d H^*_T(U^d, \Phi_{T,G}(IC(U^d_G))),$$ \hspace{1cm} (6.18)

and satisfy the commutation relations

$$[\tilde{P}^i_m, \tilde{P}^j_n] = -m \delta_{m,-n}(\alpha_i, \alpha_j)\varepsilon_1 \varepsilon_2.$$ \hspace{1cm} (6.19)

The same is true for the non-localized equivariant cohomology with compact supports.

We define the $A$-form $\mathfrak{Heis}_A(\mathfrak{h})$ of the Heisenberg vertex algebra as the vertex $A$-subalgebra of $\mathfrak{Heis}(\mathfrak{h})$ generated by $\tilde{P}^i_n$. 
6(iv). **Virasoro algebra.** Let us introduce 0-mode operators $P^i_0$. In §5(ii) we did not introduce them. Since they commute with all other operators, we can set them any scalars. We follow the convention in [40, §13.1.5, §14.3.1], that is

\begin{equation}
(6.20) \quad P^i_0 = \frac{a^i}{\varepsilon_1\varepsilon_2}.
\end{equation}

Here $a^i$ is the $i$th simple root, and should be identified with $a_i - a_{i+1}$ in [40] in the Fock space $F(a_1) \otimes \cdots \otimes F(a_r)$ corresponding to the equivariant cohomology of Gieseker spaces for rank $r$ sheaves. We also set $\tilde{P}^i_0 = \varepsilon_1\varepsilon_2 P^i_0 = a^i$.

We then introduce Virasoro generators by

\begin{equation}
(6.21) \quad L^i_n = -\frac{1}{4\varepsilon_1\varepsilon_2} \sum_m : P^i_m P^i_{n-m} : - \frac{n}{2} (\varepsilon_1 + \varepsilon_2) P^i_n + \frac{(\varepsilon_1 + \varepsilon_2)^2}{4\varepsilon_1\varepsilon_2} \delta_{n,0}.
\end{equation}

See [40, (13.10),(14.10)]. Let us briefly explain how to derive the above expression from [40]: The Virasoro field $T(\gamma, \kappa) = \sum L_n(\gamma, \kappa) z^{-n}$ in [40, (13.10)] is given by

\begin{equation}
(6.22) \quad T(\gamma, \kappa) = \frac{1}{2} : \alpha^2 : (\gamma) + \partial \alpha(\gamma \kappa) - \frac{1}{2} \tau(\gamma \kappa^2),
\end{equation}

where $\alpha(\gamma) = \sum \alpha_n(\gamma) z^{-n}$ is the free field. Note that $T$ and $\alpha$ are different from the usual convention, as the exponents are not $-n-1$, $-n-2$ respectively. Also $\partial = z\partial_z$.

We take $\gamma = 1$, the fundamental class of $H^0_{\mathbb{P}}(\mathbb{A}^2)$. Next note that $\alpha = \alpha^-/\sqrt{2}$ [40, (14.8)], and our $P^i$ is identified with $\alpha^-$. This is the reason we have $1/4$ instead of $1/2$. The remaining factor $-\varepsilon_1\varepsilon_2$ comes from $1^2 = -1 \otimes \text{pt}$ in [40, §13.3.2].

For the second term, note $\kappa = \hbar/\sqrt{2}$ (see [40, (14.8)]), $\hbar = -t_1 - t_2$ (see [40, §17.1.1,(18.10)] for example). We denote their $t_1$, $t_2$ by $\varepsilon_1$, $\varepsilon_2$ instead.

For the last constant term, we have $-\gamma \kappa^2 = -(\varepsilon_1 + \varepsilon_2)^2/2$ and $\tau(1) = -\int_{\mathbb{A}^2} 1 = -1/\varepsilon_1\varepsilon_2$.

The Virasoro algebra commutation relations are

\begin{equation}
(6.23) \quad [L^i_m, L^i_n] = (m - n) L^i_{m+n} + \left( 1 + \frac{6(\varepsilon_1 + \varepsilon_2)^2}{\varepsilon_1\varepsilon_2} \right) \delta_{m,-n} \frac{m^3 - m}{12}.
\end{equation}

See [40, §13.3.2]. And the highest weight is given by

\begin{equation}
(6.24) \quad L^i_0 |\alpha\rangle = -\frac{1}{4} \left( \frac{(a^i)^2}{\varepsilon_1\varepsilon_2} - \frac{(\varepsilon_1 + \varepsilon_2)^2}{\varepsilon_1\varepsilon_2} \right) |\alpha\rangle.
\end{equation}

See [40, §13.3.5].
In order to apply the result of Feigin-Frenkel to our situation later, we shift $P^i_n$ in (6.21) as $P^i_n - (\varepsilon_1 + \varepsilon_2)/\varepsilon_1\varepsilon_2\delta_{n,0}$ (see [40, §19.2.5]) so that

\begin{equation}
L^i_n = -\frac{1}{4}\varepsilon_1\varepsilon_2 \sum_m :P^i_m P^i_{n-m}: - \frac{n+1}{2}(\varepsilon_1 + \varepsilon_2)P^i_n.
\end{equation}

This is a standard embedding of the Virasoro algebra in the Heisenberg algebra, given as the kernel of the screening operator (see [28, §15.4.14]). We have

\begin{equation}
P^i_0 = \frac{1}{\varepsilon_1\varepsilon_2}(a^i - (\varepsilon_1 + \varepsilon_2))
\end{equation}
in this convention.

We modify (6.21) as

\begin{equation}
L^i_n = -\frac{1}{4}\varepsilon_1\varepsilon_2 \sum_m :P^i_m - \frac{\varepsilon_1 + \varepsilon_2}{\varepsilon_1\varepsilon_2}\delta_{m,0} :P^i_m :P^i_{n-m} - \frac{\varepsilon_1 + \varepsilon_2}{\varepsilon_1\varepsilon_2}\delta_{m,n}:
\end{equation}

\begin{equation}
\begin{align*}
&- \frac{1}{2}(\varepsilon_1 + \varepsilon_2)P^i_n + \frac{(\varepsilon_1 + \varepsilon_2)^2}{4\varepsilon_1\varepsilon_2}\delta_{n,0} \\
&- \frac{n+1}{2}(\varepsilon_1 + \varepsilon_2)(P^i_n - \frac{\varepsilon_1 + \varepsilon_2}{\varepsilon_1\varepsilon_2}\delta_{n,0}).
\end{align*}
\end{equation}

Therefore if we replace $P^i_n$ by $P^i_n - (\varepsilon_1 + \varepsilon_2)/\varepsilon_1\varepsilon_2\delta_{n,0}$, we get the above expression.

We denote by $\mathfrak{Vir}_i$ the Virasoro vertex subalgebra of $\mathfrak{Vir}(\mathfrak{h})$ generated by $L^i_n$.

Let us introduce a modified Virasoro generator $\tilde{L}^i_n = \varepsilon_1\varepsilon_2L^i_n$. We have

\begin{equation}
\tilde{L}^i_n = -\frac{1}{4} \sum_m :\tilde{P}^i_m \tilde{P}^i_{n-m}: - \frac{n+1}{2}(\varepsilon_1 + \varepsilon_2)\tilde{P}^i_n.
\end{equation}

Hence $\tilde{L}^i_n$ is an element in $\mathfrak{Vir}_{\mathfrak{A}}(\mathfrak{h})$. We denote the corresponding vertex $\mathfrak{A}$-subalgebra by $\mathfrak{Vir}_{\mathfrak{A}}(\mathfrak{h})$.

Note that the central charge $1 + 6(\varepsilon_1 + \varepsilon_2)^2/\varepsilon_1\varepsilon_2$ is equal to that of Virasoro algebras, appearing in the construction of the $\mathcal{W}$-algebra $\mathcal{W}_k(\mathfrak{g})$ as the BRST reduction of the affine vertex algebra at level $k$, if we have the relation

\begin{equation}
\frac{(\varepsilon_1 + \varepsilon_2)^2}{\varepsilon_1\varepsilon_2} = k + h^\vee - 2 + \frac{1}{k + h^\vee},
\end{equation}
see [28, §15.4.14] and Corollary B.59 below. In other words, \( k + h^\vee = -\varepsilon_2/\varepsilon_1 \) or \(-\varepsilon_1/\varepsilon_2 \). It is known that the \( \mathcal{W} \)-algebra for type \( ADE \) has a symmetry under \( k + h^\vee \leftrightarrow (k + h^\vee)^{-1} \) [28, Prop. 15.4.16]. Therefore either choice gives the same result. We here take \( k + h^\vee = -\varepsilon_2/\varepsilon_1 \), see (6.1). It is remarkable that the symmetry \( k + h^\vee \leftrightarrow (k + h^\vee)^{-1} \) corresponds to a trivial symmetry \( \varepsilon_1 \leftrightarrow \varepsilon_2 \) in geometry.

6(v). The first Chern class of the tautological bundle. Let us explain a geometric meaning of the Virasoro generators in the previous subsection. It was obtained in [40, Th. 14.2.3], based on an earlier work by Lehn [38] for the rank 1 case. Let us first consider the rank 2 case.

Consider the Gieseker space \( \tilde{U}_2^d \) of rank 2 framed sheaves on \( \mathbb{P}^2 \) with \( c_2 = d \). For \( (E, \varphi) \in \tilde{U}_2^d \), consider \( H^1(\mathbb{P}^2, E(-\ell_\infty)) \). Other cohomology groups vanish, and hence it has dimension equal to \( d \) by the Riemann-Roch formula. In the ADHM description, it is identified with the vector space \( \mathcal{V} \). When we vary \( E \), it forms a vector bundle over \( \tilde{U}_2^d \), which we denote by \( \mathcal{V} \). Its first Chern class \( c_1(\mathcal{V}) \) can be considered as an operator on \( H^1_\varepsilon(\tilde{U}_2^d) \) acting by the cup product. Then its commutator with the diagonal Heisenberg generator, restricted to \( \text{IH}^*_\varepsilon(\tilde{U}_{SL_2}^d) \), is the Virasoro generator up to constant:

\[
[c_1(\mathcal{V}), P_n^\Delta]|_{\text{IH}^*_\varepsilon(\tilde{U}_{SL_2}^d)} = nL_n,
\]

where we denote \( L_n \) in the previous subsection by \( L_n \) since \( G = SL_2 \). (See [40, Th. 14.2.3].)

Let us remark that \( c_1(\mathcal{V}) \) is defined on non-localized equivariant cohomology groups \( \text{IH}^*_{\tau,c}(\tilde{U}_2^d) \). Therefore \( \tilde{L}_n = \varepsilon_1\varepsilon_2L_n \) is also well-defined on non-localized equivariant cohomology groups for \( n \neq 0 \). The operator \( \tilde{L}_0 = \varepsilon_1\varepsilon_2L_0 \) is also well-defined as it is the grading operator ([40, Lem. 13.1.1]).

Returning back to general \( G \), we see that \( \tilde{L}_n \) is well-defined on

\[
\bigoplus_d H^*_{\tau,c}(\mathcal{U}_{L_n}^d, \Phi_{L_n,G}(\text{IC}(\mathcal{U}_{G}^d)))
\]

thanks to the decomposition (4.51). Namely this space is a module over \( \mathfrak{Vir}_{i,A} \). It lies in between the first two spaces in (6.3):

\[
\text{IH}^*_{\tau,c}(\mathcal{U}_G^d) \to H^*_{\tau,c}(\mathcal{U}_{L_1}^d, \Phi_{L_1,G}(\text{IC}(\mathcal{U}_{G}^d))) \to H^*_{\tau,c}(\mathcal{U}_T, \Phi_{T,G}(\text{IC}(\mathcal{U}_{G}^d))).
\]

The formula (6.28) relates operators \( \tilde{L}_n \) and \( \tilde{P}_n^\Delta \) acting on the middle and right spaces respectively via the second homomorphism.
6(vi). \textbf{W-algebra representation.} Let us consider the vertex algebra associated with the Heisenberg algebra, and denote it by the same notation \( \text{Heis}(\mathfrak{h}) \) for brevity. It is regarded as a vertex algebra over \( \mathbb{F} \).

We have the Virasoro vertex subalgebra \( \text{Vir}_i \) corresponding to each simple root \( \alpha_i \) as in §6(iv). Consider the orthogonal complement \( \alpha_i^\perp \) of \( \mathbb{C} \alpha_i \) in \( \mathfrak{h} \), and the corresponding Heisenberg vertex algebra \( \text{Heis}(\alpha_i^\perp) \). It commutes with \( \text{Vir}_i \), and the tensor product \( \text{Vir}_i \otimes \text{Heis}(\alpha_i^\perp) \) is a vertex subalgebra of \( \text{Heis}(\mathfrak{h}) \).

By a result of Feigin-Frenkel (see \([28, \text{Th. 15.4.12}]\)), the \( \mathcal{W} \)-algebra \( \mathcal{W}_k(\mathfrak{g}) \) is identified with the intersection

\begin{equation}
\bigcap_i \text{Vir}_i \otimes \text{Heis}(\alpha_i^\perp)
\end{equation}

in \( \text{Heis}(\mathfrak{h}) \) when the level \( k \) is generic. More precisely, \( \text{Vir}_i \otimes \text{Heis}(\alpha_i^\perp) \) is given by the kernel of a screening operator on \( \text{Heis}(\mathfrak{h}) \), and \( \mathcal{W}_k(\mathfrak{g}) \) is the intersection of the kernel of screening operators.

Now \( \mathcal{W}_k(\mathfrak{g}) \) has a representation on the direct sum of localized equivariant cohomology groups \( M_{\mathbb{F}}(a) \) (see (6.4)), as a vertex subalgebra of \( \text{Heis}(\mathfrak{h}) \).

6(vii). \textbf{Highest weight.} In this subsection we explain that we can identify \( a \) with the highest weight of the \( \mathcal{W}_k(\mathfrak{g}) \)-module \( M_{\mathbb{F}}(a) \), where the highest weight vector is \( |a\rangle \).

Let us first briefly review the definition of Verma modules of the \( \mathcal{W} \)-algebra to set up the notation. See \([2, \text{§5}]\) for detail.

Let \( \mathcal{U}(\mathcal{W}_k(\mathfrak{g})) \) be the current algebra of the \( \mathcal{W} \)-algebra as in \([2, \text{§4}]\). (The finite dimensional Lie algebra is denoted by \( \mathfrak{g} \), while \( \mathfrak{g} \) is the corresponding untwisted affine Lie algebra in \([2]\).) We denote the current algebra of the Heisenberg algebra by \( \mathcal{U}(\text{Heis}(\mathfrak{h})) \). It is a completion of the universal enveloping algebra of the Heisenberg Lie algebra. The embedding \( \mathcal{W}_k(\mathfrak{g}) \subset \text{Heis}(\mathfrak{h}) \) induces an embedding \( \mathcal{U}(\mathcal{W}_k(\mathfrak{g})) \to \mathcal{U}(\text{Heis}(\mathfrak{h})) \).

We have decompositions \( \mathcal{U}(\mathcal{W}_k(\mathfrak{g})) = \bigoplus_d \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_d, \mathcal{U}(\text{Heis}(\mathfrak{h})) = \bigoplus_d \mathcal{U}(\text{Heis}(\mathfrak{h}))_d \) by degree. Two decompositions are compatible under the embedding. Let

\begin{equation}
\mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_{\geq 0} \overset{\text{def}}{=} \bigoplus_{d \geq 0} \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_d, \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_{> 0} \overset{\text{def}}{=} \bigoplus_{d > 0} \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_d.
\end{equation}

The \textit{Zhu algebra} of \( \mathcal{U}(\mathcal{W}_k(\mathfrak{g})) \) is given by

\begin{equation}
\mathfrak{z}(\mathcal{W}_k(\mathfrak{g})) \overset{\text{def}}{=} \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_0/\sum_{r > 0} \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_{-r} \mathcal{U}(\mathcal{W}_k(\mathfrak{g}))_r.
\end{equation}
Then it is isomorphic to the center $Z(g)$ of the universal enveloping algebra $U(g)$ of $g$ ([2, Th. 4.16.3]). We further identify it with the Weyl group invariant part of the symmetric algebra of $h$ ([2, (55)]):

\[(6.36) \quad \mathfrak{z}h(W_k(g)) \cong Z(g) \cong S(h)^W.\]

We have an induced embedding $\mathfrak{z}h(W_k(g)) \to \mathfrak{z}h(\mathfrak{hei}(h)))$, where the latter is the subalgebra generated by zero modes. We have

\[(6.37) \quad \mathfrak{z}h(\mathfrak{hei}(h))) \cong S(h).\]

**Lemma 6.38.** Under the identifications (6.36, 6.37), the embedding $\mathfrak{z}h(W_k(g)) \to \mathfrak{z}h(\mathfrak{hei}(h)))$ is induced by

\[(6.39) \quad h^i \mapsto h^i + (k + h^\vee),\]

where $h^i$ is a simple coroot of $h$.

**Proof.** The assertion follows from [2, Th. 4.16.4], together with an isomorphism $\hat{\ell}_{-\rho^\vee}$ which sends the old Zhu algebra, denoted by $H^0(\mathfrak{z}h(C_k(\mathfrak{g}))''_\text{old}))$ there, to a new one $H^0(\mathfrak{z}h(C_k(\mathfrak{g}))''_\text{new}))$. The zero mode is written as $\hat{J}_i(0)$ there. We can calculate $\hat{\ell}_{-\rho^\vee}(\hat{J}_i(0)) = \hat{J}_i(0) + k + h^\vee$ by formulas in [2, bottom of p.276].

We regard $\lambda \in h^*$ as a homomorphism $S(h)^W \to \mathbb{C}$ by the evaluation at $\lambda + \rho$, where $\rho$ is the half sum of positive roots of $g$. (It is denoted by $\gamma_\lambda$ in [2, §5].) We further regard $\mathbb{C}$ as a $\mathfrak{z}h(W_k(g))$-module by the above isomorphism, and denote it by $C_\lambda$. We extend it to a $\mathfrak{u}(W_k(g))_{>0}$-module on which $\mathfrak{u}(W_k(g))_{>0}$ acts trivially. Then we define

\[(6.40) \quad M(\lambda) \overset{\text{def}}{=} \mathfrak{u}(W_k(g)) \otimes_{\mathfrak{u}(W_k(g))_{\geq 0}} C_\lambda.\]

This is called the **Verma module with highest weight** $\lambda$.

Now we turn to our $W_k(g)$-module $M_F(\mathfrak{a})$. We identify $h = \text{Lie} T$ with $h^*$ by the invariant bilinear form $(\ , \ )$. Then we have an identification

\[(6.41) \quad S(h)^W \cong \mathbb{C}[\text{Lie} T]^W = H_T^*(\text{pt})^W.\]

We regard the collection $\mathfrak{a} = (a^1, \ldots, a^l)$ as a variable in $\text{Lie} T$ by considering $a^i$ its coordinate. Hence $\mathfrak{a}$ has value in $h^*$ by the above identification.

Recall that $|\mathfrak{a}|$ is the fundamental class $1 \in I \mathcal{H}_T^0(\mathcal{U}G_0)$. Since the degree $d$ corresponds to an instanton number, $\mathfrak{u}(W_k(g))_{>0}$ acts via a homomorphism $\mathfrak{u}(W_k(g))_{>0} \to F_T$ induced from $\mathfrak{z}h(W_k(g)) \to F_T$ on $F_T(\mathfrak{a}) = I \mathcal{H}_T^0(\mathcal{U}G_0) \otimes_{A_T} F_T$. Hence we have a $W_k(g)$-homomorphism $M(\lambda) \to M_F(\mathfrak{a})$, sending $1 \in C_\lambda \subset M(\lambda)$ to $|\mathfrak{a}| \in M_F(\mathfrak{a})$. Here we generalize the above definition to $\lambda$: $\mathfrak{z}h(W_k(g)) \to F_T$. 

Proposition 6.42. (1) The highest weight $\lambda$ is given by

\begin{equation}
\lambda = \frac{a}{\varepsilon_1} - \rho.
\end{equation}

(2) $M_F(a)$ is irreducible as a $W_k(\mathfrak{g})$-module, and isomorphic to $M(\lambda)$.

Note that the Weyl group action on $a$ corresponds to the dot action on $\lambda$, $w \cdot \lambda = w(\lambda + \rho) - \rho$.

Proof. (1) Recall that our Heisenberg generators and standard generators are related by $\hat{h}^i = \varepsilon_2 P_n^i$. Then the zero mode acts by

\begin{equation}
\frac{a_i}{\varepsilon_1} - 1 - \varepsilon_2 = (\alpha_i, \frac{a}{\varepsilon_1} - \rho) + k + \hbar^\vee
\end{equation}

thanks to (6.26).

We compare this formula with a realization of $M(\lambda)$ in [2, §5.2]. Our $\hat{h}^i$ is $\hat{t} - \bar{\rho} \vee (\hat{J}_i(n)) \in \mathfrak{H}((C_k(\mathfrak{g})''_{old}))$, and $\hat{t} - \bar{\rho} \vee (\hat{J}_i(0)) = \hat{J}_i(0) + k + \hbar^\vee$ as in Lemma 6.38. Since $\hat{J}_i(0)$ acts by $\lambda(J_i)$ on $M(\lambda)$, we obtain $\lambda = a/\varepsilon_1 - \rho$.

(2) It is well-known that $M(\lambda)$ is irreducible when $\lambda$ is generic. It follows, for example, from the fact that the determinant of the Kac-Shapovalov form is a nonzero rational function, hence the form is non-degenerate if $\lambda$ is neither a zero nor a pole. (See below for the Kac-Shapovalov form.) It also means that the form is non-degenerate when one views $\lambda$ as a rational function like us. Therefore $M(\lambda) \to M_F(a)$ is injective.

