Variation of mixed Hodge structures and the positivity for algebraic fiber spaces

Yujiro Kawamata

August 10, 2010

Abstract

These are the lecture notes based on earlier papers with some additional new results. New and simple proofs are given for local freeness theorem and the semipositivity theorem. A decomposition theorem for higher direct images of dualizing sheaves of Kollár is extended to the sheaves of differential forms of arbitrary degrees in the case of a well prepared birational model. We will also prove the log versions of the results, i.e., the case where we allow horizontal boundary components.

These are the lecture notes of a mini-course given at Institut Henri Poincaré for the thematic term “Complex Algebraic Geometry” in May 2010. The author would like to thank the organizers Olivier Debarre, Christoph Sorger and Claire Voisin.

This is based on my papers [8] and [9] with some additional new results. New and simple proofs are given for local freeness theorem (proved in [7] in the case of the direct image sheaf and in [11] and [12] in the general case), and thereby the semipositivity theorem [7]. A decomposition theorem for higher direct images of dualizing sheaves of Kollár [11] is extended to the sheaves of differential forms of arbitrary degrees in the case of a well prepared birational model. We will also prove the log versions of the results, i.e., the case where we allow horizontal boundary components. We note that we have to consider differential forms of all degrees in order to use to the full power of the Hodge theory.

An algebraic fiber space is the relative version of an algebraic variety. A good birational model of an algebraic variety is a smooth model. The corresponding good model of an algebraic fiber space is a weak semistable model
found by Abramovich and Karu [1]. A well prepared model is a birational model which satisfies the same conditions as a weak semistable model except that all the fibers are reduced. One can obtain a weak semistable model from a well prepared model by a finite and flat base change.

From a well prepared model, we shall construct a good topological model by applying a method of log geometry ([5]). We associate a topological space $X^{\log}$, called a log space, to a log pair $(X, B)$ consisting of a complex analytic variety with a boundary divisor. The log space $X^{\log}$ can be regarded as a compactification of the open space $X \setminus B$. It is a real analytic manifold with boundary and corners. This compactification is homeomorphic to a closed subset of $X \setminus B$, the complement of a tubular neighborhood of $B$. But because we have points of the log space $X^{\log}$ above the boundary divisor $B$, a complicated limiting argument becomes unnecessary in the proofs of our results. For example, the monodromy actions around the singular fibers become very easily handled on the log space, because the singularities of degenerate fibers disappear in this topological model, and the fibers over the boundary have stratifications.

We define the structure sheaf of a log space in a way that it contains the logarithms of local coordinates, and then the sheaves of differential forms that they contain logarithmic differentials. We prove our main result on the existence of a cohomological mixed Hodge complex on any fiber, a concept defined by Deligne [3]. As corollaries, we obtain $E_1$ and $E_2$ degenerations of spectral sequences with respect to the Hodge and weight filtrations respectively. The decomposition theorem is obtained as a corollary of the semi-simplicity theorem for the variations of polarized pure Hodge structures and the $E_2$ degeneration theorem. For the proof of the main results, we shall treat the weak semistable case first. The general case follows easily by the flat base change theorem.

The construction of this paper is as follows. We recall some preliminary results in §§1 to 5, the weak semistable reduction theorem of Abramovich and Karu in §1, the construction of a topological space associated to a log scheme in §2, a criteria for the decomposition of an object in a derived category due to Deligne in §3, the definitions related to the cohomological mixed Hodge complex due also to Deligne in §4, and the Griffiths positivity theorem and the semi-simplicity theorem of the category of variations of polarized Hodge structures in §5.

We shall prove our results in §§6 to 8 on the existence of a mixed Hodge complex. We shall construct weight filtrations on the sheaves on the log
spaces in §6. In order to compare the weight filtrations on the topological level and the De Rham level, we introduce the sheaves of differential forms in §7 and prove Poincaré lemmas. Our construction is justified in §8 that the weight filtration and the Hodge filtration defined on a singular fiber define a cohomological mixed Hodge complex. The degenerations of spectral sequences follow from the general machinery explained in §4. The local freeness follows as a corollary.

In §9 we prove the semipositivity theorem. First we treat the case where the fiber space is weakly semistable and there is no horizontal boundary components following [7]. This is a consequence of the Griffiths positivity theorem for the open part and the boundary considerations. Then the theorem is extended to the case of a well prepared fiber space which may have horizontal boundary components.

We prove the decomposition theorem in the final §10 for the higher direct images of the constant sheaf and the sheaf of logarithmic differential forms. We use an argument concerning convolutions in a triangulated category. The theorem is a consequence of the $E_2$-degeneration of the spectral sequence associated to the weight filtration.

We work over $\mathbb{C}$ in this paper. The topology of an algebraic variety we consider is the analytic topology of the underlying complex analytic space.

1 Weak semistable reduction

We recall a weak semistable reduction theorem of Abramovich and Karu [1]. A general reference for toroidal varieties is [10].

A toroidal variety $(X, B)$ is a pair consisting of a normal variety and an effective reduced divisor such that each point $x \in X$ has a toric local model in the following sense: there is an complex analytic neighborhood $x \in U$ such that the pair $(U, B|_U)$ is complex analytically isomorphic to another pair $(U', B'|_U)$ which comes from a toric variety $(X', B')$, a normal variety with an action of an algebraic torus $X' \setminus B'$. We assume moreover that the pair is strict or without self-intersection in the sense that each irreducible component of $B$ is normal.

A toroidal variety $(X, B)$ is said to be smooth if $X$ is smooth and $B$ has only normal crossings. It is quasi-smooth if there exists a local toric model of each point which has only abelian quotient singularities.

A toroidal morphism $f : (X, B) \to (Y, C)$ between toroidal varieties is
one which has a toric local model at each point \( x \in X \) in the following sense: there is a toric morphism between local models \( f' : (X', B') \to (Y', C') \), i.e., \( f'|_{X' \setminus B'} : X' \setminus B' \to Y' \setminus C' \) is a surjective homomorphism of algebraic tori, and \( f' \) is equivariant under the torus actions.

A toric model at each point \( x \in X \) is described by a rational polyhedral closed convex cone \( \sigma_x \) in a finite dimensional real vector space with an integral lattice. By gluing these cones, we construct a fan \( \Delta_{X,B} \). Unlike the toric case, the fan is not embedded in a fixed real vector space, and the pair \((X, B)\) cannot be reconstructed from the fan. But the local structure of the pair as well as its birational modifications are completely described by the fan.

The pair \((X, B)\) is quasi-smooth if and only if each cone \( \sigma_x \) is simplicial, and smooth if and only if in addition that the lattice points on the edges of the cone generate a saturated subgroup of the lattice. A rational subdivision of the fan corresponds to a birational modification.

**Example 1.** Let \( f : (X, B) \to (Y, C) \) be a toroidal morphism between smooth toroidal varieties. Take an arbitrary point \( x \in X \) and its image \( y = f(x) \). Then there exist local coordinates \((x_1, \ldots, x_n)\) and \((y_1, \ldots, y_m)\) around \( x \) and \( y \) respectively such that we can write \( f^* y_i = \prod_j x_{r_{ij}}^j \), where the \( r_{ij} \) are non-negative integers such that \( r_{ij} \neq 0 \) for at most one \( i \) for each \( j \).

More generally, if \((X, B)\) is a quasi-smooth variety instead of a smooth one, then there is an analytic neighborhood \( U \subset X \) of the given point \( x \in X \) and a finite Galois toroidal covering \( \pi : (X', B') \to (U, B|_U) \) from a smooth toroidal variety with a point \( x' \in X' \) such that \( \pi(x') = x \). There exist local coordinates \((x'_1, \ldots, x'_n)\) around \( x' \in X \) which are semi-invariant with respect to the Galois action. Therefore we have a similar local expression also in this case.

The following theorem of Abramovich and Karu gives a well prepared birational model of an algebraic fiber space:

**Theorem 2** ([1]). Let \( f_0 : X_0 \to Y_0 \) be a surjective morphism of projective varieties with geometrically connected fibers defined over a field of characteristic zero, and \( Z \) a closed subset of \( X_0 \). Then there exist a quasi-smooth projective toroidal variety \((X, B)\), a smooth projective toroidal variety \((Y, C)\), a projective morphism \( f : X \to Y \) with geometrically connected fibers, and projective birational morphisms \( \mu_X : X \to X_0 \), \( \mu_Y : Y \to Y_0 \) such that \( \mu_Y \circ f = f_0 \circ \mu_X \) and which satisfy the following conditions:
(1) $f : (X, B) \to (Y, C)$ is a toroidal morphism.
(2) All the fibers of $f$ have the same dimension.
(3) $\mu_X^{-1}(Z) \subset B$.

Moreover there exists another smooth projective toroidal variety $(Y', C')$ and a finite surjective morphism $\pi : Y' \to Y$ such that $C' = \pi^{-1}(C)$, and satisfy the following condition:

(4) The induced morphism $f' : (X', B') \to (Y', C')$ for the normalization $(X', B')$ of the fiber product $(X, B) \times_Y Y'$ is still a toroidal morphism from a quasi-smooth projective toroidal variety to a smooth projective toroidal variety, such that all the fibers of $f'$ are reduced.

We note that the covering morphism $\pi$ is flat because $Y$ is smooth. The discriminant locus of $\pi$ is a normal crossing divisor which properly contains $C$. Therefore $\pi$ is not necessarily a toroidal morphism.

**Idea of proof.** The proof is based on the idea of De Jong’s alteration. Because of the assumption on the characteristic of the base field, the ramification theory is simple and the singularities can be resolved.

First we prove the existence of a birational model of $f_0 : X_0 \to Y_0$ which is a toroidal morphism between smooth toroidal varieties. We proceed by induction on the relative dimension $\dim X_0 - \dim Y_0$. By using the generic projection, we decompose the morphism $f_0$ to two morphisms $g : X_0 \to X_1$ and $h : X_1 \to Y_0$ such that $\dim X_0 = \dim X_1 + 1$, and set $Z_1 = \emptyset$. We replace a birational model of $h : X_1 \to Y_0$ by the induction assumption, while we prepare the morphism $g : X_0 \to X_1$ by the semistable reduction using the moduli space of pointed curves.

Secondly we modify the toroidal model by using the fans associated to the toroidal structure. The morphism becomes equi-dimensional when we subdivide the fans $\Delta_X$ and $\Delta_Y$ of $X$ and $Y$ so that the images of 1-dimensional cones in $\Delta_X$ become 1-dimensional cones in $\Delta_Y$. In order to make the fibers reduced, we apply the covering trick in [7].

We call the morphism $f : (X, B) \to (Y, C)$ a well prepared birational model of an algebraic fiber space $f_0 : X_0 \to Y_0$, and its finite base change $f' : (X', B') \to (Y', C')$ a weak semistable model. The latter is “weak” because the pair $(X', B')$ has some mild singularities, i.e., abelian quotient singularities. But these singularities cause no trouble as explained in the later sections.
2 Log space

The idea of the real oriented blowing-ups of the (quasi-)smooth toroidal pairs and the application to semistable degenerations of varieties can go back at least to a book [13]. A general reference of this section is [5] and [6].

