Abstract: Recently, catalytic enantioselective syntheses of N-C axially chiral compounds have been reported by many groups. Most N-C axially chiral compounds prepared through a catalytic asymmetric reaction possess carboxamide or nitrogen-containing aromatic heterocycle skeletons. On the other hand, although N-C axially chiral sulfonamide derivatives are known, their catalytic enantioselective synthesis is relatively underexplored. We found that the reaction (Tsuji–Trost allylation) of allyl acetate with secondary sulfonamides bearing a 2-arylethynyl-6-methylphenyl group on the nitrogen atom proceeds with good enantioselectivity (up to 92% ee) in the presence of (S,S)-Trost ligand-(allyl-PdCl)₂ catalyst, affording rotationally stable N-C axially chiral N-allylated sulfonamides. Furthermore, the absolute stereochemistry of the major enantiomer was determined by X-ray single crystal structural analysis and the origin of the enantioselectivity was considered.

1. Introduction

Atropisomers (N-C axially chiral compounds), owing to the rotational restriction around an N-C single bond, have recently attracted much attention [1–7]. In 2002 and 2005, we reported the enantioselective syntheses of ortho-tert-butyl anilides IA and IB through chiral Pd-catalyzed N-allylation (Tsuji–Trost allylation) and N-arylation (Buchwald–Hartwig amination), respectively (Scheme 1a) [8,9]. The N-allylation reaction shown in Scheme 1a was the first example of the catalytic asymmetric synthesis of N-C axially chiral compounds [8], although the enantioselectivity was by no means satisfactory. The enantioselectivity was significantly improved by using N-arylation instead of N-allylation, and N-arylated anilide products IB were obtained in 88–96% ee [9]. In 2010, as the first catalytic asymmetric synthesis of non-amide type N-C axially chiral compounds, we succeeded in the enantioselective construction of N-(ortho-tert-butylphenyl)-2-arylindoles II through chiral Pd(II)-catalyzed 5-endo-hydroaminocyclization of 2-alkynyl aniline derivatives (Scheme 1b) [10]. Since the publication of the reactions shown in Scheme 1a,b, N-C axially chiral compounds have been widely accepted as new target molecules for catalytic asymmetric reactions, and more than 130 original papers on their catalytic enantioselective syntheses have been published to date [2–7]. Most N-C axially chiral compounds, which have been prepared through catalytic asymmetric reactions, are carboxamide derivatives such as I or nitrogen-containing aromatic heterocycles such as II.
On the other hand, although N-C axially chiral sulfonamides are also known [11–14], their catalytic asymmetric synthesis was not reported until recently. Since some N-C axially chiral sulfonamides are pharmaceutically attractive compounds, their catalytic asymmetric synthesis is meaningful from the viewpoint of not only synthetic organic chemistry, but also medicinal chemistry. In 2019, we and Zhao et al. independently reported the catalytic asymmetric synthesis of N-C axially chiral sulfonamides IIIA and IIIB through N-allylation with a chiral Pd catalyst and a chiral organic base, respectively (Scheme 1c,d) [15,16]. The products in Scheme 1c (our reaction) were N-(ortho-mono-tert-butylphenyl)sulfonamides IIIA, which are rotationally somewhat unstable, while the products in Scheme 1d (Zhao’s reaction) were N-(2,6-disubstituted-phenyl)sulfonamides IIIB, which are rotationally relatively stable. Subsequently, other groups also succeeded in the catalytic enantioselective synthesis of N-(ortho-mono-tert-butylphenyl) and N-(2,6-disubstituted-phenyl)sulfonamides through similar or other asymmetric reactions [17–22]. We were curious about whether our method via chiral Pd-catalyzed N-allylation can also be applied to the enantioselective synthesis of N-(2,6-disubstituted-phenyl)sulfonamides.

In this article, we report the catalytic enantioselective synthesis of N-C axially chiral N-(2,6-disubstituted-phenyl)sulfonamides through the chiral Pd-catalyzed N-allylation of secondary sulfonamides (Scheme 2). It was found that N-allylation with N-(2-arylethenyl-6-methylphenyl)sulfonamides proceeded with good enantioselectivity in the presence of (S,S)-Trost ligand-(allyl-PdCl)$_2$ to give rotationally stable N-C axially chiral sulfonamides in a reasonable yield. Furthermore, the absolute stereochemistry of the major enantiomer was determined and the origin of the enantioselectivity was rationally explained.

