Abstract

Unsupervised learning methods have recently shown their competitiveness against supervised training. Typically, these methods use a single objective to train the entire network. But one distinct advantage of unsupervised over supervised learning is that the former possesses more variety and freedom in designing the objective. In this work, we explore new dimensions of unsupervised learning by proposing the \textit{Progressive Stage-wise Learning (PSL)} framework. For a given unsupervised task, we design multi-level tasks and define different learning stages for the deep network. Early learning stages are forced to focus on low-level tasks while late stages are guided to extract deeper information through harder tasks. We discover that by progressive stage-wise learning, unsupervised feature representation can be effectively enhanced. Our extensive experiments show that PSL consistently improves results for the leading unsupervised learning methods.

1. Introduction

Aiming at learning features from label-free data, unsupervised representation learning, including self-supervised learning, is an important problem to study. Many efforts have been made, to bridge the performance gap between supervised and unsupervised learning algorithms. These methods can be roughly divided into two categories: i) handcrafted pretext tasks, that learns data-level invariant features (e.g., jigsaw puzzle \cite{noroozi2016unsupervised}, image rotation \cite{gidon2017unsupervised}, image colorization \cite{xing2016unsupervised}) and ii) contrastive visual representation learning, which learns the similarity and dissimilarity

\begin{align*}

\end{align*}
works. Those methods have shown great promise in the area of unsupervised learning, achieving state-of-the-art results [25, 16, 40, 2]. Some recent methods show it is possible for unsupervised learned features to surpass supervised learning in some downstream applications [9]. However, performance gaps still exist between unsupervised and supervised learning methods in most cases [23]. Therefore, how to fully explore the potential of unsupervised learning and improve the learning quality is a valuable topic.

Instead of designing a new pretext task or a better contrastive learning loss, we try to look into this problem from a new perspective. As curriculum learning [5] suggests, when dealing with a complex learning target, learning things progressively can be very useful. Indeed, as humans, we learn visual concepts from easy to hard, and from elementary to fine-grained. Similarly, learning high-quality feature representations in an unsupervised manner is a challenging task, and may benefit from such ideas. In this paper, we propose PSL, a progressive stage-wise learning framework for unsupervised visual representation learning.

As presented in Fig 1, for a given unsupervised learning task $G$ (e.g., the jigsaw puzzle pretext task), we first do multi-level task design $G \rightarrow \{G_1, G_2, G_3\}$ with an increased task complexity. Then, a stage-wise network partition is performed to get early/mid/late stages (i.e., $S_1$, $S_2$ and $S_3$). Each learning stage is assigned with a task, following the principle of easy-to-hard. Then, a stage-wise training is performed. The training of lower stages become much easier as they focus on more simple tasks. The feature representations learned in upper stages are of better quality because they are trained upon the learning experience of former tasks. Our starting point is to design PSL as a plug-in learning method, which can be applied in any unsupervised learning scenarios under proper multi-level task design. We validate the effectiveness of the proposed PSL framework by evaluating our method on several unsupervised/self-supervised tasks (e.g., the jigsaw puzzle [38] and image rotation [21] pretext task and contrastive learning [10]) and present results on linear classification, semi-supervised learning and transfer learning.

In general, the contributions of this paper can be summarized as follows:

- PSL creates new dimensions for unsupervised learning research. Specifically, this includes task series, network partitions, and stage-wise training.
- PSL is design to be a general framework, that can be applied to multiple unsupervised learning tasks belonging to either pretext tasks or contrastive learning (e.g., jigsaw puzzle, image rotation, and SimCLR).
- By experiments of downstream applications (e.g., semi-supervised learning, transfer learning), we show that the feature representations learned by PSL consistently achieve better quality than the original unsupervised task.

2. Related Work

Our method falls in the area of unsupervised visual representation learning. We first revisit two categories of unsupervised learning method. Then, we review methods involving self-paced learning and local network training, which give inspiration in our PSL training scheme.

Handcrafted Pretext Tasks. Many self-supervised methods use a handcrafted pretext task to learning visual representations. Typically, a pretext task involves predicting an explicit property of an image transformation and the network is then trained to learn the feature representation. The quality of the learned representation is highly related to these tasks (e.g., predicting context [14], image rotation [21], image colorization [13, 49, 30, 32, 33], jigsaw puzzle [38, 6, 23] and visual counting [39]). Instead of designing a new pretext task, we propose a plug-in method to enhance the self-supervised learning, which can be used collaboratively with many pretext tasks.

