Abstract
In this paper, we present a linearly implicit energy-preserving scheme for the Camassa–Holm equation by using the multiple scalar auxiliary variables approach, which is first developed to construct efficient and robust energy stable schemes for gradient systems. The Camassa–Holm equation is first reformulated into an equivalent system by utilizing the multiple scalar auxiliary variables approach, which inherits a modified energy. Then, the system is discretized in space aided by the standard Fourier pseudo-spectral method and a semi-discrete system is obtained, which is proven to preserve a semi-discrete modified energy. Subsequently, the linearized Crank–Nicolson method is applied for the resulting semi-discrete system to arrive at a fully discrete scheme. The main feature of the new scheme is to form a linear system with a constant coefficient matrix at each time step and produce numerical solutions along which the modified energy is precisely conserved, as is the case with the analytical solution. Several numerical results are addressed to confirm accuracy and efficiency of the proposed scheme.

1 Introduction

In this paper, we consider the Camassa–Holm (CH) equation [2,3]

\[
\begin{align*}
  u_t - u_{xxt} + 3uu_x - 2u_xu_{xx} - uu_{xxx} &= 0, & a < x < b, & 0 < t \leq T, \\
  u(x, 0) &= u_0(x), & a \leq x \leq b, \\
  u(x + L, t) &= u(x, t), & a \leq x \leq b, & 0 \leq t \leq T,
\end{align*}
\]

(1.1)

where \( t \) is time, \( x \) is the spatial coordinate, \( L = b - a \), and \( u(x, t) \) represents the water’s free surface in non-dimensional variables. The CH equation models the unidirectional propagation of shallow water waves over a flat bottom and is completely integrable [2,7]. Thus, it has infinitely many conservation laws. The first three are

\[
\begin{align*}
  \frac{d}{dt} \mathcal{M} &= 0, & \mathcal{M} &= \int_a^b u \, dx, \\
  \frac{d}{dt} \mathcal{I} &= 0, & \mathcal{I} &= \int_a^b (u^2 + u_x^2) \, dx, \\
  \frac{d}{dt} \mathcal{H} &= 0, & \mathcal{H} &= -\frac{1}{2} \int_a^b (u^3 + uu_x^2) \, dx,
\end{align*}
\]

(1.2), (1.3), (1.4)

where \( \mathcal{M} \), \( \mathcal{I} \) and \( \mathcal{H} \) are the mass, momentum and energy of the CH equation (1.1), respectively. The aim of this paper is concerned with the numerical methods that preserve the energy.

Because the energy is the most important first integral of the CH equation, designing of energy-preserving methods attracts a lot of interest. In Ref. [18], Matsuo et al. presented an energy-conserving Galerkin scheme for the CH equation. Further analysis for the energy-preserving \( H^1 \)-Galerkin scheme was investigated in Ref. [19]. Later on, Cohen and Raynaud [6] derived a new energy-preserving scheme by the discrete gradient approach. Recently, Gong and Wang [11] proposed an energy-preserving wavelet collocation scheme for the CH equation (1.1). However, such energy-preserving schemes are fully implicit that typically need iterative solvers at each time step. This quickly becomes a computationally expensive procedure. To address this drawback and maintain the desired energy-preserving property, Eidnes et al. [9] constructed two linearly implicit energy-preserving schemes for the CH equation (1.1) using the Kahan’s method and the polarised discrete gradient methods, respectively. In Ref. [15], we proposed a novel linearly implicit energy-preserving scheme for the CH equation (1.1) using the invariant energy quadratization (IEQ) approach [12,24,25]. At each time step, the linearly implicit schemes only require to solve a linear system, which leads to considerably lower costs than the implicit one [8]. However, these schemes leads to a linear system with complicated variable coefficients at each time step that may be difficult or expensive to solve.

More recently, inspired by the scalar auxiliary variable (SAV) approach [21,22], Cai et al. developed a linearly implicit energy-conserving scheme for the sine-Gordon equation [1]. The resulting scheme leads to a linear system with constant coefficients that is easy to implement. The purpose of this paper is to apply the idea of the SAV approach to develop an efficient and energy-preserving scheme for the CH equation (1.1). However, the classical SAV approach can not be directly applied to develop energy-preserving schemes for the CH equation. Actually, following the classical SAV approach, we introduce the auxiliary variable, as follows:

\[
q = \sqrt{\int_a^b \left( u^3 + uu_x^2 \right) \, dx + C_0},
\]

(1.5)
where $C_0$ is a constant large enough to make $q$ well-defined. The energy is then rewritten as

$$\mathcal{H} = -\frac{1}{2}q^2 + \frac{1}{2}C_0. \quad (1.6)$$

According to the energy variational, the CH equation (1.1) can be reformulated into an equivalent system, as follows:

$$\begin{align*}
\partial_t u &= D \left( -\frac{3u^2 + u_x^2}{2\sqrt{(u^3 + uu_x^2, 1) + C_0}} + \frac{\partial_x (2uu_x)}{2\sqrt{(u^3 + uu_x^2, 1) + C_0}} q \right), \\
\frac{d}{dt} q &= 0, \\
\begin{bmatrix} u(x, 0) = u_0(x), \\ q(0) = \sqrt{\int_a^b \left( u_0(x)^3 + u_0(x)\partial_x u_0(x)^2 \right) dx + C_0}, \\
u(x + L, t) = u(x, t) \end{bmatrix},
\end{align*} \quad (1.7)$$