**2. Results and Discussion**

**2.1. Survey of 2,6-Disubstituents on N-Aryl Group**

It is well known that in an allylation using a chiral $\pi$-allyl-Pd catalyst, the asymmetric induction on a nucleophile is more difficult than that on an allyl group because a
nucleophile approaches from the opposite site of the Pd atom possessing a chiral ligand (Scheme 2) [23–26]. Trost ligands are demonstrated to provide the effective chiral circumstance for a highly asymmetric induction on a prochiral nucleophile [27–29]. Indeed, in the Pd-catalyzed N-allylation with N-(ortho-tert-butylphenyl)sulfonamides (Scheme 1c), the use of other chiral ligands other than Trost ligands caused a significant decrease in enantioselectivity [15,30–32]. Hence, we explored the N-allylation of secondary sulfonamides bearing various 2,6-disubstituted-phenyl groups in the presence of Trost ligand-Pd catalysts (screening of 2,6-disubstituents, Table 1).

* (S,S)-DACH Trost ligand was used. * (S,S)-DACH naphthyl Trost ligand was used.

The reaction of allyl acetate with the anion species prepared from 4-tosyl amide 1a–i and NaH (1 equiv) in THF was conducted for 5–27 h at −20 °C in the presence of (S,S)-Trost ligand (4.4 mol%) and (allyl-Pd-Cl)<sub>2</sub> (2.2 mol%). In the N-allylation of 2-tert-butyl-6-methylphenyl derivative 1a, the chemical yield and enantioselectivity (58%, 10% ee) were significantly lowered in comparison with those (quant, 73% ee) of the ortho-mono tert-butylphenyl derivative (Entry 1). The reaction of 2-iodo-6-phenyl derivative 1b did not proceed smoothly to give N-allylation product 2b with a poor yield (10%) and low enantioselectivity (43% ee, Entry 2). Although the reaction of 2-bromo-6-phenyl derivative 1c gave the product 2c with a high yield (97%), the enantioselectivity was low (38%, Entry 3). With 2-iodo-6-methyl derivative 1d and 2-methyl-6-stylyl derivative 1e, the products 2d and 2e were obtained with high yields (94% and 91%) and moderate enantioselectivity (65% ee, Entries 4 and 5). After further screening of the ortho-substituents, it was found that N-allylation with ortho-tolylethynyl derivatives 1f–i gave relatively good results (82%–quant, 72–86% ee, Entries 6–9). In particular, with 2-methyl-6-tolylethynyl derivative 1f, a maximum enantioselectivity (86% ee) was observed (Entry 9). Attempts were made to improve the enantioselectivity using other Trost ligands possessing a cyclohexyl skeleton.
However, a decrease in the enantioselectivity or chemical yield was observed (Entries 10 and 11).

2.2. Survey of Alkynyl Substituents

Subsequently, under the same conditions, alkynyl substituents of N-(2-ethynyl-6-methylphenyl)-4-toluenesulfonylamide substrate, which gave the best result in Table 1, were explored (Table 2). Similar to 4-tolyethylene derivative 1i, the reaction with (4-methoxyphenyl)ethynyl and phenylethynyl derivatives 1j and 1k also gave N-allylated products 2j and 2k with high yields (98 and 92%) and good enantioselectivities (88 and 89% ee, Entries 2 and 3). On the other hand, in the reaction with trimethylsilylethynyl and hexynyl derivatives 1l and 1m, a considerable decrease in the enantioselectivity was observed. In these cases, the products 2l and 2m were obtained in 75 and 77% ee, respectively (Entries 4 and 5).

2.3. Survey of Sulfonyl Substituents

The substituent effect on the sulfonyl group was further explored by using N-(2-arylethynyl-6-methylphenyl)sulfonamide substrates (Table 3).

The present reactions proceeded smoothly regardless of the electronic effect of the para-substituent on the benzenesulfonyl group, affording N-allylation products 2n–q with high yields (88%–quant) and good enantioselectivities (85–92% ee, Entries 2–5). With
benzenesulfonyl amides 1o,p bearing an electron-withdrawing substituent such as a nitro group, a slight increase in enantioselectivity was observed (89 and 92% ee, Entries 3 and 4). The reaction of methanesulfonyl amides 1r also gave the product 2r with a good enantioselectivity (87% ee, Entry 6). On the other hand, in the reaction with bulky 2,4,6-trimethylphenylsulfone amide 1s, the enantioselectivity was considerably lowered (63% ee, Entry 7).