Now we compare the graded characters. The character of $M(\lambda)$ is the same as the character of $S(th[t])$ where $\deg(t) = 1$. We have $M_F(a) = F \otimes \bigoplus_{d \in \mathbb{N}} IH^*(U_{d}^G)$. According to [20, Theorem 7.10], the character of $M_F(a)$ (with grading by the instanton number) is the same as the character of $S(tg^f[t])$ where $f$ is a principal nilpotent. Since $\dim g^f = \dim b$, the graded characters of $M(\lambda)$ and $M_F(a)$ coincide. \hfill $\square$

6(viii). Kac-Shapovalov form. We shall identify the Kac-Shapovalov form on $M(\lambda)$ with a natural pairing on $M_F(a)$ given by the Verdier duality in this subsection.

Let us denote the natural perfect pairing by

\begin{equation}
\langle \ , \ \rangle : IH^*_T(U_G^d) \otimes_{A_T} IH^*_T(U_G^d) \to A_T.
\end{equation}

We multiply it by $(-1)^{dh^\vee}$ as usual. The notation conflicts with the pairing between $U_{d,P}$ and $U_{d,P-}$ in §4(x). But the two pairings are closely related, so the same notation does not give us any confusion. (See §8(i) for a more precise relation.)
By the localization theorem and Lemma 3.6 we extend it to a perfect pairing
\begin{equation}
\langle \cdot, \cdot \rangle: M_F(a) \otimes M_F(a) \to F_T.
\end{equation}
(cf. [14, §2.6].) We multiply it by \((-1)^{\dim U_d/2}\) as in (5.7).

When we localize the equivariant cohomology groups, there is no distinction between compact support and arbitrary support. We then see that (6.46) is symmetric.

We also have the pairing
\begin{equation}
\langle \cdot, \cdot \rangle: H^*_T, c(U_d T, \Phi_{T,G}(IC(U_d G))) \otimes H^*_T(U_d T, \Phi_{B,G}(IC(U_d G))),
\end{equation}
where \(\Phi_{B,G}^{-}\) is the hyperbolic restriction with respect to the opposite Borel \(B^{-}\) thanks to Braden’s isomorphism (3.16). This pairing also extends to a pairing (6.46), which is the same as defined above thanks to the compatibility between Braden’s isomorphism and \(i^! j^! \to i^* j^!\) as in the proof of Lemma 5.52.

The Heisenberg generator \(P^i_n\) satisfies
\begin{equation}
\langle u, P^i_n v \rangle = \langle \theta(P^i_n)u, v \rangle,
\end{equation}
where \(\theta\) is an anti-involution on the Heisenberg algebra given by
\begin{equation}
\theta(P^i_n) = -P^i_{-n} - \frac{2(\varepsilon_1 + \varepsilon_2)}{\varepsilon_1 \varepsilon_2} \delta_{n0}.
\end{equation}
Let us explain the reason for this formula of \(\theta\). Thanks to a standard property of convolution algebras, the diagonal Heisenberg generator \(P^\Delta_n\) in §5(ii) was defined so that \(P^\Delta_n\) is adjoint to \(P^\Delta_{-n}\). Since the intersection pairing (5.7) is compatible with the above one, we change \(n\) to \(-n\). Moreover, since \(P^i_n\) is defined via the stable envelop and we must use the opposite Borel as in §4(x), we need to swap \(P^{(1)}_n\) and \(P^{(2)}_n\) in §6(iii). Therefore we need to change the sign of \(P^i_{-n}\). The zero mode \(P^i_0\) was defined by hand as (6.26). We must also change the sign of \(a^i\) by the same reason. Then we must correct \(-P^i_0\) by \(-2(\varepsilon_1 + \varepsilon_2)/\varepsilon_1 \varepsilon_2\).

The Virasoro generator \(L^i_n\) is mapped to \(L^i_{-n}\) by \(\theta\). This is clear from (6.30): \(c_1(V)\) is self adjoint and \(\theta(P^\Delta_n) = P^\Delta_{-n}\) as we have just explained. It can be also checked by the formula (6.25).

Therefore \(\theta\) preserves \(\mathcal{W}_k(g)\), more precisely the associated Lie algebra \(\mathfrak{L}(\mathcal{W}_k(g))\) and the current algebra \(\mathcal{U}(\mathcal{W}_k(g))\), thanks to (6.33). We have
\begin{equation}
\langle u, xv \rangle = \langle \theta(x)u, v \rangle
\end{equation}
for \(x \in \mathfrak{L}(\mathcal{W}_k(g)), u, v \in M_F(a)\). On the other hand, \(\mathcal{L}(\mathcal{W}_k(g))\) has an anti-involution as in [2, §5.5], denoted also by \(\theta\).
Proposition 6.51. Our $\theta$ coincides with one in [2, §5.5].

Proof. We use the formula [2, Prop. 3.9.1] for the Heisenberg vertex algebra. We follow various notation in [2]. Since $\hat{J}_i(n)$ is a Fourier mode of the vertex operator $Y(v, z) = \sum \hat{J}_i(n) z^{-n-1}$ with $v = \hat{J}_i(-1)|0\rangle$, we have

$$\theta(\hat{J}_i(n)) = -(e^{T^*} v)_n.$$  

Here $T^*$ must be substituted by $T_{\text{new}}^*$ in [2, (173)]. Using (6.53) $v = \hat{J}_i(-1)|0\rangle = J_i(-1)|0\rangle - \sum_{\alpha \in \Delta} \alpha(h^i) \psi_{-\alpha}(0) \psi_{\alpha}(-1)|0\rangle$ (see [2, the beginning of §4.8]), we can check (6.54) $e^{T^*} v = \hat{J}_i(-1)|0\rangle + 2(1 - (k + h^\vee))|0\rangle$. Therefore we get the same formula as (6.49) under the identification $\hat{J}_i(-1) = \varepsilon_2 P^i_n$. (This $\hat{J}_i(-1)$ is in $\mathfrak{U}(C_k(\bar{g})'')$ and we do not need to apply $\hat{t}_{-\rho^\vee}$ in the proof of Proposition 6.42, as it is in $T_{\text{new}}^*$.)

Remark 6.55. We can identify the graded dual $D(M_F(a))$ of $M_F(a)$ with $M_F(a)$ itself via $\langle \cdot, \cdot \rangle$. Then it has a $\mathcal{W}_k(\mathfrak{g})$-module structure via $\theta$ and the formula (6.48). This is the duality functor $D$ in [2, §5.5].

When $\lambda$ is generic and $M(\lambda)$ is irreducible, the dual module $D(M(\lambda))$ is isomorphic to $M(-w_0(\lambda))$, where $w_0$ is the longest element in the Weyl group by [2, Th. 5.5.4]. Under the correspondence in Proposition 6.42(1), we have

$$-w_0(\lambda) = -w_0 \left( \frac{a}{\varepsilon_1} \right) - \rho,$$

as $w_0(\rho) = -\rho$. This means that the equivariant variable $a$ is replaced by $-w_0(a)$. Since the highest weight module is invariant under the Weyl group action, we can omit $w_0$. So the equivariant variable is $-a$ for $D(M_F(a))$. Therefore we have $D(M_F(a)) \cong M_F(-a)$. This is what we already observed in a geometric way above.

The pairing $\langle \cdot, \cdot \rangle$ is uniquely determined from (6.50) and the normalization $\langle -a|a \rangle = 1$ for generic $a$. It is called the Kac-Shapovalov form. We thus see that the natural pairing on $M_F(a)$ coincides with the Kac-Shapovalov form.

7. $R$-matrix

Recall that our hyperbolic restriction $\Phi_{L,G}$ depends on the choice of a parabolic subgroup $P$. Following [40, Ch. 4] (see also [18, §1.3]), we introduce $R$-matrices giving isomorphisms between various hyperbolic
restrictions, and study their properties. They are defined as rational functions in equivariant variables, and their existence is an immediate corollary to localization theorem in the previous section.

As for the usual $R$-matrices for Yangians, they satisfy the Yang-Baxter equation and are ultimately related to the $W$-algebra.

As an application, we give a different proof of the Heisenberg commutation relation (Proposition 6.15) up to sign, which does not depend on Gieseker spaces for $SL(3)$. We hope that this proof could be generalized to other rank 2 cases $B_2, G_2$.

Since the dependence on a parabolic subgroup is important, we denote the hyperbolic restriction by $\Phi_{P,L,G}$ in this section.

7(i). Definition. Let us consider the diagram (4.12) with respect to a parabolic subgroup $P$. Let us consider the homomorphism in (3.17)

$$I_P : H^*_T(U^d_L, \Phi^P_{L,G}(\mathcal{F})) \to H^*_T(U^d_L, i^*j^*\mathcal{F}) \cong H^*_T(U^d_G, \mathcal{F})$$

for $\mathcal{F} \in D^b_T(U^d_G)$. This is an isomorphism over the quotient field $F_T$ of $A_T = \mathbb{C}[\text{Lie}(T)]$. When we want to emphasize $\mathcal{F}$, we write $I_P^F$.

Definition 7.2. Let $P_1, P_2$ be two parabolic subgroups compatible with $(G, L)$. Let us introduce the $R$-matrix

$$R_{P_1,P_2} = (I_{P_1})^{-1}I_{P_2} : H^*_T(U^d_L, \Phi^P_{P_2}_{L,G}(\mathcal{F})) \otimes_{A_T} F_T$$

$$\to H^*_T(U^d_L, \Phi^P_{P_1}_{L,G}(\mathcal{F})) \otimes_{A_T} F_T$$

When we want to view $R_{P_1,P_2}$ as a rational function in equivariant variables, we denote it by $R_{P_1,P_2}(a)$. Dependence on $\varepsilon_1, \varepsilon_2$ are not important, so they are omitted. When we want to emphasize $\mathcal{F}$, we write $R_{P_1,P_2}^\mathcal{F}$.

From the definition, we have

$$R_{P_1,P_2}R_{P_2,P_3} = R_{P_1,P_3}.$$  \hspace{1cm} (7.4)

7(ii). Factorization. Suppose that $Q_1 \subset P$ be a pair of parabolic subgroups as in §4(v). Let $M \subset L$ be the corresponding Levi subgroups. We have $\Phi^{Q_1}_{M,L} \circ \Phi^P_{L,G} = \Phi^{Q_1}_{M,G}$ by Proposition 4.16.

We further suppose that there is another parabolic subgroup $Q_2$ contained in $P$ such that the corresponding Levi subgroup is also $M$:

$$M \subset Q_1, Q_2 \subset P.$$  \hspace{1cm} (7.5)

Then we also have the factorization $\Phi^{Q_2}_{M,L} \circ \Phi^P_{L,G} = \Phi^{Q_2}_{M,G}$. It is clear from the definition that we have

$$R_{Q_1,Q_2}^\mathcal{F} = R_{Q_1,P_2,P_3}^\mathcal{F}.$$  \hspace{1cm} (7.6)
Consider the case $L = T$. Note that Borel subgroups containing a fixed torus $T$ are parametrized by the Weyl group $W$. Let us denote by $B^w$ the Borel subgroup corresponding to $w \in W$, where $B^c = B$ is one which we have fixed at the beginning. From (7.4) $R_{B^w, B^y}^{T}$ factors to a composition of $R$-matrices for two Borel subgroups related by a simple reflection, i.e., $y = ws_i$. Then we choose $P = P^w_i \supset B^w, B^{w_{si}}$ for the parabolic subgroup to use (7.6). We have

\begin{equation}
R_{B^w, B^{w_{si}}}^T = R_{B_{1,L}, B_{2,L}}^F \Phi_{L, G}(F)
\end{equation}

where $L$ is the Levi subgroup of $P$ and $B_{1,L}, B_{2,L}$ are images of $B^w, B^{w_{si}}$ in $L$ respectively. As $[L, L] \cong SL(2)$, we are reduced to study the $SL(2)$ case. The $R$-matrix for $SL(2)$ was computed in [40, Th. 14.3.1] and will be explained in §7(v).

7(iii). Intertwiner property. Let $\mathcal{F} \in D^b_T(U^d_G)$. We have representations of the Ext algebra $Ext_{D^b_T(U^d_T)}(\mathcal{F}; \mathcal{F})$ on two cohomology groups in (7.1). This is thanks to (3.8, 3.9). Since $I_P$ is defined by a natural transformation of functors, it is a homomorphism of the Ext algebra. Therefore

**Proposition 7.8.** The $R$-matrix $R_{P_1, P_2}^T$ is a homomorphism of modules over the Ext algebra $Ext_{D^b_T(U^d_T)}(\mathcal{F}; \mathcal{F})$.

7(iv). Yang-Baxter equation. Take $L = T$ and $\mathcal{F} = IC(U^d_G)$ in this subsection.

By (4.58) we can map all cohomology groups in (7.3) to the fixed one $H^*_{T}(U^d_T, \Phi_{T,G}(IC(U^d_G))) \otimes_{A_T} F_T \cong M_F(a)$ by $\varphi_w$. We conjugate the $R$-matrix as

\begin{equation}
\varphi^{-1}_{w_1} R_{B^{w_1}, B^{w_2}} \varphi_w \in \text{End}(H^*_{T}(U^d_T, \Phi_{T,G}(IC(U^d_G))) \otimes_{A_T} F_T).
\end{equation}

Remark that $H^*_T(\text{pt})$-structures are twisted by isomorphisms $w_1, w_2 : \mathbb{T} \to \mathbb{T}$, as mentioned after (4.57). In practice, we change the equivariant variable $a$ according to $w_1, w_2$.

Since $\mathcal{I}_P$ is $\varphi_w$-equivariant, (7.9) depends only on $w_1 w_2^{-1}$. Moreover by (7.4) it is enough to consider the case $w_1 w_2^{-1}$ is a simple reflection $s_i$. Therefore we define

\begin{equation}
\tilde{R}_i \overset{\text{def}}{=} \varphi^{-1}_{s_i} R_{B^{s_i}, B^{s_i}} \varphi_{s_i}.
\end{equation}

By the factorization (§7(ii)), this is the $R$-matrix for $SL(2)$. Since we only have two chambers, (7.4) implies

\begin{equation}
\tilde{R}_i(s_i a) \tilde{R}_i(a) = 1.
\end{equation}
We change the equivariant variable to \( s_i a \), as it is the \( R \)-matrix from the opposite Borel to the original Borel. In the conventional notation for the \( R \)-matrix, we write \( u = \langle \alpha_i, a \rangle \) for the variable. Then \( \langle \alpha_i, s_i a \rangle = -u \), so this equation means the unitarity of the \( R \)-matrix.

Consider \( R \)-matrices \( \tilde{R}_i, \tilde{R}_j \). By the factorization (§7(ii)), we consider them as the \( R \)-matrices for the rank 2 Levi subgroup \( L \) containing \( SL(2) \) for \( i \) and \( j \). We compute the \( R \)-matrix from a Borel subgroup of \( L \) to the opposite Borel by (7.4) in two ways to get

**Theorem 7.12.**

\[
\tilde{R}_i(s_j a) \tilde{R}_j(a) = \tilde{R}_j(s_i a) \tilde{R}_i(a) \quad \text{if } (\alpha_i, \alpha_j) = 0, 
\]

\[
\tilde{R}_j(s_i s_j a) \tilde{R}_i(s_j a) \tilde{R}_j(a) = \tilde{R}_i(s_j s_i a) \tilde{R}_j(s_i a) \tilde{R}_i(a) \quad \text{if } (\alpha_i, \alpha_j) = -1. 
\]

7(v). \( SL(2) \)-case. As we mentioned earlier, it is enough to compute the \( R \)-matrix for \( SL(2) \), which was given in [40, Th. 14.3.1]. We briefly recall the result, and point out a slight difference for the formulation.

By Proposition 7.8 and the observation that the left hand side of the formula (6.30) is contained in the Ext algebra, we deduce that the \( R \)-matrix is an intertwiner of the Virasoro algebra. This is a fundamental observation due to Maulik-Okounkov [40].

The highest weight is generic, since we work over \( \mathbf{F}_T \). Therefore the intertwiner is unique up to scalar, and we normalize it so that it preserves the highest weight vector \( |a\rangle \).

In [40] the \( R \)-matrix is given as an endomorphism on the localized equivariant cohomology group of the fixed point set via the stable envelop. On the other hand, our \( R \) is an endomorphism on \( H^*_{T}(\mathcal{U}^d_T, \Phi^\circ_{T,G}(\text{IC}(\mathcal{U}^d_G))) \).

Concretely

\[
\tilde{R} = P_{12} \tilde{R}^{MO}|_{\text{anti-diagonal part}},
\]

where \( P_{12} \) is the exchange of factors of the Fock space \( F \otimes F \), as \( s_i = P_{12} \).

By [40, Prop. 4.1.3] we have

\[
\tilde{R} = -1 + O(a^{-1}), \quad a \to \infty.
\]

7(vi). \( \mathbb{G} \)-equivariant cohomology. Recall that a larger group \( \mathbb{G} = G \times \mathbb{C}^* \times \mathbb{C}^* \) acts on \( \mathcal{U}^d_{\mathbb{G}} \) so that \( \text{IC}(\mathcal{U}^d_{\mathbb{G}}) \) is a \( \mathbb{G} \)-equivariant perverse sheaf. Therefore we can consider \( \text{IH}^*_\mathbb{G}(\mathcal{U}^d_{\mathbb{G}}) = H^*_\mathbb{G}(\mathcal{U}^d_{\mathbb{G}}, \text{IC}(\mathcal{U}^d_{\mathbb{G}})) \). It is related to the \( \mathbb{T} \)-equivariant cohomology \( \text{IH}^*_\mathbb{T}(\mathcal{U}^d_{\mathbb{T}}) \) as follows.

Let \( N(\mathbb{T}) \) (resp. \( N(T) \)) be the normalizer of \( \mathbb{T} \) (resp. \( T \)) in \( \mathbb{G} \) (resp. \( G \)). Then we have forgetful homomorphisms \( \text{IH}^*_\mathbb{G}(\mathcal{U}^d_{\mathbb{G}}) \to \text{IH}^*_N(\mathbb{T})(\mathcal{U}^d_{\mathbb{T}}) \to \text{IH}^*_\mathbb{T}(\mathcal{U}^d_{\mathbb{T}}) \). It is well-known that the first homomorphism is an isomorphism, as the cohomology of \( \mathbb{G}/N(\mathbb{T}) = G/N(T) \) is 1-dimensional (see
e.g., [34]. The Weyl group $W = N(T)/T$ acts naturally on $\text{IH}^*_T(U_G^d)$, induced from the $N(T)$-action on $U_G^d$. Moreover we have

\begin{equation}
\text{IH}^*_T(U_G^d) \overset{\cong}{\rightarrow} \text{IH}^*_N(T)(U_G^d) \overset{\cong}{\rightarrow} \text{IH}^*_T(U_G^d)^W.
\end{equation}

Let us consider the following diagram

\begin{equation}
H^*_T(U_T^d, \Phi_{T,G}^B(\text{IC}(U_G^d))) \otimes_{A_T} F_T \xrightarrow{\mathcal{I}_B} \text{IH}^*_T(U_G^d) \otimes_{A_T} F_T
\end{equation}

where $s_i$ is a simple reflection of the above $W$-action.

**Lemma 7.19.** The diagram (7.18) is commutative.

**Proof.** We have $\tilde{R}_i = \varphi^{-1}_s \mathcal{I}_B^{-1} \mathcal{I}_B \varphi$. As an endomorphism of $\text{IH}^*_T(U_G^d) \otimes_{A_T} F_T$, it is replaced by $\mathcal{I}_B \varphi^{-1}_s \mathcal{I}_B^{-1}$, as $\varphi = \text{id}$.

From the definition of $\mathcal{I}_B$, and the commutativity of the diagram (4.56), we have $\mathcal{I}_B \varphi_s = \varphi_s \mathcal{I}_B$, where $\varphi_s$, in the right hand side is the action on $U_G^d$, the rightmost arrow in (4.56). Since the $W$-action is induced from $\varphi$, the assertion follows. \hfill \Box

**Proposition 7.20.** The Weyl group action on $M_F(a) = \bigoplus d \text{IH}^*_T(U_G^d) \otimes_{A_T} F_T$ commutes with the $W_k(g)$ action. Hence $W_k(g)$ acts on the $W$-invariant part $M_F(a)^W = \bigoplus d \text{IH}^*_T(U_G^d) \otimes_{A_G} F_G$.

**Proof.** Since $W_k(g)$ is the intersection of $\mathfrak{Vir} \otimes \mathfrak{H} \mathfrak{c} \mathfrak{i} \mathfrak{s} (\alpha^+_i)$ (see (6.33)), it is enough to show that $\mathfrak{Vir} \otimes \mathfrak{H} \mathfrak{c} \mathfrak{i} \mathfrak{s} (\alpha^+_i)$ commutes with $s_i$. By the previous lemma, $s_i$ is given by the $R$-matrix.

Let us first factorize the hyperbolic restriction functors $\Phi_{T,G}^B, \Phi_{T,G}^{B_{s_i}}$ as

$$
\Phi_{T,G}^B = \Phi_{T,L_i}^{B_{L_i}} \Phi_{L_i,G}^P, \quad \Phi_{T,G}^{B_{s_i}} = \Phi_{T,L_i}^{B_{s_i}} \Phi_{L_i,G}^P
$$

by Proposition 4.16. Then the same argument as in Proposition 7.8 shows that $\tilde{R}_i$ commutes with the action of $\text{Ext}$ algebra of $\Phi_{L_i,G}^P(\text{IC}(U_G^d))$.

Since the Virasoro generators $\tilde{L}^i_n$ are in this Ext algebra, the first assertion follows.

For the second assertion, we only need to check

$$(\text{IH}^*_T(U_G^d) \otimes_{A_T} F_T)^W \cong \text{IH}^*_T(U_G^d) \otimes_{A_G} F_G.$$

By (7.17) we have a natural injective homomorphism form the right hand side to the left. On the other hand, if $m/f$ ($f \in A_T$, $m \in$
IH\((\mathcal{U}_G^d)\) is fixed by \(W\), we have
\[
\frac{m}{f} = \frac{1}{|W|} \sum_{\sigma \in W} \sigma m = \frac{1}{|W|} \left( \prod_{\sigma \in W} \sigma f \right)^{-1} \sum_{\sigma \in W} \sigma m \prod_{\tau \neq \sigma} \tau f.
\]
This is contained in the right hand side. Therefore the above follows. \(\square\)

7(vii). A different proof of the Heisenberg commutation relation. Let us go back the point before Proposition 6.15.