where $D = (1 - \partial_{xx})^{-1}\partial_x$ is a skew-adjoint operator. However, the above reformulated system has two main drawbacks for the further development of efficiently energy-preserving schemes: (i) according to the second Eq. of (1.7), $q$ reduces a constant, which fails to contribute to the numerical scheme; (ii) based on the conventional SAV discretization where $q$ is treated implicitly in time but other terms are treated explicitly, we obtain a fully explicit scheme, which may require a strict restriction on the grid ratio. To meet these challenges, we first split the energy (1.4) as three parts, where two parts are bounded from below and the rest is quadratic. Then, we utilize the multiple scalar auxiliary variables (MSAV) approach [5] to transform the original system into an equivalent form, which inherits a modified energy. Subsequently, a novel linearly implicit energy-preserving scheme is proposed by applying the linearly implicit structure-preserving method in time and the standard Fourier pseudo-spectral method in space, respectively, for the equivalent system. We show that the proposed scheme can exactly preserve the discrete modified energy and mass, respectively, and only require to solve a linear system with a constant coefficient matrix at each time step that can be solved by FFT solvers efficiently. The MSAV approach is more recently proposed by Cheng and Shen in Ref. [5] to deal with free energies with multiple disparate terms in the phase-field vesicle membrane and leads to robust energy stable schemes which enjoy the same computational advantages as the classical SAV approach. To the best of our knowledge, there is no result concerning the MSAV approach for the energy-conserving system. Taking the CH equation (1.1) for example, we first explore the feasibility of the MSAV approach and then devise a linearly implicit energy-preserving scheme.

The outline of this paper is organized as follows. In Sect. 2, based on the MSAV approach, the CH equation (1.1) is reformulated into an equivalent form. A semi-discrete system, which inherits the semi-discrete modified energy, is presented in Sect. 3. In Sect. 4, we will concentrate on the construction for the linearly implicit energy-preserving scheme. Several numerical experiments are reported in Sect. 5. We draw some conclusions in Sect. 6.

2 Model Reformulation Using the MSAV Approach

In this section, we first reformulate the CH equation into an equivalent form with a quadratic energy functional using the idea of the MSAV approach. The resulting reformulation provides an elegant platform for developing linearly implicit energy-preserving schemes.
The energy functional (1.4) can be split as the following three parts
\[ \mathcal{H} = -\frac{1}{2} \int_a^b (u + \frac{1}{2})^2 (u^2 + u_x^2) dx + \frac{1}{2} \int_a^b u^2 (u^2 + u_x^2) dx + \frac{1}{8} \int_a^b (u^2 + u_x^2) dx \]
\[ := -\frac{1}{2} \int_a^b g(u, u_x) dx + \frac{1}{2} \int_a^b h(u, u_x) dx + \frac{1}{8} \int_a^b (u^2 + u_x^2) dx. \]  
(2.1)

Subsequently, following the idea of the MSAV approach, we introduce two scalar auxiliary variables, as follows:
\[ q_1 = \sqrt{(g(u, u_x), 1) + C_1}, \quad q_2 = \sqrt{(h(u, u_x), 1) + C_2}, \]
where \((v, w)\) is the inner product defined by \((v, w) = \int_a^b vw dx\), and \(C_1\) and \(C_2\) are two constants large enough to make \(q_1\) and \(q_2\) well-defined. Eq. (2.1) can then be rewritten as
\[ \mathcal{H} = \frac{1}{8} \int_a^b (u^2 + u_x^2) dx - \frac{1}{2} q_1^2 + \frac{1}{2} q_2^2 + \frac{1}{2} C_1 - \frac{1}{2} C_2. \]  
(2.2)

According to the energy variational, the system (1.1) can be reformulated into the following equivalent form
\[
\begin{align*}
\partial_t u &= D \left( -\frac{\partial g}{\partial u} (u, u_x) - \partial_x \frac{\partial g}{\partial u_x} (u, u_x) \right) + \frac{1}{2} \sqrt{(g(u, u_x), 1) + C_1} q_1 \\
&\quad + \frac{\partial h}{\partial u} (u, u_x) - \partial_x \frac{\partial h}{\partial u_x} (u, u_x) \right) + \frac{1}{2} \sqrt{(h(u, u_x), 1) + C_2} q_2 + \frac{1}{4} (u - u_{xx}), \\
\frac{d}{dt} q_1 &= \frac{1}{2} \sqrt{(g(u, u_x), 1) + C_1} \left( \frac{\partial g}{\partial u} (u, u_x) - \partial_x \frac{\partial g}{\partial u_x} (u, u_x), u_t \right), \\
\frac{d}{dt} q_2 &= \frac{1}{2} \sqrt{(h(u, u_x), 1) + C_2} \left( \frac{\partial h}{\partial u} (u, u_x) - \partial_x \frac{\partial h}{\partial u_x} (u, u_x), u_t \right), \\
q_1(0) &= \sqrt{(g(u_0(x), \partial_x u_0(x)), 1) + C_1}, \\
q_2(0) &= \sqrt{(h(u_0(x), \partial_x u_0(x)), 1) + C_2}, \\
u(x, 0) &= u_0(x), \quad u(x, t) = u(x, t),
\end{align*}
\]

where
\[ \frac{\partial g}{\partial u} (u, u_x) = 2(u + \frac{1}{2})(2u^2 + u_x^2 + \frac{1}{2} u), \quad \frac{\partial g}{\partial u_x} = 2u_x (u + \frac{1}{2})^2, \]
\[ \frac{\partial h}{\partial u} (u, u_x) = 4u_x^3 + 2uu_x^2, \quad \frac{\partial h}{\partial u_x} = 2u_x u^2. \]

