Generalized equivariant homology on simplicial complexes

jason hanson

Abstract

A careful account is given of generalized equivariant homology theories on the category of topological pairs acted on by a group. In particular, upon restriction to the category of equivariant simplicial complexes, the equivalence of equivariant simplicial homology (also known as Bredon homology), the second derived term of the Atiyah–Hirzebruch spectral sequence, and equivariant singular homology is demonstrated.

1 Introduction and notation

Throughout, we let $G$ denote a topological group. On the category of pairs of $G$–complexes (cw–complexes with action by $G$), an extensive discussion of generalized equivariant cohomology theories is given in [Br1]; and that for generalized equivariant homology theories, although not as extensive in scope, is given in [Wil]. Our goal here is twofold. First, we wish to give a discussion of equivariant homology theories for a larger category of $G$–spaces, and to bridge some of the gaps present in both of the above references. Second, we wish to see how the theory plays out when restricted to the category of equivariant simplicial complexes; that is, we wish to provide a generalized equivariant version of the axiomatic approach given in [ES].

For the first half of this paper, we will work in the category of arbitrary $G$–pairs and equivariant maps. Specifically, the objects of the category consist of pairs $(X, A)$, where the topological spaces $A \subseteq X$ have continuous (left) $G$–action; i.e., $A$ is a $G$–subspace of $X$. The morphisms of the category are continuous equivariant maps: continuous maps $f : (X, A) \rightarrow (Y, B)$ between $G$–pairs such that $f(gx) = gf(x)$, for all $g \in G$ and $x \in X$. 

1
In the second half, we will restrict our attention to simplicial complexes with $G$–action. For us, these will be topological spaces that can be decomposed as a union of equivariant cells of the form $G/H \times \Delta_p$, where $\Delta_p$ is the standard $p$–simplex given the trivial $G$–action, and $H \leq G$ (that is, $H$ is a subgroup of $G$).

In an effort to reduce some of the notational clutter, we will introduce the following conventions. First, we will use the same label for a map and its restriction when our intentions are unambiguous. E.g., if $f : X \to Y$ is a map and $A \subseteq X$, $B \subseteq Y$ are such that $f(A) \subseteq B$, then we will write $f : A \to B$ for the corresponding restriction of domain and range. Second, any unlabeled map should be assumed to be the inclusion map; e.g., $A \to X$. Third and finally, the previous two conventions take precedence over any functor; for example, if $F$ is a covariant functor, then $F(f) : F(A) \to F(B)$ and $F(A) \to F(X)$ denote the functor $F$ applied to the restriction $f : A \to B$ and the inclusion $A \to X$, respectively.

2 Generalized equivariant homology

2.1 Axioms

Let $R$ be a ring, and suppose that $\mathcal{H}^G_\ast$ is a covariant functor from the category of $G$–pairs and equivariant maps to the category of graded $R$–modules and linear maps. In particular if $(X, A)$ is a $G$–pair, then $\mathcal{H}^G_\ast(X, A) = \oplus_{n \in \mathbb{Z}} \mathcal{H}^G_n(X, A)$ is a graded $R$–module. For a $G$–space $X$, we set $\mathcal{H}^G_\ast(X) = \mathcal{H}^G_\ast(X, \emptyset)$. Suppose that in addition, $\partial_\ast$ is a natural transformation of functors such that for $G$–pairs $(X, A)$, $\partial_n : \mathcal{H}^G_n(X, A) \to \mathcal{H}^G_{n-1}(A)$ is $R$–linear for all $n \in \mathbb{Z}$. The pair $(\mathcal{H}^G_\ast, \partial_\ast)$ is said to be a generalized equivariant homology theory if the following three axioms are satisfied.

**Axiom 1** (Exactness). If $(X, A)$ is a $G$–pair, then there is a long exact sequence of $R$–modules

$$\mathcal{H}^G_n(A) \to \mathcal{H}^G_n(X) \to \mathcal{H}^G_n(X, A) \xrightarrow{\partial_n} \mathcal{H}^G_{n-1}(A).$$

**Axiom 2** (Homotopy). Suppose that the maps $f, g : (X, A) \to (Y, B)$ are $G$–homotopic: there exists an equivariant map $F : (X, A) \times [0, 1] \to (Y, B)$, where the interval $[0, 1]$ is given the trivial $G$–action. Then $\mathcal{H}^G_\ast(f) = \mathcal{H}^G_\ast(g)$.  

2
**Axiom 3** (Excision). If \((X, A)\) is a \(G\)-pair and \(U\) is a \(G\)-subspace such that \(\bar{U} \subseteq \text{int}(A)\), then \(\mathcal{H}^G_n(X \setminus U, A \setminus U) \to \mathcal{H}^G_n(X, A)\) is an isomorphism.

Note that as a consequence of the exactness axiom, \(\mathcal{H}^G_n(A, A) = 0\); and in particular, \(\mathcal{H}^G_n(\emptyset, \emptyset) = 0\).

One may also impose conditions involving the behavior under group homomorphisms, see \cite{Lueck}; however, we will not have the need for these.

### 2.2 Fundamental properties

Many of the familiar properties of nonequivariant singular homology carry over to generalized equivariant homology. We explicitly state a few for reference.

**Proposition 2.1** (Exact sequence of triple). If \((X, B, A)\) is a triple of \(G\)-spaces, then there is a long exact sequence of \(R\)-modules:

\[
\mathcal{H}^G_n(B, A) \to \mathcal{H}^G_n(X, A) \to \mathcal{H}^G_n(X, B) \to \mathcal{H}^G_{n-1}(B, A),
\]

where \(\partial_n\) is the composition \(\mathcal{H}^G_n(X, B) \to \mathcal{H}^G_{n-1}(B) \to \mathcal{H}^G_{n-1}(B, A)\).

**Proposition 2.2** (Naturality of sequences). Given an equivariant map of \(G\)-triples \(f : (X, B, A) \to (Y, D, C)\), there is a homomorphism of long exact sequences (that is, each square commutes):

\[
\begin{array}{cccc}
\mathcal{H}^G_n(B, A) & \to & \mathcal{H}^G_n(X, A) & \to & \mathcal{H}^G_n(X, B) \\
\mathcal{H}^G_n(D, C) & \to & \mathcal{H}^G_n(Y, C) & \to & \mathcal{H}^G_n(Y, D) \\
\mathcal{H}^G_{n-1}(B, A) & \to & \mathcal{H}^G_{n-1}(D, C). \\
\end{array}
\]

**Proposition 2.3** (Strong excision). Suppose that \((X, A)\) is a \(G\)-pair and \(U\) an open \(G\)-subspace of \(A\). If there exists an open \(G\)-subspace \(V\) with \(V \subseteq U\) and such that \((X \setminus U, A \setminus U)\) is a deformation retract of \((X \setminus V, A \setminus V)\), then \(\mathcal{H}^G_n(X \setminus U, A \setminus U) \to \mathcal{H}^G_n(X, A)\) is an isomorphism.

**Proposition 2.4** (Finite disjoint unions). Suppose \((X_k, A_k)\) is a \(G\)-pair for each \(1 \leq k \leq n\), and set \(X = \bigoplus_{k=1}^n X_k\), \(A = \bigoplus_{k=1}^n A_k\). We have an isomorphism \(\Sigma_* : \bigoplus_{k=1}^n \mathcal{H}^G_* (X_k, A_k) \to \mathcal{H}^G_* (X, A)\), defined by requiring \(\Sigma_*\) to be equal to \(\mathcal{H}^G_* (X_k, A_k) \to \mathcal{H}^G_* (X, A)\) when restricted to summands \(\mathcal{H}^G_* (X_k, A_k)\).

Proofs of the above are exactly the same as for a non–generalized non–equivariant homology theory: see the proofs of theorems 10.2, 10.3, 15.3, 15.4, 12.1, and 13.2 (respectively) of chapter I in \cite{ES}.
2.3 Compact supports and disjoint unions

The analogous statement in proposition 2.4 for infinite disjoint unions requires additional assumptions. One possible route is to follow [ES] and impose a compact support axiom.

**Definition 2.5.** The generalized equivariant homology theory $({\mathcal{H}}^G_*, \partial_*)$ has compact supports if for any $G$–pair $(X, A)$ and any $x \in {\mathcal{H}}^G_*(X, A)$, there exists a compact $G$–pair $(X_c, A_c) \subseteq (X, A)$ and $x_c \in {\mathcal{H}}^G_*(X_c, A_c)$ such that $x$ is the image of $x_c$ under $H^G_* (X_c, A_c) \to H^G_*(X, A)$.

However, the compact support assumption may be too much to ask for in some situations; for instance, when $G$ is not compact. In this case, we gain a fair amount by simply imposing the arbitrary disjoint union property.

**Definition 2.6.** The generalized equivariant homology theory $({\mathcal{H}}^G_*, \partial_*)$ satisfies the arbitrary disjoint union property if for any indexing set $A$ and any collection of $G$–pairs $\{(X_\alpha, A_\alpha)\}_{\alpha \in A}$, the map $\Sigma_* : \oplus_{\alpha \in A} {\mathcal{H}}^G_*(X_\alpha, A_\alpha) \to {\mathcal{H}}^G_*(X, A)$ is an isomorphism. Here $X \equiv \sum_{\alpha \in A} X_\alpha$ and $A \equiv \sum_{\alpha \in A} A_\alpha$, and $\Sigma_*$ is uniquely defined by the requirement that it coincides with $H^G_*(X_\alpha, A_\alpha) \to {\mathcal{H}}^G_*(X, A)$ on summands $H^G_*(X_\alpha, A_\alpha)$.

**Proposition 2.7** (Direct limits). Let $(X, A)$ be a $G$–pair, and let $C$ denote the directed set of all compact $G$–pairs contained in $(X, A)$. If $({\mathcal{H}}^G_*, \partial_*)$ has compact supports, then the inclusion maps $(Y, B) \to (X, A)$ induce an isomorphism $\lim_{(Y, B) \in C} {\mathcal{H}}^G_*(Y, B) \cong {\mathcal{H}}^G_*(X, A)$.

The converse of this statement is also true; the proofs of both statements are the same as that of theorem 13 of chapter 4, section 8, in [Spa].