A log scheme \((X, M, \alpha)\) consists of a scheme \(X\), a sheaf of semi-groups with unit \(M\), and a semi-group homomorphism \(\alpha : M \to \mathcal{O}_X\) such that \(\alpha^{-1}(\mathcal{O}_X^*) \cong \mathcal{O}_X^*\), where the semi-group structure of \(\mathcal{O}_X\) is given by the multiplication.

A morphism of log schemes \((f, \phi) : (X, M, \alpha) \to (Y, N, \beta)\) consists of a morphism of schemes \(f : X \to Y\) and a semi-group homomorphism \(\phi : f^{-1}N \to M\) such that \(\alpha \circ \phi = f^* \circ f^{-1} \beta\).

**Example 3.** (1) Let \(T = \text{Spec} \mathbb{C}\), and \(M_T = \mathbb{R}_{\geq 0} \times S^1\). We define \(\alpha_T : M_T \to \mathbb{C}\) by \(\alpha_T(r, \theta) = re^{i\theta}\). Then \((T, M_T, \alpha_T)\) is a log scheme.

(2) If \((X, B)\) is a toroidal variety, then the subsheaf of \(\mathcal{O}_X\) given by
\[M = \{h \in \mathcal{O}_X \mid h|_{X \setminus B} \in \mathcal{O}_X^*\}\]
defines a log structure on \(X\).

Let \((X, M, \alpha)\) be a log scheme defined over \(\mathbb{C}\). We define the associated log space \(X^{\log}\) to be the set of all log morphisms \((f, \phi) : (T, M_T, \alpha_T) \to (X, M, \alpha)\) from the log scheme defined in the above example. Let \(\rho : X^{\log} \to X\) be the natural map defined by \(\rho(f, \phi) = \text{Im}(f)\).

**Example 4.** If \((X, B) = (\mathbb{C}, 0)\), then \(X^{\log} = \mathbb{R}_{\geq 0} \times S^1\) and \(\rho(r, \theta) = re^{i\theta}\).

Indeed let \(t\) be a coordinate on \(X\) and assume that \(f(T) = t_0\). If \(t_0 \neq 0\), then the image of \(t \in M_X\) is uniquely determined. If \(t_0 = 0\), then the image of \(t\) is of the form \((0, \theta)\).

If \((X, B)\) is a quasi-smooth toroidal variety, then the set \(X^{\log}\) has a structure of a manifold with boundary and corners as shown in the following proposition. It is a kind of a compactification of the open variety \(X \setminus B\):

**Proposition 5.** Let \((X, B)\) be a quasi-smooth toroidal variety. Then the following hold:

(1) The associated log space \(X^{\log}\) has a structure of a real analytic manifold with boundary and corners, and \(\rho : X^{\log} \to X\) is a proper continuous map of topological spaces.
The complex manifold \( X \setminus B \) is homeomorphic to a dense open subset of \( X^{\log} \). There is a small analytic open neighborhood \( U \) of \( B \subset X \) such that \( X \setminus U \) is homeomorphic to \( X^{\log} \).

**Proof.** (1) If \((X, B) = (X_1 \times X_2, p_1^*B_1 + p_2^*B_2)\) for smooth toroidal varieties \((X_i, B_i)\) with associated log spaces \(X_i^{\log}\) for \(i = 1, 2\), then we have \(X^{\log} \cong X_1^{\log} \times X_2^{\log}\) and \(\rho \cong \rho_1 \times \rho_2\).

If \((X, B)\) is a quotient of a smooth toroidal variety \((X', B')\) by a finite abelian group \(G\) acting on \(X'\) leaving \(B'\) preserved, then the associated log space \(X^{\log}\) is the quotient of \((X')^{\log}\) by the induced group action of \(G\) which is fixed point free.

Since \((X, B)\) is covered by standard open subsets as above and the set \(X^{\log}\) is globally defined, the log spaces associated to this covering are glued to yield a manifold with boundary and corners.

(2) This is because the map \(\rho\) induces a bijection \(\rho^{-1}(X \setminus B) \to X \setminus B\). \(\Box\)

**Corollary 6.** Let \(f : (X, B) \to (Y, C)\) be a well prepared toroidal morphism. Then the associated morphism of log spaces \(f^{\log} : X^{\log} \to Y^{\log}\) is a locally trivial topological fiber bundle. In particular, the higher direct image sheaves \(R^p f_* \mathbb{Z}_X^{\log}\) are locally constant sheaves on \(Y^{\log}\).

**Proof.** It follows from the fact that the induced morphism \(f : X \setminus B \to Y \setminus C\) is a locally trivial topological fiber bundle. \(\Box\)

The important advantage of \(X^{\log}\) over \(X \setminus B\) is that the geometric objects are extended over the singular fibers so that we do not need limiting argument.

### 3 Criteria for decompositions

We recall Deligne’s criteria for an object of a derived category to be decomposed into its cohomology groups.

**Proposition 7 ([2]).** Let \(x \in D^b(A)\) be an object of a bounded derived category of an abelian category \(A\). Then the following conditions are equivalent:

1. \(x \cong \bigoplus_i H^i(x)[-i] \) in \(D^b(A)\).
2. For an arbitrary exact functor \(T : D^b(A) \to D(B)\) to the derived category of an arbitrary abelian category \(B\), the Grothendieck-Verdier spectral sequence

\[
E_2^{p,q} = H^p(T(H^q(x))) \Rightarrow H^{p+q}(T(x))
\]
degenerate at $E_2$.

Proof. The condition (1) implies that $H^k(T(x)) \cong \bigoplus_{i+j=k} H^i(T(H^j(x)))$, hence (2).

We prove the converse (2) $\implies$ (1). Let $T(y) = \bigoplus_j \text{Hom}(H^i(x), y[j])[-j] \in D(\mathbb{Z}\text{-mod})$ for a fixed $i$. By assumption, the spectral sequence

$$E_2^{p,q} = \text{Hom}(H^i(x), H^q(x)[p]) \Rightarrow \text{Hom}(H^i(x), x[p+q])$$

degenerate at $E_2$. In particular, the edge homomorphism $E_\infty^i \to E_2^{0,i}$ given by

$$\text{Hom}(H^i(x), x[i]) \to \text{Hom}(H^i(x), H^i(x))$$

is surjective. Let $f_i : H^i(x)[-i] \to x$ be an arbitrary morphism which is mapped to the identity morphism of $H^i(x)[-i]$. Then the sum $\bigoplus_i f_i : \bigoplus_i H^i(x)[-i] \to x$ is a quasi-isomorphism. \hfill $\square$

**Theorem 8** ([2]). Let $x \in D^b(A)$ be an object of a bounded derived category of an abelian category $A$, $u \in \text{Hom}(x, x[2])$, and $n$ an integer. Assume that the induced morphisms $u^i : H^{n-i}(x) \to H^{n+i}(x)$ are isomorphisms for all $i \geq 0$. Then $x \cong \bigoplus_i H^i(x)[-i]$ in $D^b(A)$.

Proof. We define primitive parts of $H^{n-i}(x)$ for $i \geq 0$ by

$$0 H^{n-i}(x) = \text{Ker}(u^{i+1} : H^{n-i}(x) \to H^{n+i+2}(x)).$$

Then we have a Lefschetz decomposition

$$H^{n-i}(x) \cong \bigoplus_{k \geq 0} u^k 0 H^{n-i-2k}(x)$$

$$H^{n+i}(x) \cong \bigoplus_{k \geq 0} u^{k+i} 0 H^{n-i-2k}(x).$$

Let $T : D^b(A) \to D(B)$ be an arbitrary exact functor, and

$$E_2^{p,q} = \text{Hom}(T(H^q(x)))) \Rightarrow \text{Hom}(T(x))$$

be the spectral sequence. We shall prove that the differentials $u^r_{p,q} : E_r^{p,q} \to E_r^{p+r,q-r+1}$ vanish for all $r \geq 2$ by induction on $r$. Assume that we already
have $E_{2}^{p,q} \cong E_{r}^{p,q}$. Denote $0_{E_{r}^{p,q}} = 0_{E_{2}^{p,q}} = H_{r}^{p}(T(0H^{q}(x)))$. We have the following commutative diagram

\[
\begin{array}{ccc}
0_{E_{r}^{p,n-i}} & \xrightarrow{d_{r}^{p,n-i}} & E_{r}^{p+r,n-i-r+1} \\
\downarrow u^{i+1} & & \downarrow u^{i+1} \\
E_{r}^{p,n+i+2} & \xrightarrow{d_{r}^{p,n+i+2}} & E_{r}^{p+r,n+i-r+3}
\end{array}
\]

The left vertical arrow vanishes while the right vertical arrow is a monomorphism since $r \geq 2$. Therefore $d_{r}^{p,n-i}$ vanishes on $0_{E_{r}^{p,n-i}}$. Since $u^{k}d_{r}^{p,n-i} = d_{r}^{p,n-i+2k}u^{k}$, we have $d_{r}^{p,q} = 0$ for all $p,q$.

\[\Box\]

4 Hodge structure and Hodge complex

We recall the definitions concerning Hodge structures and Hodge complexes. The reference is [3].

A Hodge structure (HS) of weight $n$ is a pair $(H_{Z}, F)$, where $H_{Z}$ is a finitely generated $Z$-module and $F$ is a decreasing filtration on $H_{C} = H_{Z} \otimes C$ which induces a direct sum decomposition

\[H_{C} = \bigoplus_{p+q=n} F^{p}(H_{C}) \cap \overline{F^{q}(H_{C})}.\]

$F$ is called a Hodge filtration. We set $H^{p,q} = F^{p}(H_{C}) \cap \overline{F^{q}(H_{C})}$.

It is said to be polarizable if there is a non-degenerate bilinear form $Q : H_{R} \times H_{R} \to R$ for $R = H_{Z} \otimes R$ such that the following Hodge-Riemann index theorem holds:

\[i^{w}(-1)^{q+1}Q(H^{p,q}, \overline{H^{p,q}}) \gg 0\]

\[Q(H^{p,q}, \overline{H^{p',q'}}) = 0 \text{ if } p \neq p'\]

for all $p + q = p' + q' = n$.

A mixed Hodge structure (MHS) is a triple consisting of a finitely generated $Z$-module $H_{Z}$, an increasing filtration $W$ on $H_{Q} = H_{Z} \otimes Q$, and a decreasing filtration $F$ on $H_{C} = H_{Z} \otimes C$ such that $(\text{Gr}_{n}^{W}(H_{Q}), F)$ becomes a Hodge $Q$-structure of weight $n$, a Hodge structure tensorized by $Q$, where $F$ denotes the induced filtration from $F$ by abuse of notation.