**Theorem 2.1** The system (2.3) possesses the following modified energy.
\[ \frac{d}{dt} \mathcal{H} = 0, \quad \mathcal{H} = \frac{1}{8} \int_a^b (u^2 + u_x^2) dx - \frac{1}{2} q_1^2 + \frac{1}{2} q_2^2 + \frac{1}{2} C_1 - \frac{1}{2} C_2. \]

**Proof** We can deduce from (2.3) that
\[ \frac{d}{dt} \mathcal{H} = \frac{1}{4} (u - u_{xx}, u_t) - q_1 \frac{d}{dt} q_1 + q_2 \frac{d}{dt} q_2 - \frac{1}{4} u_x u_{tt} \]
\[
= \left( -\frac{\frac{\partial g}{\partial u}(u, u_x) - \partial_x \frac{\partial g}{\partial u_x}(u, u_x)}{2\sqrt{g(u, u_x)}} \right) q_1 + \left( \frac{\frac{\partial h}{\partial u}(u, u_x) - \partial_x \frac{\partial h}{\partial u_x}(u, u_x)}{2\sqrt{h(u, u_x)}} \right) q_2 \\
+ \frac{1}{4}(u - u_{xx}, u_t) - \frac{1}{4}u_xu_t|_{u=\alpha} = 0,
\]

where the last equality follows from the first equality of (2.3), the periodic boundary condition and the skew-adjoint property of \( D \).

\[\square\]

**Remark 2.1** We should note that the splitting strategy used in (2.1) is not unique. The comparisons between splitting strategies will be the subject of future investigations.

### 3 Structure-Preserving Spatial Semi-discretization

In this section, the standard Fourier pseudo-spectral method is employed to approximate spatial derivatives of the system (2.3) and we prove that the resulting semi-discrete system can exactly preserve the semi-discrete modified energy.

Choose the mesh size \( h = L/N \) with \( N \) an even positive integer, and denote the grid points by \( x_j = jh \) for \( j = 0, 1, 2, \ldots, N \); let \( U_j \) be the numerical approximation of \( u(x_j, t) \) for \( j = 0, 1, \ldots, N \) and \( U = (U_0, U_1, \ldots, U_{N-1})^T \) be the solution vector space, and define discrete inner product as

\[
\langle U, V \rangle_h = h \sum_{j=0}^{N-1} U_j V_j, \quad \langle U, 1 \rangle_h = h \sum_{j=0}^{N-1} U_j,
\]

where \( 1 = (1, 1, \ldots, 1)^T \in \mathbb{R}^N \).

Let

\( S_N = \text{span}\{g_j(x), \ 0 \leq j \leq N - 1\} \)

be the interpolation space, where \( g_j(x) \) is trigonometric polynomials of degree \( N/2 \) given by

\( g_j(x) = \frac{1}{N} \sum_{l=-N/2}^{N/2} \frac{1}{a_l} e^{il\mu(x-x_j)}, \)

with \( a_l = \begin{cases} 1, & |l| < \frac{N}{2}, \\ 2, & |l| = \frac{N}{2}, \end{cases} \)

and \( \mu = \frac{2\pi}{b-a} \). We define the interpolation operator \( I_N : C(\Omega) \to S_N \), as follows:

\( I_N u(x, t) = \sum_{j=0}^{N-1} u_j(t)g_j(x), \)

where \( u_j(t) = u(x_j, t) \). Taking the derivative with respect to \( x \), and then evaluating the resulting expression at the collocation points \( x_j \), we have

\[
\frac{\partial^s I_N u(x_j, t)}{\partial x^s} = \sum_{j=1}^{N-1} u_j \frac{d^s g_j(x_j)}{dx^s} = [D_s u]_j,
\]
where $u = (u_0, u_1, \ldots, u_{N-1})^T$ and $D_x$ is an $N \times N$ matrix, with elements given by

$$(D_x)_{j_1,j_2} = \frac{d^2g_j(x_{j_1})}{dx^2}.$$  

In particular, the first and second order differential matrices can be obtained explicitly [4]

$$(D_1)_{j,l} = \begin{cases} \frac{1}{2} \mu (-1)^{j+l} \cot (\mu \frac{x_j - x_l}{2}), & j \neq l, \\ 0, & j = l, \end{cases}$$

$$(D_2)_{j,l} = \begin{cases} \frac{1}{2} \mu^2 (-1)^{j+l+1} \csc^2 (\mu \frac{x_j - x_l}{2}), & j \neq l, \\ -\mu^2 N^2 + 2, & j = l. \end{cases}$$

**Remark 3.1** It should be remarked that, for matrices $D_1$ and $D_2$, the following result holds [10,20]

$$D_1 = F_N^H \Lambda_1 F_N, \quad \Lambda_1 = i\mu \text{ diag}[0, 1, \ldots, \frac{N}{2} - 1, 0, 1 - \frac{N}{2}, \ldots, -1],$$

$$D_2 = F_N^H \Lambda_2 F_N, \quad \Lambda_2 = -\mu^2 \text{ diag}[0^2, 1^2, \ldots, (\frac{N}{2})^2, (1 - \frac{N}{2})^2, \ldots, (-2)^2, (-1)^2],$$

where $F_N$ is the discrete Fourier transform matrix with elements $(F_N)_{j,k} = \frac{1}{\sqrt{N}} e^{-i jk \frac{\pi}{N}}$, $0 \leq j, k \leq N - 1$, $F_N^H$ is the conjugate transpose matrix of $F_N$.