**Theorem 2.8** (Arbitrary disjoint unions). If a generalized equivariant homology theory has compact supports, then it satisfies the arbitrary disjoint union property.

**Proof.** For any compact pair $(Y, B) \subseteq (X, A)$, $Y = \sum_{\alpha \in A} (Y \cap X_\alpha)$ and $A = \sum_{\alpha \in A} (B \cap A_\alpha)$ are necessarily finite sums. Thus in the commutative diagram:

$$
\begin{align*}
\oplus_{\alpha \in A} {\mathcal{H}}^G_*(Y \cap X_\alpha, B \cap A_\alpha) & \longrightarrow {\mathcal{H}}^G_*(Y, B) \\
\downarrow & \\
\oplus_{\alpha \in A} {\mathcal{H}}^G_*(X_\alpha, A_\alpha) & \longrightarrow {\mathcal{H}}^G_*(X, A),
\end{align*}
$$
the top horizontal arrow is an isomorphism by proposition 2.4. The theorem now follows from proposition 2.7 by taking direct limits over compact pairs (see theorem 4.13 of chapter VII in [ES]).

3 Reduced homology

Analogous with the non–equivariant case, a pointed $G$–space is a pair $(X, x_0)$ where $X$ is a $G$–space and $x_0 \in X$ is a distinguished point (the base point). A morphism $f : (X, x_0) \to (Y, y_0)$ of pointed $G$–spaces is an equivariant map that preserves base points: $f(x_0) = y_0$. We do not assume that the base point is fixed by the $G$–action; that is, a morphism $f$ of $G$–pairs induces an equivariant map of orbits $f : Gx_0 \to Gy_0$, and hence an equivariant map of $G$–pairs $f : (X, Gx_0) \to (Y, Gy_0)$.

**Definition 3.1.** The reduced homology of a pointed $G$–space $(X, x_0)$ is defined to be $\tilde{H}^G_n(X, x_0) = \tilde{H}^G_n(X, Gx_0)$. If $f : (X, x_0) \to (Y, y_0)$ is a morphism of pointed $G$–spaces, then $\tilde{H}^G_n(f) : \tilde{H}^G_n(X, x_0) \to \tilde{H}^G_n(Y, y_0)$ is defined to be the homomorphism $\tilde{H}^G_n(f) : \tilde{H}^G_n(X, Gx_0) \to \tilde{H}^G_n(Y, Gy_0)$.

The following properties of reduced homology are immediate from the corresponding properties in non–reduced homology.

**Theorem 3.2.** If $f : (X, x_0) \to (Y, y_0)$ and $g : (Y, y_0) \to (Z, z_0)$ are morphisms of pointed $G$–spaces, then $\tilde{H}^G_n(g \circ f) = \tilde{H}^G_n(g) \circ \tilde{H}^G_n(f)$. □

**Theorem 3.3.** If $(X, A)$ is a $G$–pair with $A \neq \emptyset$, then for any $a_0 \in A$, there is a long exact sequence

$$\tilde{H}^G_n(A, a_0) \to \tilde{H}^G_n(X, a_0) \to \tilde{H}^G_n(X, A) \xrightarrow{\partial_n} \tilde{H}^G_{n-1}(A, a_0)$$

(all maps induced by the corresponding maps in nonreduced homology). □

**Theorem 3.4.** If $f : (X, A) \to (Y, B)$ is an equivariant map of $G$–pairs and $a_0 \in A, b_0 \in B$ such that $f(a_0) = b_0$, then $f$ induces a homomorphism of long exact sequences

$$
\begin{array}{cccc}
\tilde{H}^G_n(A, a_0) & \to & \tilde{H}^G_n(X, a_0) & \to & \tilde{H}^G_n(X, A) & \xrightarrow{\partial_n} & \tilde{H}^G_{n-1}(A, a_0) \\
\downarrow \tilde{H}^G_n(f) & & \downarrow \tilde{H}^G_n(f) & & \downarrow \tilde{H}^G_n(f) & & \downarrow \tilde{H}^G_{n-1}(f) \\
\tilde{H}^G_n(B, b_0) & \to & \tilde{H}^G_n(Y, b_0) & \to & \tilde{H}^G_n(Y, B) & \xrightarrow{\partial_n} & \tilde{H}^G_{n-1}(B, b_0).
\end{array}
$$

□
A $G$–homotopy of pointed $G$–spaces $(X, x_0)$ and $(Y, y_0)$ is an equivariant map $F : (X, Gx_0) \times [0, 1] \to (Y, Gy_0)$ of $G$–pairs (where $[0, 1]$ is given the trivial $G$–action) such that $F(x_0, t) = y_0$ for all $t \in [0, 1]$.

**Theorem 3.5.** If $f, g : (X, x_0) \to (Y, y_0)$ are $G$–homotopic maps of pointed $G$–spaces, then $\overline{\delta}^G_\ast(f) = \overline{\delta}^G_\ast(g)$. \hfill \Box

In nonequivariant homology, one has the luxury of equating reduced homology with the kernel of the homology functor applied to the augmentation map. In the equivariant case, the augmentation map is required to be equivariant, which places a severe restriction on the spaces involved. That is, if $X$ is a $G$–space and $x_0 \in X$, then equivariance of the constant map $\epsilon : X \to \{x_0\}$ requires that $x_0$ be fixed by the $G$–action. However, if we are willing to restrict our consideration to such spaces, we will still have the equality $\overline{\delta}^G_\ast(X, x_0) = \ker \overline{\delta}^G_\ast(\epsilon)$, as we now demonstrate in a somewhat more general context.

Suppose that $Y$ is a $H$–space, where $H \leq G$. Recall (as in [Br2], for instance) that the balanced product $G \times_H Y$ is the quotient of the Cartesian product $G \times Y$ by the $H$–action $h \cdot (g, y) \doteq (gh, h^{-1}y)$; the equivalence class of the point $(g, y)$ is denoted $[g, y]$; and there is a well–defined $G$–action given by $g' \cdot [g, y] = [g'g, y]$. Moreover, given an equivariant map of $H$–spaces $f : X \to Y$, we have an induced equivariant map of $G$–spaces $G \times_H f : G \times_H X \to G \times_H Y$ given by $(G \times_H f)[g, x] \doteq [g, f(x)]$.

Under suitable hypotheses on $X$ and $G$, it can be show that the existence of an equivariant map $\chi : X \to Gx_0$ implies that $X$ can be identified with a balanced product $G \times_H Y$ for some $H \leq G$ and $H$–space $Y$, and the point $x_0$ corresponds under this identification to a point $[e, y_0]$ with $y_0 \in Y$ having trivial $H$–action. For instance, in the case when $X$ is Hausdorff and $G$ is compact, see propositions 4.1 of chapter I and 3.2 of chapter II in [Br2].

**Theorem 3.6.** Suppose $H \leq G$, and $(Y, y_0)$ is a pointed $H$–space with $y_0$ having trivial $H$–action. If $\epsilon_{(Y, y_0)} : Y \to \{y_0\}$ is the constant map, then

$$
\ker \overline{\delta}^G_\ast(G \times_H \epsilon_{(Y, y_0)}) \to \overline{\delta}^G_\ast(G \times_H Y, [e, y_0])
$$

is an isomorphism. Moreover, if $f : (Y, y_0) \to (Z, z_0)$ is a morphism of pointed $H$–spaces, then the following diagram commutes:

$$
\begin{array}{ccc}
\ker \overline{\delta}^G_\ast(G \times_H \epsilon_{(Y, y_0)}) & \longrightarrow & \overline{\delta}^G_\ast(G \times_H Y, [e, y_0]) \\
\downarrow & & \downarrow \\
\ker \overline{\delta}^G_\ast(G \times_H f) & \downarrow & \overline{\delta}^G_\ast(G \times_H f) \\
\ker \overline{\delta}^G_\ast(G \times_H \epsilon_{(Z, z_0)}) & \longrightarrow & \overline{\delta}^G_\ast(G \times_H Z, [e, z_0]).
\end{array}
$$
In addition, define $q$ each integer $H$

However, since $f \in H$ is trivial, since each map is an isomorphism; the kernel of the vertical arrow second from the left is $\ker H$, and that of the third arrow from the left is $\ker H_{Gx} = \ker H_{X, x_0}$, since $\ker H_{Gx_0, Gx_0} = 0$.

For the second statement of the theorem, we only need to show that $\ker H_{G \times_H f} \mapsto \ker H_{G}$. Consequently, $H_{G(\pi')} \circ H_{G(X, f)} = H_{G \times_H f} \circ H_{G(\pi)}$. The theorem follows. 

4 Associated homology of a filtration

Let us assume that there exists a $G$–filtration $\{X_k\}_{k \in \mathbb{Z}}$ of the $G$–pair $(X, A)$; that is, $X = \bigcup_{k \in \mathbb{Z}} X_k$, where for each $k \in \mathbb{Z}$, $X_k$ is a $G$–subspace of $X$ with $X_k \subseteq X_{k+1}$, and $X_k = A$ if $k < 0$.

Lemma 4.1. If $\{X_k\}_{k \in \mathbb{Z}}$ is a $G$–filtration of $(X, A)$, then the following composition is trivial:

$$
\delta_{-1} : \mathcal{F}_{n-1}^G(X_{p-1}, X_{p-2}) \to \mathcal{F}_{n-2}^G(X_{p-2}, X_{p-3}).
$$

The proof of this lemma is the usual one, see the proof of theorem 6.2 of chapter III of [ES]. We may thus make the following definition.

Definition 4.2. Let $\{X_k\}_{k \in \mathbb{Z}}$ be a $G$–filtration of the $G$–pair $(X, A)$. For each integer $q$, define

$$
A_q C_p^G(X, A) = \mathcal{F}_{p+q}^G(X_p, X_{p-1}).
$$

In addition, define

$$
A_q \partial_p : A_q C_p^G(X, A) \to A_q C_{p-1}^G(X, A)
$$

7
to be equal to the boundary map of the triple $(X_p, X_{p-1}, X_{p-2})$. The $q$–th associated equivariant homology of the filtration of $(X, A)$ is then defined to be the homology

$$A_q\mathcal{H}^G(X, A) \cong H(A_qC^*_G(X, A), A_q\partial_*).$$

of the chain complex $(A_qC^*_G(X, A), A_q\partial_*)$.