Contrastive Learning. Unsupervised contrastive learning recently attracts lots of attention, for achieving state-of-the-art results on ImageNet [10, 26, 9]. Typically, a contrastive learning method learns feature representations by contrasting positive pairs against negative pairs, which is firstly proposed by Hadsell et al. [25]. Then, Dosovitskiy et al. [16] propose to represent each instance with a parametric vector. Later, the concept of memory bank, which stores the information of instance class representation, is adopted and developed further in many works [51, 44, 37]. Besides, there are many clustering-based methods [7, 8, 1, 20, 29, 47]. Our PSL training scheme can also fit into contrastive learning methods, bringing improvement to the quality of the learned feature representation.

Self-paced Learning Many self-paced learning methods simulate the learning process of “easy-to-hard” [24, 19, 42, 18]. [24] incorporates self-paced learning into deep clustering methods by controlling the number of selected data samples. [19] uses a self-paced learning strategy by identifying reliable and unreliable clusters to improve the accuracy in the re-clustering step. These methods are based on data-level information by defining easy/hard data samples while our method focus on the task-level design.

Local Network Learning. The end-to-end training protocol inaugurated a new era in deep learning. Some works jump out of traditional forward-backward training mode, with inspiration from neuroscience. An early research [35] shows that the way of the brain processing its perceptions...
is to maximally preserve the information contained in each layer. Several methods try to explore greedy layer-wise training schemes [4, 3], in which the possibility of scaling this scheme to ImageNet is discussed. Later, GIM [36] argues that with greedy self-supervised training, end-to-end propagation of a supervised loss is not necessary. Based on GIM [36], LoCo [48] improves the performance of local contrastive learning. Inspired by these local training strategy, we propose a stage-wise training algorithm and improve the performance in multiple unsupervised learning task.

3. Method

3.1. Overview

This work aims to introduce an unsupervised pre-training strategy. Many previous methods focus on designing handcrafted pretext tasks in a self-supervised learning setting [38, 21, 13]. Correspondingly, the results are highly related to how the pretext tasks are designed. Another type of work focuses on exploring the potential behind contrastive learning. These works concentrate on learning similar/dissimilar representations from organized similar/dissimilar data pairs. Both kinds are trying to uncover internal information of unlabeled data. As unsupervised learning becomes more and more important and challenging, how to take the best advantage of existing unsupervised learning ways is vital. In another word, how to do unsupervised learning more effectively?

In this work, we provide a new dimension in enhancing the unsupervised learning representation. Inspired by curriculum learning, we try to guide the neural network to learning feature representations in a progressive way (e.g., from easy tasks to hard tasks, from low-level features to high-level). To do so, we introduce our progressive stage-wise learning (PSL) framework for unsupervised learning.

3.2. Progressive Stage-wise Learning

In this sub-section, we explain how our progressive stage-wise learning (PSL) works. Suppose we have a learning target $G$, which can be an unsupervised contrastive learning task or any pretext task in the self-supervised learning setting. We use a neural network with a block-based architecture (designed by stacking blocks vertically, such as ResNet [27] and Inception [43]). What we do can be summarized into the following steps:

**Multi-level Task Design** Firstly, for the given learning target $G$, we design a series of learning tasks that share a similar form (e.g., the same pretext task) but with different task complexity. We sort these tasks according to their complexity: $\{G_1, G_2, G_3\}$, where $G_3$ is more complex than $G_2$, and so is $G_2$ compared to $G_1$. We use $L_1, L_2, L_3$ to represent the corresponding loss function. Instead of focusing on the hardest task (e.g., $G_3$) at the very beginning, we enable easier learning targets in the early learning stage. By doing so, we can train the neural network in a progressive learning manner, which turns out to be more efficient in many different unsupervised settings. We introduce our multi-level task design for specific tasks in Sec 3.3.

**Stage-wise Network Partition** In this step, we define different learning stages, which are basically determined by the layer depth. We take ResNet-50 for an example. Based on the resolution of the feature map, we divide all layers into five large blocks: $B_1, B_2, B_3, B_4$ and $B_5$, where $B_1$ represents the layer conv1. $B_2$ consists of all layers named conv2., and so on$^1$. Further, we group every three consecutive blocks into one learning stage: Stage $S_1$ consists of $B_1, B_2$ and $B_3$; Stage $S_2$ consists of $B_2, B_3$ and $B_4$; Stage $S_3$ consists of $B_3, B_4$ and $B_5$. By doing so, we get three stages ($S_1, S_2$ and $S_3$), representing lower, mid and upper learning stages of the network. Notice that there are overlaps between each two learning stages, which is discussed more in Sec 3.4.