Applying the standard Fourier pseudo-spectral method to the system (2.3) in space and we have

$$\frac{d}{dt} U = D \left( - \frac{g_1(U, D_1 U) - D_1 g_2(U, D_1 U)}{2 \sqrt{(g(U, D_1 U), 1)_h + C_1}} q_1 + \frac{h_1(U, D_1 U) - D_1 h_2(U, D_1 U)}{2 \sqrt{(h(U, D_1 U), 1)_h + C_2}} q_2 + \frac{1}{4} (U - D_2 U) \right),$$

$$(3.1)$$

$$\frac{d}{dt} q_1 = \left( \frac{g_1(U, D_1 U) - D_1 g_2(U, D_1 U)}{2 \sqrt{(g(U, D_1 U), 1)_h + C_1}}, \frac{d}{dt} U \right)_h,$$

$$\frac{d}{dt} q_2 = \left( \frac{h_1(U, D_1 U) - D_1 h_2(U, D_1 U)}{2 \sqrt{(h(U, D_1 U), 1)_h + C_2}}, \frac{d}{dt} U \right)_h,$$

where $D = (I - D_2)^{-1} D_1$, $g_1 = \frac{\partial g}{\partial u}$, $g_2 = \frac{\partial g}{\partial u_1}$, $h_1 = \frac{\partial h}{\partial u}$, and $h_2 = \frac{\partial h}{\partial u_1}$.

**Theorem 3.1** The semi-discrete system (3.1) admits the following semi-discrete modified energy

$$\frac{d}{dt} E_h = 0, \quad E_h = \frac{1}{8} (U - D_2 U, U)_h - \frac{1}{2} q_1^2 + \frac{1}{2} q_2^2 + \frac{1}{2} C_1 - \frac{1}{2} C_2.$$  

**Proof** It follows from the semi-discrete system (3.1) that

$$\frac{d}{dt} E_h = \frac{1}{4} (U - D_2 U, \frac{d}{dt} U)_h - q_1 \frac{d}{dt} q_1 + q_2 \frac{d}{dt} q_2.$$  

© Springer
= \left\{ - \frac{g_1(U, D_1 U) - D_1 g_2(U, D_1 U)}{2\sqrt{g(U, D_1 U), 1}_h + C_1} q_1 + \frac{h_1(U, D_1 U) - D_1 h_2(U, D_1 U)}{2\sqrt{h(U, D_1 U), 1}_h + C_2} q_2 \right. \\
+ \frac{1}{4} (U - D_2 U), \frac{d}{dt} U \bigg|_h = 0,
\]

where the last equality follows from the first equality (3.1) and the skew-symmetry of $D$.

\[ \square \]

4 Construction of the Linearly Implicit Energy-Preserving Scheme

In this section, we present a linearly implicit energy-preserving scheme by utilizing the linearized Crank–Nicolson method to the semi-discrete system (3.1) in time.

Choose $\tau = T/M$ be the time step with $M$ a positive integer, and denote $t_n = n \tau$ for $n = 0, 1, 2, \ldots, M$; let $U^n_j$, $Q^n_1$ and $Q^n_2$ be the numerical approximations of $u(x_j, t_n)$, $q_1(t_n)$ and $q_2(t_n)$, respectively, for $j = 0, 1, \ldots, N$ and $n = 0, 1, 2, \ldots, M$; denote $U^n = (U^n_0, U^n_1, \ldots, U^n_N)^T$ as the solution vector at $t = t_n$ and define

\[ \delta_t U^n_j = \frac{U^{n+1}_j - U^n_j}{\tau}, \quad U^{n+\frac{1}{2}}_j = \frac{U^{n+1}_j + U^n_j}{2}, \quad \hat{U}^{n+\frac{1}{2}}_j = \frac{3U^n_j - U^{n-1}_j}{2}, \quad 0 \leq j \leq N - 1. \]

Applying the linearized Crank–Nicolson method to the semi-discrete system (3.1) in time, and we obtain a fully discretized scheme, as follows:

\[
\delta_t U^n = D \left( - \frac{g_1(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) - D_1 g_2(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j)}{2\sqrt{g(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j), 1}_h + C_1} Q^{n+\frac{1}{2}}_1 \right. \\
+ \left. \frac{h_1(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) - D_1 h_2(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j)}{2\sqrt{h(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j), 1}_h + C_2} Q^{n+\frac{1}{2}}_2 \right) \\
+ \frac{1}{4} (U^{n+\frac{1}{2}} - D_2 U^{n+\frac{1}{2}}) \right). \tag{4.1}
\]

\[
\delta_t Q^n_1 = \left\{ \left( g_1(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) - D_1 g_2(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) \right) \right\}_h, \delta_t U^n \right), \]

\[
\delta_t Q^n_2 = \left\{ \left( h_1(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) - D_1 h_2(\hat{U}^{n+\frac{1}{2}}_j, D_1 \hat{U}^{n+\frac{1}{2}}_j) \right) \right\}_h, \delta_t U^n \right), \]
for \( n = 1, \ldots, M - 1 \). Since the scheme (4.1) is three-level, we obtain \( U^1, Q^1_1 \) and \( Q^1_2 \) by