$W$ is called a weight filtration. It is graded polarizable if each graded piece $\text{Gr}_{n}^{W}(H_{Q})$ is individually polarizable.
Example 9. Let $X$ be a smooth projective variety of dimension $n$. Then the cohomology group $H^k(X, \mathbb{Z})$ carries a Hodge structure of weight $k$. If we take its primitive part, then we obtain a polarizable Hodge structure as follows.

Let $L \in H^2(X, \mathbb{Z})$ be the cohomology class of an ample divisor. For each integer $i \geq 0$, the cup product with $L^i$ yields an isomorphism $L^i : H^{n-i}(X, \mathbb{Q}) \to H^{n+i}(X, \mathbb{Q})$. The primitive part $0H^{n-i}(X, \mathbb{Q}) \subset H^{n+i}(X, \mathbb{Q})$ is defined as the kernel of the homomorphism given by the cup product with $L^{i+1}$. The Lefschetz decomposition theorem says that there is a direct sum decomposition

$$H^k(X, \mathbb{Q}) = \bigoplus_{i \geq 0} L^i H^{k-2i}(X, \mathbb{Q})$$

for $k \leq n$. The Hodge-Riemann index theorem says that the primitive part $0H^k(X, \mathbb{Q})$ carries a polarizable $\mathbb{Q}$-Hodge structure of weight $k$. The polarization comes from the cup product:

$$Q(u, v) = (u \cup v \cup L^{n-k})[X]$$

for $u, v \in 0H^k(X, \mathbb{Q})$.

A Hodge complex (HC) of weight $n$ is a triple $H = (H_Z, H_C, F)$, where $H_Z \in D^+(\mathbb{Z})$ is a left bounded complex of abelian groups whose cohomology groups $H^k(H_Z)$ are of finite type, and $H_C \in D^+F(\mathbb{C})$ is a left bounded complex of $\mathbb{C}$-modules with a decreasing filtration $F$ such that the following conditions are satisfied:

1. There is an isomorphism $H_Z \otimes \mathbb{C} \cong H_C$.
2. The spectral sequence associated to the filtration $F$

$$F^pF^q = H^p_q(\text{Gr}_F^p(H_C)) \Rightarrow H^{p+q}(H_C)$$

degenerates at $E_1$.

3. The cohomology groups $H^k(H_Z)$ with the filtrations on the $H^k(H_C)$ induced from $F$ give Hodge structures of weight $n + k$ for all $k$.

If $H$ is a Hodge complex of weight $n$, then the shifted complex $H[m]$ is a Hodge complex of weight $n + m$.

A mixed Hodge complex (MHC) is a quadruple $H = (H_Z, H_C, W, F)$, where $H_Z \in D^+(\mathbb{Z})$ is a left bounded complex of abelian groups with an increasing filtration $W$ on $H_{\mathbb{Q}} = H_Z \otimes \mathbb{Q}$, and $H_C \in D^+F(\mathbb{C})$ is a left bounded
complex of $C$-modules with an increasing filtration $W$ and a decreasing filtration $F$ such that the following conditions are satisfied:

1. There is an isomorphism $(H_Q, W) \otimes C \cong (H_C, W)$.
2. $(\text{Gr}_n^W(H_Q), F)$ is a Hodge $Q$-complex of weight $n$, a Hodge complex tensorized by $Q$, where $F$ denotes the induced filtration from $F$ by abuse of notation.

Then it follows that the triple $(H^k(H_Z), W[k], F)$ is a mixed Hodge structure.

A cohomological Hodge complex (CoHC) of weight $n$ on a topological space $X$ is a triple $H = (H_Z, H_C, F)$, where $H_Z \in D^+(Z_X)$ is a left bounded complex of constructible sheaves of abelian groups on $X$, and $H_C \in D^+ F(X)$ is a left bounded complex of sheaves of $C$-modules on $X$ with a decreasing filtration $F$ such that the following conditions are satisfied:

1. There is an isomorphism $H_Z \otimes C \cong H_C$.
2. The direct image complex $R\Gamma(X, H) = (R\Gamma(X, H_Z), R\Gamma(X, H_C, F))$ is a Hodge complex of weight $n$.

A cohomological mixed Hodge complex (CoMHC) on a topological space $X$ is a quadruple $H = (H_Z, H_C, W, F)$, where $H_Z \in D^+(Z_X)$ is a left bounded complex of constructible sheaves of abelian groups on $X$ with an increasing filtration $W$ on $H_Q = H_Z \otimes Q$, and $H_C \in D^+ F_2(X)$ is a left bounded complex of sheaves of $C$-modules on $X$ with an increasing filtration $W$ and a decreasing filtration $F$ such that the following conditions are satisfied:

1. There is an isomorphism $(H_Q, W) \otimes C \cong (H_C, W)$.
2. $(\text{Gr}_n^W(H_Q), \text{Gr}_n^W(H_C), F)$ is a cohomological Hodge $Q$-complex weight $n$ on $X$.

In this case, it follows that the direct image complex

$$R\Gamma(X, H) = (R\Gamma(X, H_Z), R\Gamma(X, H_C), W, F)$$

becomes a mixed Hodge complex.

We summarize the above definitions as follows:

$$
\begin{array}{c}
\text{CoMHC} \xrightarrow{R\Gamma} \text{MHC} \xrightarrow{H^*} \text{MHS} \\
\text{Gr}_W \downarrow \quad \text{Gr}_W \downarrow \quad \text{Gr}_W \downarrow
\end{array}
$$

$$
\begin{array}{c}
\text{CoHC} \xrightarrow{R\Gamma} \text{HC} \xrightarrow{H^*} \text{HS} \\
\end{array}
$$

**Example 10.** Let $X$ be a smooth projective variety, $B$ a normal crossing divisor, and $i: X \setminus B \to X$ the open immersion. Then the direct image sheaf
$H = R\iota_* Z_{X \setminus B}$ carries a structure of a cohomological mixed Hodge complex. We can also write $H = R\rho_* Z_{X^{\log}}$ for the real oriented blow-up $\rho : X^{\log} \to X$.

The weight filtration on $H_\mathbb{Q}$ on the $\mathbb{Q}$-level is given by the canonical filtration

$$W_q(H_\mathbb{Q}) = \tau_{\leq q}(R\iota_* Z_{X \setminus B})$$

where the truncation $\tau_{\leq q}(K^\bullet)$ of a complex $K^\bullet$ is defined by

$$\tau_{\leq q}(K^\bullet)_i = \begin{cases} K_i & \text{if } i < q \\ \text{Ker}(K_q \to K_{q+1}) & \text{if } i = q \\ 0 & \text{if } i > q. \end{cases}$$

The $\mathbb{C}$-level complex is given by the sheaves of logarithmic differential forms $H_\mathbb{C} = \Omega^\bullet_X(\log B)$. We have a quasi isomorphism

$$R\iota_* \mathcal{C}_{X \setminus B} \cong \Omega^\bullet_X(\log B)$$

by the Poincaré lemma. The weight filtration $W$ on the $\mathbb{C}$-level is given by the order of log poles; $W_q(H_\mathbb{C})$ is a complex consisting of differential forms whose log poles have order at most $q$. The residue homomorphisms give an isomorphism of filtered complexes

$$(H_\mathbb{Q}, W) \otimes \mathbb{C} \cong (H_\mathbb{C}, W).$$

The Hodge filtration is given by the stupid filtration:

$$F^p(H_\mathbb{C}) = \Omega^\geq_p(\log B).$$

For each non-negative integer $t$, let $B^{[t]}$ be the disjoint union of the irreducible components of intersections of $t$ different irreducible components of $B$. We regard $B^{[0]} = X$, and $B^{[1]}$ is the normalization of $B$. $B^{[t]}$ is dim $X - t$ equi-dimensional. The following isomorphisms given by the residue homomorphisms are fundamental:

$$\text{Gr}_q^W(\Omega^\bullet_X(\log B)) \cong \Omega^\bullet_{B^{[q]}}[-q]$$
$$F^p(\text{Gr}_q^W(\Omega^\bullet_X(\log B))) \cong \Omega^{\geq p-q}_{B^{[q]}}[-q].$$

We denote by $F(-q)$ the shifted filtration defined by $F(-q)^p = F^{p-q}$. Then the triple

$$(\mathcal{Z}_{B^{[q]}}, \Omega^\bullet_{B^{[q]}}, F(-q)[-q])$$
is a cohomological Hodge complex of weight $-q + 2q = q$, where the shift of $F$ is counted twice because the opposite filtration $\bar{F}$ is also shifted. Therefore the quadruple

$$(Ri_*Z_{X\setminus B}, \Omega^*_X(\log B), W, F)$$

is a cohomological mixed Hodge complex.

**Theorem 11 (3).** Let $H$ be a cohomological mixed Hodge complex on a topological space $X$. Then the following hold:

1. The spectral sequence associated to the Hodge filtration

$$F^p E_1^{p,q} = H^{p+q}(\text{Gr}_F^p(H_C)) \Rightarrow H^{p+q}(H_C)$$

degenerates at $E_1$.

2. The spectral sequence associated to the weight filtration

$$W^p E_1^{p,q} = H^{p+q}(\text{Gr}_W^p(H_Q)) \Rightarrow H^{p+q}(H_Q)$$

degenerates at $E_2$.

## 5 Semipositivity and semi-simplicity

Let $H$ be a locally free sheaf on a complex manifold $Y$ with a $C^\infty$ hermitian metric $h_H$. Then there is a connection $\nabla_H : H \to H \otimes \Omega^1_Y$ which is compatible with the holomorphic structure of $H$ and the metric $h_H$. Let $\Theta_H$ be the curvature form. It is a $\text{Hom}(H,H)$ valued $C^\infty$ differential forms of type $(1,1)$ given by the formula

$$\bar{\partial}\partial h_H(u,v) = -h_H(\nabla_H u, \nabla_H v) + h_H(\Theta_H u, v)$$

where $u, v$ are holomorphic local sections of $H$ and the equality holds as $C^\infty$ differential form of type $(1,1)$. The first Chern class $c_1(H)$ is given by the $C^\infty$ differential form $\frac{i}{2\pi} \text{Tr}(\Theta)$.

Let $F$ be a locally free subsheaf of $H$ with an injection $i : F \to H$ and a surjection $p : H \to G$ to the quotient sheaf $G = H/F$. The hermitian metric $h_H$ induces hermitian metrics $h_F$ and $h_G$ on $F$ and $G$ respectively. We can compare the curvature forms of these metrics:

**Proposition 12.** Define the second fundamental form by

$$b = p \circ \nabla_H \circ i \in \text{Hom}(F,G) \otimes \Omega^1_Y$$
and let $u, v$ be local holomorphic sections of $F$. Then

$$h_F(\Theta_F u, v) = h_H(\Theta_H u, v) - h_G(b(u), b(v)).$$

Proof. Omitted.