Later we will give more explicit formulae for the cells and boundary maps in the case where the filtration is by the skeleta of a simplicial $G$–complex.

5 Homology spectral sequence

For this section, suppose that we are given a $G$–filtration $\{X_k\}_{k \in \mathbb{Z}}$ of the $G$–pair $(X, A)$. We define an exact couple $D = D_{s,s}$ and $E = E_{s,s}$ of bigraded $R$–modules as follows. For all $p, q \in \mathbb{Z}$, we set

$$D_{p,q} = H_{G}^{p+q}(X_p, A)$$

and

$$E_{p,q} = H_{G}^{p+q}(X_p, X_{p-1}).$$

We also define $R$–module homomorphisms

$$i : D_{p,q} \to D_{p+1,q-1}, \quad j : D_{p,q} \to E_{p,q}, \quad k : E_{p,q} \to D_{p-1,q},$$

where $i$ is induced by $(X_p, A) \to (X_{p+1}, A)$, $j$ by $(X_p, A) \to (X_p, X_{p-1})$, and $k$ is the boundary map of the triple $(X_p, X_{p-1}, A)$. That $D$ and $E$ form an exact couple is simply a restatement of proposition $2.1$.

**Lemma 5.1.** The differential $d = j \circ k$ of the exact couple defined by (4) and (5) is equal to the boundary map in the exact sequence of the triple $(X_p, X_{p-1}, X_{p-2})$:

$$d : E_{p,q} = \mathcal{H}^G_{p+q}(X_p, X_{p-1}) \xrightarrow{\partial_{p+q}} \mathcal{H}^G_{p+q-1}(X_{p-1}, X_{p-2}) = E_{p-1,q}.$$  

**Proof.** Let $n = p + q$. From the definition of the boundary map of the triple $(X_p, X_{p-1}, A)$, we may decompose $d = j \circ k$ as

$$\mathcal{H}^G_n(X_p, X_{p-1}) \xrightarrow{\partial_n} \mathcal{H}^G_{n-1}(X_{p-1}) \xrightarrow{\partial_{n-1}} \mathcal{H}^G_{n-1}(X_{p-1}, A) \to \mathcal{H}^G_{n-1}(X_{p-1}, X_{p-2}).$$

By functoriality, the composition of the two arrows on the right is equal to $\mathcal{H}^G_{n-1}(X_{p-1}) \to \mathcal{H}^G_{n-1}(X_{p-1}, X_{p-2})$; thus the above composition is also equal to the boundary map of the triple $(X_p, X_{p-1}, X_{p-2})$.  

8
Recall (as in [Rot] chapter 11, for instance) that an exact couple induces a spectral sequence. Specifically, $D^1_{p,q} = D_{p,q}$ and $E^1_{p,q} = E_{p,q}$; $i^1 = i$, $j^1 = j$, $k^1 = k$, and $d^1 = j^1 \circ k^1$; and for $r > 1$, $D^r_{p,q} = i(D^{r-1}_{p-1,q+1})$,

$$E^r_{p,q} = \frac{\ker\{d^{r-1} : E^r_{p,q} \to E^r_{p-r+1,q+r-2}\}}{\text{im}\{d^{r-1} : E^r_{p+r-1,q-r+2} \to E^r_{p,q}\}},$$

(6)

$i^r$ is induced by $i^{r-1}$, $j^r$ is induced by $j^{r-1} \circ i^{-1}$, $k^r$ is induced by $k^{r-1}$, and $d^r = j^r \circ k^r$. In particular, $i^r$, $j^r$, $k^r$, and $d^r$ have respective bi-degrees $(1, -1)$, $(1 - r, r - 1)$, $(-1, 0)$, and $(-r, r - 1)$.

We will show that the spectral sequence induced by the exact couple in (4) and (5) converges to the filtration in homology defined by

$$\Phi^s\mathcal{H}_n^G(X, A) = \text{im}\{\mathcal{H}_n^G(X_s, A) \to \mathcal{H}_n^G(X, A)\}$$

(7)

for all integers $s$. However, we will need to make a mild assumption.

**Definition 5.2.** A $G$–filtration $\{X_p\}_{p \in \mathbb{Z}}$ of the $G$–pair $(X, A)$ is **homologically stable** with respect to the generalized equivariant homology theory $(\mathcal{H}_s^G, \partial_s)$ if for every $n \in \mathbb{Z}$, there exists $p_n \in \mathbb{Z}$ such that $\mathcal{H}_n^G(X_p, A) \to \mathcal{H}_n^G(X, A)$ is an isomorphism for all integers $p \geq p_n$.

If the $G$–filtration is stable, that is, if $X_s = X$ for sufficiently large $s$, then it is evidently homologically stable.

**Lemma 5.3.** If $\{X_p\}_{p \in \mathbb{Z}}$ is homologically stable, then $\{\Phi^s\mathcal{H}_n^G(X, A) \mid s \in \mathbb{Z}\}$ is a bounded filtration of $\mathcal{H}_n^G(X, A)$.

**Proof.** The filtration is bounded below: $\Phi^s\mathcal{H}_n^G(X, A) = 0$ for $s < 0$, since $X_s = A$ for such $s$. It is also bounded above: $\Phi^s\mathcal{H}_n^G(X, A) = \mathcal{H}_n^G(X, A)$ for all sufficiently large $s$, by hypothesis.

**Theorem 5.4.** Suppose that $\{X_p\}_{p \in \mathbb{Z}}$ is a homologically stable $G$–filtration of $X$. The spectral sequence induced by the exact couple in (4) and (5) converges to the filtration (7) of $\mathcal{H}_n^G(X, A)$, and we have $E^2_{p,q} = A_n\mathcal{H}_p^G(X, A)$.

**Proof.** The identification of the $E^2$ term and the associated homology of a filtration is implied by lemma 5.3. For convergence, the basic argument is a modification of that of theorem 11.13 in [Rot]. Specifically, fix $p, q$ and set $n = p + q$. Consider the exact sequence (for any $r$):

$$D^r_{p+r-2,q-r+2} \xrightarrow{i^r} D^r_{p+r-1,q-r+1} \xrightarrow{j^r} E^r_{p,q} \xrightarrow{k^r} D^r_{p-1,q}.$$ 

(8)
Since $D_{p+r-1,q-r+1}^r = i^{(r-1)}(D_{p,q}) = \text{im}\{\mathcal{F}_n^G(X_p, A) \to \mathcal{F}_n^G(X_{p+r-1}, A)\}$, we have that $D_{p+r-1,q-r+1}^r \cong \Phi^p\mathcal{F}_n^G(X, A)$ for sufficiently large $r$. The same argument also gives $D_{p+r-2,q-r+2}^r \cong \Phi^p\mathcal{F}_n^G(X, A)$ for sufficiently large $r$. Moreover, since $X_s = A$ for $s < 0$, we also have $D_{p-1,q}^r = i^{(r-1)}(D_{p-r,q+r-1}) = 0$ for sufficiently large $r$. Consequently, the exact sequence in (8) implies that $E_i^r \cong \Phi^p\mathcal{F}_n^G(X, A)/\Phi^{p-1}\mathcal{F}_n^G(X, A)$.

Next, we show that for fixed $n = p+q$ and sufficiently large $r$, $E_i^r = E_{p,q}^r$; so that $E_i^\infty = E_{p,q}^r$. Indeed for large $r$, $k^r(E_{p,q}) = 0$, by the above reasoning; whence $d^r(E_{p,q}) = 0$. Furthermore, we have the exact sequence

$$D_{p+2r-2,q-2r+3}^r \xrightarrow{i^r} D_{p+2r-1,q-2r+2}^r \xrightarrow{j^r} E_{p+r,q-r+1}^r.$$ 

Again by the above reasoning, we have $D_{p+2r-2,q-2r+3}^r \cong \Phi^{p+r-1}\mathcal{F}_{n+1}^G(X, A)$, and $D_{p+2r-1,q-2r+2}^r \cong \Phi^{p+r}\mathcal{F}_{n+1}^G(X, A)$; thus boundedness of the filtration implies that $i^r$ is an isomorphism for large $r$. Therefore, $j^r(D_{p+2r-1,q-2r+2}^r) = 0$; and thus $d^r(E_{p+r,q-r+1}^r) = 0$. Consequently, $E_{p,q}^{r+1} = E_{p,q}^r$. 

\[\square\]

6 Equivariant singular homology

The equivariant generalization of singular homology is defined in [Brö] and in [Ill]. We give a brief account of its construction, albeit with modified notation.

6.1 Coefficient systems

As in [Brö], one defines the category of canonical $G$-orbits to be the category $\mathcal{O}(G)$ whose objects are the left cosets of $G$, and whose morphisms are equivariant maps between these cosets. From [Arf], we have the following.

**Proposition 6.1.** Every morphism of $\mathcal{O}(G)$ is continuous.

In the following, we will make use of the following morphisms in $\mathcal{O}(G)$: if $H \leq G$ and $g \in G$, we define

$$\mu(g, H) : G/H^g \to G/H, \quad \mu(g, H)(eH^g) \doteq gH$$

(extended equivariantly). Here $H^g$ denotes the conjugate of $H$ by $g$: $H^g \doteq \{ghg^{-1} \mid h \in H\}$. When the subgroup $H$ can be discerned from context, we will write $\mu_g$ instead of $\mu(g, H)$. Also, if $H \leq K \leq G$, then we define

$$\kappa(K, H) : G/H \to G/K, \quad \kappa(K, H)(eH) \doteq eK$$
(extended equivariantly). When the subgroups $H, K$ can be deduced from context, we simply write $\kappa$ instead of $\kappa(K, H)$.

**Lemma 6.2.** The maps $\mu(g, H)$ and $\kappa(K, H)$ are well-defined, equivariant, continuous, and satisfy (i) if $gH = g'H$, then $\mu(g, H) = \mu(g', H)$, (ii) $\mu(g, H)$ is a homeomorphism with $\mu(g, H)^{-1} = \mu(g^{-1}, H^g)$, (iii) if $H \leq K \leq L \leq G$, then $\kappa(L, K) \circ \kappa(K, H) = \kappa(H, L)$, (iv) $\mu(g, H) \circ \mu(g', H^g) = \mu(g'g, H)$, and (v) if $H \leq K$, then $\mu(g, K) \circ \kappa(K^g, H^g) = \kappa(K, H) \circ \mu(g, H)$.