**Progressive Network Learning** After we get a series of multi-level tasks and a proper stage partition, we begin the training process. As shown in Fig 2, the traditional end-to-end training protocol, forces the whole neural network to learn the final target directly. Instead, we train the neural network progressively in a stage-wise manner. More specifically, we set a different learning target for each stage, following the principle of easy-to-hard. We force lower layers of the network (e.g., layers in $S_1$) to learn low-level features by solving easier tasks (e.g., $G_1$). As the lower part of the network learns a good feature representation for the easy task, we increase the task complexity for the mid and upper stages by targeting at the task $G_2$ and $G_3$. By doing so, we naturally guide the network to gain better feature representation ability as the layer goes deeper. The benefits are three-fold. Firstly, the lower stage only has to focus on the easy task, which leads to easier training. Secondly, the upper stage can take advantage of the lower stages through weight sharing when dealing with a harder task. Thirdly, the backward propagation path is much shorter within each learning stage compared to end to end training. Without gradient error accumulation, the overall training can be much more efficient and effective.

More details of our framework are shown in Fig 2. The training targets $\{G_1, G_2, G_3\}$ are assigned to stages

$^1$Here, all layers within the same block shares the same feature map resolution. The layer name conv1 and conv2.x are inherited from the notation of ResNet [27].
\{S_1, S_2, S_3\} respectively. Notice that different from end-to-end training, backward gradients only flow back to layers in the same stage.

### 3.3. Multi-level Task Design Cases

In this sub-section, we introduce our multi-level task design for several different unsupervised/self-supervised learning tasks.

#### 3.3.1 Multi-level Jigsaw Puzzle

The jigsaw puzzle task [38] was first introduced to learn visual representations from unlabeled data, which turns out to be very useful in many downstream tasks, such as detection and classification. To create a jigsaw puzzle, a 225 × 225 pixel window is randomly cropped from an image. Then, the whole window is divided into a 3 × 3 grid, leading to nine 75 × 75 pixel cells. For each cell, a 64 × 64 pixel tile is picked randomly. Then an index permutation is sampled (e.g., \{1, 2, 3, 4, 5, 6, 7, 8, 9\} → \{3, 5, 7, 8, 4, 6, 9, 2, 1\}) from a pre-defined permutation set \(C\). The obtained 9 tiles are reordered according to the permutation. Finally, the reordered tiles of the puzzle are stacked along the channels and fed to the neural network to predict the permutation, which is usually a classification task. There are several factors that influence the complexity of the jigsaw puzzle. According to [38], the permutation set \(C\) influences the jigsaw task from two aspects: the set cardinality of \(C\) and the element similarity of \(C\). Generally, the difficulty of the jigsaw task increases as the set cardinality increases or the element similarity decreases. Under the original task setting, there are \(9! = 362880\) different permutations in total for every 9 tiles. Therefore, it is nearly impossible to include all permutations in the permutation set. Previous methods [38, 6] usually define a permutation set with a fixed size (e.g., 1000) in advance.

#### 3.3.2 Multi-level Image Rotation

The Image rotation task was firstly designed in self-supervised learning [21]. Image rotation can be considered as one of the image geometric transformations, which is very easy to perform. The core idea for this task is to use the neural network to estimate geometric transformation (i.e., the angle of rotation in this case). A common practice is to define the set of geometric transformation \(R\)
### Table 2. Multi-level task design for image rotation. Set\(^{†}\) denotes the rotation transformation set.

| Task | Set\(^{†}\) | Cardinality | Angle Base |
|------|-------------|-------------|------------|
| \(\mathcal{G}_1\) | \(\mathcal{R}_1\) | 2 | 180° |
| \(\mathcal{G}_2\) | \(\mathcal{R}_2\) | 4 | 90° |
| \(\mathcal{G}_3\) | \(\mathcal{R}_3\) | 8 | 45° |

As all the image rotations of 90 degrees (e.g., 2d image rotations by 0, 9, 180 and 270 degrees). Here, we use the size of transformation set \(\mathcal{R}\) to control the task difficulty. As shown in Table 2, we defined three set of geometric transformations as all image rotations of 180/90/45 degree, with 2/4/8 operations within each set respectively. For example, \(\mathcal{R}_1 = \{0°, 180°\}\), \(\mathcal{R}_2 = \mathcal{R}_1 \cup \{90°, 270°\}\) and \(\mathcal{R}_3 = \mathcal{R}_2 \cup \{45°, 135°, 225°, 315°\}\). Notice that, \(\mathcal{R}_1 \subseteq \mathcal{R}_2 \subseteq \mathcal{R}_3\), which indicates an increase in task complexity.