Let \(\alpha_i^{d,-}\) be the element defined as in \(\alpha_i^d\) for the opposite Borel. Since the pairing can be computed from the \(SL(2) \cong [L_i, L_i]\) case, we already know that
\[
\langle \alpha_i^d, \alpha_i^{d,-} \rangle = 2d.
\]
(7.21)
We generalize this to

**Proposition 7.22.**

\[
\langle \alpha_i^d, \alpha_j^{d,-} \rangle = \pm d(\alpha_i, \alpha_j).
\]
(7.23)
The following proof does not determine \(\pm\), though we know that it is + by the reduction to the \(SL(3)\) case and the formula (5.86), which has been proved via Gieseker spaces.

**Proof.** We consider the case \((\alpha_i, \alpha_j) = -1\). The proof for the case \((\alpha_i, \alpha_j) = 0\) is similar (and simpler).

Let us study the leading part of Yang-Baxter equation (7.14). We consider \(R\)-matrices as endomorphisms of the space (6.13). By the factorization (7.6), we can use the expansion (7.16) for \(SL(2)\). Then ‘−1’ in (7.16) is replaced by the direct sum of \((-1)\) on \(U_{T,L_i}^d \cong \mathfrak{h}_{sl_2}\) and the identity on \((U_{T,L_i}^d)^\perp\) in (6.14). Let us denote it by \(s_i\).

Since \((U_{T,L_i}^d)^\perp\) is the orthogonal complement of \(\mathbb{C} \alpha_i^{d,-}\), we have
\[
\tilde{s}_i(x) = x - \langle x, \alpha_i^{d,-} \rangle \frac{\alpha_i^d}{d}, \quad \text{for } x \in U^d.
\]
(7.24)
From the Yang-Baxter equation, we have the braid relation
\[
\tilde{s}_i \tilde{s}_j \tilde{s}_i = \tilde{s}_j \tilde{s}_i \tilde{s}_j.
\]
(7.25)
Since we are considering the \(SL(3)\)-case, there is the diagram automorphism \(\sigma\) exchanging \(i\) and \(j\). By Lemma 4.64, we have \(\varphi_\sigma(\alpha_i^d) = (-1)^d \alpha_j^d\). Since \(\varphi_\sigma\) preserves the inner product, we get
\[
\langle \alpha_i^d, \alpha_j^{d,-} \rangle = \langle \alpha_j^d, \alpha_i^{d,-} \rangle.
\]
(7.26)
Now $\tilde{s}_i$ is the usual reflection with respect to the hyperplane $\tilde{\alpha}^d_{i-} = 0$. Hence we conclude $\langle \tilde{\alpha}^d_i, \tilde{\alpha}^d_j \rangle = \pm d$.

Note that $\tilde{\alpha}^d_i = \pm \tilde{\alpha}^d_j$ are excluded thanks to (4.54), which has been proved without using Gieseker spaces for $SL(3)$. □

Once we compute the inner product, the Heisenberg relation is a consequence of the factorization (6.14). The generator $P_i^n$ is the tensor product of the Heisenberg generator for the first factor and the identity in (6.14).

8. **Whittaker state**

8(i). **Universal Verma/Wakimoto modules.** Let us denote the direct sum of four $A_T$-modules over $d \in \mathbb{Z}_{\geq 0}$ in (6.3) by $M_A(a), N_A(a), D(N^-_A(a)), D(M_A(a))$ respectively. Thus we have

$$ (8.1) \quad M_A(a) \subset N_A(a) \subset D(N^-_A(a)) \subset D(M_A(a)). $$

The reason for the latter two notation will be clear soon.

The pairing (6.46) restricts to a perfect pairing

$$ (8.2) \quad \langle \cdot, \cdot \rangle : M_A(a) \otimes D(M_A(a)) \to A_T, $$
given by the Verdier duality. Similarly let us consider the space

$$ (8.3) \quad D(N_A(a)) = \bigoplus_d H^*_T(U_d^\alpha, \Phi^B_{T,G}(IC(U_d^\beta))), $$

where $\Phi^B_{T,G}$ is the hyperbolic restriction with respect to the opposite Borel $B_-$. We also have a natural embedding $D(N_A(a)) \subset D(M_A(a))$. Then we have a perfect pairing

$$ (8.4) \quad \langle \cdot, \cdot \rangle : N_A(a) \otimes D(N_A(a)) \to A_T. $$

Recall that $N_A(a), D(N_A(a))$ are modules over the integral form of the Heisenberg algebra $\mathfrak{h}$, as we remarked at the end of §6(iii). We change the latter module structure by $\theta$ in 6(viii) so that our notation is compatible with the convention in Remark 6.55.

Using Lemma 4.31, we make an identification

$$ (8.5) \quad N_A(a) \cong \bigoplus_{\lambda} \text{Sym}^{n_1} U^1 \otimes \text{Sym}^{n_2} U^2 \otimes \cdots \otimes H^*_T(S\lambda A^2), $$

where $U^d = U^d_{T,G}$ and $\lambda = (1^{n_1} 2^{n_2} \cdots)$. We also have an identification for the opposite Borel $B_-$:

$$ (8.6) \quad D(N_A(a)) \cong \bigoplus_{\lambda} \text{Sym}^{n_1} U^{1,-} \otimes \text{Sym}^{n_2} U^{2,-} \otimes \cdots \otimes H^*_T(S\lambda A^2), $$
where \( U_{d,-} = U_{T,G}^{d,-} \). Then the pairing (8.4) is the product of the pairing between \( U^d \) and \( U^{d,-} \) in \$4(x) \) and one between \( H^*_c(S\Lambda^2) \) and \( H^*_T(S\Lambda^2) \).

Moreover, two pairings (8.3) and (8.4) are compatible with the embeddings (8.1).

Let \( W_A(\mathfrak{g}) \) be the A-form of the W-algebra in \$B\).

**Proposition 8.7.** \( M_A(a), \ D(M_A(a)) \) are \( W_A(\mathfrak{g}) \)-modules.

**Proof.** Note that \( D(M_A(a)) \) is characterized as

\[
\{ m \in M_F(a) \mid \langle m, M_A(a) \rangle \in A_T \}.
\]

Therefore it is enough to show the assertion for \( M_A(a) \).

We consider \( M_A(a) \) as a subspace of \( N_A(a) \). The latter is a module over \( \text{Heis}_A(h) \), and hence over \( \text{Vir}_i, A \). By Theorem B.49, it is enough to check that \( M_A(a) \) is invariant under the intersection of \( \text{Vir}_i, A \) for all \( i \). Recall that we know that (6.31) is a \( \text{Vir}_i, A \)-module, as \( \tilde{L}^i_n \) is well-defined. Therefore it is enough to show that

\[
\mathrm{IH}^*_T, c(U^d) = \bigcap_i H^*_T, c(U^d, \Phi_{L,G}(\text{IC}(U^d)))).
\]

By Theorem 3.22 we have

\[
H^*_T, c(U^d, \Phi_{L,G}(\text{IC}(U^d))) = H^*_T, c(U^d, \Phi_{T,G}(\text{IC}(U^d))) \cap H^*_T, c(U^d, \Phi_{T,G}(\text{IC}(U^d))),
\]

where \( B^\kappa \) is the Borel subgroup corresponding to a simple reflection \( s_i \). Therefore it is enough to show that the intersection of the right hand side of (8.10) for all \( i \) is \( \mathrm{IH}^*_T, c(U^d) \). This is proved in a similar manner as Theorem 3.22. The only thing we need to use is the fact for any non-zero dominant \( \lambda \) there exists \( i \in I \) such that \( s_i(\lambda) \) is not dominant. \( \square \)

**Proposition 8.11.** The \( W_A(\mathfrak{g}) \)-submodule of \( M_F \) generated by \( |a\rangle \) is \( M_A(a) \), i.e.,

\[
M_A(a) = W_A(\mathfrak{g})|a\rangle.
\]

**Proof.** Comparison of bigraded dimensions: \( W_A(\mathfrak{g})|a\rangle \) is bigraded by the usual degree and \( c \)-deg, so that the bidegree of \( W^{(\kappa)}_n \) is \( (n, d_{\kappa} + 1) \), see \$B(ii)\. According to loc. cit., \( W_A(\mathfrak{g})|a\rangle \) is a free \( A \)-module (the bidegree of \( \varepsilon_1, \varepsilon_2, h \) equals \( (0, 1) \)) with the space of generators \( S(tw[t]) \) where \( w = \bigoplus_{\kappa=1}^\infty w^{(\kappa)} \) with the bidegree of \( w^{(\kappa)} \) equal to \( (0, d_{\kappa} + 1) \), and the bidegree of \( t \) equal to \( (1, 0) \).
On the other hand, $M_A(a)$ is bigraded by the instanton number and half the cohomological degree. It is a free $A$-module with the space of generators equal to $\bigoplus_{d \in \mathbb{N}} \text{IH}^*_c(U^d_G)$. According to [20, Theorem 7.10], $\bigoplus_{d \in \mathbb{N}} \text{IH}^*_c(U^d_G) \simeq S(tg^f[\ell])$ where $g^f = \bigoplus_{\kappa=1}^{\ell} g^f_{(\kappa)}$ with the bidegree of $g^f_{(\kappa)}$ equal to $(0, d\kappa + 1)$, and the bidegree of $t$ equal to $(1, 0)$.

On the other hand, it is clear from (8.5) that

$$N_A(a) = \mathfrak{heis}_A(h|a)$$

For a homomorphism $\chi: A \to \mathbb{C} \equiv \mathbb{C}_\chi$, the specialization

$$M_A(a) \otimes_A \mathbb{C}_\chi$$

is a module over $\mathcal{W}_k(\mathfrak{g})$ with level $k = \chi(a/\varepsilon_1) - h^\vee$. It is a Verma module with highest weight $\chi(a/\varepsilon_1) - \rho$, see §6(vii). Here $\chi$ is regarded as the assignment of variables $a$, $\varepsilon_1$, $\varepsilon_2$, or more concretely $\chi(a) = \sum \chi(a^i)\varpi_i$ for fundamental weights $\varpi_i$.

**Definition 8.15.** We call $M_A(a)$ the **universal Verma module**.

Similarly $N_A(a)$ is specialized to the Fock representation of the Heisenberg algebra by $\chi$. We call $N_A(a)$ the **universal Wakimoto module**. Similarly $D(M_A(a))$ is the universal dual Verma module, and $D(N_A(a))$ the universal dual Wakimoto module.

8(ii). $G$-equivariant cohomology. Let us consider the $G$-equivariant intersection cohomology groups as in §7(vi). We have

$$\bigoplus_d \text{IH}^*_c(U^d_G) = M_A(a)^W, \quad \bigoplus_d \text{IH}^*_c(U^d_G) = D(M_A(a))^W$$

by (7.17). Since the $W$-action commutes with the $\mathcal{W}_k(\mathfrak{g})$-action by Proposition 7.20, we see that both of (8.16) are modules over $\mathcal{W}_A(\mathfrak{g})$.

8(iii). Whittaker condition. Let $\tilde{W}^{(\kappa)}$ be as in §B(ii), which generates $\mathcal{W}_A(\mathfrak{g})$ in the sense of the reconstruction theorem. Let $[1^d] \overset{\text{def}}{=} \left[ U^d_G \right] \in \text{IH}^0_T(U^d_G)$ be the fundamental class. It conjecturally satisfies the following **Whittaker conditions**

**Conjecture 8.17.** Let $d \geq 1$, $n > 0$. We have

$$\tilde{W}^{(\kappa)}|1^d = \begin{cases} [1^{d-1}] & \text{if } \kappa = \ell \text{ and } n = 1, \\ 0 & \text{otherwise.} \end{cases}$$
Since \( \tilde{W}_n^{(\kappa)} \) is contained in \( W_A(g) \), it is a well-defined operator on \( D(M_A(a)) = \bigoplus IH_T^*(U_G^d) \). Since \( \tilde{W}_n^{(\kappa)} \) has \( c\deg = d_\kappa + 1 \) (\( d_\kappa \) is an exponent as in §8B), it sends \( |1^d> \in IH_T^0(U_G^d) \) into \( IH_T^2(d_{n+1-h\nu})(U_G^{d-n}) \).

Since \( d_\kappa \leq d_\ell = h\nu - 1 \), we have \( \tilde{W}_n^{(\kappa)}|1^d> = 0 \) unless \( n = 1, \kappa = \ell \). Also we see that \( \tilde{W}_1^{(\ell)}|1^d> \) is a multiple of \( |1^{d-1}> \) with the multiple constant of degree 0, i.e., a complex number. Moreover, if the multiple constant would be 0, it is a highest weight vector and generates a nontrivial submodule. Since \( M_F \) is irreducible, it is a contradiction. Therefore the constant cannot be zero. In particular, if we divide \( |1^d> \) by the constant, it satisfies the Whittaker condition (8.18).

Let \( |w^d> \) be the vector determined by with the normalization \( |w^0> = |1^0> = |a> \in IH_T^0(U_G^0) \). Its existence and uniqueness will follow from the discussion in §8(iv) below. (However it is not a priori clear that \( |w^d> \in D(M_A(a)) \), as for \( |1^d> \).) Therefore we already know that \( |1^d> = c_d|w^d> \) for some \( c_d \in \mathbb{C} \) by the above observation. The goal of this section is to prove a slightly weaker version of (8.18).

**Theorem 8.19.** Conjecture 8.17 holds up to sign.

Our strategy of the proof is as follows. To determine \( c_d \) up to sign, it is enough to compare pairings \( \langle 1^d|1^d \rangle \) with \( \langle w^d|w^d \rangle \). Moreover, as \( c_d \) is a complex number, we may do it after specifying equivariant variables \( \varepsilon_1, \varepsilon_2 \). We will show that

\[
\langle \varepsilon_1\varepsilon_2 \rangle^d \langle 1^d|1^d \rangle|_{\varepsilon_1,\varepsilon_2=0} = \frac{1}{d!} \langle \varepsilon_1\varepsilon_2 \rangle^d \langle 1^1|1^1 \rangle|_{\varepsilon_1,\varepsilon_2=0}^d,
\]

(8.20)

\[
\langle \varepsilon_1\varepsilon_2 \rangle^d \langle w^d|w^d \rangle|_{\varepsilon_1,\varepsilon_2=0} = \frac{1}{d!} \langle \varepsilon_1\varepsilon_2 \rangle^d \langle w^1|w^1 \rangle|_{\varepsilon_1,\varepsilon_2=0}^d.
\]

It implies that

\[
c_d^2 = c_1^{2d}.
\]

Recall that the top degree field \( \tilde{W}^{(\ell)} \) in §8B(ii) is well-defined only up to nonzero multiple even ignoring lower degree terms, as we just take it as a highest weight vector of a certain \( sl_2 \) representation. Therefore if we divide \( \tilde{W}^{(\ell)} \) by \( c_1 \), (8.18) holds up to sign.

Since \( |1^d> \) is canonically determined from geometry, it means that the top degree generator \( \tilde{W}^{(\ell)} \) is fixed without constant multiple ambiguity (up to sign). In particular, when we applied \( \tilde{W}^{(\ell)} \) to the highest weight vector \( |a> \), we get an invariant polynomial in \( a \) of degree \( h\nu \). (See 6(vii).) We do not study what this natural choice of the highest degree generator of the invariant polynomial \( S(h)^W \) is in general. But we will check that it is indeed a natural one for \( g = sl_{\ell+1} \) in §8(ix).
8(iv). **Whittaker vector and Kac-Shapovalov form.** In this sub-section, we shall prove that the Whittaker vector exists and is unique in the localized equivariant cohomology $M_{F}(a)$, which we think of Verma module with generic highest weight by Proposition 6.42. The argument is more or less standard (see e.g., [36]), but we give the detail, as we will use similar one later in §8(viii).

We have a nondegenerate Kac-Shapovalov form $\langle \ , \ \rangle$ on $M_{F}(a)$. Let $\theta$ denote the anti-involution on $\mathcal{U}(W_{F}(g))$ as in §6(viii). We have

\begin{equation}
\theta(\tilde{W}_{n}^{(k)}) = (-1)^{d+1} \tilde{W}_{n}^{(k)}.
\end{equation}

See [2, §5.5]. In particular, $\mathcal{U}(W_{A}(g))$ is invariant under $\theta$.

Let us denote the highest weight vector of $D(M_{F}(a))$ by $\langle -a \rangle$. See Remark 6.55 to see that its highest weight is $-a$.

Let $\lambda = (\lambda^{1}, \ldots, \lambda^{\ell})$ be an $\ell$-partition, i.e., it is an $\ell$-tuple of partitions $\lambda^{i} = (\lambda_{i}^{1}, \lambda_{i}^{2}, \ldots)$. We consider the corresponding operator

\begin{equation}
\tilde{W}[\lambda] \overset{\text{def}}{=} \tilde{W}_{-\lambda_{1}^{1}}^{(1)} \tilde{W}_{-\lambda_{2}^{1}}^{(1)} \cdots \tilde{W}_{-\lambda_{1}^{\ell}}^{(\ell)} \tilde{W}_{-\lambda_{2}^{\ell}}^{(\ell)} \cdots
\end{equation}

in the current algebra of the $W$-algebra. Then

\begin{equation}
\tilde{W}[\lambda]|a\rangle
\end{equation}

form a PBW base of $M_{F}(a)$. We define the Kac-Shapovalov form

\begin{equation}
K \equiv K^{d} \overset{\text{def}}{=} \langle -a|\theta(\tilde{W}[\lambda])\tilde{W}[\mu]|a\rangle_{\lambda \mu},
\end{equation}

where $\lambda, \mu$ runs over $\ell$-partitions whose total sizes are $d$. We consider it as a matrix, and an entry is denoted by $K_{\lambda \mu}$.

Let $(1^{d}) = (1, \ldots, 1)$ be the partition of $n$ whose all entries are 1. Let $\lambda_{0} = (\emptyset, \ldots, \emptyset, (1^{d}))$ be the $\ell$-partition where the first $(\ell-1)$ partitions are all $\emptyset$ and the last one is $(1^{d})$. The corresponding operator $\tilde{W}[\lambda_{0}]$ is $(\tilde{W}_{-1}^{(\ell)})^{d}$.

We have

\begin{equation}
\langle -a|\theta(\tilde{W}[\lambda])|w^{d}\rangle = \begin{cases} 1 & \text{if } \lambda = \lambda_{0}, \\ 0 & \text{otherwise} \end{cases}
\end{equation}

from (8.18) by the induction on $d$. Note that $|w^{0}\rangle = |a\rangle$, and hence $\langle -a|a\rangle = 1$.

Let us write the Whittaker vector $|w^{d}\rangle$ in the PBW base as

\begin{equation}
|w^{d}\rangle = \sum_{\mu} a_{\mu} \tilde{W}[\mu]|a\rangle.
\end{equation}
By (8.25) we have
\[ (8.27) \quad \sum_{\mu} K_{\lambda \mu} a_\mu = \delta_{\lambda \lambda_0}. \]
In other words,
\[ (8.28) \quad a_\mu = K^{-1}_{\mu \lambda_0}, \]
where \( K^{-1} = (K_{\mu \lambda}) \) is the inverse of \( K \). In particular, the existence and the uniqueness of \( |w^d\rangle \) follow.

We also get
\[ (8.29) \quad \langle w^d | w^d \rangle = K^{\lambda_0, \lambda_0}. \]

8(v). **Lattices.** Let
\[ (8.30) \quad \hat{W}_n^{(\kappa)} = (\varepsilon_1 \varepsilon_2)^{-1} W_n^{(\kappa)} \]
for \( \kappa = 1, \ldots, \ell, n \in \mathbb{Z} \).

**Lemma 8.31.** \( M_\mathcal{A}(a) \) is invariant under \( \hat{W}_m^{(\kappa)} \) with \( m > 0 \). Equivalently \( D(M_\mathcal{A}(a)) \) is invariant under \( \hat{W}_m^{(\kappa)} \) with \( m > 0 \).

**Proof.** Recall that \( M_\mathcal{A}(a) \) is graded by the instanton number \( d \):
\[ M_\mathcal{A}(a) = \bigoplus_d M_{d, \mathcal{A}}. \]
In algebraic terms, it is the grading by \( L_0 \). Let us take \( \hat{W}_m^{(\kappa)} \) with \( m > 0 \). We show
\[ (8.32) \quad \hat{W}_m^{(\kappa)} x \in M_{d-m, \mathcal{A}} \]
for any \( x \in M_{d, \mathcal{A}} \) by an induction on \( d \). If \( d = 0 \), we have \( \hat{W}_m^{(\kappa)} x = 0 \). Therefore the assertion is true.