2.4. Absolute Stereochemistry and Origin of Enantioselectivity

The absolute stereochemistry of the major enantiomer was determined to be (P)-configuration by X-ray single crystal structural analysis of 2o (Figure 1) with the flack parameter 0.02(6) [33,34]. Although the absolute stereochemistries of other ortho-ethyl sulfonylamides 2f–s were not determined exactly, the major enantiomers of 2f–s (+61.5–196.7°), which have large positive [α]D values such as 2o (+201°), were also predicted to possess the (P)-configuration (only methanesulfonylamide 2r showed a small positive [α]D value = +7.7°). Moreover, in the previously reported reaction of N-(ortho-mono-tert-butylphenyl)sulfonylamides using (S,S)-Trost ligand (Scheme 1c), since the N-allylated products IIIA possessing (P)-configuration were obtained as the major enantiomer, the ethynyl group is expected to act as a bulky substituent in a similar way to the tert-butyl group.

The (P)-selectivity in the present reaction may be rationalized on the basis of a working model proposed by Trost (Figure 2) [35,36]. Among four possible transition states TS-A–D in the reaction with (S,S)-Trost ligand, TS-B and TS-C should be significantly destabilized because of the strong steric repulsion between the ortho-ethyl sulfonylamido or ortho-methyl group and Ph (wall) group (green color) on the phosphorus atom. TS-D may also not be favorable, due to the strong repulsion between the ortho-ethyl sulfonylamido and Ph (wall) group (blue color). As a result, the reaction preferentially proceeds via TS-A, leading to (P)-2 as a major enantiomer. In other 2,6-disubstituted phenyl derivatives 1a–e except for ortho-ethyl sulfonylamido derivatives, the reaction may proceed via TS-D as well as TS-A, resulting in the decrease in enantioselectivity. Since a linear ortho-aryl ethynyl group brings about the considerable steric interaction with Ph (wall) groups (blue color) on the back side in TS-D, the reaction via TS-D may be disfavored, resulting in a good enantioselectivity. With a substrate 1s bearing a bulky sulfonyl group (R1 = 2,4,6-Me3C6H2), the destabilization in TS-A may be caused by the steric repulsion between the Ph (wall) group on the front side and R1 substituent, leading to the decrease in the enantioselectivity (Table 3, Entry 7).
2.5. Rotational Stability of Sulfonamide Products

The rotational barriers of N-(ortho-mono-tert-butylphenyl)sulfonamide derivatives III\textsubscript{Ar} and III\textsubscript{As}, which were previously reported, were 25.2 and 25.5 kcal mol\textsuperscript{-1} at 298 K, respectively (Figure 3), and the ee of III\textsubscript{Ar} and III\textsubscript{As} decreased gradually at rt in CCl\textsubscript{4} ($t_{1/2}$ at 298K = 1.9 and 3.6 days). On the other hand, in N-(2-arylethynyl-6-methylphenyl)sulfonamide products 2\textsubscript{r} and 2\textsubscript{i}, the decrease in the ee was not observed even after standing for a few days at rt in CCl\textsubscript{4}. The barrier values of 2\textsubscript{r} and 2\textsubscript{i} were evaluated to be 28.3 and 28.7 kcal mol\textsuperscript{-1} at 333 K, which are ca. 3 kcal mol\textsuperscript{-1} higher than those of III\textsubscript{Ar} and III\textsubscript{As}.

**Figure 2.** Origin of enantioselectivity in N-allylation with (S,S)-Trost ligand.

**Figure 3.** Rotational stability of several sulfonamides bearing ortho-substituents.

In N-allyl-N-(2-(4-tolyl)ethynyl)phenyl sulfonamide 3 bearing no methyl group at the other ortho-position, the enantiomers could not be separated through a chiral HPLC method because of the rotationally unstable structure. Indeed, two allylic hydrogens (Ha and Hb) in III \textsubscript{Ar} and 2 were detected as nonequivalent signals in the $^1H$ NMR, while those in 3 showed an equivalent NMR signal, which suggests the quick rotation around the N-Ar bond at the NMR time scale (Supplementary Materials).