**Proof.** Since $(ghg^{-1})gH = gH$, $\mu(g, H)$ is well-defined; and since $H \leq K$, $\kappa(K, H)$ is also well-defined. Both maps are a priori equivariant, and by proposition 6.1 continuous. Properties (i) and (iv) follow from the fact $H^{g_1g_2} = (H^{g_2})^{g_1}$; the other properties follow by computation. □

A covariant $R$–coefficient system for $G$ is a covariant functor $\mathcal{M}$ from $\mathcal{O}(G)$ to the category of left $R$–modules and linear maps. Note that if $H \leq G$, then $\mathcal{M}(\mu_g) : \mathcal{M}(G/H^g) \to \mathcal{M}(G/H)$ is an isomorphism for any $g \in G$. Now given a $G$–set $S$, the orbit $[s] \equiv Gs$ of $s \in S$ can be identified setwise with the the coset $G/G_s$, where $G_s$ is the stabilizer subgroup of $s$. However, this identification depends on the choice of orbit representative $s$; indeed, if $s' = gs$, then $G_{s'} = G_s^g$. To avoid this dependence, we make the following definition.

**Definition 6.3.** Let $S$ be a $G$–set and $\mathcal{M}$ a covariant $R$–coefficient system for $G$. For $s \in S$, we define the orbit module to be

\[
\mathcal{M}[s] \equiv \left( \bigoplus_{gG_s \in G/G_s} \mathcal{M}(G/G_s^g) \otimes_R R\{gs\} \right) / J_{\mathcal{M}}[s],
\]

where $J_{\mathcal{M}}[s]$ is defined to be the submodule generated by all elements of the form $x \otimes gs - \mathcal{M}(\mu(g, G_s))(x) \otimes s$, where $g \in G$ and $x \in \mathcal{M}(G/G_s^g)$.

Here $R\{gs\}$ denotes the free $R$–module with generator $gs \in S$; its usage is merely to provide a convenient indexing scheme. We use square brackets to denote elements of $\mathcal{M}[s]$; i.e., we write $[x \otimes gs]$ instead of $x \otimes gs + J_{\mathcal{M}}[s]$.

**Lemma 6.4.** If $[s'] = [s]$, then $\mathcal{M}[s'] = \mathcal{M}[s]$.

**Proof.** Suppose $s' = gs$. It suffices to show $J_{\mathcal{M}}[s'] = J_{\mathcal{M}}[s]$, for which in turn, it suffices to show $J_{\mathcal{M}}[s'] \subseteq J_{\mathcal{M}}[s]$. Define $\omega(x_1, g_1) \equiv x_1 \otimes g_1 s - \mathcal{M}(\mu_g)(x_1) \otimes s \in J_{\mathcal{M}}[s]$. One then computes that $x' \otimes gs' - \mathcal{M}(\mu_g')(x') \otimes s' = \omega(x', g'g) - \omega(\mathcal{M}(\mu_{g'})(x'), g)$. □
Lemma 6.5. The map $\mathcal{M}(G/G_g^s) \rightarrow \mathcal{M}[s]$ given by $x \mapsto [x \otimes gs]$ is an isomorphism for any $g \in G$ and $s \in S$.

Proof. By lemma 6.4, we may assume $g = e$. Injectivity follows from the fact that $x \otimes s \not\in J\mathcal{M}[s]$ unless $x = 0$. Surjectivity follows from the identity $[x' \otimes g's] = \left[\mathcal{M}(\mu_{g'H})(x') \otimes s\right]$. □

The orbit module allows us to extend a given covariant coefficient system $\mathcal{M}$ for $G$ to a covariant functor from the category of $G$–sets and equivariant maps to the category of left $R$–modules and linear maps.

Definition 6.6. Suppose $\mathcal{M}$ is a covariant $R$–coefficient system for $G$. Define $\mathcal{M}(\emptyset) = 0$. For a $G$–set $S \neq \emptyset$, define

$$
\mathcal{M}(S) = \bigoplus_{[s] \subseteq S} \mathcal{M}[s]
$$

(the sum is over orbits $[s]$ of $S$). Moreover, if $S, S'$ are $G$–sets and $f : S \rightarrow S'$ is equivariant, then define

$$
\mathcal{M}(f) : \mathcal{M}(S) \rightarrow \mathcal{M}(S')
$$

by extending $\mathcal{M}(f)([x \otimes s]) = \left[\mathcal{M}(\kappa(G_{f(s)}, G_s))(x) \otimes f(s)\right]$ linearly, where $s \in S$ and $x \in \mathcal{M}(G/G_s)$.

That $\mathcal{M}(f)$ is independent of the choice of orbit representative $s$ follows from lemma 6.2 and functoriality of $\mathcal{M}$, as does the following.

Theorem 6.7. Suppose $\mathcal{M}$ is a covariant coefficient system. If $S$ is a $G$–set, then $\mathcal{M}(\text{id}_S)$ is the identity. Moreover, if $f : S \rightarrow S'$ and $f' : S' \rightarrow S''$ are equivariant maps of $G$–sets, then $\mathcal{M}(f' \circ f) = \mathcal{M}(f') \circ \mathcal{M}(f)$. □

A generalized equivariant homology theory $(\mathcal{H}_G^*, \partial_*)$ induces a covariant coefficient system by restricting $\mathcal{H}_G^*$ to $O(G)$. However if $X$ is a $G$–space and $x \in X$, we potentially need to distinguish between the homology module $\mathcal{H}_G^*([x])$ and the orbit module $\mathcal{H}_G^*[x]$. These two modules are isomorphic in the case when $G$ is a compact Lie group and $X$ is Hausdorff, for then the quotient space $G/G_x$ and the subspace $[x]$ are equivariantly homeomorphic (see proposition 4.1 of chapter 1 in [Br2]), and lemma 6.5 applies. On the other hand, if $G$ is not compact Lie, then the two modules need not coincide.

12
6.2 Equivariant singular homology

Given a space $X$, we let $S_n(X)$ denote the set of all singular $n$–simplices: the set of all (continuous) maps $\sigma : \Delta_n \to X$, where $\Delta_n$ denotes the standard $n$–simplex. In particular when $n < 0$, we have $S_n(X) = \emptyset$. If $X$ is a $G$–space, then $S_n(X)$ is a $G$–set, where $g \sigma : \Delta_n \to X$ is the map $(g \sigma)(x) = g(\sigma(x))$.

Let $\Delta_n^{(k)}$ denote the $k$–th face of $\Delta_n$; and if $\sigma$ is a singular $n$–simplex, we let $\sigma^{(k)} : \Delta_{n-1} \to X$ denote the composition of the identification map $\Delta_{n-1} \to \Delta_n^{(k)}$ followed by $\sigma$. Each map $\partial_n^{(k)} : S_n(X) \to S_{n-1}(X)$, with $\partial_n^{(k)}(\sigma) = \sigma^{(k)}$, is equivariant; so we may make the following definition.

**Definition 6.8.** If $X$ is a $G$–space and $M$ is a covariant coefficient system, we define for each integer $n$

$$S_n^G(X; M) = M(S_n(X)),$$

and the graded $R$–module $S^G_*(X; M) = \oplus_{n \in \mathbb{Z}} S_n(X; M)$. In addition, we define the map

$$\partial_n : S_n^G(X; M) \to S_{n-1}^G(X; M)$$

by $\partial_n = \sum_{k=0}^n (-1)^k M(\partial_n^{(k)})$.

As in the nonequivariant case, one verifies that $\partial_{n-1} \circ \partial_n = 0$. Moreover, if $(X, A)$ is a $G$–pair, then $S_n^G(A; M)$ is necessarily a summand of $S_n^G(X; M)$, and $\partial_n(S_n^G(A; M)) \subseteq S_{n-1}^G(A; M)$.

**Definition 6.9.** If $(X, A)$ is a $G$–pair, and $M$ is a covariant coefficient system, we define $S_n^G(X, A; M) = S_n^G(X; M)/S_n^G(A; M)$, and we define $\partial_* : S_*^G(X, A; M) \to S_{*-1}^G(X, A; M)$ to be the map induced by $\partial_* : S_*^G(X; M) \to S_{*-1}^G(X; M)$ under this quotient. We then define the **equivariant singular homology** of $(X, A)$ to be the $R$–module

$$H_*^G(X, A; M) = H(S_*^G(X, A; M), \partial_*);$$

i.e., the homology of the chain complex $(S_*^G(X, A; M), \partial_*)$.

In particular, $H_*^G(X, A; M)$ is trivial for $n < 0$. From [Brö] (in the case $G$ is discrete) and [IM] (in the general case), we have the following.

**Proposition 6.10.** Equivariant singular homology $(H_*^G, \partial_*)$ with coefficients in a covariant coefficient system $M$ is a generalized equivariant homology theory. Moreover when restricted to $O(G)$, $H_*^G$ is trivial if $n \neq 0$, and can be naturally identified with $M$ otherwise.
That is, there are isomorphisms $i_H : H^G_0(G/H; \mathcal{M}) \to \mathcal{M}(G/H)$ for each $H \leq G$ such that if $\eta : G/H \to G/K$ is equivariant, then $\mathcal{M}(\eta) \circ i_H = i_K \circ H^G_0(\eta)$.