\[
\delta_t U^0 = D \left( -\frac{\left( g_1(U^0, D_1U^0) - D_1g_2(U^0, D_1U^0) \right)}{2\sqrt{\langle g(U^0, D_1U^0), 1 \rangle_h + C_1}} Q^1_1 + \frac{\left( h_1(U^0, D_1U^0) - D_1h_2(U^0, D_1U^0) \right)}{2\sqrt{\langle h(U^0, D_1U^0), 1 \rangle_h + C_2}} Q^1_2 + \delta_t U^0 \right),
\]

\[
\delta_t Q^0_1 = \left( \frac{\left( g_1(U^0, D_1U^0) - D_1g_2(U^0, D_1U^0) \right)}{2\sqrt{\langle g(U^0, D_1U^0), 1 \rangle_h + C_1}}, \delta_t U^0 \right),
\]

\[
\delta_t Q^0_2 = \left( \frac{\left( h_1(U^0, D_1U^0) - D_1h_2(U^0, D_1U^0) \right)}{2\sqrt{\langle h(U^0, D_1U^0), 1 \rangle_h + C_2}}, \delta_t U^0 \right).
\]

The initial and boundary conditions in (2.3) are discretized as

\[
U^n_j = u_0(x_j), \quad Q^n_1 = \sqrt{\langle g(U^0, D_1U^0), 1 \rangle_h + C_1}, \quad Q^n_2 = \sqrt{\langle h(U^0, D_1U^0), 1 \rangle_h + C_2},
\]

\[
U_{j+N}^n = U_j^n, \quad j = 0, 1, 2, \ldots, N.
\]

Then, we show that the proposed scheme (4.1), (4.2) can exactly preserve the discrete energy and mass, respectively.

**Theorem 4.1** The proposed scheme (4.1), (4.2) satisfies the following discrete modified energy

\[
E_h^{n+1} = E_h^n, \quad E_h^n = \frac{1}{8} \langle U^n - D_2U^n, U^n \rangle_h - \frac{1}{2} (Q^n_1)^2 + \frac{1}{2} (Q^n_2)^2 + \frac{1}{2} C_1 - \frac{1}{2} C_2.
\]

for \( n = 0, 1, \ldots, M - 1 \).

**Proof** It is readily to obtain from (4.1) that

\[
\delta_t E_h^n = \frac{1}{4} \langle U^{n+\frac{1}{2}} - D_2U^{n+\frac{1}{2}}, \delta_t U^n \rangle_h - Q^{n+\frac{1}{2}}_1 \delta_t Q^n_1 + Q^{n+\frac{1}{2}}_2 \delta_t Q^n_2
\]

\[
= \left\{ -\frac{\left( g_1(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}) - D_1g_2(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}) \right)}{2\sqrt{\langle g(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}), 1 \rangle_h + C_1}} Q^{n+\frac{1}{2}}_1 + \frac{\left( h_1(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}) - D_1h_2(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}) \right)}{2\sqrt{\langle h(\hat{U}^{n+\frac{1}{2}}, D_1\hat{U}^{n+\frac{1}{2}}), 1 \rangle_h + C_2}} Q^{n+\frac{1}{2}}_2 + \delta_t U^n \right\}_h = 0,
\]

which further implies

\[
E_h^{n+1} = E_h^n, \quad n = 1, 2, \ldots, M - 1,
\]

where the last equality of (4.4) follows from the first equality of (4.1) and the skew-symmetry of \( D \). An argument similar to (4.2) used in (4.4) shows that

\[
E^1_h = E^0_h.
\]

This completes the proof. \( \square \)
Theorem 4.2  The scheme $(4.1), (4.2)$ possesses the discrete mass

\[ M^{n+1} = M^n, \quad M^n = \langle U^n, 1 \rangle_h, \quad n = 0, 1, 2, \ldots, M - 1. \]

**Proof**  According to Remark 3.1, for \( j = 0, 1, 2, \ldots, N - 1 \), we have

\[ (F_N 1)_j = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} e^{-ij \frac{2\pi}{N}} = \begin{cases} \sqrt{N}, & j = 0, \\ 0, & 1 \leq j \leq N - 1, \end{cases} \]

and the elements of matrix \((I - \Lambda_2)^{-1} \Lambda_1\) in the first row are all zero.

Taking the discrete inner product of $(4.1)$ with $1$, we then obtain

\[
\langle \delta_t U^n, 1 \rangle_h = \left\{ \begin{array}{l}
D \left(-\frac{g_1(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) - D_1 g_2(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}})}{2\sqrt{\langle g(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \rangle_h + C_1}} Q_1^{n+\frac{1}{2}} + \\
+ \frac{h_1(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) - D_1 h_2(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}})}{2\sqrt{\langle h(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \rangle_h + C_2}} Q_2^{n+\frac{1}{2}} + \\
+ \frac{1}{4}(U^{n+\frac{1}{2}} - D_2 U^{n+\frac{1}{2}})_h, 1 \rangle_h + \frac{1}{4}(U^{n+\frac{1}{2}} - D_2 U^{n+\frac{1}{2}})_h, F_N 1 \rangle_h = 0,
\end{array} \right.
\]

which further shows

\[ M^{n+1} = M^n, \quad n = 1, 2, \ldots, M - 1. \]