2.6. Application to Enantioselective Double N-Alllylation

Since N-allyl-N-(2,6-disubstituted-phenyl)sulfonamide products 2 were revealed to be rotationally stable at rt, we further investigated the enantioselective construction of two N-C chiral axes through a double N-allylation with bis-sulfonamide substrate (Scheme 3).
In the presence of an achiral Pd catalyst, the double N-allylation with N-(2-bromo-6-tolyethynylphenyl)bis-sulfonamide 4 proceeds smoothly to give a 1:1 mixture of diastereomeric double allylation products chiral-5 and meso-5 (82% yield). The stereochemistry of both diastereomers was determined by chiral HPLC method. That is, the HPLC of one diastereomer (chiral-5) using a CHIRALPAK AD-H column gave two peaks corresponding to enantiomers, while for the other diastereomer (meso-5), the enantiomer separation by chiral HPLC was not observed. No isomerization between chiral-5 and meso-5 was detected even after standing for a several days at rt.

Scheme 3. Enantioselective double N-allylation with bis-sulfonamide substrate 4.

Subsequently, the enantioselective double N-allylation with 4 was conducted at −20 °C in the presence of (S,S)-Trost ligand-Pd catalyst. In this case, the double N-allylated products chiral-5 and meso-5 were obtained in a diastereomer ratio of 3.1:1 (88% yield). After the removal of meso-5 via MPLC separation, the optical purity of the obtained chiral-5 was found to be 99% ee. Since no the diastereoselectivity was observed at all under the achiral reaction conditions, it is obvious that the chiral axis constructed in the first N-allylation does not influence asymmetric induction in the second N-allylation (the stereoselectivity is only determined by the chiral catalyst).

The significantly high optical purity of double N-allylation product chiral-5 in comparison with mono-N-allylation products 2 (for example, 2g: 72% ee, Entry 7 in Table 1) can be rationally explained on the basis of the Horeau principle [37–39]. The product distributions (the enantiomeric excess and diastereomer ratio) in double asymmetric reactions are represented in Equations A and B (Scheme 4). When the ee (72% ee, x = 0.86) of 2-bromo-6-arylethynyl derivative 2g is used as the value (x) for the first asymmetric induction in Scheme 3, the ee of chiral-5 and the diastereomer ratio were calculated to be 95% and 3.2, respectively, which are similar to the experimental values (99% ee and dr = 3.1). Thus, it was revealed that bis-sulfonamide bearing two N-C chiral axes is obtained in a high optical purity through an asymmetric double N-allylation.

3. Materials and Methods

3.1. General Information

Melting points were uncorrected. $^1$H and $^{13}$C NMR spectra were recorded on a 400 MHz spectrometer. In $^1$H and $^{13}$C NMR spectra, chemical shifts were expressed in δ (ppm) downfield from CHCl$_3$ (7.26 ppm) and CDCl$_3$ (77.0 ppm), respectively. HRMS were recorded on a double-focusing magnetic sector mass spectrometer using electron impact ionization. Column chromatography was performed on silica gel (75–150 μm). Medium-pressure liquid chromatography (MPLC) was performed on a 25 × 4 cm i.d. prepacked column (silica gel, 10 μm) with a UV detector. Column chromatography was performed on silica gel (7 μm) with concentrations reported in g/100 mL. Melting points were uncorrected.