**Theorem 6.11.** Equivariant singular homology satisfies the arbitrary sum property.

**Proof.** Let $\{(X_\alpha, A_\alpha)\}_{\alpha \in A}$ be a collection of $G$–pairs, and set $X = \sum_{\alpha \in A} X_\alpha$ and $A = \sum_{\alpha \in A} A_\alpha$. From definitions 6.6, 6.8, and 6.9 we may make the identification $S^G_*(X, A; \mathcal{M}) = \bigoplus_{\alpha \in A} S^G_*(X_\alpha, A_\alpha; \mathcal{M})$; and under this identification, $\partial^* = \bigoplus_{\alpha \in A} \partial^*_\alpha$, where $\partial^*_\alpha : S^G_*(X_\alpha, A_\alpha; \mathcal{M}) \to S^G_{*-1}(X_\alpha, A_\alpha; \mathcal{M})$. □

**Theorem 6.12.** If $G$ is compact, then equivariant singular homology has compact supports.

**Proof.** Let $(X, A)$ be a $G$–pair. Note that $G/H$ is compact for any $H \leq G$, and the orbit under $G$ of the image of any singular simplex of $X$ is also compact. For $y \in S^G_*(X; \mathcal{M})$, let $X(y)$ denote the union of all orbits $G \cdot \text{im}(\sigma)$, where $[x_\sigma \otimes \sigma]$ is a nonzero summand of $y$ for some $\sigma \in S_*(X)$ and $x_\sigma \in \mathcal{M}(G/G_\sigma)$; observe that $X(y)$ is compact. Given $x \in H^G_0(X, A; \mathcal{M})$, represent $x$ by some $y \in S^G_*(X; \mathcal{M})$ and take $X_c = X(y), A_c = X(\partial y)$. □

### 7 Homology of an equivariant simplex

Most of the ideas and proofs in this section are equivariant generalizations of those given in [ES], chapter III, sections 3 and 4.

Let $s$ denote an ordered $p$–simplex with vertices $v_0 < v_1 < \cdots < v_p$. We let $s_k$ denote the $k$–th face of $s$: the ordered $(p - 1)$–simplex with the vertex $v_k$ omitted. Also, we let $\hat{s}_k$ denote the simplicial subcomplex of $s$ obtained by removing the interior of $s_k$ from $\partial s$; that is, $\hat{s}_k$ is the union of all $l$–faces of $s$, with $l \neq k$. The $G$–action on the equivariant simplex $G/H \times s$ (with $H \leq G$) will always be on the first factor only: $g \cdot (g'H, x) = (gg'H, x)$.

**Lemma 7.1.** If $H \leq G$, $p \geq 1$, and $0 \leq k \leq p$, then the map

$$[s : s_k]^H_* : S^G_*(G/H \times s, G/H \times \partial s) \to S^G_{*-1}(G/H \times s_k, G/H \times \partial s_k),$$

defined as the composition

$$S^G_*(G/H \times s, G/H \times \partial s) \xrightarrow{\partial} S^G_{*-1}(G/H \times \partial s, G/H \times \hat{s}_k) \xrightarrow{\partial} S^G_{*-1}(G/H \times \partial s, G/H \times \hat{s}_k),$$

is an isomorphism.
Proof. \((G/H \times s, G/H \times \partial s) \rightarrow (G/H \times \partial s, G/H \times \partial s)\) induces an isomorphism in homology by strong excision. Moreover, since \(G/H \times \partial s\) is an equivariant strong deformation retract of \(G/H \times s\), \(\partial\) is an isomorphism by the long exact sequence of the triple \((G/H \times s, G/H \times \partial s, G/H \times \partial s)\).

**Lemma 7.2.** Suppose \(f : s \rightarrow s'\) is a simplicial map of \(p\)-simplices and \(\eta : G/H \rightarrow G/K\) is equivariant. If there exists \(k, l\) with \(f(\hat{s}_k) = \hat{s}'_l\) and \(f(s_k) = s'_l\), then \(S^*_G((\eta \times f) \circ [s : s_k]^H = [s' : s'_l]^K \circ S^*_G(\eta \times f)).

Proof. This follows from Lemma 7.1 and the following commutative diagram.

\[
\begin{array}{c}
\delta_* \downarrow \\
\delta^*_{s-1} (G/H \times s, G/H \times \partial s) \rightarrow \delta^*_{s-1} (G/K \times s', G/K \times \partial s') \\
\delta_* \downarrow \\
\delta^*_{s-1} (G/H \times s, G/H \times \partial s) \rightarrow \delta^*_{s-1} (G/K \times s', G/K \times \partial s')
\end{array}
\]

Indeed, the square on the top commutes by naturality of the long exact sequence of a triple, and the square on the bottom by functoriality.

**Theorem 7.3.** Suppose \(H \leq G\), \(s\) is a \(p\)-simplex, and \(\pi : G/H \times s \rightarrow G/H\) is the projection map. The map

\[\zeta(H, s)_* : S^*_G(G/H \times s, G/H \times \partial s) \rightarrow S^*_G(G/H)\]

defined inductively by

\[\zeta(H, s)_* = \begin{cases} 
S^*_G(\pi) & \text{if } p = 0 \\
(-1)^p \zeta(H, s_{p-1}) \circ [s : s_p]^H & \text{if } p > 0
\end{cases}
\]

is an isomorphism.

Proof. When \(p = 0\), \(\pi\) is an equivariant homeomorphism; the result then follows by induction and Lemma 7.1.

**Lemma 7.4.** If \(f : s \rightarrow s'\) is an order–preserving simplicial map of \(p\)-simplices and \(\eta : G/H \rightarrow G/K\) is equivariant, then \(\zeta(K, s')_* \circ S^*_G(\eta \times f) = S^*_G(\eta \times f) \circ \zeta(H, s)_*\).
Proof. For \( p = 0 \), the statement of the theorem follows by functoriality and the identity \( \pi \circ (\eta \times f) = \eta \circ \pi \). For \( p > 0 \), \( f(s_p) = s'_p \) and \( f(\hat{s}_p) = \hat{s}'_p \), as \( f \) is order–preserving; induction in conjunction with lemma 7.2 and equation 9 thus yield the theorem.

Lemma 7.5. If \( \rho : s \to s \) is a simplicial map that exchanges exactly two vertices, then \( \partial_s G(G/H \times s, G/H \times \partial s) \to \partial_s G(G/H \times s, G/H \times \partial s) \) is multiplication by \(-1\).

Proof. Consider the case \( p = 1 \); that is, \( \partial s = \{v_0, v_1\} \). For \( k = 0, 1 \), let \( i_k : G/H \to G/H \times \partial s \) be the map \( i_k(gH) = \left(gH, v_k\right) \), and \( \pi_k : G/H \times \partial s \to G/H \times \{v_k\} \) the map \( \pi_k(gH, v) = \left(gH, v_k\right) \). Now by proposition 2.4 we have an isomorphism \( S_s : \partial_s G(G/H) \to \partial_s G(G/H) \to \partial_s G(G/H \times \partial s) \) given by \( S_s(x, y) = \partial_s G(i_0)(x) + \partial_s G(i_1)(y) \). Since \( \pi_k \circ i_k = i_k \), one computes that \( \partial_s G(\pi_k) \circ S_s(x, y) = \partial_s G(i_k)(x + y) \). Thus \( \ker \partial_s G(\pi_k) \) is the image of \( \{(x, -x) \mid x \in \partial_s G(G/H)\} \) under \( S_s \). Further, since \( (id \times \rho) \circ i_k = i_{k'} \), where \( k' = 1 \), when \( k = 0, 1 \), one computes \( \partial_s G(id \times \rho) \circ S_s(x, -x) = -S_s(x, -x) \).

That is, the vertical arrow on the left in the diagram

\[
\begin{align*}
\ker \partial_s G/G(G/H \times \partial s) & \xrightarrow{(\cong)} \tilde{\partial}_s G(G/H \times \partial s) \\
\downarrow \partial_s G/G(G/H \times \partial s) & \quad \downarrow \tilde{\partial}_s G(G/H \times \partial s) \\
\ker \partial_s G/G(G/H \times \partial s) & \xrightarrow{(\cong)} \tilde{\partial}_s G(G/H \times \partial s)
\end{align*}
\]

is multiplication by \(-1\). The above diagram commutes: the square on the left by theorem 3.9 (since \( s \) has trivial \( H \)-action, \( G \times H s = G/H \times s \)), the square on the right by theorem 3.3. However, since \( G/H \times s \) is contractible, \( \partial_s \) is an isomorphism; and the lemma follows when \( p = 1 \).

In the case \( p > 1 \), there is a vertex \( v_k \) such that \( \rho(v_k) = v_k \). Therefore, \( \rho(\hat{s}_k) = \hat{s}_k \) and \( \rho(s_k) = s_k \). Thus by lemma 7.2 \( \partial s_{k-1} G(G/H \times \rho) \circ [s : s_k]_s^H = [s : s_k]_s^H \circ \partial s_k G(G/H \times \rho) \), and \( -[s : s_k]_s^H = [s : s_k]_s^H \circ \partial s_k G(G/H \times \rho) \) follows inductively. Since \( [s : s_k]_s^H \) is an isomorphism, we are done.

Theorem 7.6. If \( s \) is a \( p \)-simplex, \( \phi : s \to s \) is a simplicial map that permutes the vertices, and \( \eta : G/H \to G/K \) is \( G \)-equivariant, then \( \zeta(K, s)_{\phi} \circ \partial s_k G(\eta \times \phi) = (\text{sign } \phi) \partial s_{k-p} G(\eta) \circ \zeta(H, s)_{\phi} \).

Proof. Let \( i : s \to s \) and \( j : G/H \to G/H \) denote the identity maps. Since \( \eta \times \phi = (\eta \times i) \circ (j \times \phi) \), by lemma 7.3 \( \zeta(K, s)_{\phi} \circ \partial s_k G(\eta \times \phi) = \).

16
Theorem 7.7. Suppose $s, s'$ are ordered $p$–simplices with respective vertices $v_1 < \cdots < v_p$ and $v'_1 < \cdots < v'_p$, and that $f : s \to s'$ is a simplicial map such that $f(v_k) = v'_{\phi(k)}$, $0 \leq k \leq p$, for some permutation $\phi$. Then

$$ \zeta(K, s) \circ s^G(\eta \times i) \circ \sigma^G_{s}(j \times \phi) = s^G_{s-p}(\eta) \circ \zeta(H, s) \circ s^G_{s}(j \times \phi). $$

However, $\phi$ is the composition of simplicial reflections, say $\phi = \rho_1 \circ \cdots \circ \rho_n$; and so $j \times \phi = (j \times \rho_1) \circ \cdots \circ (j \times \rho_n)$. Hence by lemma 7.5 and functoriality, $s^G_{s}(j \times \phi) = (-1)^n = \text{sign } \phi$. The theorem now follows.