A variation of mixed Hodge structures (VMHS) over a complex manifold $Y$ consists of a locally constant sheaf $H_Z$, an increasing filtration $W$ by locally constant subsheaves on a locally constant sheaf $H_Q = H_Z \otimes \mathbb{Q}$, and a decreasing filtration $F$ by locally free subsheaves on a locally free sheaf $H_C = H_Z \otimes \mathcal{O}_Y$ which satisfy the following conditions:

1. For each $y \in Y$, the data induced on the fiber $(H_{Z,y}, (H_{Q,y}, W), (H_C \otimes \mathbb{C}_y, W, F))$ is a mixed Hodge structure.
2. The connection, called the Gauss-Manin connection $\nabla : H_C \to H_C \otimes \Omega^1_Y$ for which sections of $H_Z$ are flat, satisfies the Griffiths transversality:

$$\nabla : F^p(H_C) \to F^{p-1}(H_C) \otimes \Omega^1_Y$$
for all $p$.

Example 13. Let $f : (X, B) \to (Y, C)$ be a well prepared toroidal morphism, and $n$ an integer. We denote by $f^* : X \setminus f^{-1}(C) \to Y \setminus C$ the restriction. Let

$$\Omega^1_{X/Y}(\log) = \Omega^1_X(\log B)/f^*\Omega^1_Y(\log C)$$

$$\Omega^p_{X/Y}(\log) = \bigwedge^p \Omega^1_{X/Y}(\log).$$

Then $R^n f^\circ_* Z_{X \setminus f^{-1}(C)}$ carries a structure of VMHS, and the associated Hodge to de Rham spectral sequence

$$E_1^{p,q} = R^q f^\circ_* \Omega^p_{X/Y}(\log) \Rightarrow R^{p+q} f^\circ_* (f^\circ)^{-1}\mathcal{O}_{Y \setminus C}$$
degenerates at $E_1$ ([3]), and gives the Hodge filtration.

If $W_q(H_Q) = H_Q$ and $W_{q-1}(H_Q) = 0$, then our data is called a variation of Hodge structures (VHS) of weight $q$.

A VHS is said to be polarizable if there is a locally constant symmetric bilinear form $Q : H_R \times H_R \to \mathbb{R}_Y$ which induces polarizations of Hodge structures on fibers. A VMHS is said to be graded polarizable if each graded pieces $\text{Gr}^W_q(H_Q)$ is a polarizable variation of Hodge structures.
Theorem 14 ([4]). Let \((H, F, Q)\) be a polarized variation of Hodge structures on a complex manifold \(Y\). Assume that \(F^m(H_C) \not= 0\) and \(F^{m+1}(H_C) = 0\). Then the Gauss-Manin connection induces a connection on \(F^m(H_C)\) whose curvature is positive semi-definite.

Proof. Let \(i : F^m(H_C) \to H_C\) and \(p : H_C \to H_C/F^m(H_C)\) be the natural homomorphisms. We introduce a hermitian metric \(h_H\) on \(H_C\) by \(h_H(u, \overline{v}) = Q(u, \overline{v})\). The Gauss-Manin connection \(\nabla_H\) is flat, and \(\Theta_H = 0\).

Let \(h_F\) and \(h_G\) be the induced hermitian metrics on the subsheaf \(F^m(H_C)\) and the quotient sheaf \(H_C/F^m(H_C)\) respectively. We calculate the curvature \(\Theta_F\) using the second fundamental form \(b = p \circ \nabla_H \circ i\). By the Griffiths transversality, the image of \(b\) lies in \(\text{Gr}^{W_m-1}(H_C) \otimes \Omega^1_Y\).

For holomorphic sections \(u, v\) of \(F^m(H_C)\), we have

\[
Q(\Theta_F u, \overline{v}) = Q(\Theta_H u, \overline{v}) - Q(b(u), \overline{b(v)})
\]

by Proposition 12. Since the non-degenerate bilinear form \(Q\) has opposite signs on \(\text{Gr}^W_m(H_C)\) and \(\text{Gr}^{W_m-1}(H_C)\), we obtain the desired semipositivity. \(\square\)

The following semi-simplicity theorem is very useful:

Theorem 15 ([3]). Let \(Y\) be a complex manifold. Then the category of polarized variations of Hodge structures on \(Y\) is semi-simple in the sense that arbitrary injective homomorphism splits over \(\mathbb{Q}\).

Proof. Let \(H_1 \to H\) be an injective homomorphism of variations of Hodge structures. We take the orthogonal complement \(H_{2,\mathbb{Q}}\) of \(H_{1,\mathbb{Q}}\) in \(H_{\mathbb{Q}}\) with respect to the polarization \(Q\). Then \(H_2 = H \cap H_{2,\mathbb{Q}}\) is again a polarized variation of Hodge structures. Indeed, if \(u = \sum u^{p,q} \in H_{2,\mathbb{C}}\), then \(Q(u^{p,q}, v) = Q(u^{p,q}, v^{q,p}) = Q(u, v^{q,p}) = 0\) for all \(v = \sum v^{p,q} \in H_{1,\mathbb{C}}\), hence \(u^{p,q} \in H_{2,\mathbb{C}}\). Moreover we have \(H_{1,\mathbb{C}} \cap H_{2,\mathbb{C}} = 0\) because of the Riemann-Hodge index theorem. \(\square\)

6 Weight filtration of the \(\mathbb{Q}\)-level complex

Let \(f : (X, B) \to (Y, C)\) be a weakly semistable toroidal model of an algebraic fiber space. Let \(\rho_X : X^{\log} \to X\) and \(\rho_Y : Y^{\log} \to Y\) be the associated log spaces with the induced continuous map \(f^{\log} : X^{\log} \to Y^{\log}\) which is topologically locally trivial. Let \(y \in Y\) be an arbitrary point, and \(\bar{y} \in Y^{\log}\).
a point above \(y\). If \(y\) is contained in exactly \(s\) irreducible components of \(C\), then \(\rho_Y^{-1}(y)\) is homeomorphic to \((S^1)^s\), and \(\bar{y}\) is parametrized by angles \((\theta_1, \ldots, \theta_s)\).

Let \(E = f^{-1}(y)\) and \(D = (f^{\log})^{-1}(\bar{y})\) be the fibers. We shall put a weight filtration on a complex of sheaves \(R(\rho_X)_*\mathbf{Z}_D\) on \(E\) in this section.

Let \(\{E_i\}\) be the set of irreducible components of \(E\). A closed stratum \(E_I\) of \(E\) is an irreducible component of the intersection of some of the \(E_i\). Let \(t = t(E_I) = \text{codim}_E E_I\). We note that \(t\) is not necessarily equal to the number of the \(E_i\) which contain \(E_I\). Let \(D_I = \rho_X^{-1}E_I \cap D\). Then \(\rho_X^{-1}E_I\) is homeomorphic to the product \(D_I \times \rho_Y^{-1}(y)\). We denote \(E[I] = \bigcup_{t(E_I) = t} E_I\) and \(D[I] = \bigcup_{t(E_I) = t} D_I\).

Let \(G_I\) be the union of all the strata which is properly contained in \(E_I\). Then \((E_I, G_I)\) is a quasi-smooth toroidal variety. Let \(\rho_I : E_I^{\log} \to E_I\) be the associated log space. We can see that \(\rho_I : D_I \to E_I^{\log}\) is a \(t\)-times direct sum of oriented \(S^1\) fiber bundles corresponding to the normal directions of \(E_I\) in \(E\).

We have a Mayor-Vietoris exact sequence

\[
0 \to \mathbf{Z}_D \to \mathbf{Z}_{D[0]} \to \mathbf{Z}_{D[1]} \to \mathbf{Z}_{D[2]} \to \cdots
\]

Thus \(R(\rho_X)_*\mathbf{Z}_D\) is a convolution of the following complex

\[
R(\rho_X)_*\mathbf{Z}_{D[0]} \to R(\rho_X)_*\mathbf{Z}_{D[1]} \to R(\rho_X)_*\mathbf{Z}_{D[2]} \to \cdots
\]

Now we define a weight filtration on \(R(\rho_X)_*\mathbf{Z}_D\) so that \(W_q(R(\rho_X)_*\mathbf{Z}_D)\) is the convolution of the following complex:

\[
\tau_{\leq q}(R(\rho_X)_*\mathbf{Z}_{D[0]}) \to \tau_{\leq q+1}(R(\rho_X)_*\mathbf{Z}_{D[1]}) \to \cdots
\]

where \(\tau\) denotes the canonical filtration, i.e.,

\[
H^p(\tau_{\leq q+t}(R(\rho_X)_*\mathbf{Z}_{D[i]})) = \begin{cases} H^p(R(\rho_X)_*\mathbf{Z}_{D[i]}) & \text{if } p \leq q + t \\ 0 & \text{otherwise} \end{cases}
\]

Then we have the following direct sum decomposition:

**Proposition 16.**

\[
\text{Gr}_q^W(R(\rho_X)_*\mathbf{Z}_D) \cong \bigoplus_{t \geq 0} R^{q+t}(\rho_X)_*\mathbf{Z}_{D[0]}[-q - 2t].
\]
Proof. It is clear from the construction. \hfill \square

**Corollary 17.** The monodromy actions of the group \( \pi_1(\rho_Y^{-1}(y), \bar{y}) \cong \mathbb{Z}^s \) on the cohomology groups \( H^p(D, \mathbb{Z}_D) \) are unipotent for all \( p \).

Proof. We have \( H^p(D, \mathbb{Z}_D) = H^p(E, R(\rho_X)_\ast \mathbb{Z}_D) \). The monodromy actions on the graded pieces \( H^p(E, \text{Gr}^W_\ast (R(\rho_X)_\ast \mathbb{Z}_D)) \) are trivial, because \( \rho_X^{-1}(E_I) \) are just homeomorphic to the product spaces. By the spectral sequence

\[
E_2^{p,q} = H^{p+q}(E, \text{Gr}^W_\ast (R(\rho_X)_\ast \mathbb{Z}_D)) \Rightarrow H^{p+q}(D, \mathbb{Z}_D)
\]

we conclude the proof. \hfill \square

7 Sheaves on log spaces

Let \((X, B)\) be a quasi-smooth toroidal variety, and \( \rho : X^\log \to X \) the associated log space. We shall define the “structure sheaf” \( \mathcal{O}_{X^\log} \) and the De Rham complex \( \Omega^\bullet_{X^\log} \) in this section.