In accordance with the experimental procedure for the synthesis of 2c, 2s was prepared from 1s (125 mg, 0.3 mmol). The reaction was conducted for 23 h at −20 °C. Purification of the residue by column chromatography (hexane/AcOEt = 30) gave 2s (117 mg, 85%). The ee (63% ee) of 2s was determined by HPLC analysis using a chiral column (CHIRALCEL OD-3) (25 cm × 0.46 cm i.d.; 1% i-ProOH in hexane; flow rate, 0.8 mL/min; (−)-2s (major); tr = 13.2 min, (−)-2s (minor); tr = 10.1 min). 2s: white solid; mp 171–172 °C (62% ee); IR (neat) 2212, 1337, 1155 cm−1; [α]D = +155.4° (62% ee, CHCl3, c = 1.00); 1H NMR (400 MHz, CDCl3) δ: 7.14 (1H, d, J = 2.4 Hz), 7.05–7.08 (3H, m), 7.02 (2H, d, J = 8.5 Hz), 6.73 (2H, s), 6.00 (1H, dddd, J = 17.1, 10.0, 8.5, 5.7 Hz), 5.07 (1H, dd, J = 17.1, 1.4 Hz), 5.04 (1H, d, J = 10.0 Hz), 4.63 (1H, ddt, J = 14.2, 5.7, 1.4 Hz), 4.42 (1H, dd, J = 14.2, 8.5 Hz), 2.44 (6H, s), 2.40 (3H, s), 2.36 (3H, s), 2.29 (3H, s), 2.09 (3H, s); 13C{1H} NMR (100 MHz, CDCl3) δ: 141.5, 141.1, 139.5, 138.3, 137.7, 136.0, 135.8, 133.3, 132.2, 132.1, 131.6, 128.7, 124.4, 119.9, 119.0, 93.2, 86.6, 53.1, 24.2, 21.5, 20.8, 20.7, 19.6; MS (ESI-TOF) m/z: [M + Na]+ 480; HRMS (ESI-TOF) m/z: [M + Na]+ Calcd for C21H21NNaO2S 480.1973; Found 480.1960.

N-(2-(p-Tolylethynyl)phenyl)-4-methylbenzenesulfonamide (6). In accordance with the experimental procedure for the synthesis of 1b, 6 was prepared from 2-(4-tolylethynyl)-4-methylaniline (558 mg, 2.7 mmol, commercially available) and 4-tosyl chloride (567 mg, 2.7 mmol; calcd for C21H19NNaO2S 480.1973; Found 480.1960.

N-Allyl-N-(2-(p-tolylethynyl)phenyl)-4-methylbenzenesulfonamide (3). In accordance with the experimental procedure for the synthesis of 2c, 3 was prepared from 6 (109 mg, 0.3 mmol). The reaction was conducted for 20 h at −20 °C. Purification of the residue by column chromatography (hexane/AcOEt = 20) gave 3 (150 mg, quant). 3: white solid; mp 66–69 °C; IR (neat) 2214, 1344, 1159 cm−1; 1H NMR (400 MHz, CDCl3) δ: 7.64 (2H, d, J = 8.5 Hz), 7.48 (1H, m), 7.27–7.34 (3H, m), 7.09–7.17 (6H, m), 5.87 (1H, ddt, J = 17.1, 10.0, 6.6 Hz), 5.10 (1H, dd, J = 17.1, 0.9 Hz), 5.05 (1H, dd, J = 10.0, 0.9 Hz), 4.38 (2H, d, J = 6.6 Hz), 2.38 (3H, s), 2.23 (3H, s); 13C{1H} NMR (100 MHz, CDCl3) δ: 143.1, 139.6, 138.7,
In accordance with the experimental procedure for the synthesis of 1b, 4 was prepared from 2-bromo-4-methyl-6-(4-tolylenyl)aniline (1.694 g, 5.6 mmol) and benzene-1,3-disulfonyl chloride (704 mg, 2.6 mmol). Purification of the residue by column chromatography (hexane/AcOEt = 10) gave the mixture of meso-1 and chiral-2 (241 mg, 0.088 mmol) and allyl acetate (194 µmol, 0.02 mmol). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html (accessed on 1 October 2022).

Refinement and further calculations were carried out using SHELXL [43]. The chiral crystal (P)-2o (CCDC 2210583) shows the correct absolute structure and the flack parameter is 0.02(6). 4. Conclusions

We found that the N-allylation of secondary sulfonamides bearing a 2-ethynyl-6-methylphenyl group on the nitrogen atom proceeds with good enantioselectivity in the presence of (S,S)-Trost ligand-(allyl-PdCl) 2 catalyst, giving optically active N-C axially chiral N-allylated sulfonamides with good yields. The N-C axially chiral sulfonamide products were also revealed to possess relatively high rotational barriers and can be handled without a decrease in the ee at room temperature. Furthermore, the absolute stereochemistry of the major enantiomer was determined by X-ray single crystal structural analysis and the origin of the enantioselectivity was rationally explained on the basis of a working model by Trost.

In addition, the double N-allylation with bis-sulfonamide substrate gave a N-allylated product with two N-C chiral axes in a high optical purity.