Proof. Define $\chi : s \to s$ and $\iota : s \to s'$ to be the simplicial maps such that $\chi(v_k) = v_{\phi(k)}$ and $\iota(v_k) = v'_k$, for $0 \leq k \leq p$. Then $\eta \times f = (i \times \iota) \circ (\eta \times \chi)$, where $i : G/K \to G/K$ is the identity, $\chi$ permutes the vertices of $s$ with $\text{sign } \chi = \text{sign } \phi$, and $\iota$ is order preserving. The statement of the theorem follows now from functoriality, lemma 7.4, and theorem 7.6.

Theorem 7.8. If $H \leq G$ and $s$ is a $p$–simplex, then $\zeta(H, s^k)_{s-1} \circ [s : s^k]_s^H = (-1)^k \zeta(H, s)_s$.

Proof. If $k = p$, then this is just equation (9), so we can assume that $k < p$. Let $\rho_j$ denote the reflection of $s$ that exchanges vertices $v_j$ and $v_{j+1}$, but leaves all other vertices fixed ($0 \leq j < p$); and set $\phi = \rho_1 \circ \rho_2 \circ \cdots \circ \rho_{p-1}$, so that $\phi(v_i) = v_i$ if $0 \leq i < k$, $\phi(v_k) = v_p$, and $\phi(v_i) = v_{i-1}$ if $k < i \leq p$. Note that $\text{sign } \phi = (-1)^{p-k}$, $\phi(s_k) = s_p$, and $\phi(s_{k}) = s_{p}$. The diagram

$$ \begin{array}{ccc}
\sigma^G_{s}(G/H \times s, G/H \times \partial s) & \xrightarrow{[s : s^k]^H} & \sigma^G_{s-1}(G/H \times s_k, G/H \times \partial s_k) \\
\sigma^G_{s}(id \times \phi) \downarrow & & \downarrow \sigma^G_{s-1}(id \times \phi) \\
\sigma^G_{s}(G/H \times s, G/H \times \partial s) & \xrightarrow{[s : s^k]^H} & \sigma^G_{s-1}(G/H \times s_p, G/H \times \partial s_p) \\
\zeta(H,s)_s \downarrow & & \downarrow \zeta(H,s^k)_{s-1} \\
\sigma^G_{s-p}(G/H) & \xrightarrow{(-1)^p} & \sigma^G_{s-p}(G/H)
\end{array} $$

commutes: the top square by lemma 7.2 and the bottom square by equation (9). Now by theorem 7.6 the two vertical arrows on the left can be identified with $(-1)^{p-k}\zeta(H, s)_s$. Moreover, the simplicial map $\phi : s_k \to s_p$ is order–preserving, so by lemma 7.4 the vertical arrows on the right can be identified with $\zeta(H, s^k)_{s-1}$. Consequently, $\zeta(H, s_k)_{s-1} \circ [s : s^k]_s^H = (-1)^p(-1)^{p-k}\zeta(H, s)_s = (-1)^k\zeta(H, s)_s.$

\[ \square \]
8 Homology of a simplicial complex

For the remainder, we assume that $G$ is a locally compact Hausdorff topological group.

**Definition 8.1.** Let $V$ be a $G$–set. An abstract simplicial $G$–complex is a collection of finite nonempty subsets $\mathcal{S}$ of $V$ satisfying (i) if $v \in V$, then \{v\} $\in \mathcal{S}$, (ii) if $S \in \mathcal{S}$ and $R \subseteq S$, then $R \in \mathcal{S}$, (iii) if $S \in \mathcal{S}$, then $gS \in \mathcal{S}$ for all $g \in G$, and (iv) if $S \in \mathcal{S}$ and $g \in G$, then $gx = x$ for all $x \in S$.

Note that an abstract simplicial $G$–complex is a (nonequivariant) abstract simplicial complex via conditions (i) and (ii).

We recall the standard construction for the realization of an abstract simplicial complex in the nonequivariant case. Let $RV$ denote the real vector space with basis $V$, and we give it the co–limit topology induced from the metric topology on finite subspaces. For each abstract simplex $S \in \mathcal{S}$, we form the convex hull $|S| \subseteq RV$ of $S$. The realization of $\mathcal{S}$ is then the union $|\mathcal{S}| \doteq \bigcup_{S \in \mathcal{S}} |S|$, but with the coherent topology with respect to the constituent simplices. Observe that the $G$–action on $V$ extends linearly to a $G$–action on $|\mathcal{S}|$. However, this action will not be continuous unless $G$ is discrete. On the other hand, using this construction, we may now identify an abstract simplex $S \in \mathcal{S}$ with its realization $|S| \subseteq RV$. In the following, we will use lower case Roman letters to emphasize that we have made this identification; i.e., we write $s \in \mathcal{S}$ to mean $s = |S|$ for some $S \in \mathcal{S}$.

In [Arf], a construction is given for the realization of an abstract simplicial $G$–complex, where $G$ is any locally compact Hausdorff topological group; in the case when $G$ is finite, the resulting space is equivariantly homeomorphic to the above realization. We give a brief outline of the construction. As a set, the realization $\text{top}_G(\mathcal{S})$ is the quotient of the disjoint union $\sum_{s \in \mathcal{S}} G/G_s \times s$ under the following equivalence relation. For $s, t \in \mathcal{S}$, $(g_s G_s, x_s) \in G/G_s \times s$ and $(g_t G_t, x_t) \in G/G_t \times t$ are identified if there exists $g \in G$ and $r \in \mathcal{S}$ such that $x_s \in r \subseteq s$, $x_t \in gr \subseteq t$, and $g_s^{-1} g t g \in G_r$. Let $\chi_s : G/G_s \times s \to \text{top}_G(\mathcal{S})$ be the map induced by inclusion; the image of $\chi_s$ is given the quotient topology, and $\text{top}_G(\mathcal{S})$ is given the coherent topology with respect to all such images.

In this section, we will require the services of the following properties of $\text{top}_G(\mathcal{S})$. 

18
1. With the exception of the Hausdorff axiom, $\text{top}_G(\mathcal{G})$ is an equivariant cw–complex with respect to the maps $\{\chi_s\}_{s \in \mathcal{R}}$, where $\mathcal{R}$ is any collection of orbit representatives for $\mathcal{G}$.

2. $\chi_{gs} = \chi_s \circ (\mu(g,G_s) \times g^{-1})$, where $g^{-1} : gs \rightarrow s$ is left multiplication by $g^{-1}$. Consequently, $\chi_{gs}$ and $\chi_s$ have the same images in $\text{top}_G(\mathcal{G})$.

3. $\chi_{s_k} \circ (\kappa(G_{s_k}, G_s) \times id) = \chi_s|G/G_s \times s_k$ for each face $s_k$ of $s$.

In addition, if $\mathcal{R}$ is an abstract simplicial $G$–complex with $\mathcal{R} \subseteq \mathcal{G}$, then $\text{top}_G(\mathcal{R})$ is a $G$–subspace of $\text{top}_G(\mathcal{G})$. Details are provided in [Arf].

We say that $X$ is a simplicial $G$–complex if it is the realization of an abstract simplicial $G$–complex, and we let $C_*(X)$ denote the underlying abstract simplicial $G$–complex; i.e., $X = \text{top}_G(C_*(X))$. More generally, we say that $(X, A)$ is a pair of simplicial $G$–complexes if $X$ and $A$ are simplicial $G$–complexes with $C_*(A) \subseteq C_*(X)$. We let $C_p(X)$ denote the collection of all simplices of $X$ of dimension $p$, so that $C_*(X) = \bigcup_{p \in \mathbb{Z}} C_p(X)$. Note that $C_p(X)$ is a $G$–set, as are $C_p(A) \subseteq C_p(X)$ and $C_p(X, A) = C_p(X) \setminus C_p(A)$.

If $(X, A)$ is a pair of simplicial $G$–complexes, we may filter by equivariant cell dimension. That is, since it is an equivariant cw–complex, $X$ is partitioned by open equivariant cells $\chi_s(G/G_s \times \text{int}(s))$ of dimension $\dim(s)$, where $s$ is in any collection of orbit representatives in $C_*(X)$. We let $X^p$ denote the $p$–skeleton of $X$: the collection of all open equivariant cells of dimension $q$ with $q \leq p$. The desired filtration is then by sets $X^p \upharpoonright X^p \cup A$.

In the following discussion, it will be assumed that for each (nonequivariant) simplex $s$, we have chosen a preferred ordering of its vertices; however, the vertices of the complex to which $s$ belongs is may or not be (globally) ordered. Also, it is not assumed that the group action preserves the preferred vertex ordering; i.e., the vertex ordering of $gs$, for $g \in G$, induced by that of $s$ is not necessarily the preferred one. We will let $\text{sign}(g, s)$ denote the sign of any vertex permutation that puts the vertices of $gs$ into preferred order.

### 8.1 Alternate description of chains and boundaries

Throughout this section, we assume that $(\mathfrak{H}_*, \partial_*)$ is a generalized equivariant homology theory that satisfies the arbitrary sum property. In the absence of this, all of the results will hold for simplicial complexes that have a finite

---

1 If $G_s$ is not a closed subset of $G$, which it is not assumed to be, $G/G_s$ is not Hausdorff.
number of equivariant cells in each dimension. Throughout, we let \((X, A)\) be a pair of simplicial \(G\)-complexes.

**Lemma 8.2.** If \(\mathcal{R}\) is a collection of orbit representatives for \(C_p(X, A)\), then

\[ \Theta_*: \bigoplus_{s \in \mathcal{R}} \mathcal{H}_G^{s}(G/G_s \times s, G/G_s \times \partial s) \to \mathcal{H}_G^s(X_p, X_{p-1}), \]

given by \(\Theta_*(x) = \mathcal{H}_G^s(\chi_s)(x)\) for \(x \in \mathcal{H}_G^{s}(G/G_s \times s, G/G_s \times \partial s)\), is an isomorphism.