Suppose that the statement is true for \( d' < d \). We may assume \( x = \hat{W}_{-n}^{(\kappa)} x' \) with \( n > 0, x' \in M_{d-n, \mathcal{A}} \) by Proposition 8.11. Since \( \hat{W}_{-n}^{(\kappa)} x' \in M_{d-n, \mathcal{A}} \) by the induction hypothesis, it is enough to show that \( [\hat{W}_m^{(\kappa)}, \hat{W}_{-n}^{(\kappa)}] x' \in M_{d, \mathcal{A}} \). In the Heisenberg algebra, we have \( [a, b] \in \varepsilon_1 \varepsilon_2 \tilde{H}_0^0(\mathfrak{g}) \) for \( a, b \in \tilde{H}_0^0(\mathfrak{g}) \) from the relation (6.19). Since \( \mathcal{W}_\mathcal{A}(\mathfrak{g}) \to \tilde{H}_0^0(\mathfrak{g}) \) is an embedding, we have the same assertion for \( \mathcal{W}_\mathcal{A}(\mathfrak{g}) \). Therefore the assertion follows. \( \square \)

Let \( \mathcal{R} \subset \mathcal{F} = \mathbb{Q}(\varepsilon_1, \varepsilon_2) \) be the local ring of regular functions at \( \varepsilon_1 = \varepsilon_2 = 0 \). Let \( \mathcal{R}_T = \mathcal{R}(a) \). We set
\[ (8.33) \quad M_{\mathcal{R}}(a) = M_\mathcal{A}(a) \otimes_{\mathcal{A}_T} \mathcal{R}_T, \quad D(M_{\mathcal{R}}(a)) = D(M_\mathcal{A}(a)) \otimes_{\mathcal{A}_T} \mathcal{R}_T, \]
\[ N_{\mathcal{R}}(a) = N_\mathcal{A}(a) \otimes_{\mathcal{A}_T} \mathcal{R}_T, \quad D(N_{\mathcal{R}}(a)) = D(N_\mathcal{A}(a)) \otimes_{\mathcal{A}_T} \mathcal{R}_T. \]
These modules are the localization with respect to the ideal
\[ (8.34) \quad \text{Ker}(\mathcal{A}_T = \mathbb{C}[\varepsilon_1, \varepsilon_2, a] = \mathbb{C}[\text{Lie } T] \to \mathbb{C}[a] = \mathbb{C}[\text{Lie } T]) \]
consisting of polynomials vanishing on Lie $T$.

From the definition, operators $\hat{W}_n^{(\kappa)}$ are well-defined on four modules in (8.33). Moreover operators $\check{W}_n^{(\kappa)}$ and $\hat{W}_n^{(\kappa)}$ are well-defined on $M_R(a)$ and $D(M_R(a))$ respectively if $n > 0$ by Lemma 8.31.

By the localization theorem, the first and the third homomorphisms in (6.3) become isomorphisms over $R_T$. Therefore

\begin{equation}
M_R(a) \xrightarrow{\sim} N_R(a), \quad D(N_R(a)) \xrightarrow{\sim} D(M_R(a)).
\end{equation}

Recall that we have Heisenberg operators $P_i^n = (\varepsilon_1 \varepsilon_2)^{-1} \tilde{P}_n$, coupled with the fundamental class $1 \in H^0_T(A^2)$. Let

\begin{equation}
P[\lambda] = P_{-\lambda_1}^1 P_{-\lambda_2}^1 \cdots P_{-\lambda_\ell}^\ell P_{-\lambda_2}^1 \cdots
\end{equation}

for $i = 1, \ldots, \ell$, $n \in \mathbb{Z}$, and an $\ell$-partition $\lambda = (\lambda^1, \ldots, \lambda^\ell)$. It is a well-defined operator on $D(M_R(a))$ by the proof of Lemma 8.31.

Replacing $P_i^n$ by $\tilde{P}_n$, we introduce similar operators $\tilde{P}[\lambda]$.

**Proposition 8.37.** We have

\begin{equation}
D(M_R(a)) = \text{Span}_{R_T} \{ P[\lambda]|a \},
\end{equation}

where $\lambda$ runs all $\ell$-partitions.

**Proof.** Thanks to (8.35), it is enough to show the assertion for $D(N_R(a))$. We shall prove that $D(N_A(a))$ is spanned by $P[\lambda]$ over $A$.

Recall that $N_A(a) = \text{Span}_{A_T} \{ \tilde{P}[\lambda]|a \}$, see (8.13). From the commutation relation

\begin{equation}
[P_m, \check{P}_n^j] = -m \delta_{m,-n} (\alpha_i, \alpha_j),
\end{equation}

we clearly have a perfect pairing between $N_A(a)$ and $\text{Span}_{A_T} \{ P[\lambda]|a \}$. The assertion follows. $\square$

8(vi). **Pairing at** $\varepsilon_1, \varepsilon_2 = 0$. We consider the pairing $\langle \ , \ \rangle$ on $M_F(a)$ in §6(viii), and restrict it to $D(M_R(a))$.

**Lemma 8.40.** We decompose $D(M_R(a))$ as $\bigoplus D(M_{d,R})$ by the instanton number $d$ as before.

1. $(\varepsilon_1 \varepsilon_2)^d \langle \ , \ \rangle$ takes values in $R_T$ on $D(M_{d,R})$.
2. Let $\langle \ , \ \rangle_0$ be its specialization at $\varepsilon_1 = \varepsilon_2 = 0$. For $m > 0$, we have

\begin{equation}
\langle x, \hat{W}_m^{(\kappa)} y \rangle_0 = \begin{cases} (-1)^{d+1} \langle \check{W}_m^{(\kappa)} x, y \rangle_0 & \text{if } m = 1, \\
0 & \text{otherwise}. \end{cases}
\end{equation}
Proof. (1) Thanks to (8.35), it is enough to show the assertion for $D(N_R(a))$. By (8.3) and $U^d_\epsilon = S^d A^2$, it is enough to show that the intersection pairing $\langle \cdot, \cdot \rangle$ on $H^*_\tau(S^d A^2)$ satisfies the same property. Note that $S^d A^2$ is a smooth orbifold. Since we only have a single fixed point $d \cdot 0$ in $S^d A^2$ and the weight of the tangent space there is $\varepsilon_1, \varepsilon_2, \varepsilon_1, \varepsilon_2, \ldots$ ($d$ times), the fixed point formula implies the assertion.

(2) Suppose $x \in D(M_{d,R}), y \in D(M_{d_--m,R})$ with $m > 0$. Then

$$\langle \varepsilon_1 \varepsilon_2 \rangle^d \langle x, \hat{W}_m^{(\kappa)} y \rangle = (-1)^{d+1} (\varepsilon_1 \varepsilon_2)^{m-1} (\varepsilon_1 \varepsilon_2)^{d-m} (\hat{W}_m^{(\kappa)} x, y)$$

by (8.21). Now we specialize $\varepsilon_1, \varepsilon_2 = 0$ to get the assertion.

Let us consider $M_0(a) \overset{\text{def}}{=} D(M_R(a)) \otimes_{R_T} \mathbb{C}/ \text{Rad}(\cdot, \cdot)_0$, where $R_T \to \mathbb{C}$ is the evaluation at $\varepsilon_1 = \varepsilon_2 = 0$, and $\text{Rad}(\cdot, \cdot)_0$ is the radical of $(\cdot, \cdot)_0$. Then (8.41) implies that $\hat{W}_m^{(\kappa)} = 0$ if $m > 1$, and $\hat{W}_0^{(\kappa)} = 0$ if $m = 1$.

Proposition 8.43. (1) $P_{-1} = 0$ if $m > 1$, and $P_{-1}, \hat{P}_{-1}$ are well-defined on $M_0(a)$. And we have

$$\langle x, P_{-1} y \rangle_0 = -\langle \hat{P}_{-1} x, y \rangle_0.$$ (8.44)

(2) We have commutation relations

$$[P_{-1}^{(i)}, P_{-1}^{(j)}] = 0, \quad [\hat{P}_{-1}^{(i)}, \hat{P}_{-1}^{(j)}] = 0, \quad [\hat{P}_{-1}^{(i)}, P_{-1}^{(j)}] = -\langle \alpha_i, \alpha_j \rangle.$$ (8.45)

(3) $M_0(a)$ is isomorphic to the polynomial ring in $P_{-1}^{(i)}$ ($i = 1, \ldots, \ell$). The pairing $\langle \cdot, \cdot \rangle_0$ is the induced pairing on the symmetric power from the pairing

$$\langle P_{-1}^{(i)} a, P_{-1}^{(j)} a \rangle_0 = -\langle \alpha_i, \alpha_j \rangle.$$ (8.46)

Proof. The same argument as above shows (1).

By Proposition 8.37 and (1), $M_0(a)$ is spanned by monomials in $P_{-1}$ applied to $[a]$.

(2) follows from Proposition 6.15.

(3) Let us replace $\hat{P}_{-1}, \hat{P}_{-1}$ by $Q_{-1}, \tilde{Q}_{-1}$ corresponding to an orthonormal basis of $\mathfrak{h}$ so that the commutation relation is $[\tilde{Q}_{-1}^{(i)}, Q_{-1}^{(j)}] = -\delta_{ij}$. Then (8.44) implies that monomials in $Q_{-1}^{(i)}$ are orthogonal. More precisely, the pairing is the standard one on $\mathbb{C}[Q_{-1}]$ up to sign:

$$\langle (Q_{-1}^{(i)})^n a, (Q_{-1}^{(j)})^m a \rangle_0 = (-1)^{n!} \delta_{mn},$$ (8.47)

and the pairing factors on $M_0(a) = \mathbb{C}[Q_{-1}] \otimes \cdots \otimes \mathbb{C}[Q_{-1}]$. This proves the assertion. □
8(vii). Proof, a geometric part.

Lemma 8.48. The first equality of (8.20) is true.

Proof. We have a natural homomorphism $\text{IH}_T^*(U_G^d) \to H_T^*(U_G^d)$ and the image of $1^d$ is the fundamental class $[U_G^d]$. Then $\langle 1^d | 1^d \rangle$ is equal to $\iota_*^{-1}[U_G^d]$, where $\iota: \{d-0\} \to U_G^d$ is the embedding of the $T$-fixed point $d-0$, and we use the localization theorem to invert $\iota_*: H_T^*(\{d-0\}) \to H_T^*(U_G^d)$ over $F_T$.

Let us consider the embedding $\xi: (U_G^d)^T = S^d \mathbb{A}^2 \to U_G^d$ of the $T$-fixed point set. Then

\begin{equation}
\xi_*: H_T^*(S^d \mathbb{A}^2) \to H_T^*(U_G^d)
\end{equation}

is an isomorphism over $R_T$. Since $H_T^*(S^d \mathbb{A}^2) \cong A_T[S^d \mathbb{A}^2]$, we have

\begin{equation}
\xi_*^{-1}[U_G^d] = f_d(a, \varepsilon_1, \varepsilon_2)[S^d \mathbb{A}^2]
\end{equation}

for $f_d(a, \varepsilon_1, \varepsilon_2) \in R_T$.

We have $\varepsilon_* = \xi_* \varepsilon_*$ for $\{d-0\} \to S^d \mathbb{A}^2$, and $\xi_*^{-1}[S^d \mathbb{A}^2] = (\varepsilon_1 \varepsilon_2)^{-d}/d!$. Therefore

\begin{equation}
d! (\varepsilon_1 \varepsilon_2)^d \langle 1^d | 1^d \rangle |_{\varepsilon_1, \varepsilon_2 = 0} = f_d(a, 0, 0).
\end{equation}

We replace the group $T$ by $T$ in (8.49) and denote the homomorphism by $\xi_*^T$, i.e., $\xi_*^T: H_T^*(S^d \mathbb{A}^2) \to H_T^*(U_G^d)$. It is an isomorphism over $C(a)$. Then we have

\begin{equation}
(\xi_*^T)^{-1}[U_G^d] = f_d(a, 0, 0)[S^d \mathbb{A}^2],
\end{equation}

where $[U_G^d]$, $[S^d \mathbb{A}^2]$ are considered in $T$-equivariant homology groups.

Let us take the projection $\pi: \mathbb{A}^2 \to \mathbb{A}^1$ and the factorization morphism $\pi_{a, G}^d: U_G^d \to S^d \mathbb{A}^1$. Let $S^d\pi: S^d \mathbb{A}^2 \to S^d \mathbb{A}^1$ denote the induced projection. Let $(S^d \mathbb{A}^1)_0$ be the open subset of $S^d \mathbb{A}^1$ consisting of distinct $d$ points. Then $\xi$ induces a morphism between inverse images $(S^d a)^{-1}(S^d \mathbb{A}^1)_0$ and $(\pi_{a, G}^d)^{-1}(S^d \mathbb{A}^1)_0$. We get

\begin{equation}
(\xi_*^T)^{-1}[\pi_{a, G}^d](S^d \mathbb{A}^1)_0 = f_d(a, 0, 0)(S^d a)^{-1}(S^d \mathbb{A}^1)_0
\end{equation}

by restricting (8.52) to open subsets. Now by the factorization we deduce $f_d(a, 0, 0) = f_1(a, 0, 0)^d$. \hfill \square

Remark 8.54. This result is also a simple consequence of a property of Nekrasov’s partition function

\begin{equation}
Z_{\text{inst}}^{\varepsilon_1, \varepsilon_2, a, \Lambda} \overset{\text{def}}{=} \sum_{d=0}^{\infty} \langle 1^d | 1^d \rangle \Lambda^{2h^V d}
\end{equation}

stating that

\begin{equation}
\varepsilon_1 \varepsilon_2 \log Z_{\text{inst}}^{\varepsilon_1, \varepsilon_2, a, \Lambda} = f_{\text{inst}}^{\varepsilon_1, \varepsilon_2}(a, \Lambda) + o(\varepsilon_1, \varepsilon_2)
\end{equation}
at $\varepsilon_1 = \varepsilon_2 = 0$. This property was proved by [55, 58] for type $A$ and by [13] for general $G$.

8(viii). **Proof, a representation theoretic part.** We shall complete the proof of the second equation in (8.20) in this subsection.

Let $F^{(\kappa)} \in S(\mathfrak{h})^W$ be one of generators as in §B(v). It has degree $d_\kappa + 1$.

**Lemma 8.57.** Following relations hold as operators on $D(M_{\mathbb{R}}(a)) \otimes_{\mathbb{R}} \mathbb{C}$:

(8.58) $\tilde{W}^{(\kappa)}_1 = \sum_i F^{(\kappa)}(a^1, \ldots, P^{(i)}_{1}, \ldots, a^\ell),$

(8.59) $\tilde{W}^{(\kappa)}_{-1} = \sum_i F^{(\kappa)}(a^1, \ldots, P^{(i)}_{-1}, \ldots, a^\ell).$

**Proof.** At first sight, the formula (B.47) seems to imply $\tilde{W}^{(\kappa)}_{-1} = 0$, and hence also $\tilde{W}^{(\kappa)}_1 = 0$ thanks to the anti-involution $\theta$. But (B.47) is the formula in the $W$-algebra at $\varepsilon_1 = \varepsilon_2 = 0$, and we want to consider $\tilde{W}^{(\kappa)}_1$ on $D(M_{\mathbb{R}}(a))$. Since the highest weight $\lambda = a/\varepsilon_1 - \rho$ cannot be specialized at $\varepsilon_1 = 0$, it could be nontrivial.

Let $\tilde{W}^{(\kappa)}$ be the state corresponding to the field $Y(\tilde{W}^{(\kappa)}; z) = \sum \tilde{W}^{(\kappa)}_n z^{-n-d_\kappa-1}$ as in (B.14). By (B.47) we have

(8.60) $\tilde{W}^{(\kappa)} = \tilde{W}^{(\kappa)}_{-d_\kappa-1}|0\rangle = F^{(\kappa)}(\tilde{P}^{(i)}_{-1})|0\rangle$

at $\varepsilon_1 = \varepsilon_2 = 0$. It implies that

(8.61) $Y(\tilde{W}^{(\kappa)}, z) = :F^{(\kappa)}(\tilde{P}^{(i)}(z)):+ o(\varepsilon_1, \varepsilon_2),$

where $o(\varepsilon_1, \varepsilon_2)$ is a field in $\mathcal{W}_A(\mathfrak{g})$ which vanishes at $\varepsilon_1 = \varepsilon_2 = 0$.

Let the field act on $M_{\mathbb{R}}(a)$ and specialize at $\varepsilon_1 = \varepsilon_2 = 0$. The point is that $\tilde{P}^{(i)}_0$ acts on $M_{\mathbb{R}}(a)$ by $a^i$ at $\varepsilon_1 = \varepsilon_2 = 0$. Therefore the field

(8.62) $\tilde{P}^{(i)}(z) = \sum_n \tilde{P}^{(i)}_n z^{-n-1}$

is specialized to

on $M_{\mathbb{R}}(a)$.

Let us specialize (8.61) at $\varepsilon_1 = \varepsilon_2 = 0$. Then $\tilde{P}^{(i)}(z)$ is replaced by (8.62), and the normal ordering by the usual multiplication. Therefore we obtain

(8.63) $Y(\tilde{W}^{(\kappa)}, z) = F^{(\kappa)}(a^i z^{-1} + \sum_{n<0} \tilde{P}^{(i)}_n z^{-n-1}).$

Taking coefficients of $z^{-d_\kappa}$ and then applying $\theta$, we obtain (8.58).
Next we study the action of $Y(\hat{W}(\kappa), z)$ on $D(M_{R}(a))$. Let us consider $\tilde{W}_{-1}^{(\kappa)}$ in (8.61). So we take coefficients of $z^{-d_{\kappa}}$. The term $o(\varepsilon_{1}, \varepsilon_{2})$ can be represented as a linear combination of monomials in $\tilde{P}_{m}^{(i)}$ with coefficients in the maximal ideal of $R$. We have at least one $\tilde{P}_{m}^{(i)}$ with $m < 0$ in each monomial. It can be divided, as an operator on $D(M_{R}(a))$, by $\varepsilon_{1}\varepsilon_{2}$ thanks to Lemma 8.31. Therefore $o(\varepsilon_{1}, \varepsilon_{2})/\varepsilon_{1}\varepsilon_{2}$ still specialized to 0 at $\varepsilon_{1} = \varepsilon_{2} = 0$. Therefore (8.61) implies (8.59). □

Lemma 8.64. The determinant of the matrix
\[
\left( \frac{\partial F^{(\kappa)}(a^{i})}{\partial a^{i}} \right)_{i, \kappa=1, \ldots, \ell}
\]
is a nonzero constant multiple of the discriminant $\Delta(a)$.

Proof. Consider $F = (F^{(1)}, \ldots, F^{(\ell)})$ as the morphism from $h$ to $h/W$, written in a coordinate system on $h/W$. Then the matrix in question is the differential of $F$. Since $h \to h/W$ is a covering branched along root hyperplanes, we deduce that a) its determinant is nonzero, and b) it is divisible by $\Delta(a)$. The degree of the determinant is the sum $\sum d_{\kappa}$, which is equal to the number of positive roots. Therefore we get the assertion. □

Since $\Delta(a)$ is invertible in $C(a)$, we deduce

Lemma 8.65. $M_{0}(a)$ is isomorphic to the polynomial ring in $\hat{W}_{-1}^{(\kappa)}$ $(\kappa = 1, \ldots, \ell)$.

Now the specialization of the Whittaker vector $|w^{d}\rangle$ in $M_{0}(a)$ is characterized by the conditions
\[
(8.66) \quad \tilde{W}_{1}^{(\kappa)}|w^{d}\rangle = \begin{cases} 
|w^{d-1}\rangle & \text{if } \kappa = \ell, \\
0 & \text{if } \kappa \neq \ell.
\end{cases}
\]
The existence and the uniqueness in $M_{0}(a)$ are proved exactly as in §8(iv). Moreover the pairing $\langle w^{d}|w^{d}\rangle_{0}$ is an entry of the inverse of the matrix
\[
(8.67) \quad K_{0}^{d} \overset{\text{def}}{=} (\langle -a|\hat{W}[m]|\hat{W}[n]|a\rangle_{0})_{m,n},
\]
where $m = (m_{1}, \ldots, m_{\ell})$, $n = (n_{1}, \ldots, n_{\ell}) \in \mathbb{Z}_{\geq 0}^{\ell}$ and
\[
(8.68) \quad \hat{W}[m] := (\hat{W}_{1}^{(1)})^{m_{1}} \cdots (\hat{W}_{1}^{(\ell)})^{m_{\ell}}, \\
\hat{W}[n] := (\hat{W}_{1}^{(1)})^{n_{1}} \cdots (\hat{W}_{1}^{(\ell)})^{n_{\ell}}.
\]
Here multi-indices $m$, $n$ runs over $\sum m_{\kappa} = \sum n_{\kappa} = d$ for each $d$.

Now the matrix $K_{0}^{d}$ is the $d^{th}$ symmetric power of $K_{0}^{d=1}$, and hence we complete the proof of (8.20).
8(ix). Type A. Let us consider the special case $\mathfrak{g} = \mathfrak{sl}_r$ in this section. Let us switch to the notation for $\mathfrak{gl}_r$. We have standard generators of the invariant polynomial ring:

\begin{equation}
F^{(\kappa)} = \sum_{i_1 < i_2 < \cdots < i_\kappa} h^{i_1} h^{i_2} \cdots h^{i_\kappa},
\end{equation}

where $(h^1, \ldots, h^r)$ is the standard coordinate system of the Cartan subalgebra of $\mathfrak{gl}_r$ such that $(h^i, h^j) = \delta_{ij}$.

Let us denote by $\tilde{Q}^{(i)}_n, Q^{(i)}_n$ the Heisenberg algebra generators corresponding to $\tilde{P}^{(i)}_n, P^{(i)}_n$. Then

\begin{equation}
\tilde{W}_{-1}^{(\kappa)} |\mathbf{a}\rangle = \sum_{i_1 < i_2 < \cdots < i_\kappa} \sum_{l=1}^p \tilde{Q}^{(i_1)}_0 \tilde{Q}^{(i_2)}_0 \cdots \tilde{Q}^{(i_l)}_{-1} \cdots \tilde{Q}^{(i_\kappa)}_0 |\mathbf{a}\rangle
= \sum_{i_1 < i_2 < \cdots < i_\kappa} \sum_{l=1}^p a_{i_1} a_{i_2} \cdots \hat{a}_{i_l} \cdots a_{i_\kappa} Q^{i_l}_{-1} |\mathbf{a}\rangle.
\end{equation}

We use the Heisenberg algebra commutation relation

\begin{equation}
[\tilde{Q}^i_1, Q^{j}_{-1}] = \delta_{ij}
\end{equation}

to get

\begin{equation}
\tilde{Q}^i_1 W_{-1}^{(p)} |\mathbf{a}\rangle = \sum_{i_1 < i_2 < \cdots < i_p, i_1 = i} a_{i_1} a_{i_2} \cdots \hat{a}_{i_1} \cdots a_{i_p} |\mathbf{a}\rangle
= \frac{\partial}{\partial a_i} e_p(\mathbf{a}) |\mathbf{a}\rangle,
\end{equation}

where $e_p(\mathbf{a})$ is the $p$th elementary symmetric polynomial in $\mathbf{a}$.