By an argument similar to $(4.1)$ used as above, we obtain

\[ M^1 = M^0. \]

This completes proof. \(\square\)

Besides its energy-preserving property, a most remarkable thing about the above scheme is that it can be solved efficiently. Let

\[
G_1 = \frac{1}{2\sqrt{\langle g(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \rangle_h + C_1}} \left( g_1(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) - D_1 g_2(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \right),
\]

\[
G_2 = \frac{1}{2\sqrt{\langle h(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \rangle_h + C_2}} \left( h_1(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) - D_1 h_2(\hat{U}^{n+\frac{1}{2}}, D_1 \hat{U}^{n+\frac{1}{2}}) \right).
\]
Equation (4.1) can then be rewritten as

\[
\begin{align*}
U^{n+\frac{1}{2}} &= U^n + \frac{\tau}{2} D \left( - G_1 Q_1^{n+\frac{1}{2}} + G_2 Q_2^{n+\frac{1}{2}} + \frac{1}{4} \left( U^{n+\frac{1}{2}} - D_2 U^{n+\frac{1}{2}} \right) \right), \\
Q_1^{n+\frac{1}{2}} &= Q_1^n + \left( G_1, U^{n+\frac{1}{2}} - U^n \right)_h, \\
Q_2^{n+\frac{1}{2}} &= Q_2^n + \left( G_2, U^{n+\frac{1}{2}} - U^n \right)_h.
\end{align*}
\]  

(4.5)

Next, by eliminating \( Q_1^{n+\frac{1}{2}} \) and \( Q_2^{n+\frac{1}{2}} \) from (4.5), we have

\[
\begin{bmatrix}
I - \frac{\tau}{8} D_1
\end{bmatrix} U^{n+\frac{1}{2}} = -\frac{\tau}{2} DG_1 \langle G_1, U^{n+\frac{1}{2}} \rangle_h + \frac{\tau}{2} DG_2 \langle G_2, U^{n+\frac{1}{2}} \rangle_h + r^n,
\]

(4.6)

where

\[
r^n = U^n - \frac{\tau}{2} DG_1 Q_1^n + \frac{\tau}{2} DG_2 Q_2^n + \frac{\tau}{2} DG_1 \langle G_1, U^n \rangle_h - \frac{\tau}{2} DG_2 \langle G_2, U^n \rangle_h.
\]

Denote \( A^{-1} = \left( I - \frac{\tau}{8} D_1 \right)^{-1} \) and

\[
\gamma_1^n = -\frac{\tau}{2} A^{-1} DG_1, \quad \gamma_2^n = \frac{\tau}{2} A^{-1} DG_2, \quad b^n = A^{-1} r^n,
\]

the above equation is equivalent to

\[
U^{n+\frac{1}{2}} = \gamma_1^n \langle G_1, U^{n+\frac{1}{2}} \rangle_h + \gamma_2^n \langle G_2, U^{n+\frac{1}{2}} \rangle_h + b^n.
\]  

(4.7)

We take the inner product of (4.7) with \( G_1 \) and have

\[
\langle G_1, U^{n+\frac{1}{2}} \rangle_h = \langle G_1, \gamma_1^n \rangle_h \langle G_1, U^{n+\frac{1}{2}} \rangle_h + \langle G_1, \gamma_2^n \rangle_h \langle G_2, U^{n+\frac{1}{2}} \rangle_h + \langle G_1, b^n \rangle_h.
\]  

(4.8)

Taking the inner product of (4.7) with \( G_2 \), we then obtain

\[
\langle G_2, U^{n+\frac{1}{2}} \rangle_h = \langle G_2, \gamma_1^n \rangle_h \langle G_1, U^{n+\frac{1}{2}} \rangle_h + \langle G_2, \gamma_2^n \rangle_h \langle G_2, U^{n+\frac{1}{2}} \rangle_h + \langle G_2, b^n \rangle_h.
\]  

(4.9)

Equations (4.8) and (4.9) form a \( 2 \times 2 \) linear system for the unknowns \( \langle G_1, U^{n+\frac{1}{2}} \rangle_h, \langle G_2, U^{n+\frac{1}{2}} \rangle_h \).

Solving \( \langle G_1, U^{n+\frac{1}{2}} \rangle_h, \langle G_2, U^{n+\frac{1}{2}} \rangle_h \) from the \( 2 \times 2 \) linear system (4.8) and (4.9) and \( U^{n+\frac{1}{2}} \) is then updated from (4.7). Subsequently, \( Q_1^{n+\frac{1}{2}} \) and \( Q_2^{n+\frac{1}{2}} \) are obtained from the second and third equality of (4.5), respectively. Finally, we have

\[
U^{n+1} = 2U^{n+\frac{1}{2}} - U^n,
\]

\[
Q_1^{n+1} = 2Q_1^{n+\frac{1}{2}} - Q_1^n \quad \text{and} \quad Q_2^{n+1} = 2Q_2^{n+\frac{1}{2}} - Q_2^n.
\]

**Remark 4.1** We should remark that, compared with the scheme obtained by the classical SAV approach, the proposed scheme need to solve an additional \( 2 \times 2 \) linear system, however, the main computational cost still comes from (4.6). Thus, our scheme enjoys the same computational advantages as the ones obtained by the classical SAV approach. In addition, in our computation, \( U^{n+\frac{1}{2}} \) can be efficiently obtained from (4.7) by the FFT, when ones note Remark 3.1.