*Proof.* The map \(\theta : \sum_{s \in \mathcal{R}}(G/G_s \times s, G/G_s \times \partial s) \to (X_p, X_{p-1})\), defined by \(\theta|(G/G_s \times s, G/G_s \times \partial s) = \chi_s\), induces an isomorphism in homology. Indeed, 

\(G/G_s \times \partial s\) is a equivariant retract of \(G/G_s \times (s \setminus \{s_b\})\), where \(s_b\) is the barycenter of \(s\). So by excising \(G/G_s \times \partial s\) from \((G/G_s \times s, G/G_s \times (s \setminus \{s_b\}))\), \(\theta\) is the same in homology as the restriction

\[ \sum_{s \in \mathcal{R}} \{G/G_s \times \text{int}(s), G/G_s \times (\text{int}(s) \setminus \{s_b\})\} \]

(\(\Theta_*\) is the same in homology as the restriction

\[ \bigcup_{s \in \mathcal{R}} \{\chi_s(G/G_s \times \text{int}(s)), \chi_s(G/G_s \times (\text{int}(s) \setminus \{s_b\}))\} \]

(for more details, see the proof of lemma 39.2 in [Mun]). As this map is an equivariant homeomorphism, the lemma now follows from theorem 2.8.

**Theorem 8.3.** If \((X, A)\) is a pair of simplicial \(G\)-complexes, then the map

\[ \alpha_{p,q} : \mathcal{H}_q^G(C_p(X, A)) \to \mathcal{A}_{q}C_p^G(X, A), \]

defined by

\[ \alpha_{p,q}([x \otimes gs]) = \text{sign}(g, s) \mathcal{H}_p^G(\chi_{gs}) \circ \zeta(G^o_s, gs)^{-1}(x) \]

for all \(x \in \mathcal{H}_q^G(G/G_s^o)\) and \(s \in C_p(X, A)\), is an isomorphism.

*Proof.* Set \(n = p + q\). By lemmas 6.5 and 8.2, and theorem 7.3, we have that the following sequence of compositions is an isomorphism:

\[ \mathcal{H}_q^G(C_p(X, A)) \leftarrow \oplus_{s \in \mathcal{R}} \mathcal{H}_q^G(G/G_s) \leftarrow \mathcal{H}_q^G(G/G_s \times s, G/G_s \times \partial s) \Theta^*_s \mathcal{H}_n^G(X_p, X_{p-1}). \]
We claim that this is precisely \( \alpha_{p,q} \). Indeed, \( [x \otimes gs] = [\mathcal{S}_q^G(\mu_g)(x) \otimes s] \), so that \( [x \otimes gs] \) maps to \( \mathcal{S}_n^G(\chi_s) \circ \zeta(G_s, s)^{-1} \circ \mathcal{S}_q^G(\mu_g)(x) \) under the above composition. However,

\[
\mathcal{S}_n^G(\chi_s) \circ \zeta(G_s, s)^{-1} \circ \mathcal{S}_q^G(\mu_g) = (\text{sign } g^{-1}) \mathcal{S}_n^G(\chi_s) \circ \mathcal{S}_q^G(\mu_g \times g^{-1}) \circ \zeta(G_s^g, gs)^{-1} = (\text{sign } g^{-1}) \mathcal{S}_n^G(\chi_s) \circ \zeta(G_s^g, gs)^{-1}
\]

by theorem 7.7 and functoriality. Moreover, \( \text{sign } g^{-1} = \text{sign}(g, s) \).

\( \square \)

**Lemma 8.4.** Suppose \( G/H \times s \) is an equivariant \( p \)-simplex. If we identify \( s \) with \( \{eH\} \times s \), then the following diagram commutes:

\[
\begin{array}{ccc}
\mathcal{A}_q C_p^G(G/H \times s) & \xrightarrow{\mathcal{A}_q \partial_p} & \mathcal{A}_q C_{p-1}^G(G/H \times s) \\
\alpha_{p,q} & \uparrow & \alpha_{p-1,q} \\
\mathcal{S}_q^G(C_p(G/H \times s)) & \xrightarrow{\partial_p} & \mathcal{S}_q^G(C_{p-1}(G/H \times s)),
\end{array}
\]

where for all \( x \in \mathcal{S}_q^G(G/H^g) \), we have \( \partial_p[x \otimes gs] = \sum_{k=0}^{p} (-1)^k [x \otimes gs_k] \).

**Proof.** It suffices to verify the formula for \( \partial_p \) in the case \( g = e \). We set \( X = G/H \times s \). Since \( C_p(X) = \{ gs \ | \ gH \in G/H \} \) and \( C_{p-1}(X) = \{ gs_k \ | \ gH \in G/H, 0 \leq k \leq p \} \), linearity implies that we only need to show that

\[
\text{proj}_k \circ \partial_p[x \otimes s] = (-1)^k [x \otimes s_k],
\]

where \( \text{proj}_k : \mathcal{S}_q^G(C_p(X)) \rightarrow \mathcal{S}_q^G[s_k] \) is the projection map. Now, \( X_p = X^p = G/H \times s \) and \( X_{p-1} = X^{p-1} = G/H \times \partial s \).

Set \( n = p + q \). We claim that in the diagram

\[
\begin{array}{ccc}
\mathcal{S}_q^G(C_p(G/H \times s)) & \xrightarrow{\alpha_{p,q}} & \mathcal{S}_n^G(X_p, X_{p-1}) \\
\partial_p & \downarrow & A_q \partial_p \\
\mathcal{S}_q^G(C_{p-1}(G/H \times s)) & \xrightarrow{\alpha_{p-1,q}} & \mathcal{S}_n^G(X_{p-1}, X_{p-2}) \\
\text{proj}_k & \downarrow & \text{proj}_k \\
\mathcal{S}_q^G[s_k] & \xrightarrow{\alpha_{p-1,q}} & \mathcal{S}_n^G(G/H \times \partial s, G/H \times \partial s) \\
\mathcal{S}_q^G[s_k] & \xrightarrow{\alpha_{p-1,q}} & \mathcal{S}_n^G(G/H \times s_k, G/H \times \partial s_k),
\end{array}
\]
the bottom two squares commute, and that (ii) the composition of vertical arrows on the right is equal to $[s : s_k]^H_n$. The formula for $\partial_p$ then follows:

\[
\alpha_{p-1,q} \circ \text{proj}_k \circ \partial_p([x \otimes s]) = [s : s_k]^H_n \circ \alpha_{p,q}([x \otimes s]) = [s : s_k]^H_n \circ \zeta(H, s)_{n-1}(x) = (-1)^k \zeta(H, s_k)^{-1}_{n-1}(x) = (-1)^k \alpha_{p-1,q}([x \otimes s]),
\]

by theorems 7.8 and 8.3 and the fact that $\chi_s$ and $\chi_{s_k}$ are both the identity in this case.

Let us justify claim (i). For the middle square of diagram (10), theorem 8.3 gives

\[
\mathcal{S}_{n-1}^G(i_k) \circ \alpha_{p-1,q}([x \otimes s]) = \mathcal{S}_{n-1}^G(i_k) \circ \alpha_{p-1,q}([x \otimes s]) = \mathcal{S}_{n-1}^G(i_k) \circ \zeta(H, s)_{n-1}(x),
\]

where $i_k : (X_{p-1}, X_{p-2}) \to (G/H \times \partial s, G/H \times \hat{s}_k)$ is the inclusion. If $l = k$, then this is just $\alpha_{p-1,q}([x \otimes s])$. However, if $l \neq k$, then $s_l \subseteq \hat{s}_k$, so that we can factor $i_k \circ \chi_{s_l}$ as

$(G/H \times s_l, G/H \times \partial s_l) \to (G/H \times \hat{s}_k, G/H \times \hat{s}_k) \to (G/H \times \partial s, G/H \times \hat{s}_k)$

($\chi_{s_l}$ is the inclusion map in this case); hence $\mathcal{S}_{n}^G(i_k \circ \chi_{s_l}) = 0$. The bottom square in diagram (10) also commutes by theorem 8.3.

To justify claim (ii), we see that the composition of the top two vertical arrows on the right in diagram (10) is equal to the boundary map

\[
\mathcal{S}_{n}^G(G/H \times s, G/H \times \partial s) \xrightarrow{\partial_p} \mathcal{S}_{n-1}^G(G/H \times \partial s, G/H \times \hat{s}_k),
\]

by definition of the boundary map of a triple. The claim now follows from definition of the incidence map (lemma 7.1).

\[\text{Theorem 8.5. If } (X, A) \text{ is a } G\text{-pair of simplicial } G\text{-complexes, the diagram}
\]

\[
\begin{array}{ccc}
\mathcal{A}_q C_p^G(X, A) & \xrightarrow{A_q \partial_p} & \mathcal{A}_q C_{p-1}^G(X, A) \\
\alpha_{p,q} \uparrow & & \alpha_{p-1,q} \uparrow \\
\mathcal{S}_q^G(C_p(X, A)) & \xrightarrow{\partial_p} & \mathcal{S}_q^G(C_{p-1}(X, A))
\end{array}
\]

\[\text{is commutative, where } \mathcal{S}_q^G \text{ is defined by the } q\text{-th layer of the incidence map.}
\]
commutes, where for all \( x \in \mathfrak{G}_q^G(G/G_q^G) \) and \( s \in C_p(X, A) \),
\[
\partial_p[x \otimes gs] = \sum_{k=0}^p (-1)^k [\mathfrak{G}_q^G(\kappa(G_q^G))](x) \otimes gs_k.
\]

**Proof.** Again, it suffice to assume \( g = e \). We make the abbreviations \( H \cong G_s \) and \( n \cong p + q \). Note that \( s^{p-1} = \partial s \). The following diagram commutes:
\[
\begin{array}{ccc}
\mathfrak{G}_n^G(X_p, X_{p-1}) & \xrightarrow{A_q \partial_p} & \mathfrak{G}_{n-1}^G(X_{p-1}, X_{p-2}) \\
\mathfrak{G}_n^G(\chi_s) & \uparrow & \mathfrak{G}_{n-1}^G(\chi_s) \\
\mathfrak{G}_n^G(G/H \times s, G/H \times \partial s) & \xrightarrow{\partial_n} & \mathfrak{G}_{n-1}^G(G/H \times \partial s, G/H \times s^{p-2}) \\
\alpha_{p,q} \uparrow \zeta(H, s)^{-1} & \uparrow \alpha_{p-1,q} & \oplus_{k=0}^p \mathfrak{G}_q^G[s] \\
\mathfrak{G}_q^G[s] & \xrightarrow{\partial_p} & \mathfrak{G}_q^G[s_k].
\end{array}
\]