The determinant of the $r \times r$-matrix $(\partial e_p(\mathbf{a})/\partial a_i)_{i,p=1,\ldots,r}$ is equal to $\prod_{i<j} (a_i - a_j)$. Therefore the matrix is invertible. This, in particular, implies that $\{W_{-1}^{(p)} |\mathbf{a}\rangle\}_{p=1,\ldots,r}$ form a basis of $(M(\mathbf{a})_0)_1$.

**Proposition 8.73.** The Whittaker vector $|w_1\rangle$ at the instanton number 1 is given by

\begin{equation}
\sum_i \frac{Q^i_1 |\mathbf{a}\rangle}{\prod_{j:j \neq i} (a_j - a_i)}.
\end{equation}

**Proof.** We have

\begin{equation}
W_{-1}^{(p)} Q^i_{-1} |\mathbf{a}\rangle = \frac{\partial}{\partial a_i} e_p(\mathbf{a}) |\mathbf{a}\rangle
\end{equation}
as above. Now it is elementary to check that

$$\sum_i \frac{\partial}{\partial a_i} c_p(a) \prod_{j \neq i} (a_j - a_i) = 0$$

if \( p < r \). If \( p = r \), we have

$$\sum_i \frac{\partial}{\partial a_i} c_p(a) \prod_{j \neq i} (a_j - a_i) = \sum_i \prod_{j \neq i} (a_j - a_i) = 1.$$  \[ \square \]

Now we have

$$\langle w_1 | w_1 \rangle_0 = \sum_i \prod_{j \neq i} \frac{1}{(a_j - a_i)^2}.$$  

This coincides with what is known from geometry.

**Appendix A. Appendix: exactness of hyperbolic restriction**

A(i). **Zastava spaces.** Let us denote by \( \text{Bun}_{G,B} \) the corresponding moduli space of \( G \)-bundles endowed with the following structures:

a) A trivialization at the infinite line \( \mathbb{P}_\infty^1 = \ell_\infty \).

b) A \( B \)-structure on the horizontal line \( \mathbb{P}_h^1 = \{ y = 0 \} \).

These two structures are required to be compatible at the intersection of \( \mathbb{P}_\infty^1 \) and \( \mathbb{P}_h^1 \) in the obvious way.

The connected components of \( \text{Bun}_{G,B} \) are numbered by positive elements of the coroot lattice of \( G_{\text{aff}} \) (cf. [20, §9]); for such element \( \alpha \) we denote by \( \text{Bun}_\alpha^{G,B} \) the corresponding connected component.

We will also denote by \( Z^\alpha_G \) the corresponding “Zastava” space (a.k.a. “flag Uhlenbeck space”) defined in [20]. We are going to need the following properties of \( Z^\alpha_G \). (Some of them are proved for the space \( \text{QMap}(\mathbb{P}_h^1, \mathfrak{g}_{b,p}) \) of based quasi-maps to a flag scheme \( \mathfrak{g}_{b,p} \) of a Kac-Moody Lie algebra \( \mathfrak{g} \) associated with its parabolic \( p \). Since \( Z^\alpha_G \) is the fiber product \( \text{QMap}(\mathbb{P}_h^1, \mathfrak{g}_{b,p}) \times_{\text{QMap}(\mathbb{P}_h^1, \mathfrak{g}_{b,p})} \mathcal{U}_G^p \) for a Borel subalgebra \( b \) of an affine Lie algebra \( \mathfrak{g} \) and a maximal parabolic \( p \), we can deduce assertions for \( Z^\alpha_G \) from those for \( \text{QMap}(\mathbb{P}_h^1, \mathfrak{g}_{b,p}) \).)

(Z1) \( Z^\alpha_G \) is an irreducible affine scheme of dimension \( 2|\alpha| \) endowed with an action of \( T \times \mathbb{C}^* \times \mathbb{C}^* \) which contains \( \text{Bun}_\alpha^{G,B} \) as an open subset (here we set \( |\alpha| = \sum a_i \) if \( \alpha = \sum a_i \alpha_i \) where \( \alpha_i \) are the simple coroots of \( G_{\text{aff}} \)).

(Z2) There is a (factorization) map \( \pi^\alpha_2: Z^\alpha_G \to S^\alpha(\mathbb{A}_h^1) \). This map is \( T \times \mathbb{C}^* \times \mathbb{C}^* \)-equivariant if we let \( T \times \mathbb{C}^* \times \mathbb{C}^* \) act on \( S^\alpha(\mathbb{A}_h^1) \) just
through the horizontal $\mathbb{C}^*$ (denoted by $\mathbb{C}^*_h$) and it admits a $T \times \mathbb{C}^* \times \mathbb{C}^*$-equivariant section $\iota^\alpha$. In particular, the fibers of $\pi^\alpha_2$ are stable under $T \times \mathbb{C}^*_v$ where the $\mathbb{C}^*_v = \mathbb{C}^*$-action comes from the vertical action on $\mathbb{A}^2$. All of these fibers have dimension $|\alpha|$. (See Conjecture 2.27, which is reduced to Conjecture 15.3 and proved for affine Lie algebras in §15.6 in [20].)

(Z3) Let set $\mathcal{F}^\alpha = (\pi^\alpha_2)^{-1}(\alpha \cdot 0)$. Let $\rho: \mathbb{C}^* \to \widetilde{T} = T \times \mathbb{C}^*_v$ be any one-parameter subgroup which is a regular dominant coweight of $G_{\text{aff}}$ (i.e. such that $\langle \rho, \beta \rangle > 0$ for any affine positive root $\beta$). Then the corresponding $\mathbb{C}^*$-action contracts $Z_G^\alpha$ to $\iota^\alpha(S^\alpha(\mathbb{A}^1_h))$, and hence $\mathcal{F}^\alpha$ to $\iota^\alpha(\alpha \cdot 0)$. (cf. Proposition 2.6 and Corollary 10.4 in [20]).

(Z4) Let $\alpha_0$ denote the affine simple coroot and let $d$ be the coefficient of $\alpha_0$ in $\alpha$ (in other words, $d = \langle \alpha, \omega_0 \rangle$ where $\omega_0$ denotes the corresponding fundamental weight of $G_{\text{aff}}$). Then there is a (“forgetting the $B$-structure”) $T \times \mathbb{C}^* \times \mathbb{C}^*$-equivariant map $f_\alpha: Z_G^\alpha \to U_G^d$ which fits into a commutative diagram

\[
\begin{array}{ccc}
Z_G^\alpha & \xrightarrow{f_\alpha} & U_G^d \\
\downarrow{\pi^\alpha_2} & & \downarrow{\pi_G^d} \\
S^\alpha \mathbb{A}^1_h & \longrightarrow & S^d \mathbb{A}^1_h
\end{array}
\]

where the bottom horizontal map sends a divisor $\sum \beta_i x_i$ to $\sum \langle \beta_i, \omega_0 \rangle x_i$.

A(ii). Plan of the proof. Let us discuss our strategy for proving Theorem 4.20. Using arguments similar to those of [42] it is not difficult to see that Theorem 4.20 would follow if we could prove that for any $x \in U_L^d$ the dimension of $\mathcal{A}_x$ and $\mathcal{R}_x$ is equal to $\dim U^d_T - \dim U^d_B$. However, at the moment we do not know how to prove this directly. So, our actual strategy will be slightly different. First, recall that we have

\[ (U^d_G)^T = S^d(\mathbb{A}^2), \]

and that we denote by $U^d_B$, $U^d_B^-$ the corresponding attracting and repelling sets. Also we denote by $p: U^d_B \to S^d(\mathbb{A}^2)$ the corresponding map (sometimes we shall denote it by $p^d$ when dependence on $d$ is important). Then we are going to proceed in the following way:

1) Prove that the dimension of the preimage of $S^d(\mathbb{A}^1) \subset S^d(\mathbb{A}^2)$ under the map $p: U^d_B \to S^d(\mathbb{A}^2) = U^d_T \cap U^d_B$ has dimension $\frac{\dim U^d_T}{2}$ (here $\mathbb{A}^1 \subset \mathbb{A}^2$ is any line). The proof will involve some facts about the Zastava spaces from [20].

2) Deduce Theorem 4.20 for $L = T$ from 1).
3) Using Proposition 4.16 deduce Theorem 4.20 for arbitrary $L$ from the case $L = T$.

A(iii). **Attractors and repellents on the Uhlenbeck space: maximal torus case.** Let us first look more closely at the case when $P = B$: a Borel subgroup of $G$. In this case $L = T$: a maximal torus of $G$.

Let us also define the set $S^d \subset U_G^d$ to be the attracting set in $U_G^d$ with respect to the torus $T$ to $S^d(A^1_v \setminus 0)$ where $A^1_v$ is the vertical line. In other words, $S^d = p^{-1}(S^d(A^1_v \setminus 0))$.

**Proposition A.1.** We have

$$\dim S^d \leq \frac{dh}{2}.$$  

**Corollary A.2.** Let $A^1 \hookrightarrow A^2$ be any linear embedding. Then

$$\dim p^{-1}(S^d(A^1_v)) \leq \frac{\dim U_G^d}{2}.$$  

Corollary A.2 clearly follows from A.1. Indeed, first of all, it is clear that it is enough to prove Corollary A.2 when $A^1 = A^1_v$. In this case, $S^d$ is open in $p^{-1}(S^d(A^1_v))$, hence we have $\dim S^d \leq \dim p^{-1}(S^d(A^1_v))$.

On the other hand, (the vertical) $A^1$ acts naturally on $p^{-1}(S^d(A^1_v))$ by shifts and any point of $p^{-1}(S^d(A^1_v))$ lies in an open subset of the form $x(S^d)$ for some $x \in A^1$, hence the opposite inequality follows.

Let us now pass to the proof of Proposition A.1.

A(iv). **The map $f_d$.** We have the natural (forgetting the flag) birational map $f_d: Z_{d\delta} \to U_G^d$, which we shall simply denote by $f_d$. This map gives an isomorphism between the open subset of $U_G^d$ consisting of (generalized) bundles which are trivial on the horizontal $P^1_h$ and the open subset of $Z_{d\delta}^d$ consisting of (generalized) bundles which are trivial on the horizontal $P^1_h$ (and then the $B$-structure on the horizontal $P^1_h$ is automatically trivial).

A(v). **The central fiber.** Recall that $F_{d\delta}$ denotes the preimage of $d\delta \cdot 0$ under the map $\pi_{d\delta}: Z_{d\delta}^d \to S^d(A^1_h)$. Again, to simplify the notation, we shall just write $F_d$ instead of $F_{d\delta}$. According to (Z2), $\dim F_d = dh^\vee$.

We claim that

1) $S^d$ lies in the open subset of $U_G^d$ over which $f_d$ is an isomorphism.
2) $f_d^{-1}(S^d) \subset F_d$.

The first statement is clear, since the image of $S^d$ in $S^d(A^1_v)$ under the factorization morphism $\pi_v^d$ (to the symmetric product of the vertical
line) must lie in $S^d(A^1_n \setminus 0)$. To prove the second statement, let us note that $f^{-1}_d(S^d)$ must lie in the attracting set in $Z^d_G$ with respect to the torus $T$ to $f^{-1}_d(S^d(A^1_n \setminus 0))$. It is clear that $f^{-1}_d(S^d(A^1_n \setminus 0)) \subset F^d$ and thus the statement follows, since every fiber of the map $\pi_{2d}: Z^d_G \rightarrow S^d(A^1_n)$ is stable under the action of $T$.

Hence we get $\dim S^d \leq dh^\vee = \dim F^d$.

A(vi). **Good coweights.** Let $X$ be an affine variety endowed with an action of $T \times \mathbb{C}^*$ (here $T$ can be any torus). Let $x$ be any $T \times \mathbb{C}^*$-fixed point (in practice this point will always be unique, but this is not needed formally for what follows) and let $Y \subset X^T$ be the $\mathbb{C}^*$-attractor to $x$ inside $X^T$. Let now $\lambda: \mathbb{C}^* \rightarrow T$ be any coweight. Let us denote by $A_\lambda$ the attractor to $Y$ with respect to the $\mathbb{C}^*$-action given by $\lambda$. Let us also denote by $\tilde{A}_\lambda$ the attractor to $x$ with respect to the $\mathbb{C}^*$-action given by the cocharacter $(\lambda, 1)$ of $T \times \mathbb{C}^*$.

We say that $\lambda$ is good if $A_\lambda = \tilde{A}_\lambda$.

**Lemma A.3.** For any $\lambda$ as above, the coweight $n\lambda$ is good for $n \in \mathbb{N}$ large enough.

**Proof.** Obviously, there exists a closed $T$-equivariant embedding of $X$ into a vector space $V$ such that the action of $T \times \mathbb{C}^*$ on $V$ is linear and such that $x$ corresponds to $0 \in V$. Then it is clear that if $\lambda$ is good for $V$, then it is also good for $X$. Hence we may assume that $X = V$.

In this case, we see that $n\lambda$ is good if and only if for every weight of $T \times \mathbb{C}^*$ on $V$ of the form $(\theta, k)$ the following condition is satisfied:

$$n\langle \lambda, \theta \rangle + k > 0 \text{ if and only if either } \langle \lambda, \theta \rangle > 0, \text{ or } \langle \lambda, \theta \rangle = 0 \text{ and } k > 0.$$  

Now, every $n \in \mathbb{N}$ such that $n|\langle \lambda, \theta \rangle| > |k|$ for any $(\theta, k)$ as above such that $\langle \lambda, \theta \rangle \neq 0$ will satisfy the conditions of the Lemma. □

Let $\lambda$ be as before and assume in addition that

(i) $x$ is the only fixed point of $\mathbb{C}^*$ acting by means of the coweight $(\lambda, 1)$;

(ii) $X^{\lambda(\mathbb{C}^*)} = X^T$

(in this case we automatically have $(X^T)^{\mathbb{C}^*} = \{x\}$). Let us denote by $\tilde{\Phi}$ the hyperbolic restriction for $(\lambda, 1)$ (acting from sheaves on $X$ to sheaves on $\{x\}$), by $\Phi$ the hyperbolic restriction for $\lambda: \mathbb{C}^* \rightarrow T$ (acting from sheaves on $X$ to sheaves on $X^T$) and by $\Phi_0$ the hyperbolic restriction for the action of $\mathbb{C}^*$ on $X^T$ (from sheaves on $X^T$ to sheaves on $\{x\}$). Then the definition of “goodness” implies

**Lemma A.4.** Assume that $\lambda$ is good and satisfies the conditions (i) and (ii). Then we have $\tilde{\Phi} = \Phi_0 \circ \Phi$. 

A(vi). **Exactness of twisted hyperbolic restriction.** Let \( \tilde{T} = T \times \mathbb{C}^* \) and let us make it act on \( \mathcal{U}_G^d \) so that the action of \( \mathbb{C}^* \) comes from the hyperbolic action of \( \mathbb{C}^* \) on \( \mathbb{A}^2 \) of the form \( z(x, y) = (z^{-1}x, zy) \). Note that \( (\mathcal{U}_G^d)^{\tilde{T}} \) consists of one point.

Let us fix \( d \) and let us choose a dominant regular coweight \( \lambda : \mathbb{C}^* \to T \) which is good in the sense of Subsection A(vi) (such \( \lambda \) exists because of Lemma A.3). Then the fact that \( \lambda \) is regular implies that it satisfies the conditions (i) and (ii). Consider the corresponding functors \( \Phi, \Phi \) and \( \Phi_0 \). Obviously we have \( \Phi = \Phi_{T,G}^d \), so we shall write \( \Phi_{T,G}^d \) instead of \( \Phi \). Also, to emphasize the dependence on \( d \) we set \( \Phi_0^d \) instead of \( \Phi_0 \).

According to Lemma A.4 we have \( \Phi_{T,G}^d = \Phi_0^d \circ \Phi_{T,G}^d \).

**Theorem A.5.** The complex of vector spaces \( \Phi_{T,G}^d(\text{IC}(\mathcal{U}_G^d)) \) is concentrated in degree 0.

**Proof.** We will use the same notations as before for \( L = T \) replaced with \( \tilde{T} \), such as \( i_{\tilde{T},G}^\circ, j_{\tilde{T},G}^\circ, p_{\tilde{T},G}^\circ, i_{\tilde{T},G}^\circ, j_{\tilde{T},G}^\circ, p_{\tilde{T},G}^\circ \). The attracting set is denoted by \( A_{\lambda,\tilde{T},G}^d \). According to [12, Theorem 1], the natural morphism \( (p_{\tilde{T},G}^\circ)^* (j_{\tilde{T},G}^\circ)^! \text{IC}(\mathcal{U}_G^d) \to (p_{\tilde{T},G}^\circ)! (j_{\tilde{T},G}^\circ)^* \text{IC}(\mathcal{U}_G^d) = \Phi_{T,G}^d(\text{IC}(\mathcal{U}_G^d)) \) is an isomorphism. We will prove that \( (p_{T,G}^\circ)! (j_{T,G}^\circ)^* \text{IC}(\mathcal{U}_G^d) \) is concentrated in nonpositive degrees. A similar (dual) argument proves that \( (p_{\tilde{T},G}^\circ)^* (j_{\tilde{T},G}^\circ)^! \text{IC}(\mathcal{U}_G^d) \) is concentrated in nonnegative degrees. In other words, we must prove that \( H^*_c(\Phi_{\lambda,\tilde{T},G}^d, \text{IC}(\mathcal{U}_G^d)) \) lives in nonpositive cohomological degrees.

Now \( \text{IC}(\mathcal{U}_G^d) \) is smooth along the stratification

\[
\mathcal{U}_G^d = \bigsqcup_{m + |\lambda| = d} \text{Bun}_G^m \times S_\lambda(\mathbb{A}^2),
\]

the dimension of a stratum being equal to \( 2l(\lambda) + 2mh^\vee \). Here for a partition \( \lambda = (\lambda_1, \ldots, \lambda_l) \) we set \( l(\lambda) = l \). The perverse sheaf \( \text{IC}(\mathcal{U}_G^d) \) lives in cohomological degrees \( \leq -2l(\lambda) - 2mh^\vee \) on the stratum \( \text{Bun}_G^m \times S_\lambda(\mathbb{A}^2) \). We have \( A_{\lambda,\tilde{T},G}^d \cap (\text{Bun}_G^m \times S_\lambda(\mathbb{A}^2)) = (A_{\lambda,\tilde{T},G}^m \cap \text{Bun}_G^m) \times S_\lambda(\mathbb{A}^2) \). Now it follows from Corollary A.2 and the goodness assumption on \( \lambda \) that \( \dim(A_{\lambda,\tilde{T},G}^m) \leq mh^\vee \). Evidently, \( \dim S_\lambda(\mathbb{A}^2) = l(\lambda) \).

So the restriction of \( \text{IC}(\mathcal{U}_G^d) \) to \( A_{\lambda,\tilde{T},G}^d \cap (\text{Bun}_G^m \times S_\lambda(\mathbb{A}^2)) \) lives in degrees \( \leq -2l(\lambda) - 2mh^\vee \). Now an application of the Cousin spectral sequence for the stratification of \( A_{\lambda,\tilde{T},G}^d \) finishes the proof. \( \square \)
The following corollary is not needed for the rest, but we include it for the sake of completeness.

**Corollary A.6.** \( \dim S^d = \dim p^{-1}(S^d(A^1)) = dh^v. \)

**Proof.** We need to show that \( \dim A^d_{\lambda,T,G} \) is at least \( dh^v. \) By induction on \( d \) we may assume that this is true for all \( d' < d. \) Assume that \( \dim A^d_{\lambda,T,G} < dh^v. \) Then repeating the argument from the above proof we see that \( \tilde{\Phi}^d_{T,G}(IC(U^d_G)) \) is concentrated in strictly negative cohomological degrees, which contradicts Theorem A.5. \( \square \)

**Remark A.7.** The above argument only shows that the dimension of the whole of \( S^d \) is equal to \( dh^v, \) but doesn’t show that this is true for each of its irreducible components (however, we believe that this is true).

A(viii). **Exactness of \( \Phi_{T,G}. \)** We can now show that \( \Phi^d_{T,G}(IC(U^d_G)) \) is perverse. Indeed, using the factorization argument and induction on \( d, \) we may assume that \( \Phi^d_{T,G}(IC(U^d_G)) \) is perverse away from the main diagonal \( A^2 \subset S^d(A^2). \) Since according to \([12]\) the complex \( \Phi^d_{T,G}(IC(U^d_G)) \) is semi-simple and since it is also equivariant with respect to the action of \( A^2 \) on \( S^d(A^2) \) by shifts, it follows that we just need to prove that \( \Phi^d_{T,G}(IC(U^d_G)) \) doesn’t have any direct summands which are isomorphic to constant sheaves on \( A^2 \) sitting in cohomological degrees \( \neq -2. \) But if such a direct summand existed, it would imply that \( \tilde{\Phi}^d_{T,G}(IC(U^d_G)) = \tilde{\Phi}^d_{T,G}(IC(U^d_G)) \) has non-zero cohomology in degree \( \neq 0, \) which contradicts Theorem A.5.

A(ix). **Exactness of \( \Phi_{L,G}. \)** Let us now show that \( \Phi^d_{L,G}(IC(U^d_G)) \) is perverse. Indeed, first of all, according to Braden’s theorem \([12]\), \( \Phi^d_{L,G}(IC(U^d_G)) \) is a semi-simple complex, which is constructible with respect to the stratification \((2.3)\). In other words, it is a direct sum of (possibly shifted) simple perverse sheaves, where each such sheaf is isomorphic to the Goresky-MacPherson extension of a local system \( E \) on \( Bun^d_L \times S^d(A^2) \) for some \( d_1 \) and \( \lambda \) as in \((2.3)\).