### 3.3.3 Multi-level Contrastive Learning

Contrastive learning has recently become a dominant approach in the area of self-supervised learning [10, 26, 11]. Typically, contrastive learning approaches learn representations by contrasting positive pairs against negative pairs. For example, SimCLR [10] makes use of multiple data augmentation operations to generate positive data pairs. Then a based encoder network is trained to maximize the similarity of positive data pairs meanwhile minimize the similarity of negative data pairs using a contrastive loss. We design our multi-level contrastive tasks based on the setting of SimCLR [10]. We control the task difficulty by manipulating the augmentation set \(\mathcal{T}\). For the low-level task (e.g., \(\mathcal{G}_1\)), we use a simple augmentation scheme and we increase the complexity of the augmentation scheme for high-level tasks (e.g., \(\mathcal{G}_3\)). Three kinds of augmentation are adopted: i) geometric transformation of data, such as cropping and resizing; ii) appearance transformation, such as color distortion and iii) other transformation, such as Gaussian blur and Sobel Filtering. As shown in Table 3, we set \(\mathcal{T}_1 = \{\text{Random Crop}\}\) as the first augmentation set for task \(\mathcal{G}_1\) and we add color distortion into the augmentation set \(\mathcal{T}_2\) for task \(\mathcal{G}_2\). Other transformation operations are included in the augmentation set \(\mathcal{T}_3\) for task \(\mathcal{G}_3\). Notice that \(\mathcal{T}_1 \subseteq \mathcal{T}_2 \subseteq \mathcal{T}_3\).

### Algorithm 1 Progressive Stage-wise Learning Algorithm.

**Input:** Learning Target \(\mathcal{G}\), Learning Loss \(\mathcal{L}\), backbone Network \(f\), projection head \(g_1\), \(g_2\) and \(g_3\), batch size \(N\)  
1. \(\mathcal{G} \rightarrow \{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}\) \text{▷ Multi-level Task Design}  
2. \(\mathcal{L} \rightarrow \{\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3\}\)  
3. \(f \rightarrow \{S_1, S_2, S_3\}\) \text{▷ Stage-wise Network Partition}  
4. for \(i \in \{1, 2, 3\}\) do  
   5. for sampled minibatch \(\{x_k\}_{k=1}^N\) do  
   6. Data pre-processing for task \(\mathcal{G}_i\)  
   7. \(h_k = f(x_k|S_i)\) \text{▷ Forward propagation}  
   8. \(z_k = g_i(h_k)\)  
   9. Computer gradient with respect to \(\mathcal{L}_i(x_k, z_k)\)  
   10. Update layers within \(S_i\)  
   11. Update \(g_i\)  
   12. end for  
5. end for  
6. Return \(f\), and discard \(g_1\), \(g_2\) and \(g_3\)

### 3.4 Stage-wise Network Training

As explained in section 3.2, three learning tasks \(\{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}\) are obtained, corresponding to three losses \(\{\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3\}\), and stages \(S_1, S_2, S_3\). Unlike traditional end-to-end learning, we adopt a local learning strategy. To be specific, the gradient of each learning stage does not flow back to other stages. For example, gradients generated by \(\mathcal{L}_2\) only influence layers within \(S_2\) (i.e., \(B_2, B_3\) and \(B_4\)) during the second learning stage. This allow the corresponding layers focus on the current learning target, which turns out to be good for overall training. Our learning algorithm is summarized in Algorithm 1. After we finish multi-level task design and stage-wise network partition, we start progressive stage-wise learning. There are three learning stages in total. During the \(i\)-th stage, we do data pre-processing first, which is determined by the specific learning task \(\mathcal{G}_i\). Then we do forward propagation with \(h_k = f(x_k|S_i)\) representing the output feature of stage \(S_i\). Then, \(h_k\) is sent to a decoder \(g_i\) for further processing before applying the stage loss \(\mathcal{L}_i\). Only layers within \(S_i\) and the decoder \(g_i\) are updated. After the training, all decoders will be removed and no extra computation cost is introduced in \(f\).