First we consider the case where \( X = \mathbb{C}^n \) with coordinates \((x_1, \ldots, x_n)\) and \( B = \text{div}(x_1 \cdots x_r) \). Then we define

\[
\mathcal{O}_{X^\log} = \sum_{k_1, \ldots, k_r \in \mathbb{Z}_{\geq 0}} \rho^{-1}(\mathcal{O}_X) \prod_{i=1}^r (\log x_i)^{k_i}
\]

where the symbols \( \log x_i \) are regarded as holomorphic functions over the open subset \( \rho^{-1}(X \setminus \text{div}(x_i)) \), while locally constant sections over the boundary \( \rho^{-1}(\text{div}(x_i)) \). They are algebraically independent as long as they are symbols. We note that the right hand side of the above definition does not change if we replace the symbols \( \log x_i \) by the shifts \( \log x_i + c_i \) for arbitrary constants \( c_i \in \mathbb{C} \). Thus \( \mathcal{O}_{X^\log}|_{\rho^{-1}(X \setminus B)} = \mathcal{O}_X|_{X \setminus B} \), and the stalk \( \mathcal{O}_{X^\log, \bar{x}} \) at a point \( \bar{x} \in \rho^{-1}(B) \) is isomorphic to a polynomial ring \( \mathcal{O}_{X,0}[t_{i_1}, \ldots, t_{i_l}] \), where the \( t_i \) are independent variables corresponding to the symbols \( \log x_i \) if \( \rho(\bar{x}) \) is contained in exactly \( l \) irreducible components \( B_{i_1}, \ldots, B_{i_l} \) of \( B \).

Next if \( \pi : (X, B) \to (X, B)/G = (X', B') \) is a quotient of the above pair \( (X, B) \) by a finite abelian group \( G \), then we define \( \mathcal{O}_{(X')^\log} = (\pi^\log_* \mathcal{O}_{X^\log})^G \). We note that the action of \( G \) on \( X^\log \) is free, hence the stalks are isomorphic to polynomial rings for suitable number of variables.
In the general case, the structure sheaves for an open covering of $X^{\log}$ are glued together to yield the structure sheaf of $X^{\log}$ because they coincide with the usual structure sheaves when restricted to $X \setminus B$.

The sheaf of differentials is defined by the following formula:

$$\Omega_{X^{\log}}^p = \rho^{-1}(\Omega_X^p (\log B)) \otimes_{\rho^{-1}(\mathcal{O}_X)} \mathcal{O}_{X^{\log}}.$$  

The differential $d : \Omega_{X^{\log}}^p \to \Omega_{X^{\log}}^{p+1}$ is defined by the rule $d(\log x) = dx/x$. It follows that the De Rham complex $\Omega^\bullet_{X^{\log}}$ does not have higher cohomologies:

**Proposition 18** (Poincaré lemma \[8\]).

$$C_{X^{\log}} \cong \Omega^\bullet_{X^{\log}}$$

$$R\rho_* \Omega_{X^{\log}}^p \cong \Omega_X^p (\log B)$$

$$R\rho_* C_{X^{\log}} \cong \Omega^\bullet (\log B)$$

Let $f : (X, B) \to (Y, B)$ be a well prepared toroidal morphism. Then the sheaves of relative differential forms are defined similarly:

$$\Omega_{X^{\log}/Y^{\log}}^p = \rho^{-1}(\Omega_{X/Y}^p (\log Y)) \otimes_{\rho^{-1}(\mathcal{O}_X)} \mathcal{O}_{X^{\log}}.$$  

In the following, we denote $\rho' = (\rho_X, f^{\log}) : X^{\log} \to X \times_Y Y^{\log}$ with the projections $q_1 : X \times_Y Y^{\log} \to X$ and $q_2 : X \times_Y Y^{\log} \to Y^{\log}$.

**Proposition 19** (Poincaré lemma 2 \[8\]).

$$(f^{\log})^{-1}(\mathcal{O}_{Y^{\log}}) \cong \Omega_{Y^{\log}}^\bullet$$

$$R\rho'_* \Omega_{X^{\log}/Y^{\log}}^p \cong q_1^{-1}(\Omega_{X/Y}^p (\log Y)) \otimes_{q_2^{-1}(\mathcal{O}_Y)} q_2^{-1}(\mathcal{O}_{Y^{\log}})$$

$$R\rho'_*(f^{\log})^{-1}(\mathcal{O}_{Y^{\log}}) \cong q_1^{-1}(\Omega_{X/Y}^\bullet (\log Y)) \otimes_{q_2^{-1}(\mathcal{O}_Y)} q_2^{-1}(\mathcal{O}_{Y^{\log}})$$

Now we define sheaves on the fiber $D$ and its strata $D_I$. The restriction of $\rho_X$ to $D$ is denoted by $\rho_D$. Let $y_i$ be the local coordinates at $y \in Y$ which define irreducible components of $C$ passing through $y$. Then the symbols $\log y_i$ are replaced by $0$ on $D$. We write this fact by $\sim$ in the following definition:

$$\mathcal{O}_D = (\mathcal{O}_{X^{\log}} \otimes_{\rho_X^{-1}(\mathcal{O}_X)} \rho_D^{-1}(\mathcal{O}_E))/\sim$$

$$\mathcal{O}_{D_I} = (\mathcal{O}_{X^{\log}} \otimes_{\rho_X^{-1}(\mathcal{O}_X)} \rho_D^{-1}(\mathcal{O}_{E_I}))/\sim$$

$$\Omega_D^p = \rho_D^{-1}(\Omega_{E/C}(\log) \otimes_{\rho_D^{-1}(\mathcal{O}_E)} \mathcal{O}_D) = \Omega_{X^{\log}/Y^{\log}}^p \otimes_{\mathcal{O}_{X^{\log}}} \mathcal{O}_D$$

$$\Omega_{D_I}^p = \rho_D^{-1}(\Omega_{E/C}(\log) \otimes_{\rho_D^{-1}(\mathcal{O}_E)} \mathcal{O}_{D_I}) = \Omega_{X^{\log}/Y^{\log}}^p \otimes_{\mathcal{O}_{X^{\log}}} \mathcal{O}_{D_I}$$
Let
\[ \Omega_{E/C}^p(\log) = \Omega_{X/Y}^p(\log) \otimes O_E. \]

**Corollary 20** (Poincaré lemma 3 [8]).

\[ \begin{align*}
C_D & \cong \Omega^*_D, & C_{D_1} & \cong \Omega^*_{D_1}, \\
R_{\rho_D^*}\Omega_D^p & \cong \Omega_E^p(\log), & R_{\rho_D^*}\Omega_{D_1}^p & \cong \Omega_{E/C}^p(\log) \otimes O_E O_{E_1} \\
R_{\rho_D^*}C_D & \cong \Omega^*_E(\log), & R_{\rho_D^*}C_{D_1} & \cong \Omega^*_E(\log) \otimes O_E O_{E_1}.
\end{align*} \]

The formation of the canonical extension is easily understood when we consider the structure sheaf of the log space as follows. Let \((Y, C)\) be a smooth toroidal variety, \(H_Z\) a locally constant sheaf of free abelian groups on \(Y \setminus C\), and let \(H = H_Z \otimes O_{Y \setminus C}\) be the associated locally free sheaf on the open part \(Y \setminus C\). Let \(y \in C\) be an arbitrary point on the boundary, \(x_j\) the local coordinates corresponding to the local branches of \(C\) passing through \(y\), and \(T_j\) the monodromy transformations of the local system \(H_Z\) around the branches of \(C\) corresponding to the \(x_j\). We assume that the local monodromies \(T_j\) are unipotent for any \(y\). Then the canonical extension \(\tilde{H}\) of \(H\) is defined as a locally free sheaf on \(Y\) generated locally around \(y\) by the following type of local sections of \(H\):

\[ \exp\left(-\frac{1}{2\pi i} \sum \log T_j \log x_i\right) v \]

where the \(v\) are multivalued flat sections of \(H_Z\) and the power series for \(\exp\) is finite because the \(\log T_j\) are nilpotent. We note that the above expressions are single valued sections of \(H\) because the monodromy transformations are cancelled.

**Proposition 21.** Let \(H_Z^\log\) be the local system on the log space \(Y^\log\) obtained by extending the local system \(H_Z\). Then

\[ H_Z^\log \otimes O_{Y^\log} \cong  \rho_{Y}^{-1} \tilde{H} \otimes \rho_Y^{-1} O_Y O_{Y^\log}. \]

**8 Existence of a cohomological mixed Hodge complex**

We shall prove the existence of a cohomological mixed Hodge complex on a singular fiber of a weakly semistable algebraic fiber space.
Theorem 22. Let $f : (X, B) \to (Y, C)$ be a weakly semistable algebraic fiber space, i.e., a projective surjective toroidal morphism from a quasi-smooth toroidal variety to a smooth toroidal variety having connected, reduced and equi-dimensional geometric fibers. Let $f^{\log} : X^{\log} \to Y^{\log}$ be the induced continuous map between the associated log spaces $\rho_X : X^{\log} \to X$ and $\rho_Y : Y^{\log} \to Y$. Let $y \in Y$ be an arbitrary point, $\bar{y} \in \rho_Y^{-1}(y)$, $E = f^{-1}(y)$ and $D = (f^{\log})^{-1}(\bar{y})$. Denote $\rho_D = \rho_X|_D$. Then the following data is a cohomological mixed Hodge complex on $E$.

1. $HZ = R\rho_D^*Z_D$.
2. $HC = \Omega^\bullet_{E/C}(\log)$.
3. A weight filtration $W_q(R\rho_D^*Q_D)$ on $HQ$ is defined as a convolution of the following complex of objects:

$$
\tau_{\leq q}(R\rho_D^*Q_D[0]) \to \tau_{q+1}(R\rho_D^*Q_D[1]) \to \tau_{q+2}(R\rho_D^*Q_D[2]) \to \ldots
$$

where $\tau$ denotes the canonical filtration.

4. A weight filtration $W_q(\Omega^\bullet_{E/C}(\log))$ on $HC$ is defined as a convolution of the following complex of objects:

$$
W_q(\Omega^\bullet_{E/C}(\log) \otimes O_E O_E[t]) \to W_{q+1}(\Omega^\bullet_{E/C}(\log) \otimes O_E O_E[t]) \to \ldots
$$

where $W$ denotes the filtration determined by the order of log poles.

5. A Hodge filtration on $HC$ is the stupid filtration:

$$
F^p(\Omega^\bullet_{E/C}(\log)) = \Omega^{\geq p}_{E/C}(\log).
$$

Proof. By the Poincaré lemma, we have $HZ \otimes C \cong HC$, and

$$
\text{Gr}_q(HQ) \cong \bigoplus_{t \geq 0} R^{q+t}\rho_D^*Q_D[1][q - 2t]
$$

$$
\text{Gr}_q(HC) \cong \bigoplus_{t \geq 0} \text{Gr}_q^W(\Omega^\bullet_{E/C}(\log) \otimes O_E O_E[t])[-t]
$$

$$
\text{Gr}_{q+t}(\Omega^\bullet_{E/C}(\log) \otimes O_E O_E[t])[-t] \cong R^{q+t}\rho_D^*C_D[1][q - 2t].
$$

We shall prove that

$$
(\text{Gr}_q^W(\Omega^\bullet_{E/C}(\log) \otimes O_E O_E[t]), F)
$$

is a cohomological mixed Hodge complex of weight $q$ on $E$. 