**Lemma A.8.** Any such \( E \) is necessarily of the form \( \mathbb{C}_{Bun^d_L} \otimes E' \) where \( E' \) is some local system on \( S^d(A^2). \)

**Proof.** To prove this it is enough to show that the restriction of \( \Phi^d_{L,G}(IC(U^d_G)) \) to \( Bun^{d_1}_L \times S^{d_2}(A^2) \) (here \( d = d_1 + d_2 \)) is isomorphic to the exterior tensor product of the constant sheaf of \( Bun^{d_1}_L \) and some complex on \( S^{d_2}(A^2). \) Moreover, it is enough to construct such an isomorphism on some Zariski open subset \( U \) of \( Bun^{d_1}_L \times S^{d_2}(A^2) \) (this follows from the
fact that a local system which is constant on a Zariski dense subset is constant everywhere). Let us choose a projection $a : \mathbb{A}^2 \to \mathbb{A}^1$ and let $\pi_{a,L} : \text{Bun}_{L}^{d_1} \to S^{d_1}(\mathbb{A}^1)$ be the corresponding map. Let $U$ be the open subset of $\text{Bun}_{L}^{d_1} \times S^{d_2}(\mathbb{A}^2)$ consisting of pairs $(\mathcal{F}, x)$ such that $\pi_{a,L}^* x$ is disjoint from the projection of $x$ to $S^{d_2}(\mathbb{A}^1)$. Then locally in étale topology near every point of $U$ the scheme $\mathcal{U}_G^d$ looks like the product $\text{Bun}_{C_0}^d \times \mathcal{U}_G^d$ and the statement follows.

Now, we can finish the proof. Indeed, recall that the closure of $\text{Bun}_{L}^{d_1} \times S_{\lambda}(\mathbb{A}^2)$ admits a finite birational map from $\mathcal{U}_L^{d_1} \times \overline{S}(\mathbb{A}^2)$, where $\overline{S}$ stands for the closure of $S$ in $S^{d_2}(\mathbb{A}^2)$. Thus for any $\mathcal{E}$ as above we see that $\text{IC}(\mathcal{E})$ is the direct image of $\text{IC}(\mathcal{U}_L^{d_1}) \boxtimes \text{IC}(\mathcal{E}')$ under this map. Moreover, the complex $\Phi_{T,L}^*(\text{IC}(\mathcal{E}))$ is equal to the direct image of $\Phi_{T,L}(\text{IC}(\mathcal{U}_L^{d_1})) \boxtimes \text{IC}(\mathcal{E}')$. Hence, we see that it is perverse and non-zero. Thus, if for some $i \neq 0$ the complex $\text{IC}(\mathcal{E})[i]$ is a direct summand of $\Phi_{L,G}(\text{IC}(\mathcal{U}_G^d))$, then $\Phi_{T,L}(\Phi_{L,G}(\mathcal{U}_G^d))$ is not perverse. Since $\Phi_{T,L} \circ \Phi_{L,G} \simeq \Phi_{T,G}$, this contradicts Subsection A(viii). \qed

Recall $\mathcal{U}_{P,0}^d \overset{\text{def.}}{=} p^{-1}(d \cdot 0)$, see (4.38).

**Corollary A.9.** $\dim \mathcal{U}_{P,0}^d \leq dh^\vee - 1$.

**Proof.** We will argue by induction in $d$. We assume the claim for all $d' < d$. We know that the dual space $(U^d)^* \simeq H^*(p^{-1}(d \cdot 0), j^* \text{IC}^!(\mathcal{U}_G^d))$ lives in degree 0. We consider the Cousin spectral sequence for the stratification $\mathcal{U}_{P,0}^d = \bigsqcup_{d' \leq d} (\mathcal{U}_{P,0}^{d'} \cap \text{Bun}_{C_0}^d)$. By the induction assumption, all the strata for $d' < d$ contribute to nonpositive degrees of $H^*(p^{-1}(d \cdot 0), j^* \text{IC}^!(\mathcal{U}_G^d))$ only. If we had $\dim \mathcal{U}_{P,0}^d > dh^\vee - 1$, the fundamental classes of the top dimensional components of $\mathcal{U}_{P,0}^d$ would contribute to the strictly positive degrees in $H^*(p^{-1}(d \cdot 0), j^* \text{IC}^!(\mathcal{U}_G^d))$, and nothing would cancel their contribution. This would contradict to $H^0_{\text{c}}(p^{-1}(d \cdot 0), j^* \text{IC}^!(\mathcal{U}_G^d)) = 0$. \qed

**Appendix B. Integral form of the W-algebra**

The purpose of this section is to introduce an $A$-form of the $W$-algebra, generalizing the $A$-form $\mathfrak{vir}_{i,A}$ of the Virasoro algebra in §6(iv), where the commutation relations of integral generators of the Heisenberg algebra and the Virasoro algebra are (see (6.19), (6.28))

\[(B.1) \quad \left[ \tilde{P}_m, \tilde{P}_n \right] = -m \delta_{m,-n} (\alpha_i, \alpha_j) \varepsilon_1 \varepsilon_2,
\]

\[\left[ \tilde{L}_m, \tilde{L}_n \right] = \varepsilon_1 \varepsilon_2 \left\{ (m - n) \tilde{L}_{m+n} + (\varepsilon_1 \varepsilon_2 - 6(\varepsilon_1 + \varepsilon_2)^2) \delta_{m,-n} \frac{m^3 - m}{12} \right\}, \]
and they are related by

\[ \mathcal{L}_i = -\frac{1}{4} \sum_m \tilde{P}_m^{i} \tilde{P}^{i}_{n-m} - \frac{n+1}{2} (\varepsilon_1 + \varepsilon_2) \tilde{P}^i_n. \]

Let \( g \) be a complex simple Lie algebra. We do not assume \( g \) is of type ADE in this section. Let \( (\ , \ ) \) be the normalized bilinear form so that the square length of a long root is 2. Let \( \ell \) be its rank and let \( d_1 \leq \cdots \leq d_\ell \) be the exponents of \( g \), counted with multiplicities. For example, \( g = \mathfrak{sl}_\ell + 1 \), we have \( d_1 = 1, d_2 = 2, \ldots, d_\ell = \ell \). We have \( d_\ell = h^\vee - 1 \). The multiplicity of the exponent is equal to 1, except \( d_{\ell/2} = d_{\ell/2 + 1} = \ell - 1 \) for \( D_\ell \) with \( \ell \) even.

**B(i). Integral form of the BRST complex.** In order to define an \( A \)-form of the \( \mathcal{W} \)-algebra, we need to recall briefly the BRST complex used in the definition of the \( \mathcal{W} \)-algebra in [28, Ch. 15]. We assume that the reader is familiar with [28, Ch. 15], as we skip details.

Let \( g = \mathfrak{n}_+ \oplus \mathfrak{h} \oplus \mathfrak{n}_- \) be the Cartan decomposition of \( g \). Let \( \Delta_{\pm} \) denote the set of positive/negative roots. Let \( I \) be the set of simple roots.

We consider the vertex superalgebra \( C_k^*(g) \), which is the tensor product of the affine vertex algebra \( V_k(g) \) of level \( k \) and the fermionic vertex superalgebra \( \bigwedge_{n_+}^* \). We have two anti-commuting differentials \( d_{st} \) and \( \chi \) on \( C_k^*(g) \) so that \( \mathcal{W}_k(g) \) is defined as the 0th cohomology with respect to \( d = d_{st} + \chi \).

We do not need the definition of \( d_{st}, \chi \). We start with the subcomplex \( C_k^*(g)_{0} \) as the cohomology of \( C_k^*(g) \) is a tensor product of \( C_k^*(g)_{0} \) and another complex, whose cohomology is trivial (see [28, Lem. 15.2.7]).

We take a basis \( \{ J^a \} \) of \( g \) consisting of root vectors and vectors \( h^i \), dual to simple roots \( \alpha_i \) with respect to \( (\ , \ ) \). Let \( c_{ab}^{\bar{d}} \) be the structure constants of \( g \) with respect to the basis \( \{ J^a \} \). Latin indices are used to denote arbitrary basis elements, Latin indices with bar are used to denote elements in \( b_- = h \oplus n_- \). Therefore \( \{ J^a \}_{a \in \Delta_{-} \cup I} \) is a basis of \( b_- \). Greek indices are used to denote basis elements of \( n_+ \). We also have a basis \( \{ \psi_{\alpha}^{*} \}_{\alpha \in \Delta_{+}} \) of \( n_+^* \). We denote the corresponding fields by \( \tilde{J}^a(z) \) and \( \psi^*_\alpha(z) \), where the former has a correction term (see [28, (15.2.1)]). The field \( \tilde{J}^a(z) \) satisfies the commutation relation for the affine Lie algebra at the level \( k + h^\vee \) instead of \( k \) because of the correction terms (cf. [2, (4.8.1)]):

\[
(B.2) \quad [\tilde{J}^a(z), \tilde{J}^b(w)] = \sum_{c} c_{ce}^{ab} \tilde{J}^c(w) \delta(z - w) + (k + h^\vee) \partial_w \delta(z - w).
\]
Now the complex $C^*_k(\mathfrak{g})_0$ is spanned by monomials of the form
\begin{equation}
\hat{J}_{\alpha}^{(1)} \cdots \hat{J}_{\alpha}^{(r)} \psi_{\alpha(1),m_1}^* \cdots \psi_{\alpha(s),m_s}^*, \quad (B.3)
\end{equation}
and the action of the differentials is given by the following formulas
\begin{equation}
[x, \hat{J}^a(z)] = \sum_{i \in I} \sum_{\beta \in \Delta_+} c_{a_i}^{\beta} \psi^*_\beta(z),
\end{equation}
\begin{equation}
[x, \psi^*_\alpha(z)]_+ = 0,
\end{equation}
\begin{equation}
[d_{st}, \hat{J}^a(z)] = \sum_{b, \alpha} c_b^{\alpha} \cdot \hat{J}^b(z) \psi^*_\alpha(z) + k \sum_{\alpha}(J^a, J^\alpha) \partial_z \psi^*_\alpha(z) - \sum_{\alpha, \beta, \gamma} c_{\beta}^{\gamma} \psi^*_\beta(z) \psi^*_\gamma(z),
\end{equation}
\begin{equation}
[d_{st}, \psi^*_\alpha(z)]_+ = -\frac{1}{2} \sum_{\beta, \gamma} c_{\alpha}^{\beta} \psi^*_\beta(z) \psi^*_\gamma(z),
\end{equation}
together with $\chi(0) = d_{st}(0) = 0$. Here the formulas are copied from [28, 15.2.4] except that the first one is simplified as we only consider a field for $J^a$ in $\mathfrak{b}_-$. The bidegree is defined by
\begin{equation}
\text{bideg } \hat{J}^a(z) = (-n, n),
\end{equation}
\begin{equation}
\text{bideg } \psi^*_\alpha(z) = (l, -l + 1),
\end{equation}
where $n$ is the principal gradation of $J^a$ and $l$ is the height of the root $\alpha$. (See [28, 15.1.7] for definitions of the principal gradation and the height.) Therefore $\chi$ has bidegree $(1, 0)$, and $d_{st}$ has bidegree $(0, 1)$. We get the double complex $C^*_k(\mathfrak{g})_0 = \bigoplus_{p, q} C^{p,q}_k(\mathfrak{g})_0$. From the definition of the bidegree, we see that $C^{p,q}_k(\mathfrak{g})_0 = 0$ unless $p \geq 0$, $-p \leq q \leq 0$.

Now we rewrite the complex suitable for our purpose. By (6.1) we replace $k$ by $-(h^\vee + \varepsilon_2/\varepsilon_1)$.

Next let us introduce a modification $\hat{h}^a(z)$ of $\hat{J}^a(z)$, like $\tilde{P}_m$ of $P^m_i$ in §6(iii). There is a simple recipe for this. Reading formulas in [28, §15.4.10], we note that $\hat{J}^a(z)$ for $\bar{a} \in I$ is denoted by $\hat{h}^i(z)$ and satisfies the commutation relation
\begin{equation}
[\hat{J}^a(z), \hat{h}^i(z)] = m \delta_{m,-n}(\alpha_i, \alpha_j)(k + h^\vee).
\end{equation}
See also (B.2). This Heisenberg operator gives the embedding $W_k(\mathfrak{g}) \to \mathfrak{sg} \mathfrak{sis}(\mathfrak{h})$. Comparing (B.1) with (B.6), we find that it is natural to set
\begin{equation}
\hat{J}^a(z) = \varepsilon_1 \hat{h}^i(z).
\end{equation}
We also rescale $\chi$ by a function $\varphi$ in $\varepsilon_1, \varepsilon_2$ as $\tilde{\chi} = \varphi \chi$. Unless $\varphi$ vanishes, the cohomology group is independent of $\varphi$. However we will specialize $\varepsilon_1, \varepsilon_2$ to 0, the result will be different. Therefore the choice of
ϕ is important. Remember that our goal is to realize a generator \( \widehat{W}_{n}^{(\kappa)} \) in geometry. We want to assign it with the perverse cohomological degree 2(\( d_{\kappa} + 1 \)) as \( \tilde{L}_{i}^{\kappa} \) in §6(iv) is of degree 4. This generator is a sum of a main term \( X_{0} \) of bidegree \((d_{\kappa}, -d_{\kappa})\) plus correction terms \( X_{1}, X_{2}, \ldots \) of bidegree \((p, -p)\) with \( 0 \leq p < d_{\kappa} \) determined by the condition \( \tilde{\chi}X_{\kappa} = -d_{st}X_{\kappa - 1} \). (See [28, 15.2.11].) Therefore we want all \( X_{0}, X_{1}, \ldots \) to have the same (perverse) cohomological degree. This is achieved if \( \phi \) is of degree \(-2\). We still have ambiguity, but look at the formulas \((B.4)\) and \((B.7)\), the simplest solution is to absorb \( 1/\varepsilon_{1} \) in \( \tilde{\chi}J_{b}^{\alpha}(z) \) to \( \tilde{\chi}, \)

We thus arrive at the following:

\[(B.8)\]

\[
[\tilde{\chi}, J_{b}^{\alpha}(z)] = \sum_{i \in I} \sum_{\beta \in \Delta_{+}} c_{\alpha \beta}^{\beta \beta} \psi_{\beta}^{\star}(z),
\]

\[
[\tilde{\chi}, \psi_{\alpha}^{\star}(z)]_{+} = 0,
\]

\[
[d_{st}, J_{b}^{\alpha}(z)] = \sum_{b, \alpha} c_{b, \alpha}^{\beta \alpha}: J_{b}^{\rho}(z) \psi_{\alpha}^{\star}(z); - \left( h^{\vee} \varepsilon_{1} + \varepsilon_{2} \right) \sum_{\alpha} (J_{b}^{\alpha}, J_{b}^{\alpha}) \partial_{z} \psi_{\alpha}^{\star}(z)
\]

\[- \varepsilon_{1} \sum_{\alpha, \beta, \delta} \partial_{\alpha} \psi_{\beta}^{\star}(z) \psi_{\alpha}^{\star}(z),
\]

\[
[d_{st}, \psi_{\alpha}^{\star}(z)]_{+} = \frac{1}{2} \sum_{\beta, \gamma} \psi_{\beta}^{\star}(z) \psi_{\gamma}^{\star}(z).
\]

**Definition B.9.** We consider an \( A \)-span of monomials of the form \((B.3)\) replacing \( \hat{J} \) by \( J \). We define the differentials \( d_{st}, \tilde{\chi} \) by \((B.8)\). We get a double complex \( C_{A}(g) \) defined over \( A \). Its total cohomology group \( H_{A}^{*}(g) \) is a vertex superalgebra defined over \( A \).

The argument in the proof of [28, Th. 15.1.9] goes over \( A \), and we get

\[(B.10)\]

\[H_{A}^{i}(g) = 0 \quad \text{for } i \neq 0.\]

We have

\[(B.11)\]

\[H_{A}^{0}(g) \otimes_{A} F \cong H_{F}^{0}(g),\]

as the localization is an exact functor. Here \( H_{F}^{0}(g) \) is the cohomology group of the complex \( C_{A}(g) \otimes_{A} F \). It is isomorphic to \( W_{k}(g) \otimes_{C(k)} F \) as \( \varepsilon_{1} \neq 0 \) in \( F \), where \( k = -h^{\vee} - \varepsilon_{2}/\varepsilon_{1} \) as before.

**Proposition B.12.** \( H_{A}^{0}(g) \) is free over \( A \).
Proof. Note that the complex $C^\bullet_A(g)_0$ is a direct sum of its homogeneous components with respect to the $\mathbb{Z}$-gradation. Each component forms a subcomplex and is free of finite rank over $A$. Hence results in the homological algebra can be applied. Since only the $0$th cohomology survives, a component $M$ of $H^0_A(g)$ is quasi-isomorphic to a complex of projective modules $P^\bullet$ with $P^i = 0$ for $i < 0$. Then we compute $\operatorname{Ext}^\bullet_A(M, N)$ via $P^\bullet$ to deduce $\operatorname{Ext}^{>0}_A(M, N) = 0$ for any $N$. Therefore $M$ is projective. Since $A$ is a polynomial ring, $H^0_A(g)$ is free. \hfill $\Box$

Thus $H^0_A(g)$ is an $A$-form of the $W$-algebra.

**Definition B.13.** We denote $H^0_A(g)$ by $W_A(g)$. It is called an $A$-form of the $W$-algebra.

Let us introduce a new degree, which corresponds to the half of the (perverse) cohomological degree in the geometric side. Let us denote it by $c\deg$. We set $c\deg |0\rangle = 0$, $c\deg \varepsilon_1 = c\deg \varepsilon_2 = 1$. The degree of operators $\check{J}^a(z)$ and $\psi^*_a(z)$ is the first component of the bidegree. Then we put $c\deg \check{J}^a(z) = c\deg \check{J}^a(z) + 1$ by (B.7). For example, $\check{P}_m^i$ in §6(iii) is a Fourier mode of $\check{J}^a(z)$ for $J^a = h^i$. Therefore $c\deg \check{P}_m^i = 1$.

From the definition (B.8) we see that both $\check{\chi}$ and $d_{st}$ have degree 0. Therefore this degree descends to the cohomology group $H^0_A(g) = W_A(g)$. Hence $W_A(g)$ is a graded $A$-module, where $A = \mathbb{C}[\varepsilon_1, \varepsilon_2]$ is graded in the same way.

Be warned that $c\deg$ is not a $\mathbb{Z}$-grading of the vertex algebra in the sense of [28, §1.3.1]. All Fourier modes of vertex operators $Y(A, z)$, say $\check{J}^a(z)$, have the same degree, which is equal to the degree of the corresponding states $A = Y(A, z)|0\rangle|_{z=0}$. The translation operator $T$ is of degree 0.

B(ii). **Generators** $\widetilde{W}_n^{(\kappa)}$. The $W$-algebra $W_k(g)$ is generated by certain elements $W_\kappa (\kappa = 1, \ldots, \ell)$ in the sense of the reconstruction theorem. (See [28, 15.1.9].) Moreover the subspace spanned by $W_\kappa$ generates a PBW basis of $W_k(g)$. (See [2, §3.6 and Prop. 4.12.1] for the meaning of this statement.)

We briefly recall the definition of $W_\kappa$ and see that their simple modifications live in our integral form and generate a PBW base of $W_A(g)$. Let us change notation from $W_\kappa$ to $W^{(\kappa)}$ in order to avoid a possible conflict with Fourier modes.

We have a regular nilpotent element $p_-$ in $n_-$ so that $\chi$ is given by $\langle p_- \bullet \rangle = \chi (\bullet)$. (See [28, 15.2.9].) Let $a_-$ be the kernel of $\operatorname{ad} p_-$. It is a maximal abelian Lie subalgebra of $g$. 

The cohomology \( H^i \) of the complex \( C^\bullet_a(\mathfrak{g})_0 \) with respect to \( \chi \) vanishes for \( i \neq 0 \) and \( H^0 \) is equal to \( V(a_-) \), the vertex algebra associated with \( a_- \). It is a commutative vertex algebra, and isomorphic to the symmetric algebra \( \text{Sym}(a_- \otimes t^{-1}\mathbb{C}[t^{-1}]) \) of \( a_- \otimes t^{-1}\mathbb{C}[t^{-1}] \). Therefore a basis of \( a_- \) gives a PBW base of \( V(a_-) \).

There is a standard choice of a basis of \( a_- \). We take an \( \mathfrak{sl}_2 \)-triple \( \{p_+, p_0, p_-\} \) for \( p_- \), and decompose \( g \) into a direct sum of \( (2d_\kappa + 1) \)-dimensional representations \( R_\kappa \) (\( \kappa = 1, \ldots, \ell \)). We choose a decomposition for \( g = D_\ell \) with \( \ell \) even, \( \kappa = \ell/2, \ell/2 + 1 \). We then choose a lowest weight vector \( p^{(\kappa)}_- \) in \( R_\kappa \). Then \( \{p^{(\kappa)}_-\}_{\kappa=1,\ldots,\ell} \) is a base of \( a_- \).

The vectors \( p^{(\kappa)}_- \) are unique up to constant multiple, and we fix them hereafter. In fact, our geometric consideration of the \( W \)-algebra will give us a canonical choice of \( p^{(\kappa)}_- \) for \( \kappa = \ell \), at least up to sign. See several paragraphs after Theorem 8.19.

The same is true over \( \mathbb{A} \). The cohomology of \( C^\bullet_\mathbb{A}(\mathfrak{g})_0 \) with respect to \( \chi \) vanishes except the degree 0, and \( H^0 \) is equal to \( V(a_-) \otimes_{\mathbb{C}} \mathbb{A} \). The PBW base is its \( \mathbb{A} \)-basis.