Notice that there are overlappings between each stage. Another stage partition approach is to cut the encoder into several non-overlapping parts and train the whole network in a greedy layer-wise manner like GIM [36]. In the case of GIM, upper layers/stages cannot receive gradient feedback from lower layers/stages. However, as the difficulty of the multi-level task increases, the quality of the intermediate representation of lower stages has a large influence on the final performance of the upper stages. Therefore, it is necessary for stages to have overlapping layers, which play a role in connecting and communicating between stages.
4. Experiment

In this section, we conduct experiments to validate the effectiveness of the proposed Progressive Stage-wise Learning (PSL) framework. Firstly, we apply PSL on several different kinds of unsupervised/self-supervised learning tasks to evaluate the quality of the learned representation on ImageNet [12]. Then, we report experiment results of downstream tasks, i.e., semi-supervised and transfer learning.

4.1. Implementation Details

Generally, we conduct contrast experiments on three different unsupervised/self-supervised learning methods. The basic implementation details for each task as follows:

**Jigsaw puzzle.** We perform multi-level task design $\mathcal{G} \rightarrow \{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}$ following Sec 3.3.1. Correspondingly, we use three different cardinality $\{500, 1000, 2000\}$ for the permutation set $\{\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3\}$, with $\mathcal{C}_1 \subseteq \mathcal{C}_2 \subseteq \mathcal{C}_3$, representing an increase in task complexity. We use ResNet-50 [27] as our backbone network and do PSL training on 8-gpus. For each input image, we resize the shorter side to resolution 256, randomly crop a 225x225 image and apply horizontal flip with 50% probability. For the training, we use mini-batch size of 256, initial learning rate of 0.01 with the learning rate dropped by a factor of 10. Following [23], we use momentum of 0.9, weight decay 1e-4 with no decay for the bias parameters. For each training stage of PSL, we train for 60 epochs and use the learning rate schedule of 20/20/10/10.

**Image rotation.** We perform multi-level task design $\mathcal{G} \rightarrow \{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}$ following Sec 3.3.2. Correspondingly, we set the rotation transformation set $\mathcal{T}_1 = \{0^\circ, 180^\circ\}$, $\mathcal{T}_2 = \{(90 \times i)^\circ | 0 \leq i \leq 3\}$ and $\mathcal{T}_3 = \{(45 \times i)^\circ | 0 \leq i \leq 7\}$. Notice that $\mathcal{T}_1 \subseteq \mathcal{T}_2 \subseteq \mathcal{T}_3$, representing an increase in task complexity. We use RevNet50 [22] as our backbone network and do PSL training on 8-gpus. For each input image, we resize the shorter side to 256 and do the rotation transformation according to the transformation set. We perform a center crop on the rotated image remaining the resolution and then randomly crop 224x224 image. For the training, we use mini-batch size of 256, initial learning rate of 0.01 with the learning rate dropped by a factor of 10. For each training stage of PSL, we train for 60 epochs and use the learning rate schedule of 20/20/10/10.

**Contrastive learning.** We perform multi-level task design $\mathcal{G} \rightarrow \{\mathcal{G}_1, \mathcal{G}_2, \mathcal{G}_3\}$ following Sec 3.3.3. Correspondingly, we set the transformation set as: $\mathcal{T}_1 = \{\text{Random crop}\}$, $\mathcal{T}_2 = \mathcal{T}_1 \cup \{\text{Color Distortion}\}$ and $\mathcal{T}_3 = \mathcal{T}_2 \cup \{\text{Gaussian Blur, Sobel Filtering}\}$. Notice that $\mathcal{T}_1 \subseteq \mathcal{T}_2 \subseteq \mathcal{T}_3$, representing an increase in task complexity. We use RevNet50 as our backbone network and a 2-layer MLP projection head to project the representation to a 128-dimensional space. Limited by computing resources, we use mini-batch size of 256 and train for 200 epochs (60/70/70 epochs for each learning stage) on 8-gpus. Notice that the max performance is not obtained in 200 epochs and 256 batch-size, reasonable results and fair comparison can still be achieved. Based on SimCLR [10], We use NT-Xent loss, learned in LARS optimizer with learning rate of 0.3 with a cosine decay schedule without restart. Similarly, we apply PSL on the data-augmentation part of MoCov2 [11] and get an improvement of 0.6%.