20
We have an exact sequence

\[0 \to \Omega^1_{E/I}(\log G/I) \to \Omega^1_{E/C}(\log) \otimes O_E \to O_{E/I}^* \to 0\]

where the last arrow is given by the residue homomorphisms along the normal directions of \(E_I\) in \(E\).

Let \(G_J\) be a closed stratum on \(E_I\), an irreducible component of the intersection of some of the irreducible components of \(G_I\). Let \(s = \text{codim}_{E_I} G_J\). When we derive a differential form on \(G_J\) from a section of \(\Omega^\bullet_{E/C}(\log) \otimes O_E\), we take residues \(s\) times in the normal directions of \(G_J\) in \(E_I\) and \(t'\) times in the directions of \(O^*_{E_I}\) of the above exact sequence, where we have \(0 \leq t' \leq t\). In order to obtain the graded piece of degree \(q + t\), we have to take residues \(q + t\) times. Thus we have \(q + t = s + t'\). The degree of the differential form drops also by \(q + t\). Therefore we obtain

\[(Gr^W_{q+t}(\Omega^\bullet_{E/C}(\log) \otimes O_E)\otimes O_{E[I]}[-t], F) \cong \left(\left(\begin{array}{c} t \\ t' \end{array}\right)\right)\Omega^*_{Gr}[-t-q-t], F(-q-t)).\]

Since

\[-t - q - t + 2(q + t) = q\]

the last term is a cohomological Hodge complex of weight \(q\).

The formula obtained in the above proof \(q = s + t' - t\) says that the shift of the weight along the degeneration of fibers can be in both positive and negative directions, while the shift of the cohomology degree \(s + t' + t\) is in one direction.

The following is an immediate corollary:

**Corollary 23.** Assume the conditions of the theorem. Then the following hold:

1. The spectral sequence associated to the Hodge filtration

\[F^p E^{p,q}_1 = H^q(E, \Omega^p_{E/C}(\log)) \Rightarrow H^{p+q}(D, C)\]

degenerates at \(E_1\).

2. The spectral sequence associated to the weight filtration

\[W^p E^{p,q}_1 = H^{p+q}(E, Gr^W_{p}(R\rho_{D*}Q_D)) \Rightarrow H^{p+q}(D, Q)\]

degenerates at \(E_2\).
The upper semi-continuity theorem yields the local freeness theorem:

**Corollary 24.** Assume the conditions of the theorem. Then the following hold:

1. The higher direct image sheaves $R^q f_* \Omega^p_{X/Y}(\log)$ on $Y$ are locally free for all $p, q$.
2. Let $\tilde{H}^k$ be the canonical extension of the higher direct image sheaf $R^k f_* C_{X/B} \otimes_{C_{Y/C}} O_{Y/C}$ for any integer $k$. Then there is an isomorphism

$$\tilde{H}^k \cong R^k f_* \Omega^\bullet_{X/Y}(\log).$$

Moreover

$$F^p(\tilde{H}^k) \cong R^k f_* \Omega^{\geq p}_{X/Y}(\log)$$

gives an increasing filtration by locally free subsheaves of the canonical extension.

**Proof.** (1) The rank of the cohomology groups $\bigoplus_{p+q=k} H^q(E, \Omega^p_{E/C}(\log))$ for $E = f^{-1}(y)$ is independent of $y \in Y$. Hence the assertion follows from the upper semi-continuity theorem.

(2) We have

$$\rho_Y^{-1} \tilde{H}^k \otimes_{\rho_Y^{-1} O_Y} O_{Y^{\log}} \cong R^k f^{\log}_* C_{X^{\log}} \otimes O_{Y^{\log}}$$

$$\cong \rho_Y^{-1} R^k f_* \Omega^\bullet_{X/Y}(\log) \otimes_{\rho_Y^{-1} O_Y} O_{Y^{\log}}$$

$$\rho_Y^{-1} F^p(\tilde{H}^k) \otimes_{\rho_Y^{-1} O_Y} O_{Y^{\log}} \cong F^p(R^k f^{\log}_* C_{X^{\log}} \otimes O_{Y^{\log}})$$

$$\cong \rho_Y^{-1} F^p(R^k f_* \Omega^\bullet_{X/Y}(\log)) \otimes_{\rho_Y^{-1} O_Y} O_{Y^{\log}}$$

hence the result. \[\square\]

The above assertion can be derived from the nilpotent orbit theorem ([14]). Our proof is more geometric.

**9 Semipositivity theorem**

A locally free sheaf $F$ on a proper algebraic variety $Y$ is said to be numerically semipositive if the tautological invertible sheaf $O_{P(F)}(1)$ on the associated projective space bundle is nef. It is equivalent to saying that, for all morphisms $\phi : \Gamma \to Y$ from a smooth projective curve $\Gamma$ and for all quotient invertible sheaves $G$ of the inverse images $\phi^* F$, the inequalities $\deg_{\Gamma}(G) \geq 0$ hold.
Theorem 25. Let \( f : (X, B) \to (Y, C) \) be a well prepared algebraic fiber space of relative dimension \( n \), i.e., a projective surjective toroidal morphism from a quasi-smooth toroidal variety to a smooth toroidal variety having connected and equi-dimensional geometric fibers. Then the sheaves \( f_\ast \Omega^n_{X/Y}(\log) \) and \( R^kf_\ast \Omega^n_{X/Y}(\log) \) are numerically semipositive locally free sheaves for all non-negative integers \( k \).

If \( f : (X, B) \to (Y, C) \) is weakly semistable, i.e., if all the geometric fibers are reduced, then \( \Omega^n_{X/Y}(\log) = \omega_{X/Y}(B^h) \) is the relative dualising sheaf twisted by the horizontal part of the boundary \( B \). But the both sides are different in the general case.

Proof. At first, we consider the case where \( f \) is weakly semistable and there is no horizontal component of the boundary, i.e., \( B = f^{-1}(C) \). The following proof is essentially in [7].

Let \( H_t = R^t f_\ast \Omega^{\bullet}_{X/Y}(\log) \). It is a locally free sheaf on \( Y \) which is the canonical extension of a variation of Hodge structures on \( Y \setminus C \). We denote \( F_{n-k} = f_\ast \Omega^{n-k}_{X/Y}(\log) \) and \( F_{n+k} = R^k f_\ast \Omega^n_{X/Y}(\log) \). They are locally free subsheaves of the \( H_t \) which coincide with the canonical extensions of the highest Hodge filtration for \( t = n-k \) or \( t = n+k \).

Let \( L \) be the cohomology class of an ample divisor on \( X \). By the Lefschetz theorem, we have an isomorphism \( L^k : H_{n-k} \to H_{n+k} \) which sends \( F_{n-k} \) to \( F_{n+k} \). The primitive part

\[
\delta H_{n-k} = \text{Ker}(L^{k+1} : H_{n-k} \to H_{n+k+2})
\]

is the canonical extension of a polarized variation of Hodge structures on \( Y \setminus C \). We note that \( F_{n-k} \) is contained in \( \delta H_{n-k} \).

We shall prove that \( F_t \) for \( t = n-k \) is semipositive. Let \( \phi : \Gamma \to Y \) and \( G \) as above. We assume first that the image of \( \phi \) is general in the sense that \( \Gamma^o = \phi^{-1}(Y \setminus C) \not= \emptyset \). The bilinear form \( Q(u, v) = \int u \cup v \cup L^k \) induces a positive definite hermitian metric \( h_F \) on \( F_t|_{Y \setminus C} \). Let \( h_G \) be the induced hermitian metric on \( G|_{\Gamma^o} \). By the Griffiths semipositivity, the curvature form of \( h_G \) is semi-positive.

We regard \( h_G \) as a hermitian metric on the whole space \( \Gamma \) with singularities along the boundary \( \Gamma - \Gamma^o \), namely a singular hermitian metric. It can be written locally near a point \( y \in \Gamma - \Gamma^o \) in a form \( h_G = e^g h_0 \) for a \( C^\infty \) hermitian metric \( h_0 \) and a locally integrable function \( g \). Then we can express the curvature current \( \Theta_G \) of \( h_G \) in a form \( \Theta_G = \Theta_0 + \partial \bar{\partial} g \), where \( \Theta_0 \) is the
due to the singularities of functions and logarithmic functions. Therefore the boundary contribution that the function $g$ is the logarithm of a function which is expressed by $C^\infty$ functions and logarithmic functions. Therefore the boundary contribution due to the singularities of $h_\theta$ vanishes, and we have

$$\deg_\Gamma(G) = \int_{\Gamma_0} \frac{i}{2\pi} \Theta_G \geq 0.$$  

Next we consider the case where $\phi(\Gamma)$ is contained in the boundary $C$. Let $C_I$ be the irreducible component of the intersection of some of the irreducible components of $C$ such that the image of $\phi$ is contained in $C_I$ and general in the sense that $\Gamma^0 = \phi^{-1} (C_I^I) \neq \emptyset$ where we set $C_I^I = C_I \setminus \bar{C}^{[s+1]}$ for the image $\bar{C}^{[s+1]}$ of $C^{[s+1]}$ in $C_I$ with $s = \text{codim}_Y C_I$.

For $y \in C_I^I$ and $\bar{y} \in \rho_Y^{-1} (y)$, we use the notation as in the previous sections such as $E = f^{-1} (y)$ and $D = (f^{\log})^{-1}(\bar{y})$. Moreover we denote $C_I^{\log} = \rho_Y^{-1} (C_I^I)$, $E_I^{\log} = f^{-1}(C_I^I)$ and $D_I = \rho_X^{-1} (E_I^I) = f^{\log} (C_I^{\log})$. The mixed Hodge structure defined previously on $H^I(D, \mathbb{Z})$ varies continuously when $\bar{y}$ moves, and becomes a continuous variation of mixed Hodge structures $H^I_{Z \log} = R^f f^{\log} \mathbb{Z}_{D_I}$ on $C_I^{\log}$.

Since the weight filtration $W$ is flat along this variation, there exists a filtration, denoted by $W$ again, on $H^I_{t,I} = H_t \otimes_{\mathcal{O}_Y} \mathcal{O}_{C_I}$ by locally free subsheaves on $C_I^I$ such that

$$W_q (H^I_{Z \log} \otimes \mathcal{O}_{C_I^{\log}}) \cong \rho_Y^{-1} W_q (H^I_{t,I}) \otimes_{\mathcal{O}_{C_I}} \mathcal{O}_{C_I^{\log}}.$$  

The Hodge filtration $F$ on $H^I_{Z \log}$ also comes from downstairs:

$$F^p (H^I_{Z \log} \otimes \mathcal{O}_{C_I^{\log}}) \cong \rho_Y^{-1} F^p (H^I_{t,I}) \otimes_{\mathcal{O}_{C_I}} \mathcal{O}_{C_I^{\log}}.$$  

We denote by $F_{t,I}^c = F^c (H_{t,I}^I)$ the highest Hodge part, which coincides with $F_t \otimes \mathcal{O}_Y \mathcal{O}_{C_I}$. The canonical extension $H_{t,I}$ (resp. $F_{t,I}$) of $H_{t,I}^o$ (resp. $F_{t,I}^o$) across the boundary $\bar{C}^{[s+1]}$ coincides with $H_t \otimes \mathcal{O}_Y \mathcal{O}_{C_I}$ (resp. $F_t \otimes \mathcal{O}_Y \mathcal{O}_{C_I}$).