**Remark 4.2** We should note that the energy (2.2) is equivalent to the energy (1.4) in continuous sense, but not for the discrete sense. This indicates that the scheme (4.1) cannot preserve the

following discrete energy

\[ H_n = -\frac{h}{2} \sum_{j=0}^{N-1} \left( (U^n_j)^3 + U^n_j \cdot (D^1 U^n)_j \right), \quad 0 \leq n \leq M. \] (4.10)

5 Numerical Examples

In this section, we report the numerical performance, accuracy, CPU time and invariants-preserving properties of the proposed scheme (4.1) (denoted by MSAV-LCNS). In addition, the following structure-preserving schemes are chosen for comparisons:

- IEQ-LCNS the linearly implicit energy-preserving scheme given in Ref. [15];
- EPFPS the energy-preserving Fourier pseudo-spectral scheme;
- MSFPS the multi-symplectic Fourier pseudo-spectral scheme;
- LICNS the linear-implicit Crank–Nicolson scheme described in Ref. [14];
- LILFS the leap-frog scheme stated in Ref. [14].

It is noted that EPFPS and MSFPS are obtained by using the Fourier pseudo-spectral method instead of the wavelet collocation method in Refs. [11,26], respectively. As a summary, a detailed table on the properties of each scheme has been given in Table 1.

In our computation, the FFT is also adopt as the solver of linear systems given by MSAV-LCNS [see (4.6)], the standard fixed-point iteration is used for the fully implicit schemes, and the Jacobi iteration method is employed for the linear systems given by IEQ-LCNS, LICNS and LILFS. Here, the iteration will terminate if the infinity norm of the error between two adjacent iterative steps is less than \(10^{-14}\). All diagrams presented below refer to the numerical integration of the CH equation (1.1) with parameters \(C_1 = 0\) and \(C_2 = 0\), and are carried out via Matlab 7.0 with AMD A8-7100 and RAM 4GB. In order to quantify the numerical solution, we use the \(l^2\)- and \(l^\infty\)-norms of the error between the numerical solution \(U^n_j\) and the exact solution \(u(x_j, t_n)\), respectively, as

\[ e_{h,2}(t_n) = h \sum_{j=0}^{N-1} (U^n_j - u(x_j, t_n))^2, \quad e_{h,\infty}(t_n) = \max_{0 \leq j \leq N-1} |U^n_j - u(x_j, t_n)|, \quad n \geq 0. \]
5.1 Smooth Periodic Solution

The CH equation (1.1) admits smooth periodic traveling wave solutions

\[ u(x, t) = \phi(x - ct), \quad c \in \mathbb{R}, \]

when three parameters \( m, M, z \) fulfill the relation \( z < m < M < c \), where \( m = \min_{x \in \mathbb{R}} \phi, \ M = \max_{x \in \mathbb{R}} \phi \) and \( z = c - M - m \) (see Ref. [17]). However, the solutions can only be given implicitly by

\[
|x - x_0| = \int_{\phi_0}^{\phi} \frac{\sqrt{c - y}}{\sqrt{(M - y)(y - m)(y - z)}} dy,
\]

(5.1)

where \( \phi(x_0) = \phi_0 \). In order to remove the singularities of the integral at \( y = m \) and \( y = M \), we transform (5.1) into

\[
|x - x_0| = 2 \int_{\theta_0}^{\theta} \frac{\sqrt{A - \sin^2 t}}{\sqrt{B + \sin^2 t}} dt
\]

(5.2)

by the change of variables

\[ \phi = m + (M - m) \sin^2 \theta, \]

where \( A = \frac{c - m}{M - m} \) and \( B = \frac{m - z}{M - m} \). The exact solution is obtained by periodic extension of the initial data, which is constructed as follows:

Step 1 Setting \( x_0 = 0 \) and \( \theta_0 = 0 \) and computing a grid on the interval \([0, \pi]\) with \( \mathbb{N} \) equispaced nodes \( \theta_j \) given by

\[ \theta_j = \frac{\pi}{\mathbb{N}} j, \quad j = 0, 1, 2, \ldots, \mathbb{N} - 1. \]

Step 2 Computing \( \phi_j = m + (M - m) \sin^2 \theta_j, \quad j = 0, 1, 2, \ldots, \mathbb{N} - 1 \) and \( x_j \) is obtained by using the Gaussian-Legendre quadrature formula for the integral

\[ 2 \int_{\theta_0}^{\theta_j} \frac{\sqrt{A - \sin^2 t}}{\sqrt{B + \sin^2 t}} dt, \quad j = 0, 1, 2, \ldots, \mathbb{N} - 1. \]

Step 3 Performing a spline interpolation for points \((x_j, \phi_j), \quad j = 0, 1, 2, \ldots, \mathbb{N} - 1\) to obtain \( \phi \) as a function of \( x \).

We take the bounded computational domain as the interval \([0, L]\) with a periodic boundary condition and choose parameters \( m = 0.3, \ M = 0.7 \) and \( c = 1 \), which gives rise to a smooth traveling wave with period \( L \approx 6.56 \) (see Ref. [16]).