### Table 4

| Method                      | Arch | # Param(M) | Top 1 |
|-----------------------------|------|------------|-------|
| Colorization [49]           | R50  | 24         | 39.6  |
| BigBiGAN [15]               | R50  | 24         | 56.6  |
| LA [51]                     | R50  | 24         | 58.8  |
| NPID++ [37]                 | R50  | 24         | 59.0  |

| PIRL [37]                   | R50  | 24         | 63.6  |
| CPC v2 [28]                 | R50  | 24         | 63.8  |
| PCL [34]                    | R50  | 24         | 65.9  |
| SwAV [9]                    | R50  | 24         | 75.3  |
| Jigsaw [38]                 | R50  | 24         | 45.7  |
| Jigsaw + PSL                | R50  | 24         | 50.9  |
| Rotation [21]               | Rv50w4× | 86       | 47.3  |
| Rotation*                   | Rv50 | 24         | 48.6  |
| Rotation+ PSL               | Rv50 | 24         | 53.3  |
| SimCLR [10]                 | R50  | 24         | 61.9  |
| SimCLR+ PSL                 | R50  | 24         | 64.3  |
| MoCov2 [11]                 | R50  | 24         | 67.5  |
| MoCov2+ PSL                 | R50  | 24         | 68.1  |

2 Compared with ResNet [27], RevNet [22] is more suitable in image rotation tasks [31]. We don’t use RevNet50w4×, which is reported with better performance, because scaling up model complexity is not discussed in this paper.

3 1000 epochs with batch-size 4096 is reported with the best performance in SimCLR [10].
Table 5. Jigsaw Puzzle task of ResNet-50 top-1 center-crop accuracy for linear classification on the ImageNet dataset. Here $B_1 \sim B_5$ represent the blocks defined in Sec 3.2. The supervised results are presented for reference. Jigsaw is end-to-end trained with the task $G_1$. SL is short for stage-wise learning. In SL, we do stage-wise training with the jigsaw puzzle task $G_1$ as the learning target of each stage. PSL$_f$ is a full-gradient version of PSL. More discussion can be found in ablation in Sec 4.5.

| Method | Arch | $B_1$ | $B_2$ | $B_3$ | $B_4$ | $B_5$ |
|--------|------|-------|-------|-------|-------|-------|
| Supervised | R50 | 11.6  | 33.3  | 48.7  | 67.9  | 75.5  |

| PSL | R50 | 10.9  | 27.0  | 43.2  | 50.9  | 38.5  |
| PSL$_f$ | R50 | 10.8  | 27.3  | 43.1  | 51.0  | 38.2  |

Table 6. Image rotation task of RevNet-50 top-1 center-crop accuracy for linear classification on the ImageNet dataset. Here $B_1 \sim B_5$ represent the block defined in Sec 3.2. The supervised results are presented for reference. Rotation is end-to-end trained with the task $G_3$. SL is short for stage-wise learning. In SL, we do stage-wise training with the image rotation task $G_3$ as the learning target of each stage. PSL$_f$ is a full-gradient version of PSL. More discussion can be found in ablation in Sec 4.5.

| Method | Arch | $B_1$ | $B_2$ | $B_3$ | $B_4$ | $B_5$ |
|--------|------|-------|-------|-------|-------|-------|
| Supervised | Rv50 | 11.7  | 32.6  | 47.8  | 66.6  | 74.3  |
| Rotation | Rv50 | 11.0  | 30.1  | 40.2  | 48.6  | 46.5  |
| SL | Rv50 | 11.9  | 29.1  | 41.5  | 50.7  | 47.9  |
| PSL | Rv50 | 11.3  | 30.8  | 42.9  | 53.3  | 49.5  |
| PSL$_f$ | R50 | 10.5  | 31.1  | 42.1  | 52.9  | 49.7  |

Table 7. Semi-supervised learning on ImageNet. We use ResNet-50 as our backbone networks and report single-crop top-5 accuracy on the ImageNet validation set. All models are self-supervised trained on ImageNet and finetuned on 1% and 10% of the ImageNet training data, following [46, 37]. The supervised results are presented for reference.