Let $q$ be the smallest integer such that the surjective homomorphism $\phi^* F_t \rightarrow G$ induces a non-zero homomorphism $W_q (F_{t,I}) \rightarrow G$. Then we have a non-zero homomorphism $\text{Gr}^W_q (F_{t,I}) \rightarrow G$. The graded piece $\text{Gr}^W_q (H_{t,I})$ is a direct sum of the canonical extensions of variations of (pure) Hodge structures on $C_I$ defined by irreducible components of the intersection of some of the irreducible components of $E_I = f^{-1} (C_I)$. Therefore we infer that $\deg_\Gamma(G) \geq 0$ by the first part of this proof.
Now we consider the generalization to the case of well prepared algebraic fiber spaces without horizontal boundary components. Let \( \pi_Y : Y' \to Y \) a finite surjective Galois base change morphism such that the induced algebraic fiber space \( f' : X' \to Y' \) is weakly semistable. We denote by \( \pi_X : X' \to X \) the induced finite morphism. We note that the ramification of \( \pi_Y \) occurs not only along the boundary divisor \( C \), though we have \( C' = \pi_Y^{-1}(C) \). Our assertion follows from the following two lemmas.

**Lemma 26.**

1. \( \pi_Y^* \Omega^p_{X'/Y'}(\log) \cong \Omega^p_{X'/Y'}(\log) \) for all \( p \).

2. \( R^q f_* \Omega^p_{X/Y}(\log) \) is locally free for all \( p, q \).

3. \( \pi_Y^* R^q f_* \Omega^p_{X/Y}(\log) \cong R^q f'_* \Omega^p_{X'/Y'}(\log) \) for all \( p, q \).

**Proof.** (1) The isomorphism is the pull-back homomorphism. We check that it is bijective. If \( x \in X \setminus f^{-1}(C) \), then it is bijective in a neighborhood of \( x \) because \( f \) is smooth there. If \( f(x) \in C \) but \( f(x) \) is not contained in any irreducible component of the discriminant locus of \( \pi_Y \) other than those of \( C \), then we have \( \pi_Y^* \Omega^p_{X}(\log B) \cong \Omega^p_{X'}(\log B') \) and \( \pi_Y^* \Omega^p_{Y}(\log C) \cong \Omega^p_{Y'}(\log C') \), hence an isomorphism in a neighborhood of \( x \). Therefore our homomorphism is bijective outside a codimension 2 subset, and we are done.

(2) Since \( (\pi_Y^* \pi_Y^* \Omega^p_{X/Y}(\log))^G \cong \Omega^p_{X/Y}(\log) \), we have

\[
R^q f_* \Omega^p_{X/Y}(\log) \cong (\pi_Y^* R^q f'_* \Omega^p_{X'/Y'} (\log))^G.
\]

Since \( \pi_Y \) is flat, we have our assertion.

(3) This follows from the local freeness theorem and the upper-semicontinuity theorem.

**Lemma 27.** Let \( \pi : Y' \to Y \) be a finite surjective morphism of proper varieties, and let \( F \) be a locally free sheaf on \( Y \). Then \( F \) is numerically semipositive if and only if \( \pi^* F \) is numerically semipositive.

**Proof.** The assertion is reduced to the case where the rank of \( F \) is equal to 1, and the latter is clear.

We postpone the proof of the theorem in the case where there are horizontal boundary components to the end of the next section.
10 Decomposition theorem

We use the following notation. \( f : (X, B) \to (Y, C) \) is the given well prepared algebraic fiber space. We write \( B = B^h + B^v \) for \( B^v = f^{-1}(C) \) (\( h \) stands for horizontal and \( v \) the vertical). We denote by \( B^h_I \) an irreducible component of the intersection of some of the irreducible components of \( B^h \), where \( I \) stands for a set of indices which determines \( B^h_I \) in a similar way as in the previous sections. Such \( B^h_I \) is called a stratum of \( X \) in this proof. For a fixed stratum \( B^h_I \), we denote by \( G^I = B^v \cap B^h_I \) the horizontal boundary component such that \( f^I = f^h \circ \sigma \).

First we prove the decomposition theorem for the constant sheaf:

**Theorem 28.** Let \( f : (X, B) \to (Y, C) \) be a well prepared algebraic fiber space, and \( f^\log : X^\log \to Y^\log \) the associated map of log spaces. Then

\[
Rf^\log_* \mathbb{Q}_{X^\log} \cong \bigoplus_i R^i f^\log_* \mathbb{Q}_{X^\log}[-i].
\]

**Proof.** First we prove the theorem under the additional condition that there is no horizontal component of \( B \), i.e., \( B = f^{-1}(C) \).

Let \( L \in H^2(X, \mathbb{Z}) \) be the class of an ample divisor on \( X \), and \( y \in Y \setminus C \) a point. Then the fiber \( f^{-1}(y) \) is a smooth projective variety and the Lefschetz decomposition theorem holds. Therefore we have a decomposition theorem for the fiber by Theorem 8. Since our sheaves are locally constant on the whole log space \( Y^\log \), the Lefschetz decomposition theorem extends to singular fibers, and we are done in this case.

We define a weight filtration \( W \) on a higher direct image \( R\sigma_* \mathbb{Q}_{X^\log} \) on \( B^h_0 \) as the canonical filtration \( \tau \) as before. Then we have

\[
\text{Gr}^W_q (R\sigma_* \mathbb{Q}_{X^\log}) \cong \bigoplus_{\text{codim } B^h_I = q} \mathbb{Q}_{B^h_I}[-q]
\]

where the \( B^h_I \) are regarded as closed subspaces of \( B^h_0 \). There is an induced weight filtration, denoted again by \( W \), on the higher direct image.
$R_{f}^{\log}Q_{X}^{\log}$ on $Y^{\log}$ such that

$$\text{Gr}^{W}_q (R_{f}^{\log}Q_{X}^{\log}) \cong \bigoplus_{\text{codim } B_l^h = q} R_{f}^{\log}Q_{B_l^h}^{\log}[-q].$$

In other words, we have distinguished triangles

$$W_{q-1} (R_{f}^{\log}Q_{X}^{\log}) \to W_q (R_{f}^{\log}Q_{X}^{\log}) \to \text{Gr}^{W}_q (R_{f}^{\log}Q_{X}^{\log}) \to W_{q-1} (R_{f}^{\log}Q_{X}^{\log})[1]$$

so that $R_{f}^{\log}Q_{X}^{\log}$ is a convolution of a complex of objects

$$\cdots \to \bigoplus_{\text{codim } B_l^h = q} R_{f}^{\log}Q_{B_l^h}^{\log}[-2q] \to \bigoplus_{\text{codim } B_l^h = q-1} R_{f}^{\log}Q_{B_l^h}^{\log}[-2q+2] \to \cdots \to \bigoplus_{\text{codim } B_l^h = 1} R_{f}^{\log}Q_{B_l^h}^{\log}[-2] \to R_{f}^{\log}Q_{B_0^h}^{\log}.$$

By the theorem in the case of no horizontal boundary components, we have

$$R_{f}^{\log}Q_{B_l^h}^{\log} \cong \bigoplus_{p} R_{p}^{f}Q_{B_l^h}^{\log}[-p].$$

With respect to this decomposition, the boundary morphisms of the above complex are the sums of the Gysin homomorphisms

$$R_{p}^{f}Q_{B_l^h}^{\log} \to R_{p+2}^{f}Q_{B_j^h}^{\log}$$

for immersions $B_l^h \subset B_j^h$ of codimension 1.

We shall prove the following isomorphisms by induction on $q$:

$$W_q := W_q (R_{f}^{\log}Q_{X}^{\log}) \cong \bigoplus_{p} H^p (W_q (R_{f}^{\log}Q_{X}^{\log}))[-p].$$

There is a spectral sequence associated to the weight filtration

$$E_1^{p,q} = H^{p+q} (\text{Gr}^{W}_{-p} (R_{f}^{\log}Q_{X}^{\log})) = \bigoplus_{\text{codim } B_l^h = -p} R^{2p+q} f_{*}^{\log}Q_{B_l^h}^{\log}$$

where the differentials $d_1^{p,q}$ are nothing but the Gysin homomorphisms above. It degenerates at $E_2$ by [3]; we have $d_r^{p,q} = 0$ for all $r \geq 2$.
By the semi-simplicity of the category of polarized variations of Hodge structures (Theorem 15) with the aid of the Lefschetz decomposition theorem, we have isomorphisms

\[ E^{p,q}_1 \cong E^{p,q}_2 \oplus \text{Im}(d^p_{1,q-1}) \oplus \text{Im}(d^p_{1,q}) \]

for all \( p, q \). Here we note that the local systems are defined on the whole space and the decompositions hold on \( Y^{\log} \).

We put

\[ G^W_{1,q} := \bigoplus_k H^i(\text{Gr}^W_q(Rf_{\ast}^\log Q_X^{\log}))[\cdot \cdot \cdot -i] \cong \bigoplus_k E^{q-k} [-q - k] \]

The Gysin homomorphism \( G^W_{1,q} \rightarrow G^W_{1,q-1} \) coincides with the boundary homomorphism \( \bigoplus_k d^{q-k} [-q - k] \). Let \( G^W_{2,q} = \bigoplus_k E^{q-k} [-q - k] \). Then we have

\[ G^W_{1,q} \cong G^W_{2,q} \oplus \bigoplus_k (\text{Im}(d^{q-1-k}) \oplus \text{Im}(d^{q-k})) [-q - k] \]

We define objects \( W'_q \) by the following distinguished triangles

\[ W'_q \rightarrow W_q \rightarrow \bigoplus_k \text{Im}(d^{q-1-k}) [-q - k] \rightarrow W'_q[1] \]

where the second arrow is the composition of the morphism to \( G^W_{1,q} \) and the projection. In particular \( W'_q \cong 0 \) for \( q < 0 \) and \( W'_q \cong W_q \cong Rf_{\ast}^\log Q_X^{\log} \) for sufficiently large \( q \). We consider the following 9 term diagram

\[
\begin{array}{ccccccccc}
W'_{q-1} & \longrightarrow & W_{q-1} & \longrightarrow & \bigoplus_k \text{Im}(d^{q-k}) [q - 1 - k] & \longrightarrow \\
| & & | & & | & & |
W'_q & \longrightarrow & W_q & \longrightarrow & \bigoplus_k \text{Im}(d^{q-1-k}) [q - k] & \longrightarrow \\
| & & | & & | & & |
G_{2,q} & \longrightarrow & G_{1,q} & \longrightarrow & \bigoplus_k (\text{Im}(d^{q-1-k}) \oplus \text{Im}(d^{q-k})) [q - k] & \longrightarrow \\
| & & | & & | & & |
\cdots & \longrightarrow & G_{2,q}[-q] & \longrightarrow & G_{2,q-1}[-q + 1] & \longrightarrow & \cdots & \longrightarrow & G_{2,1}[-1] & \longrightarrow & G_{2,0}
\end{array}
\]

where the last column is the distinguished triangle corresponding to the direct sum. By the octahedral axiom, we conclude that the first column is also distinguished. Therefore \( Rf_{\ast}^\log Q_X^{\log} \) is also a convolution of the complex

\[ \cdots \rightarrow G_{2,q}[-q] \rightarrow G_{2,q-1}[-q + 1] \rightarrow \cdots \rightarrow G_{2,1}[-1] \rightarrow G_{2,0} \]

28
whose boundary morphisms are zero.