To test the temporal discretization errors of the different numerical schemes, we fix the Fourier node 32 such that the spatial discretization errors are negligible. Table 2 shows the temporal errors and convergence rates for different numerical schemes under different time steps at \( t = 6.56 \). Figure 1 shows the CPU times of the six schemes for the smooth solution under different grid points till \( t = 6.56 \) with \( \tau=6.56e–04 \). From Table 2 and Fig. 1, we can draw the following observations: (i) all schemes have second order accuracy in time errors; (ii) the error provided by MSAV-LCNS has the same order of magnitude as the ones provided by IEQ-LCNS and LICNS. (iii) the costs of EPFPS is most expensive while the one of MSAV-LCNS is cheapest.

To further investigate the invariants-preservation of the proposed scheme, Figure 2 shows the errors of the invariants under \( N=32 \) and \( \tau=0.0082 \) over the time interval \( t \in [0, 656] \). From Fig. 2a–c, we make the following observations: (i) EPFPS can exactly preserve the energy...

[see (4.10)] and the energy errors of others are remained around a small order of magnitude. (ii) LICNS and LILFS can exactly preserve the momentum and MSAV-LCNS, IEQ-LCNS, EPFPS and MSFPS can preserve the momentum approximately. (iii) MSAV-LCNS, IEQ-LCNS, EPFPS and MSFPS can preserve the mass to round-of errors while LICNS and LILFS admit large errors. From Fig. 2d, it is clearly demonstrated that the proposed scheme can exactly preserve the discrete modified energy. Similar observations on the errors of the invariants are made in the next three examples and we will omit these details for brevity. Here, we should note that the modified energy (4.3) and the energy (4.10) are an approximate version of the continue energy (1.4), and the errors show the stability and capability for long-term computation of the numerical scheme.
5.2 Two-Peakon Interaction

We consider the two-peakon interaction of the CH equation (1.1) with the initial condition [23]

\[ u_0(x) = \phi_1(x) + \phi_2(x), \quad 0 \leq x \leq 25, \]

where

\[ \phi_i(x) = \begin{cases} \frac{c_i}{\cosh(L/2)} \cosh(x - x_i), & |x - x_i| \leq L/2, \\ \frac{c_i}{\cosh(L/2)} \cosh(L - (x - x_i)), & |x - x_i| > L/2, \end{cases} \]

\[ i = 1, 2. \]

The parameters are \( c_1 = 3, \ c_2 = 1, \ x_1 = -8, \ x_2 = 0, \ L = 25 \) and a periodic boundary condition is considered. Figure 3 shows the contour plot of the two-peakon interaction. We can see clearly that the taller wave overtakes the shorter one and afterwards both waves retain their original shapes and velocities. The errors of invariants under \( N = 1024 \) and \( \tau = 0.0001 \) over the time interval \( t \in [0, 10] \) are plotted in Fig. 4, which behaves similarly as that of Fig. 2.

5.3 Three-Peakon Interaction

Subsequently, we consider the three-peakon interaction of the CH equation (1.1) with the initial condition [23]

\[ u_0(x) = \phi_1(x) + \phi_2(x) + \phi_3(x), \quad 0 \leq x \leq 30, \]

where

\[ \phi_i(x) = \begin{cases} \frac{c_i}{\cosh(L/2)} \cosh(x - x_i), & |x - x_i| \leq L/2, \\ \frac{c_i}{\cosh(L/2)} \cosh(30 - (x - x_i)), & |x - x_i| > L/2, \end{cases} \]

\[ i = 1, 2, 3. \]

The parameters are \( c_1 = 2, \ c_2 = 1, \ c_3 = 0.8, \ x_1 = -5, \ x_2 = -3, \ x_3 = -1, \ L = 30 \) and a periodic boundary condition is chosen. Figure 5 shows the contour plot of three-peakons interaction, which shows that the moving peak interaction is resolved very well. The errors in invariants over the time interval \( t \in [0, 10] \) are displayed in Fig. 6, which demonstrates that our scheme has a good conservation of the invariants.
5.4 A Solution with a Discontinuous Derivative

Finally, we consider the following initial condition, which has a discontinuous derivative [23]

\[ u_0(x) = \frac{10}{(3 + |x|)^2}, \quad -30 \leq x \leq 30. \]
Fig. 6 The errors in invariants under $N = 2048$ and $\tau = 0.0001$ over the time interval $t \in [0, 10]$.

Fig. 7 The solution with discontinuous derivative of the CH equation (1.1) under $N = 1024$ and $\tau = 0.001$.

with a periodic boundary condition.

Figure 7 shows the contour plot of the solutions with discontinuous derivative. Figure 8 shows the errors in invariants over the time interval $t \in [0, 20]$. From Figs. 7 and 8, it is clearly demonstrated that the proposed scheme has a good resolution of the solution comparable with that in Refs. [13,23], and can preserve the modified energy exactly.
6 Concluding Remarks

In this paper, we present a novel linearization (energy quadratization) strategy to develop second order, fully discrete, linearly implicit scheme for the CH equation (1.1). The proposed scheme is proven to preserve the discrete modified energy and enjoys the same computational advantages as the schemes obtained by the classical SAV approach. Several numerical examples are presented to illustrate the efficiency of our numerical scheme. Comparing with some existing structure-preserving schemes of same order in both time and space, our scheme shows remarkable efficiency. The presented strategy can be directly extended to propose linearly implicit energy-preserving schemes for a broad class of energy-conserving systems, such as the KdV equation, etc. However, to the best of our knowledge, the construction of arbitrarily high-order linearly implicit energy-preserving schemes is still not available for the CH equation (1.1), which is an interesting topic for future studies.