| Task | 1% labels | 10% labels |
|------|-----------|------------|
| Supervised | 48.4 | 80.4 |
| Jigsaw [38] | 45.4 | 79.6 |
| Jigsaw+PSL | 48.7 | 83.5 |
| Rotation [21] | 52.1 | 82.5 |
| Rotation+PSL | 54.8 | 83.7 |

4.3. Semi-supervised Learning

Following the experiment setup of [46, 37], we perform semi-supervised image classification on ImageNet to evaluate the effectiveness of the pre-trained network in data-efficient settings. We do a class-balanced data selection to obtain 1% and 10% of the ImageNet training data and finetune the whole pre-trained network. Table 7 reports the top-5 accuracy of the resulting models on the ImageNet validation set. By contrast experiments on two pretext tasks, the proposed PSL training method can improve the top-5 accuracy by a large margin. In the jigsaw puzzle task, PSL brings an improvement of 3.3% and 3.9% for 1% and 10% labeled data respectively. For the image rotation task, PSL improves the performance by 2.7% and 1.2% respectively.

4.4. Transfer Learning

To further investigate the generalization ability of our method, we conduct transfer learning experiments including object detection on PASCAL VOC [17] and image classification results on three datasets. In this subsection, we use ResNet-50 as our backbone network both jigsaw puzzle and image rotation tasks. Results are reported in Table 8 and Table 9.

4.4.1 Object Detection

Following previous works [23, 37], we perform object detection experiments on the PASCAL VOC dataset [17] using VOC07+12 training split. We use Faster RCNN [41] object detector and ResNet-50 C4 [27] backbone. We follow the same training schedule as [23, 37] to finetune all models on VOC with BatchNorm parameters fixed during finetuning. We report our performance of $\{AP_{50}, AP_{75}, \Delta AP_{75}\}$ in Table 8. Compared with the vanilla pretext task, our PSL training scheme can substantially improve the three indicators, representing an enhancement of the learned feature representation. In the jigsaw puzzle pretext task, we get an improvement of $\{2.2, 3.8, 2.4\}$ respectively, while in the
We design Ablation: Progressive Mechanism. Here we discuss the effectiveness of the progressive mechanism. We design the setting of \[23\], we evaluate feature representations extracted from five intermediate blocks of the pre-trained network, and report the best classification results in Table 9. We report transfer learning performance on PASCAL \[17\], Places \[50\] and iNat18 \[45\]. In PASCAL, our PSL training improves the jigsaw puzzle task by 2.7%, and image rotation task by 2.4%. In Places, the PSL training improves the performance by 3.5% and 1.1% while in iNat18, the improvement is 2.8% and 2.9% for these two tasks respectively.

4.5. Analysis

Ablation: Progressive Mechanism. Here we discuss the effectiveness of the progressive mechanism. We design a gradient association in each learning stage. Specifically, the gradient of \(L_3\) will not flow back to \(B_1\) and the gradient of \(L_3\) will not influence \(B_1\) and \(B_2\). We implement the full gradient version of PSL where in each learning stage, all layers are updated without gradient restriction. We show the linear classification results on ImageNet dataset as PSL in Table 5 and Table 2. From the results, we conclude that full gradient training does not necessarily bring an improvement in the unsupervised training performance. Therefore, we set gradient restriction in each learning stage, which will also reduce the computation cost during training.

Local Training. We do not adopt a greedy block-wise learning scheme like \[36\]. Instead, we enhance stage-wise learning by enabling gradient flow between stages. A similar approach is adopted in LoCo \[48\], where gradient connections are enabled in adjacent blocks. In PSL, block connections are further enhanced (e.g., learning stage \(S_3\) have impact on \(B_3\), which is also included in learning stage \(S_1\)). By comparing PSL and PSL\(_f\) in Table 5 and 6, we show that this design helps enhance the learning quality of various unsupervised tasks.

5. Conclusion

In this work, we present a Progressive Stage-wise Learning (PSL) framework for unsupervised/self-supervised learning. Through multi-level task design and progressive stage-wise training, PSL improves many mainstream unsupervised methods. We provide experiments in three different tasks (i.e., jigsaw puzzle, image rotation and contrastive learning) in this paper and validate the effectiveness of PSL. Our future work involves exploring PSL on other tasks and searching for the optimal architecture for PSL framework. We hope PSL can be a universal unsupervised training approach in enhancing the learned feature representation.