**Lemma 29.** Let

\[ W'_{q-1} \to W'_q \to G_{2,q} \to W'_{q-1}[1] \]

be the distinguished triangle above. Then the connecting homomorphisms on cohomologies \( H^p(G_{2,q}) \to H^{p+1}(W'_{q-1}) \) are zero for all \( p, q \). Thus the associated long exact sequence of cohomologies splits into short exact sequences

\[ 0 \to H^p(W'_{q-1}) \to H^p(W'_q) \to H^p(G_{2,q}) \to 0. \]

**Proof.** We proceed by induction on \( q \). We assume that the assertion is already proved for all \( q' < q \). We claim that the homomorphism \( H^p(G_{2,q}) \to H^{p+1}(W'_q) \) factors through homomorphisms \( H^p(G_{2,q}) \to H^{p+1}(W'_{q-r}) \) for \( q' < q \) by the descending induction on \( q' \). If we take \( q' = 0 \), then we obtain our assertion.

Assume that our homomorphism is factored through a homomorphism \( H^p(G_{2,q}) \to H^{p+1}(W'_{q-r}) \) for some \( r > 0 \). We compose it with a homomorphism \( H^{p+1}(W'_{q-r}) \to H^{p+1}(G_{2,q-r}) \) coming from the given distinguished triangle

\[ W'_{q-r-1} \to W'_{q-r} \to G_{2,q-r} \to W'_{q-r-1}[1] \]

The composite homomorphism \( H^p(G_{2,q}) \to H^{p+1}(G_{2,q-r}) \) is nothing but the one induced from the \( d_{r,q-k} \). By the construction of \( G_{2,q} \) or the \( E_2 \)-degeneration of the spectral sequence, this homomorphism is zero. Therefore the homomorphism \( H^p(G_{2,q}) \to H^{p+1}(W'_{q-r}) \) factors through \( H^p(G_{2,q}) \to H^{p+1}(W'_{q-r-1}) \).

We consider the following diagram

\[
\begin{array}{ccc}
W'_{q-1} & \longrightarrow & W'_q \\
\downarrow & & \downarrow \\
\bigoplus_i H^i(W'_{q-1})[-i] & \longrightarrow & \bigoplus_i H^i(W'_q)[-i] \\
\downarrow & & \downarrow \\
\bigoplus_i H^i(G_{2,q})[-i] & \longrightarrow & \bigoplus_i H^i(G_{2,q})[-i]
\end{array}
\]

Both rows are distinguished by the above lemma. The first vertical arrow is an isomorphism by the induction hypothesis. The third vertical arrow is also an isomorphism. Therefore there is an isomorphism, which is not unique, at the middle vertical arrow which makes the diagram commutative.

Now we prove the decomposition theorem for the sheaves of logarithmic differential forms:
Theorem 30. Let \( f : (X,B) \to (Y,C) \) be a well prepared algebraic fiber space. Then
\[
Rf_* \Omega^k_{X/Y} (\log) \cong \bigoplus_i R^i f_* \Omega^k_{X/Y} (\log)[-i]
\]
for all \( k \).

Proof. We shall prove an isomorphism of their sum
\[
\bigoplus_k Rf_* \Omega^k_{X/Y} (\log)[-k] \cong \bigoplus_i \bigoplus_k R^i f_* \Omega^k_{X/Y} (\log)[-i - k]
\]
The following proof is very similar to that of the previous theorem, so we will only explain the outline.

We treat the case \( B = f^{-1}(C) \) first again. By the \( E_1 \)-degeneration of the spectral sequence associated to the Hodge filtration, we have Lefschetz type isomorphisms for the direct sum \( \bigoplus_k Rf_* \Omega^k_{X/Y} (\log)[-k] \). Therefore we obtain the assertion in this case by Theorem 8.

In the general case, we define a weight filtration on \( \bigoplus_k \Omega^k_{X/Y} (\log)[-k] \) by the order of log poles along \( B \) so that we have
\[
\text{Gr}_q^W \left( \bigoplus_k \Omega^k_{X/Y} (\log)[-k] \right) \cong \bigoplus_{\text{codim } B^h_i = q} \Omega^k_{B^h_i/Y} (\log)[-k - q]
\]
where the \( B^h_i \) are regarded as closed subspaces of \( X \) whose boundaries have only vertical components. We note that the isomorphism does not hold for individual \( k \). There is an induced weight filtration, denoted again by \( W \), on the higher direct image \( \bigoplus_k Rf_* \Omega^k_{X/Y} (\log)[-k] \) on \( Y \) such that
\[
\text{Gr}_q^W \left( \bigoplus_k Rf_* \Omega^k_{X/Y} (\log)[-k] \right) \cong \bigoplus_{\text{codim } B^h_i = q} Rf_* \Omega^k_{B^h_i/Y} (\log)[-k - q].
\]
Thus \( \bigoplus_k Rf_* \Omega^k_{X/Y} (\log)[-k] \) is a convolution of a complex of objects
\[
\cdots \to \bigoplus_{\text{codim } B^h_i = q} Rf_* \Omega^k_{B^h_i/Y} (\log)[-k - 2q] \to \bigoplus_{\text{codim } B^h_i = q-1} Rf_* \Omega^k_{B^h_i/Y} (\log)[-k - 2q + 2] \to \cdots \to \bigoplus_{\text{codim } B^h_i = 1} Rf_* \Omega^k_{B^h_i/Y} (\log)[-k] \to \bigoplus_{\text{codim } B^h_i = 0} Rf_* \Omega^k_{B^h_i/Y} (\log)[-k].
\]
By the theorem in the case of no horizontal boundary components, we have
\[
\bigoplus_k Rf_* \Omega^k_{B^h_I/Y} \otimes (\log)[−k] \cong \bigoplus_i \bigoplus_k R^i f_* \Omega^k_{B^h_I/Y} \otimes (\log)[−i − k].
\]

With respect to this decomposition, the boundary morphisms of the above complex are the sums of the Gysin homomorphisms
\[
R^q f_* \Omega^k_{B^h_I/Y} \otimes (\log) \to R^{q+1} f_* \Omega^{k+1}_{B^h_J/Y} \otimes (\log)
\]
for immersions $B^h_I \subset B^h_J$ of codimension 1. We note that underlying varieties of $B^h_\emptyset$ and $X$ are the same but their boundaries are different.

We shall prove the following isomorphisms by induction on $q$:
\[
W_q := W_q \left( \bigoplus_k Rf_* \Omega^k_{X/Y} \otimes (\log)[−k] \right)
\]
\[
\cong \bigoplus_i \bigoplus_k H^i(W_q(Rf_* \Omega^k_{X/Y} \otimes (\log)))[−i − k].
\]

There is a spectral sequence associated to the weight filtration
\[
E^{p,q}_1 = \bigoplus_k H^{p+q−k}(Gr^W_p(Rf_* \Omega^k_{X/Y} \otimes (\log)))
\]
\[
= \bigoplus_k \bigoplus_{\text{codim } B^h_I = −p} R^{2p+q−k} f_* \Omega^k_{B^h_I/Y} \otimes (\log) \Rightarrow \bigoplus_k R^{p+q−k} f_* \Omega^k_{X/Y} \otimes (\log) \quad (10.2)
\]

where the differentials $d_1^{p,q}$ are nothing but the Gysin homomorphisms above. It degenerates at $E_2$ by [3]; we have $d_2^{p,q} = 0$ for all $r \geq 2$.

By the semi-simplicity we have again isomorphisms
\[
E^{p,q}_1 \cong E^{p,q}_2 \oplus \text{Im}(d_1^{p−1,q}) \oplus \text{Im}(d_1^{p,q})
\]
for all $p, q$. We put
\[
G_{1,q} := \bigoplus_k Gr^W_q(Rf_* \Omega^k_{X/Y} \otimes (\log))[−k]
\]
\[
\cong \bigoplus_i \bigoplus_k H^i(Gr^W_q(Rf_* \Omega^k_{X/Y} \otimes (\log)))[−i − k] \cong \bigoplus_k E^{−q,k}_1[q − k]
\]
and $G_{2,q} = \bigoplus_k E^{−q,k}_2[q − k]$. The rest of the proof is exactly the same as that of the previous theorem. \qed
We remark that Kollár’s result on the sheaf of top differential forms $\omega_X$ holds without the assumptions on the well preparedness of the morphism, because $\omega_X$ behaves well under the birational morphisms by the Grauert-Riemenschneider vanishing theorem.

\textit{Proof of Theorem 23 continued.} We continue the proof of the semipositivity theorem in the case where there are horizontal boundary components. We use spectral sequences (10.1) and (10.2) associated to the weight filtrations, which will be denoted by $I^p,q_1$ and $II^p,q_1$. The second one $II^p,q_1$ is obtained from the first one $I^p,q_1$ by the decomposition with respect to the Hodge filtration:

$$\bigoplus_k \text{Gr}_k^F (I^p,q_1|_{Y\setminus C} \otimes \mathcal{O}_{Y\setminus C}) \cong II^p,q_1|_{Y\setminus C}.$$ 

They degenerate at the $E_2$-terms.

Let $F$ denote either $f_*\Omega^k_{X/Y}(\log)$ or $R^k f_*\Omega^n_{X/Y}(\log)$. It has an induced weight filtration, and we have

$$\text{Gr}^W(F) \cong \bigoplus_p F^{k+p}(II^p,q_2^{k-p}) \quad \text{or} \quad \bigoplus_p F^{n+p}(II^p,q_2^{p,k+n-p}).$$

Since $F^{k+p+1}(II^p,q_2^{p,k-p}) = 0$ and $F^{n+p+1}(II^p,q_2^{p,k+n-p}) = 0$, we deduce that $\text{Gr}^W(F)$ is numerically semipositive, hence so is $F$. \qed