Let \( 0\tilde{W}^{(\kappa)}(z) \) be the linear combination of \( \tilde{J}^a(z) \) corresponding to \( p^{(\kappa)}_- \), and let \( 0\tilde{W}^{(\kappa)}(-1) \) be its constant part. Then \( 0\tilde{W}^{(\kappa)}(-1)|0\rangle \) is contained in the kernel of \( \tilde{\chi} \). We construct a cocycle \( \tilde{W}^{(\kappa)}(-1) \) with respect to \( d = d_{\text{st}} + \tilde{\chi} \) which is the main term \( 0\tilde{W}^{(\kappa)}(-1)|0\rangle \) of bidegree \((d_\kappa, -d_\kappa)\) plus a sum of terms of bidegree \((p, -p)\) with \( 0 \leq p < d_\kappa \), as we mentioned above. It is unique up to an element in \( \text{Ker} \tilde{\chi} \) of a lower degree. We fix \( \tilde{W}^{(\kappa)} \) hereafter. We write

\[(B.14) \quad Y(\tilde{W}^{(\kappa)}(z), \chi) = \sum_{n \in \mathbb{Z}} \tilde{W}_n^{(\kappa)} \chi^{-n - d_\kappa - 1}.
\]

Let us check that \( ^c\text{deg} \tilde{W}^{(\kappa)} = d_\kappa + 1 \). Since \( d_{\text{st}} \) and \( \tilde{\chi} \) preserve \( ^c\text{deg} \), we have \( ^c\text{deg} \tilde{W}^{(\kappa)} = ^c\text{deg} 0\tilde{W}^{(\kappa)}|0\rangle \). (Remember that we modify \( \chi \) to \( \tilde{\chi} \) so that this is achieved.) Now the latter does not contain \( \psi_\alpha(z) \), its degree is equal to the first component of the bidegree plus 1, i.e., \( d_\kappa + 1 \). Thus \( ^c\text{deg} \tilde{W}^{(\kappa)} = d_\kappa + 1 \). This is what we want from a geometry side.

B(iii). Grading vs filtration. Let us make the relation between \( W_\chi(\mathfrak{g}) \) and \( W_\mathbb{A}(\mathfrak{g}) \) more precise so that we could easily transfer computation in the literature to our setting.

Recall that the complexes (B.4) and (B.8) become the same if we put \( \varepsilon_1 = (k + h^\vee)^{-1} \), \( \varepsilon_2 = -1 \) and identify \( \tilde{\chi} \) (resp. \( \tilde{J}^a(z) \)) with \( \chi/\varepsilon_1 \) (resp. \( \varepsilon_1 \tilde{J}^a(z) \)). As \( H_\mathbb{A}^0(\mathfrak{g}) = 0 \) and \( W_\mathbb{A}(\mathfrak{g}) \) is free, the Künneth spectral sequence degenerate at \( E_2 \), and hence the specialization commutes with
the cohomology. In particular, the homomorphism $\widetilde{J}^\alpha(z) \mapsto \widetilde{J}(z)/\varepsilon_1$ induces an isomorphism

$$\tag{B.15} W_k(\mathfrak{g}) \cong \mathcal{W}_A(\mathfrak{g}) \otimes \mathcal{A}/(\varepsilon_1 - (k + h^\vee)^{-1}, \varepsilon_1 + 1).$$

Under this isomorphism standard generators $W_n^{(\kappa)}$ and our $\widetilde{W}_n^{(\kappa)}$ are related by

$$\tag{B.16} \text{our } \widetilde{W}_n^{(\kappa)} = \varepsilon_1^{d_\kappa + 1} \text{ standard } W_n^{(\kappa)},$$

as they are defined in the same way.

From this consideration, we can recover $\mathcal{W}_A(\mathfrak{g}) \otimes \mathcal{A} B_1$ with $B_1 = \mathbb{C}[\epsilon_1] = \mathcal{A}/(\epsilon_2 + 1)$ from $W_k(\mathfrak{g})$ as follows. Let us consider $k$ as a variable and understand that $W_k(\mathfrak{g})$ is a vertex algebra defined over $\mathbb{C}(k)$. We identify $\mathbb{C}(k) = \mathbb{C}(\varepsilon_1)$ via $\varepsilon_1 = (k + h^\vee)^{-1}$. Then $\mathcal{W}_A(\mathfrak{g}) \otimes \mathcal{A} B_1 \otimes \mathcal{B}_1 \subset \mathbb{C}(k)$ is isomorphic to $W_k(\mathfrak{g})$, the cohomology of the complex over $\mathbb{C}(k)$ by the Künneth spectral sequence as above. Then we have an embedding $\mathcal{W}_A(g) \otimes \mathcal{A} B_1 \rightarrow W_k(\mathfrak{g})$, and the image is the $B_1$-submodule generated by $\varepsilon_1^{d_\kappa + 1} W_n^{(\kappa)}$. We denote $\mathcal{W}_A(g) \otimes \mathcal{A} B_1$ by $\mathcal{W}_{B_1}(g)$ hereafter.

Note further that the entire $\mathcal{W}_A(g)$ can be recovered from $\mathcal{W}_{B_1}(g)$ as follows. Since $\mathcal{W}_A(g)$ is graded by $\epsilon$-deg, we have an induced filtration $0 = F_{-1} \subset F_0 \subset F_1 \subset \cdots$ on $\mathcal{W}_{B_1}(g)$ such that $\varepsilon_1 F_p \subset F_{p+1}$. Then we can recover $\mathcal{W}_A(g)$ as the associated Rees algebra:

$$\tag{B.17} \mathcal{W}_A(g) = \bigoplus_p \varepsilon_2^p F_p.$$

In fact, we have a natural surjective homomorphism from the left hand side to the right, and it is also injective as $\mathcal{W}_A(g)$ is torsion free over $\mathcal{B}_1 = \mathbb{C}[\varepsilon_2]$. Note also the specialization at $\varepsilon_2 = 0$ can also be recovered as the associated graded of the filtration.

The filtration $\tilde{F}_\bullet$ on $\mathcal{W}_{B_1}(g)$ can be defined directly. From its definition, we assign $\epsilon$-deg($\varepsilon_1^{d_\kappa + 1} W_n^{(\kappa)}$) = $d_\kappa + 1$ and $\epsilon$-$\text{deg} \varepsilon_1 = 1$. This gives us the filtration on $\mathcal{W}_{B_1}(g)$.

Let us explain how the formula for $W_n^{(1)}$ given in [28, (15.3.1)] can be understood in our framework, for example. The field $T(z)$ written there is already divided by $k + h^\vee$ so that its Fourier modes gives Virasoro generators $L_n$. Therefore $W_n^{(1)} = (k + h^\vee) L_n$ and hence $\widetilde{W}_n^{(1)} = \varepsilon_2^2 (k + h^\vee) L_n = -\varepsilon_1 \varepsilon_2 L_n$. This is compatible (up to sign) with modified Virasoro generators in §6(iv), as $\tilde{L}_n^{(i)} = \varepsilon_1 \varepsilon_2 L_n^{(i)}$.

B(iv). **Specialization at $\varepsilon_1 = 0$.** In this subsection, we study the specialization at $\varepsilon_1 = 0$. This is the classical limit of the $\mathcal{W}$-algebra,
but it also contains $\varepsilon_2$ as a parameter. The relevant computation can be found in [28, §15.4.1~6].

Let us set $\varepsilon_1 = 0$ in (B.8). Since $\bar{J}^a(z)$ and $\bar{J}^b(z)$ commute at $\varepsilon_1 = 0$ (see (B.2)), the complex is identified with polynomials in the commuting variables $\bar{J}^a_n$ ($n < 0$) and anti-commuting variables $\psi^*_a,m$ ($m \leq 0$). Therefore

$$C^\bullet_A(g_0) \otimes_A B_2 \cong \text{Sym}_-((-t))/b_-[[t]] \otimes_\mathbb{C} \bigwedge^n_+[[t]]^* \otimes B_2,$$

where $B_2 = \mathbb{C}[\varepsilon_2] = A/\varepsilon_1 A$. The differential is specialized as

\begin{align*}
[d_{st}, \bar{J}^a(z)] &= \sum_{b,\alpha} c_{b,\alpha}^{\alpha^a} \bar{J}^b(z) \psi^*_a(z) - \varepsilon_2 \sum_{\alpha} (\bar{J}^a, J^\alpha) \partial_2 \psi^*_a(z), \\
[d_{st}, \psi^*_a(z)] &= -\frac{1}{2} \sum_{\beta,\gamma} c_{\beta,\gamma}^{\alpha^a} \psi^*_\beta(z) \psi^*_\gamma(z),
\end{align*}

where power series in $z$ contain only terms with non-negative degrees in $z$. This is exactly the same complex as in [28, §15.4.2], if we set $\varepsilon_2 = -1$. It is the complex at the classical limit $k \to \infty$.

By [28, Cor. 15.4.6], the cohomology group $H^i_{\varepsilon_1=0}(g)$ of this complex (at $\varepsilon_2 = -1$) vanishes for $i \neq 0$, and $H^0_{\varepsilon_1=0}(g)$ is isomorphic to the ring of functions on $a_+[[t]]$, where $a_+$ is the kernel of $\text{ad} p_+$. Here $p_+$ is as in the previous subsection.

In fact, $a_+[[t]]$ is obtained as the quotient of the space of connections of the form

$$\nabla = \partial_t + p_- + A(t), \quad A(t) \in b_+[[t]],$$

modulo the action of the gauge transformations $N_+[[t]]$. This is the space $\text{Op}_G(D)$ of $G$-opers on the formal disk $D = \text{Spec} \mathbb{C}[[t]]$. There exists a unique gauge transformation in $N_+[[t]]$ so that $\nabla$ is transformed into the same form with $A(t) \in a_+[[t]]$.

It is easy to put $\varepsilon_2$ in this picture. The term with $\varepsilon_2$ corresponds to the differential of the gauge transformation. Therefore the cohomology of our complex is the ring of functions on the quotient space of $(-\varepsilon_2)$-connections

$$\nabla = -\varepsilon_2 \partial_t + p_- + A(t)$$

modulo $N_+[[t]]$. It is the space of $(-\varepsilon_2)$-opers on $D$. This notion appears for example in [7, §5.2]. See also §B(v) below.
We have a structure of a vertex Poisson algebra on $H^0_{g=0}(g)$ by [28, 16.2.4]. It is defined by renormalizing the polar part of vertex operators

\[(B.22) \quad Y_-(A, z) = \left. \frac{1}{\varepsilon_1} Y_-(\hat{A}, z) \right|_{\varepsilon_1 = 0}.
\]

We can further make $\varepsilon_2 = 0$. Then we get $(p_- + b_+[[t]])/N_+[[t]]$. This space is also equal to $a_+[[t]]$. The proof in [28, 15.4.5] works also at $\varepsilon_2 = 0$. In fact, the result is a consequence of a classical result of Kostant: $(p_- + b_+)/N_+ \cong a_+$. See [7, §5.4] for further detail. Therefore the cohomology group $H^{0,\varepsilon_2=0}(g)$ of the complex at $\varepsilon_1 = \varepsilon_2 = 0$ vanishes for $i \neq 0$, and $H^{0,\varepsilon_1=0}(g) \cong V(a_-)$.

The argument for (B.15) works also here, i.e., the specialization commutes with cohomology group. We have

\[(B.23) \quad \mathcal{W}_{A}(g) \otimes_{A} B_2 \cong H^{0,\varepsilon_1=0}(g),
\]

\[\mathcal{W}_{A}(g) \otimes_{A} C \cong H^{0,\varepsilon_1,\varepsilon_2=0}(g) \cong V(a_-),
\]

where $B_2 = A/\varepsilon_1 A$, $C = A/(\varepsilon_1, \varepsilon_2)$.

**B(v). The opposite spectral sequence.** The embedding of the $\mathcal{W}$-algebra into the Heisenberg algebra is given by considering the ‘opposite’ spectral sequence associated with the double complex $C^k_\varepsilon(g)_0$, where the $E_1$-term is the cohomology with respect to $d_{st}$. The detail is explained in [28, §15.4.10], and we give a brief review in order to see that the embedding is compatible with integral forms.

Let $\hat{H}^i_k(g)$ be the $i$th cohomology of the complex $C^k_\varepsilon(g)_0$ with respect to $d_{st}$. This notation is taken from [28] and has nothing to do with our notation for elements in the integral form. Let $\hat{h}^i(z)$ denote $\hat{J}^\alpha(z)$ for $\alpha = i \in I$. Then we have

\[(B.24) \quad [d_{st}, \hat{h}^i(z)] = 0, \quad [d_{st}, \psi^*_{\alpha_i}(z)]_+ = 0
\]

by (B.4). Therefore we have linear maps $\mathbb{C} [\hat{h}^i_{n_i}]_{i \in I, n_i < 0} \rightarrow \hat{H}^0_k(g)$, $\mathbb{C} [\hat{h}^i_{n_i}]_{j \in I, n_j > 0} \rightarrow \hat{H}^1_k(g)$ respectively. In fact, they live in the uppermost row as bideg $\hat{h}^i(z) = (0, 0)$, bideg $\psi^*_{\alpha_i}(z) = (1, 0)$. Then by considering the limit $k \rightarrow \infty$, one can see that both cohomology groups are exactly the same as the above spaces respectively if $k$ is generic. Moreover one can identify $\hat{H}^0_k(g)$ with the Heisenberg vertex algebra associated with the Cartan subalgebra $\mathfrak{h}$ of $g$. This is because $\hat{h}^i_{n_i}$ satisfies the commutation relation (B.6). Modified generators $\overline{h}^i_{n_i} = \hat{h}^i_{n_i}/\sqrt{k + h^x}$ satisfy the usual commutation rule

\[(B.25) \quad [\overline{h}^i_{m_i}, \overline{h}^j_{n_j}] = m \delta_{m_i-n_i}(\alpha_i, \alpha_j).
\]
And $\tilde{H}_1^k(g)$ is its module. It is a direct sum of $(#I)$ Fock modules. The highest weights are given by the formula

\begin{equation}
(B.26) \quad \tilde{h}_0^i \psi^{\ast}_{\alpha_j,j}|0\rangle = -\frac{(\alpha_i, \alpha_j)}{\sqrt{k + h^\vee}} \psi^{\ast}_{\alpha_j,j}|0\rangle.
\end{equation}

Another differential $\chi$ induces a homomorphism $\tilde{H}_1^k(g) \to \tilde{H}_1^k(g)$. Since $\tilde{H}_1^k(g)$ lives only at bidegree $(1,0)$, we have $W_k(g) = H_0^k(g) \simeq \ker \chi$ for generic $k$.

Moreover $\chi$ is the sum of the residue of the field $\psi^{\ast}_{\alpha_i}(z)$, which is given by the vertex operator in terms of the Heisenberg algebra:

\begin{equation}
(B.27) \quad \psi^{\ast}_{\alpha_i}(z) = V_{-\alpha_i/\sqrt{k + h^\vee}}(z)
\end{equation}

where

\begin{equation}
(B.28) \quad V_\lambda(z) = S_\lambda z^{\lambda_0} \exp \left( -\lambda \sum_{n<0} \frac{b_n}{n} z^{-n} \right) \exp \left( -\lambda \sum_{n>0} \frac{b_n}{n} z^{-n} \right).
\end{equation}

This formula is given in [28, (5.2.8)]. The operator $S_\lambda$ sends the highest weight vector $|0\rangle$ to the highest weight vector $|\lambda\rangle$ and commutes with all $b_n$, $n \neq 0$. And $\lambda b_n$ is replaced by

\begin{equation}
(B.29) \quad \lambda b_n = -\frac{\tilde{h}_n^i}{\sqrt{k + h^\vee}} = -\frac{\hat{h}_n^i}{k + h^\vee},
\end{equation}

and $S_\lambda$ sends $|0\rangle$ to $\psi^{\ast}_{\alpha_i,0}|0\rangle$ here.

Now we consider the cohomology group $\tilde{H}_A^0(g)$ over $A$. The 0th cohomology $\tilde{H}_A^0(g) = \ker d_{st}$ is a direct sum of $A[\tilde{P}_n]_{i \in I, n<0}$ with bidegree $(0,0)$ and the other parts with bidegree $(p,-p)$ with $p > 0$. Here we put $\tilde{P}_n^i = \varepsilon_1 \tilde{h}_n^i$ so that they satisfy the commutation relation (6.19). Since $d_{st}$ on $(p,-p)$ part is injective for generic $(\varepsilon_1, \varepsilon_2)$ by the above computation, it is injective as an $A$-homomorphism. Therefore we have

Lemma B.30.

\begin{equation}
(B.31) \quad \tilde{H}_A^0(g) = A[\tilde{P}_n]_{i \in I, n<0}|0\rangle.
\end{equation}

This is an $A$-form of the Heisenberg vertex algebra, denoted by $\tilde{\text{Heis}}_A(h)$ in 6(iii).

We have an induced homomorphism $W_A(g) = H_A^0(g) \to \tilde{H}_A^0(g)$, taking the bidegree $(0,0)$ component. It is injective as $\ker d_{st} = 0$ on $(p,-p)$ with $p > 0$. Therefore we can consider $W_A(g)$ as an $A$-submodule of $\tilde{H}_A^0(g)$. We have an induced homomorphism $\tilde{\chi}: \tilde{H}_A^0(g) \to \tilde{H}_A^1(g)$ and the double complex tells us that $W_A(g)$ is contained in $\ker \tilde{\chi}$. 
When we compare the embedding with the usual one \( \mathcal{W}_k(\mathfrak{g}) \to \widetilde{H}_k^0(\mathfrak{g}) \) in the literature via the identification of \( \mathcal{W}_k(\mathfrak{g}) \) and \( \mathcal{W}_A(\mathfrak{g}) \) in §B(iii), we use the relations \( \widetilde{P}^i_n = \varepsilon_1 \tilde{P}^i_n \) as before.

For example, consider \( \widetilde{W}^{(1)}_n \) for \( \mathfrak{g} = \mathfrak{sl}_2 \). It is given by (6.28) up to sign, and is contained in \( \widetilde{H}_A^1(\mathfrak{g}) \). The formula follows from the computation in the literature, say [28, §15.4.14], with the rule for the change of generators above.

Let us look at \( \widetilde{H}_A^1(\mathfrak{g}) \) more closely. From the definition, we have

\[
\begin{align*}
C_{A}^{1,-1}(\mathfrak{g})_0 &= \bigoplus_{i,m<0} A[\tilde{P}^i_{n},j \in I,n<0 \tilde{f}_{i,m}|0], \\
C_{A}^{1,0}(\mathfrak{g})_0 &= \bigoplus_{i,m \leq 0} A[\tilde{P}^i_{n},j \in I,n<0 \psi_{\alpha_i,m}^*]|0),
\end{align*}
\]

where \( \tilde{f}_{i,m} \) is the Fourier mode of \( \tilde{f}^a(z) \) corresponding to the basis element \( f_i = f^a_i \). The differential \( d_{st} : C_{A}^{1,-1}(\mathfrak{g})_0 \to C_{A}^{1,0}(\mathfrak{g})_0 \) can be calculated from (B.8), in particular we have

\[
\begin{align*}
[d_{st}, \tilde{P}^i(z)] &= 0, \\
[d_{st}, \tilde{f}_i(z)] &= \frac{2}{\langle \alpha_i, \alpha_i \rangle} \left( \tilde{P}^i(z) \psi_{\alpha_i}^*(z) \cdot -\varepsilon_2 \partial_z \psi_{\alpha_i}^*(z) \right).
\end{align*}
\]

See the formula in the middle of [28, p.261]. From the second formula we have

\[
-\varepsilon_2 \partial_z \psi_{\alpha_i}^*(z) = :\tilde{P}^i(z) \psi_{\alpha_i}^*(z):
\]

modulo \( d_{st} \)-exact term. If \( \varepsilon_2 \) would be invertible, we could replace \( \psi_{\alpha_i,m}^*|0 \) with \( m \neq 0 \) in (B.32) by an element in \( A[\tilde{P}^i_n,\psi_{\alpha_i,m}^*]|0) \) so that \( \widetilde{H}_A^1(\mathfrak{g}) \) is isomorphic to \( \bigoplus \, A[\tilde{P}^i_n,\psi_{\alpha_i,0}^*]|0) \). As \( \varepsilon_2 \) is not invertible in \( A \), this cannot be true.

From this consideration, we set \( \varepsilon_2 = -1 \) in the double complex (B.8), and consider it over \( B_1 = \mathbb{Q}[\varepsilon_1] \), as in §B(iii). We denote it by \( C_{B_1}^*(\mathfrak{g})_0 \). This is not any loss of the information for our purpose, as \( \mathcal{W}_A(\mathfrak{g}) \) can be recovered from \( \mathcal{W}_B(\mathfrak{g}) \) together with its natural filtration, as explained in §B(iii).

However, the higher cohomology groups \( \widetilde{H}_A^{>0}(\mathfrak{g}) \) may not vanish nor be free. Hence the cohomology group \( \widetilde{H}_{B_1}^*(\mathfrak{g})_0 \) of \( C_{B_1}^*(\mathfrak{g})_0 \) with respect to \( d_{st} \) may be different from \( \widetilde{H}_A^1(\mathfrak{g}) \otimes_A B_1 \). We will see that \( \widetilde{H}_{B_1}^*(\mathfrak{g}) \) behaves better than \( \widetilde{H}_A^*(\mathfrak{g}) \) at \( \varepsilon_2 = 0 \) below.

Let us study first two terms of \( \widetilde{H}_{B_1}^*(\mathfrak{g}) \). We have \( \widetilde{H}_{B_1}^{0,0}(\mathfrak{g}) \cong B_1[\tilde{P}^i_n,j \in I,n<0|0) \) by the same argument as in (B.31). Let \( \widetilde{H}_{B_1}^{1,0}(\mathfrak{g}) \) be the \((1,0)\) part of the
cohomology. We do not know \( \tilde{H}^1_{B_1}(g) \cong \tilde{H}^{1,0}_{B_1}(g) \), but \( \tilde{\chi} \) maps \( \tilde{H}^0_{B_1}(g) \) to \( \tilde{H}^{1,0}_{B_1}(g) \) anyway. From the above argument we have a surjective homomorphism \( \bigoplus B_1[\tilde{P}^{j}_{n}]_{\psi_{\alpha,0}} \to \tilde{H}^{1,0}_{B_1}(g) \). It is an isomorphism for generic \( \varepsilon_1 \), in other words over \( \mathbb{C}(\varepsilon_1) \). Therefore it must be injective also over \( B_1 \). We thus get

**Lemma B.36.**

\[
\begin{align*}
\tilde{H}^0_{B_1}(g) &\cong B_1[\tilde{P}^{j}_{n}]_{\varepsilon_1 < 0}[0], \\
\tilde{H}^{1,0}_{B_1}(g) &\cong \bigoplus_{i} B_1[\tilde{P}^{j}_{n}]_{\varepsilon_1 < 0}\psi_{\alpha,i,0}[0].
\end{align*}
\]

The substitution \( \varepsilon_2 = -1 \) makes the vertex operator (B.28) well-defined: We replace \( \lambda b_n \) by (B.29), hence

\[
\lambda b_n = -\tilde{P}^{j}_{n}.
\]

The vertex operator is a homomorphism between \( B_1 \)-modules.