Indeed, the top square commutes by proposition \[7.4\] and the bottom square commutes by lemma \[8.3\]. Thus we have
\[
A_q \partial_p \circ \alpha_{p,q}([x \otimes s]) = A_q \partial_p \circ \mathfrak{G}_n^G(\chi_s) \circ \zeta(H, s)^{-1}(x)
\]
\[
= \mathfrak{G}_{n-1}^G(\chi_s) \circ \alpha_{p-1,q} \circ \partial_p(x \otimes s)
\]
\[
= \sum_{k=0}^p (-1)^k \mathfrak{G}_{n-1}^G(\chi_s) \circ \alpha_{p-1,q}([x \otimes s_k])
\]
\[
= \sum_{k=0}^p (-1)^k \mathfrak{G}_{n-1}^G(\chi_s) \circ \zeta(H, s_k)^{-1}(x),
\]

since \( \chi_{s_k} : (G/H \times s_k, G/H \times \partial s_k) \to (G/H \times \partial s, G/H \times s^{p-2}) \) is the inclusion. Set \( H_k \cong G_{s_k} \) and \( \kappa_k \cong \kappa(H_k, H) \), and let \( i : (s, \partial s) \to (X_p, X_{p-1}) \) denote the inclusion map. Since \( H \leq H_k \), one sees that \( \chi_{s_k} \circ (\kappa_k \times i) = \chi_s \) when restricted to \( (G/H \times s_k, G/H \times \partial s_k) \). Thus, by lemma \[7.4\]
\[
A_q \partial_p \circ \alpha_{p,q}([x \otimes s]) = \sum_{k=0}^p (-1)^k \mathfrak{G}_{n-1}^G(\chi_{s_k}) \circ \mathfrak{G}_{n-1}^G(\kappa_k \times i) \circ \zeta(H, s_k)^{-1}(x)
\]
\[
= \sum_{k=0}^p (-1)^k \mathfrak{G}_{n-1}^G(\chi_{s_k}) \circ \zeta(H_k, s_k)^{-1} \circ \mathfrak{G}_q^G(\kappa_k)(x)
\]
\[
= \sum_{k=0}^p (-1)^k \alpha_{p-1,q}([\mathfrak{G}_q^G(\kappa_k)(x) \otimes s_k]). \qedhere
\]
Theorem 8.6. If \((X, A)\) is a \(G\)-pair of simplicial \(G\)-complexes, then we have \(A_q \tilde{\delta}_p^G(X, A) \cong \mathcal{A}_0 H_p^G(X, A; \tilde{\mathcal{H}}_q^G)\).

Proof. By proposition 6.10, \(H_0^G\) (with coefficients in \(\tilde{\mathcal{H}}_q^G\) understood) and \(\tilde{\delta}_q^G\) define equivalent covariant coefficient systems upon restriction to \(O(G)\). In particular, \(H_0^G(C_p(X, A); \tilde{\delta}_q^G) = \tilde{\delta}_q^G(C_p(X, A)).\) That is, the associated chains for \((\tilde{\delta}_q^G, \partial_q)\) and \((H_q^G, \partial_q)\) are isomorphic by theorem 8.3. Furthermore by theorem 8.5 under this isomorphism the boundary maps are identical since \([\tilde{\delta}_q^G(\kappa(G_{sk}, G_s))(x) \otimes s_k] = [H_0^G(\kappa(G_{sk}, G_s); \tilde{\delta}_q^G)(x) \otimes s_k].\)

8.2 Consequences of the spectral sequence

As in the previous subsection, we assume that we are given a \(G\)-pair \((X, A)\) of simplicial \(G\)-complexes, and that the generalized equivariant homology theory \((\tilde{\delta}_p^G, \partial^*_p)\) satisfies the arbitrary sum property, or that \(X\) (hence \(A\)) is finite in each dimension. In addition, to make use of the spectral sequence, we must also assume that \((X, A)\) is homologically stable; that is, the \(G\)-filtration \(\{X_p = X_p \cup A\}_{p \in \mathbb{Z}}\) is homologically stable. This is necessarily the case if \((X, A)\) is finite dimensional; in the next subsection, we will give criteria under which this is the case for the infinite dimensional case.

Theorem 8.7. If \(\mathcal{M}\) is a covariant coefficient system and \((X, A)\) is a \(G\)-pair of simplicial \(G\)-complexes, then

\[
H_n^G(X_p, X_{p-1}; \mathcal{M}) \cong \begin{cases} 
\mathcal{M}(C_p(X, A)) & \text{if } n = p, \\
0 & \text{if } n \neq p.
\end{cases}
\]

Proof. This follows from theorem 8.3 and proposition 6.10.

Theorem 8.8. Suppose \((X, A)\) is a \(G\)-pair of simplicial \(G\)-complexes that is stable with respect to equivariant singular homology, and that \(\mathcal{M}\) is a coefficient system. Then \(H_n^G(X, A; \mathcal{M}) \cong \mathcal{A}_0 H_n^G(X, A; \mathcal{M})\).

Proof. By theorem 5.4 the spectral sequence converges with \(E^2_{p,q} = A_q H_p^G(X, A; \mathcal{M})\). However by theorem 8.7 \(E^1_{p,q} = 0\) if \(q \neq 0\). So by dimensional considerations, the spectral sequence collapses at the \(E^2\)-term. Moreover by theorem 8.7 and the exact sequence of the triple \((X_r, X_{r-1}, A)\), we have (i) \(H_p^G(X_r, A; \mathcal{M}) \cong H_p^G(X_{r-1}, A; \mathcal{M})\) for all \(r \neq p, p + 1,\) and (ii) \(H_p^G(X_p, A; \mathcal{M}) \rightarrow H_p^G(X_{p+1}, A; \mathcal{M})\) is an epimorphism. By induction,
(i) yields $H^G_p(X_{p-1}, A; M) \cong H^G_p(A, A; M) = 0$. Therefore, in the notation of section [5] we have $\phi^{p-1}H^G_p(X, A; M) = 0$. From (i) we also have $H^G_p(X_{p+1}, A; M) \cong H^G_p(X_{p+k}, A; M)$ for all $k > 1$; and so

$$\phi^pH^G_p(X, A; M) = \text{im}\{H^G_p(X_p, A; M) \to H^G_p(X, A; M)\} = H^G_p(X, A; M),$$

by (ii) and homological stability. Consequently, $E^2_{p,0} \cong \phi^pH^G_p(X, A; M) \cong H^G_p(X, A; M)$. \hfill $\square$

**Theorem 8.9.** If $(X, A)$ is a $G$–pair simplicial $G$–complexes that is stable with respect to both equivariant singular homology and $(\mathcal{S}^G_s, \partial_s)$, then the spectral sequence of the filtration $\{X^n \cup A \mid n \in \mathbb{Z}\}$ converges to $\mathcal{S}^G_s(X, A)$, with $E^2_{p,q} \cong H^G_p(X, A; \mathcal{S}^G_q)$.

**Proof.** The spectral sequence converges with $E^2_{p,q} = A_p\mathcal{S}^G_p(X, A)$, by theorem [5.4] By theorems 8.8 and 8.6, $E^2_{p,q} \cong A_0H^G_p(X, A; \mathcal{S}^G_q) \cong H^G_p(X, A; \mathcal{S}^G_q)$. \hfill $\square$

### 8.3 A criterion for homological stability

**Theorem 8.10.** Suppose that $(\mathcal{S}^G_s, \partial_s)$ has compact supports, and that there exists an integer $n_0$ such that $\mathcal{S}^G_n(G/H) = 0$ for all $n \leq n_0$ and all $H \leq G$. If $(X, A)$ is a $G$–pair of simplicial $G$–complex such that the subspaces $X_p$ are compact, then $\{X_p\}_{p \in \mathbb{Z}}$ is homologically stable with respect to $(\mathcal{S}^G_s, \partial_s)$.

**Proof.** Set $p_0 = n - n_0$. Theorem 8.3 implies that $\mathcal{S}^G_{n+1}(X_{p+1}, X_p)$ is isomorphic to $\mathcal{S}^G_{n-p}(C_{p+1}(X_{p+1}, X_p))$; and thus $\mathcal{S}^G_{n+1}(X_{p+1}, X_p) = 0$ for $n - p \leq n_0$. From the exact sequence

$$\mathcal{S}^G_{n+1}(X_{p+1}, X_p) \xrightarrow{\delta_n} \mathcal{S}^G_n(X_p, A) \to \mathcal{S}^G_n(X_{p+1}, A) \to \mathcal{S}^G_n(X_{p+1}, X_p),$$

$\mathcal{S}^G_n(X_p, A) \to \mathcal{S}^G_n(X_{p+1}, A)$ is an isomorphism for all $p \geq p_0$. It follows that $\mathcal{S}^G_n(X_{p_0}, A) \to \mathcal{S}^G_n(X_p, A)$ is an isomorphism for all $p \geq p_0$; and hence inclusion induces $\mathcal{S}^G_n(X_p, A) \cong \lim_{r \geq p} \mathcal{S}^G_r(X_r, A)$, for each $p \geq p_0$ (see corollary 4.8 of chapter VIII in [ES]). Now, $\{(X_r, A) \mid r \geq p\}$ is cofinal in the set $\mathcal{C}$ of all compact pairs $(Y, B) \subseteq (X, A)$; hence inclusion also induces $\lim_{r \geq p} \mathcal{S}^G_n(X_r, A) \cong \lim_{(Y, B) \in \mathcal{C}} \mathcal{S}^G_n(Y, B)$ (see corollary 4.14 of chapter VIII in [ES]). The lemma now follows by proposition 2.7 \hfill $\square$

The subspaces $X_p$ will be compact, for instance, when $X$ is Hausdorff and finite in each dimension, and $G$ is compact. In particular, theorem 8.10 applies to equivariant singular homology in this case.