Now we let \( \varepsilon_1 = 0 \). We have the Künneth theorem

\[
\begin{align*}
0 &\to \tilde{H}^n_{B_1}(g) \otimes_{B_1} \mathbb{C} \to H^n(C^{\bullet}_{B_1}(g) \otimes_{B_1} \mathbb{C}) \to \text{Tor}^1_{B_1}(\tilde{H}^{n+1}_{B_1}(g), \mathbb{C}) \to 0,
\end{align*}
\]

where \( \mathbb{C} = B_1/\varepsilon_1 B_1 \). The middle term is the cohomology at the classical limit, and is known (see [28, §15.4.8]). In particular, we get

\[
\begin{align*}
\mathbb{C}[\tilde{P}^{j}_{n}]_0 &\cong \tilde{H}^0_{B_1}(g) \otimes_{B_1} \mathbb{C} \cong H^0(C^{\bullet}_{B_1}(g) \otimes_{B_1} \mathbb{C}), \\
\mathbb{C}[\tilde{P}^{j}_{n}]_1 &\cong \tilde{H}^{1,0}_{B_1}(g) \otimes_{B_1} \mathbb{C} \cong H^1(C^{1,\bullet}_{B_1}(g) \otimes_{B_1} \mathbb{C}), \\
\mathbb{C}[\tilde{P}^{j}_{n}]_{-p} &\cong \tilde{H}^{p+1}_{B_1}(g) \otimes_{B_1} \mathbb{C} = H^1(C^{p+1,\bullet}_{B_1}(g) \otimes_{B_1} \mathbb{C}) = 0 \text{ for } p > 0.
\end{align*}
\]

Next we study \( \tilde{\chi} \) at \( \varepsilon_1 = 0 \). Recall that \( \tilde{\chi} = \chi/\varepsilon_1 \), so we need to divide \( \int \chi(z) \) in (B.28) by \( \varepsilon_1 \). We see that the induced operator

\[
\begin{align*}
\tilde{\chi} |_{\varepsilon_1 = 0} : \tilde{H}^0_{B_1}(g) \otimes_{B_1} \mathbb{C} &\cong \mathbb{C}[\tilde{P}^{j}_{n}]_0 \\
&\to \tilde{H}^1_{B_1}(g) \otimes_{B_1} \mathbb{C} = \bigoplus \mathbb{C}[\tilde{P}^{j}_{n}]_{\psi_{\alpha,i,0}}[0]
\end{align*}
\]

is given by the formula

\[
\sum_i \sum_{j=1}^l (\alpha_i, \alpha_j) \sum_{m \leq 0} V_i[m] \frac{\partial}{\partial \tilde{P}^j[m-1]},
\]

with

\[
\sum_{n \leq 0} V_i[n] z^{-n} = S_i \exp \left( \sum_{n < 0} \frac{\tilde{P}^i_n}{n} z^{-n} \right).
\]
Here the operator $S_1$ sends the highest weight vector $|0\rangle$ to $\psi^*_{a_i,0}|0\rangle$. The point here is the commutation relation $[\tilde{P}_m^i, \tilde{P}_n^j] = m\varepsilon_1(\alpha_i, \alpha_j)\delta_{m,-n}$ at $\varepsilon_2 = -1$. This vanishes at $\varepsilon_1 = 0$, and hence only linear terms in the expansion of the second exponential in (B.28) survive.

This computation appears in the study of the classical limit of the $\mathcal{W}$-algebra [27, Chap. 8]. In particular, the followings were shown there:

- $\tilde{H}_B^0(\mathfrak{g}) \otimes_{B_1} \mathbb{C}$ is isomorphic to the ring of functions on the space $\text{MOp}_G(D)_{\text{gen}}$ of generic Miura opers on the formal disk $D$.
- Each generic Miura oper can be uniquely transformed into the following form

$$(B.44) \quad \nabla = \partial_t + p_- + u(t), \quad u(t) \in \mathfrak{h}[[t]].$$

- The kernel of $\tilde{\chi}|_{\varepsilon_1=0}$ is isomorphic to the ring of functions on the space $\text{Op}_G(D)$ of opers. The inclusion $\text{Ker}(\tilde{\chi}|_{\varepsilon_1=0}) \to \tilde{H}_B^0(\mathfrak{g}) \otimes_{B_1} \mathbb{C}$ is given by the forgetting morphism $\text{MOp}_G(D)_{\text{gen}} \to \text{Op}_G(D)$.

We do not recall the definition of generic Miura opers here, as it is enough to consider the space of connections of the form (B.44). The morphism $\text{MOp}_G(D)_{\text{gen}} \to \text{Op}_G(D)$ is given just by considering a connection in (B.44) as a $G$-oper. As we have already known that $\mathcal{W}_A(\mathfrak{g})$ at $\varepsilon_1 = 0, \varepsilon_2 = -1$ is the ring of functions on $\text{Op}_G(D)$ in §B(iv), we get

$$(B.45) \quad \mathcal{W}_B(\mathfrak{g}) \otimes_{B_1} \mathbb{C} = \text{Ker}(\tilde{\chi}|_{\varepsilon_1=0}).$$

Finally we study the filtration in the both sides of (B.45). The left hand side has a filtration as it comes from the specialization of the grading on $\mathcal{W}_A(\mathfrak{g})$ at $\varepsilon_1 = 0, \varepsilon_2 = -1$. On the other hand, we have filtration on $\tilde{H}_B^0(\mathfrak{g})$ and $\tilde{H}_B^0(\mathfrak{g}) \otimes_{B_1} \mathbb{C}$ given by $\deg \tilde{P}_n^i = 1$, as they are polynomial rings (see Lemma B.36 and (B.40)). Since $\tilde{H}_A^0(\mathfrak{g})$ is also free by Lemma B.30, the filtrations come from the specialization. We give an induced filtration on $\text{Ker}(\tilde{\chi}|_{\varepsilon_1=0})$ as a subspace of $\tilde{H}_B^0(\mathfrak{g}) \otimes_{B_1} \mathbb{C}$. Then (B.45) respects the filtration as the inclusion $\mathcal{W}_B(\mathfrak{g}) \to \tilde{H}_B^0(\mathfrak{g})$ does.

On the ring of functions on $\text{Op}_G(D)$, the filtration can be understood by considering $(-\varepsilon_2)$-opers [6, §3.1.14] as follows. A filtration on an algebra can be identified with a graded flat $\mathbb{C}[\varepsilon_2]$-algebra with $\deg \varepsilon_2 = 1$. The latter is considered as the ring of functions on a flat affine scheme $X$ over $\mathbb{A}^1 = \text{Spec} \mathbb{C}[\varepsilon_2]$ with a $G_m$-action compatible with the action by homotheties on $\mathbb{A}^1$. The space of $(-\varepsilon_2)$-opers provides such
a scheme, where the \( \mathbb{G}_m \)-action is given by \( \nabla \mapsto \lambda \nabla \) for \( \lambda \in \mathbb{G}_m \). More precisely, we need to compose it with a gauge transformation so that the form (B.20) is preserved. Since \( (-\varepsilon_2) \)-opers appear at the specialization at \( \varepsilon_1 = 0 \) in §B(iv), our filtration is given in this way.

The action is induced from the action \( \lambda \text{Ad}(\lambda) \) on \( \mathfrak{a}_+ \) under \( \text{Op}_{\mathbb{G}}(D) \cong \mathfrak{a}_+[[[t]]] \), where \( \text{Ad}(\lambda) \) is given by the \( SL_2 \) embedding associated with the nilpotent element \( p_- \). It is known that the degrees of the \( \mathbb{G}_m \)-action on \( \mathfrak{a}_+ \) are given by \( d_\kappa + 1 \) (\( \kappa = 1, \ldots, \ell \)), hence are the same as our "deg" by §B(ii). This is another reason why we define the degree in that way.

We can define the \( \mathbb{G}_m \)-action on \( \text{MOp}_{\mathbb{G}}(D) \) in the same way so that the morphism \( \text{MOp}_{\mathbb{G}}(D) \to \text{Op}_{\mathbb{G}}(D) \) is \( \mathbb{G}_m \)-equivariant. Under \( \text{MOp}_{\mathbb{G}}(D) \cong \mathfrak{h}[[[t]]] \), it is just homotheties on \( \mathfrak{h} \). The corresponding filtration is the same as ours.

The homomorphism between the associated graded of \( \ker(\tilde{\chi}|_{\varepsilon_1=0})_{\varepsilon_2=-1} \) and \( \widetilde{H}^2_{\mathfrak{b}_1}(\mathfrak{g}) \otimes_{\mathfrak{b}_1} \mathbb{C} \) is induced by the morphism

\[
\text{(B.46)} \quad \{ \nabla = p_- + u(t) \mid u(t) \in \mathfrak{h}[[[t]]] \} \to \{ \nabla = p_- + A(t) \mid A(t) \in \mathfrak{b}_+[[[t]]] \} / N_+[[[t]]]
\]

of 0-opers.

Let us write down the embedding of the \( \mathcal{W} \)-algebra into the Heisenberg algebra at \( \varepsilon_1 = \varepsilon_2 = 0 \) induced from the morphism (B.46) of 0-opers explicitly. It is given in [27, §3.3.4]. Let \( F^{(\kappa)} \in S(\mathfrak{h})^W \) (\( \kappa = 1, \ldots, \ell \)) be generators of degree \( d_\kappa - 1 \), corresponding to \( p_-^{(\kappa)} \) in §B(ii). We regard it as a polynomial in \( h^i \), i.e., \( F^{(\kappa)}(h^i) = F^{(\kappa)}(h^1, \ldots, h^\ell) \).

Then \( \tilde{W}_n^{(\kappa)} \) (at \( \varepsilon_1, \varepsilon_2 = 0 \)) is given by the formula

\[
\text{(B.47)} \quad F^{(\kappa)} \left( \sum_{n<0} \tilde{P}^{(i)}_n z^{-n-1} \right) = \sum_{n<0} \tilde{W}_n^{(\kappa)} z^{-n-d_\kappa - 1}.
\]

For example, we have

\[
\text{(B.48)} \quad \tilde{L}_n = -\frac{1}{4} \sum_{n<l<0} \tilde{P}_l \tilde{P}_{n-l}
\]

for \( \mathfrak{sl}_2 \).

B(vi). **Kernel of the screening operator.** Recall that we have a natural inclusion \( \mathcal{W}_{\mathfrak{b}_1}(\mathfrak{g}) \subset \ker(\tilde{\chi}|_{\varepsilon_2=-1}) \) from the construction. They coincide for generic \( \varepsilon_1 \). We prove a stronger result.
Theorem B.49. We have isomorphisms
\[ \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cong \operatorname{Ker}(\widetilde{\chi}_{\epsilon_2=-1}), \]
\[ \mathcal{W}_A(\mathfrak{g}) \cong \bigcap_i \mathcal{Vir}_{i,A}|_{\epsilon_1 \rightarrow \epsilon'_1} \otimes_A \mathfrak{Heis}_A(\alpha^+_1), \]
where \( \mathcal{Vir}_{i,A}|_{\epsilon_1 \rightarrow \epsilon'_1} \) is the \( A \)-form of the Virasoro algebra with \( \epsilon_1 \) replaced by \( \epsilon'_1 = \frac{\epsilon_1(\alpha_1, \alpha_2)}{2} \). Moreover (B.50) preserves filtrations.

Proof. Let us first consider (B.50) and denote \( \tilde{\chi} \) at \( \epsilon_2 = -1 \) also by \( \tilde{\chi} \) for brevity:
\[ \tilde{\chi}: \tilde{H}^0_{\mathcal{B}_i}(\mathfrak{g}) \to \tilde{H}^1_{\mathcal{B}_i}(\mathfrak{g}). \]
We know that both \( \tilde{H}^0_{\mathcal{B}_i}(\mathfrak{g}) \) and \( \tilde{H}^1_{\mathcal{B}_i}(\mathfrak{g}) \) are free over \( \mathcal{B}_i \) (see Lemma B.36). We also know that their specialization is the cohomology group at \( \epsilon_1 = 0, \epsilon_2 = -1 \) (see (B.40)). Therefore we have an exact sequence
\[ 0 \to \operatorname{Ker} \tilde{\chi} \otimes_{\mathcal{B}_i} \mathbb{C} \to \operatorname{Ker}(\tilde{\chi}|_{\epsilon_1=0}) \to \operatorname{Tor}_{\mathcal{B}_i}(\operatorname{Cok} \tilde{\chi}, \mathbb{C}) \to 0. \]

We have a homomorphism from \( \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \otimes_{\mathcal{B}_i} \mathbb{C} \) to the first term \( \operatorname{Ker} \tilde{\chi} \otimes_{\mathcal{B}_i} \mathbb{C} \), and its composition to the middle term is an isomorphism by (B.45). Therefore we have
\[ \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cong \operatorname{Ker} \tilde{\chi} \otimes_{\mathcal{B}_i} \mathbb{C} \cong \operatorname{Ker}(\tilde{\chi}|_{\epsilon_1=0}). \]

Since (B.45) preserves the filtration, we have an induced isomorphism between the associated graded
\[ \operatorname{gr} (\mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \otimes_{\mathcal{B}_i} \mathbb{C}) \cong \operatorname{gr} (\operatorname{Ker} \tilde{\chi} \otimes_{\mathcal{B}_i} \mathbb{C}). \]

Let \( 0 = F_{-1} \subset F_0 \subset F_1 \subset \cdots \) be the filtration on \( \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \) as before. Then the filtration on \( \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \otimes_{\mathcal{B}_i} \mathbb{C} \) is given by
\[ 0 \subset F_0/\epsilon_1 \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cap F_0 \subset F_1/\epsilon_1 \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cap F_1 \subset \cdots, \]
as \( \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \otimes_{\mathcal{B}_i} \mathbb{C} \cong \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g})/\epsilon_1 \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \). From the definition of \( F_p \), we have \( \epsilon_1 \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cap F_p = \epsilon_1 F_{p-1} \). Therefore
\[ \operatorname{gr} (\mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \otimes_{\mathcal{B}_i} \mathbb{C}) = \bigoplus_{p>0} F_p/\epsilon_1 F_{p-1} \cong \operatorname{gr} \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g})/\epsilon_1 \operatorname{gr} \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}). \]

(Here we have used \( \operatorname{gr} W/\epsilon_1 \operatorname{gr} W = \bigoplus (F_p/F_{p-1})/\epsilon_1 (F_{p-1}/F_{p-2}) \) as \( \epsilon_1 \) shift the grading by 1). The same is true for \( \operatorname{gr} (\operatorname{Ker} \tilde{\chi} \otimes_{\mathcal{B}_i} \mathbb{C}). \)

By graded Nakayama’s lemma, we conclude \( \operatorname{gr} \mathcal{W}_{\mathcal{B}_i}(\mathfrak{g}) \cong \operatorname{gr} \operatorname{Ker} \tilde{\chi}. \)

Using it again, we get (B.50).

Next consider (B.51). Since both sides are Rees algebras of the corresponding vertex algebras at \( \epsilon_2 = -1 \) with the induced filtration,
it is enough to show that we have a filtration preserving isomorphism at \( \varepsilon_2 = -1 \):

\[
\mathcal{W}_{B^1}(g) \cong \bigcap_i \mathcal{W}_{\mathfrak{vir}, B^1}|_{\varepsilon_1 \rightarrow \varepsilon'_i} \otimes_{B^1} \mathfrak{hes}_{B^1}(\alpha_i^+) ,
\]

where \( \mathcal{W}_{\mathfrak{vir}, B^1}, \mathfrak{hes}_{B^1}(\alpha_i^+) \) are defined in an obvious manner.

We use (B.50) \( \mathcal{W}_{B^1}(\mathfrak{sl}_2) = \mathcal{W}_{\mathfrak{vir}, B^1} \cong \text{Ker}(\chi|_{\varepsilon_2 = -1}) \) for \( g = \mathfrak{sl}_2 \) and the observation that \( \chi \) is the sum of operators over \( i \in I \), we see that the right hand side is \( \text{Ker}(\chi|_{\varepsilon_2 = -1}) \). The substitution \( \varepsilon_1 \rightarrow \varepsilon'_1 = \frac{(\alpha_i, \alpha_j)\varepsilon_1}{2} \) is necessary, as the Heisenberg commutation (6.19) involves \( (\alpha_i, \alpha_j) \). Now we use (B.50) for the original \( g \) and deduce (B.58).

From this result, we extend the duality for the \( \mathcal{W} \)-algebra in [28, Prop. 15.4.16] from generic to arbitrary level.

**Corollary B.59.** Let \( ^Lg \) be the Langlands dual of \( g \). Then we have

\[
\mathcal{W}_{A}(g) \cong \mathcal{W}_{A}(^Lg)|_{\varepsilon_1 \rightarrow r^\vee \varepsilon_2},
\]

where \( r^\vee \) is the maximal number of edges connecting two vertices of the Dynkin diagram of \( g \) (the lacing number).

This is because \( \mathcal{W}_{\mathfrak{vir}, A} \) is invariant under \( \varepsilon_1 \leftrightarrow \varepsilon_2 \) and \( (\varepsilon_1, \varepsilon_2) \rightarrow (c\varepsilon_1, c\varepsilon_2) \) \( (c \in \mathbb{C}^*) \).

**B(vii). The embedding** \( \mathcal{W}_{A}(g) \rightarrow \mathcal{W}_{A}(l) \). The result in this subsection will not be used elsewhere, but shows that the hyperbolic restriction functor \( \Phi_{L,G} \) for general \( L \) corresponds to in the \( \mathcal{W} \)-algebra side.

Let \( L \) be a standard Levi subgroup of \( G \) with Lie algebra \( l \). We can write \( l \) as \( [l, l] \oplus \mathfrak{z}(l) \), where \( \mathfrak{z}(l) \) denotes the center of \( l \). The above discussion can be applied to the Lie algebra \( l \) instead of \( g \) and we get a well-defined vertex operator algebra \( \mathcal{W}_{A}(l) \) over \( A \) and we have an embedding \( \mathcal{W}_{A}(l) \hookrightarrow \mathfrak{hes}_{A}(\mathfrak{z}(l)) \). It is also clear that \( \mathcal{W}_{A}(l) \) is isomorphic to \( \mathcal{W}_{A}([l, l]) \otimes_{A} \mathfrak{hes}_{A}(\mathfrak{z}(l)) \).

**Theorem B.61.** There exists an embedding \( \mathcal{W}_{A}(g) \rightarrow \mathcal{W}_{A}(l) \) compatible with the embedding of both algebras into \( \mathfrak{hes}_{A}(\mathfrak{z}(l)) \).

**Proof.** Clearly, it is enough to construct any map \( \mathcal{W}_{A}(g) \rightarrow \mathcal{W}_{A}(l) \) whose composition with the embedding \( \mathcal{W}_{A}(l) \hookrightarrow \mathfrak{hes}_{A}(\mathfrak{z}(l)) \) gives the map \( \mathcal{W}_{A}(g) \hookrightarrow \mathfrak{hes}_{A}(\mathfrak{z}(l)) \) constructed before. To this end, we are going to construct another double complex structure on \( C_{A}^*(g)_0 \) (with the same total complex).

Let \( p \) be the parabolic subalgebra containing \( l \) and \( n_+ \) and let \( n(p) \) be its nilpotent radical. We can write \( n_+ = n_+(l) \oplus n(p) \). Accordingly,
we can decompose $\chi = \chi_1 + \chi_2$ where $\chi_1 \in n_+(l)^*$ and $\chi_2 \in n(p)^*$. Let $h_l \in z(l)$ denote the (unique) element such that for every simple root $\alpha_i$ we have $ad_{h_l}(e_i) = e_i$ if $e_i$ is not in $l$ and $ad_{h_l}(e_i) = 0$ otherwise. Let $h_{st}$ denote the (unique) element such that for every simple root $\alpha_i$ we have $ad_{h_{st}}(e_i) = e_i$ if $e_i$ is not in $l$ and $ad_{h_{st}}(e_i) = 0$ otherwise.

Now define a new grading on $C_\Lambda^\bullet(g)_0$ in a way similar to (B.5) but where instead of the principal gradation and the root height we use the eigenvalue with respect to $ad_{h_{st}}$. Then the action of $\chi_2$ has bidegree $(1, 0)$ and the action of $d_{st} + \chi_1$ has bidegree $(0, 1)$. In this way we get a new bicomplex structure on $C_\Lambda^\bullet(g)_0$ with the same total differential and total degree.

It is easy to see that we have $C_{p,q}^\bullet(g)_0 = 0$ unless $p \geq 0$ and $p+q \geq 0$. Note that it is no longer true that for $p = 0$ the complex $C_{0,q}^\bullet(g)_0$ vanishes unless $q = 0$; moreover, the complex $C_{0,\bullet}^\bullet(g)_0$ (with respect to the differential $d_{st} + \chi_1$) is just $C^\bullet(g)_0$. Thus we get a morphism $H^0(C_\Lambda^\bullet(g)_0) \to H^0(C_\Lambda^\bullet(l)_0)$ by mapping every cocycle to its degree $(0, 0)$-component with respect to the above grading. 

\[ \square \]
