Abstract This paper presents an investigation into the evolution and dynamics of the simplest generalization of binary cellular automata: Affine continuous cellular automata (ACCAs), with [0, 1] as state set and local rules that are affine in each variable. The focus lies on legal outer-totalistic ACCAs, an interesting class of dynamical systems that exhibit some behavior that is not observed in the binary case. A unique combination of computer simulations (sometimes quite advanced) and a panoply of analytical methods allows to lay bare the dynamics of each and every one of these continuous cellular automata. The results also show that in the class of ACCAs considered, all types of sensitivity can be observed: sensitivity to a change of the number of cells in the grid, sensitivity to slight changes in the parameters of a local rule and sensitivity to the change of a single value in an initial configuration.

1 Introduction

Continuous cellular automata (CCAs) can be seen as a generalization of cellular automata (CAs), in which time and space are still discrete, but cells can take states from some infinite (often continuous) set. One of the best-known examples of such dynamical systems are coupled map lattices [1–3]. A well-known generalization of binary CAs to CCAs with [0, 1] as state set is obtained by “fuzzification” in [4] and was further studied, for example, in [5,6]. This fuzzification process allows to associate with every binary CA some particular CCA (a so-called Fuzzy CA) through an extension of the domain of the local rule. The relationship between Fuzzy CAs and elementary CAs (ECAs) can be found in [7].

A further generalization of the above idea has resulted in the definition of affine CCAs (ACCAs) [8]. This kind of CCAs is considered to be the simplest possible generalization of binary CAs—of course, apart from the Fuzzy CAs—as they have a local rule that is affine in each variable. It appears that ACCAs exhibit a much richer behavior than the binary CAs they stem from. For example, most density-conserving ACCAs can solve the relaxed density classification
problem, which is not possible with binary CA, a result obtained through a theoretical study of the dynamics of density-conserving ACCAs [9]. It is known that CCAs, although they include “cellular automata” in their name, usually have a much more complicated dynamics than classical CAs. Together with the introduction of continuity in the set of states and sometimes also in the set of parameters that define the local rule (as in the case of ACCAs), phenomena such as bifurcation or phase transition occur naturally. This translates into a much greater difficulty in studying the dynamics of such dynamical systems. For this reason, the investigation of the dynamics of CCAs is often performed through computer simulation only (see, for example, [3,4,10–13]).

However, it should be emphasized that the results of computer simulations should be handled with care, and this for several reasons. First of all, the results may depend on the precision arithmetic used. Secondly, it is not obvious how convergence should be decided upon. Also, in computer simulations, there is no possibility to consider all grids and all corresponding initial configurations and one usually sets a certain “large enough” number of cells and selects some “large enough” subset of initial configurations. However, we must be aware that, for example, for 100 cells, there are as many as $2^{100}$ binary initial configurations, so any reasonable subset suitable for computer simulations will be a tiny fraction of a percent of the total. Additionally, oftentimes CAs and CCAs behave differently depending on the number of cells (for example, the dependence on parity in the case of CAs with radius 1). Furthermore, when the phenomena observed, such as bifurcations or phase transitions, are characterized by numerical parameters, the values of the latter can only be found approximately. Finally, simulations may indicate the existence of a phase transition, but in reality it may not exist (or vice versa). Despite all the reasons described above, computer simulations can be an important tool in studying the dynamics of CCAs as a source of inspiration (see, for example, [5,9,14]).

The situation is quite different for analytical research as its results are fully trustable. Unfortunately, so far there are only a few papers on CCAs and all of them deal with the one-dimensional case only. One of the types of CCAs for which researchers have been able to analyze the dynamics analytically is the class of fuzzy CAs. One can find papers describing the dynamics of individual Fuzzy CAs, like fuzzy rule 90 [6], 110 [15], 123, 30 [16] or 184 [17], as well as papers adopting a much more general approach (see, for instance, [18,19]). The dynamics of Fuzzy CAs called weighted average rules is theoretically explained in [5]. This detailed analytical study confirmed, among other things, the empirical observation that all weighted average rules are periodic in time and space. It is safe to say that all of the 256 elementary Fuzzy CAs have been examined. In contrast, the study of ACCAs has just been initiated. Virtually the only class of ACCAs whose dynamics has been thoroughly examined is the class of one-dimensional density-conserving ACCAs with radius 1 [9].

In this paper, we focus on another class of one-dimensional ACCAs with radius 1: ACCAs that are both outer-totalistic and legal. The first property means that such ACCAs update the value of a cell only on the basis of the current value of the cell and the sum of the values of all other cells in the neighborhood of that cell. The second property ensures that nothing can be produced from zeros. A combination of these two properties is very often used when modeling various phenomena (see [20] for some examples). In particular, it is a basic assumption in each “full of common sense” Lifelike CA, i.e., being similar to Conway’s Game of Life [21,22]. Thus, such Fuzzy CAs are used to create one-dimensional and two-dimensional CCAs that generalize the Game of Life [23]. For this reason, legal outer-totalistic ACCAs are at the core of interest.

Our motivation to consider one-dimensional ACCAs only is rather simple: We have set ourselves the goal to explore the dynamics theoretically and not by analyzing computer simulations only. As will become clear, even in the one-dimensional case this is a challenging task. Up to now, there are no such theoretical results on the dynamics of two-dimensional cellular automata, such as the mentioned Game of Life, despite the ample interest of researchers (see, for instance, [24–26]). Moreover, even in the case of one-dimensional cellular automata, virtually all existing research describes the dynamics on the basis of computer simulations (see, for instance, [27,28]).

Among the ECAs, there are 64 outer-totalistic CAs. Only four of them are still outer-totalistic after the “fuzzification” process and all show a very simple dynamics. Restricting our attention to the legal ones, we are left with only two ECAs, i.e., only two ECAs are still legal and outer-totalistic after fuzzification: ECA 0 (the zero rule) and ECA 204 (the identity rule). The situation looks quite different for ACCAs. There are
infinite many legal outer-totalistic ACCAs and their dynamics are very diverse, which will be extensively demonstrated in this paper. To be more precise, we will uncover the dynamics of all such ACCAs. Preliminary hypotheses will be generated on the basis of computer simulations, but will then be confirmed analytically. More specifically, we will use the results of preliminary computer simulations (sometimes quite advanced) to identify the proper mathematical tools for our theoretical analysis. This approach will allow to lay bare the dynamics of each and every outer-totalistic legal ACCA. The results also imply that in this class of continuous cellular automata one can observe all types of sensitivity: sensitivity to a change of the number of cells in the grid, sensitivity to slight changes in the parameters of a local rule and sensitivity to the change of a single value in an initial configuration. All the results presented in this paper are new (except when the rule single value in an initial configuration. All the results in the grid, sensitivity to slight changes in the parameter analysis. This approach will allow to lay bare the dynamics of all such ACCAs. Preliminary demonstrated in this paper. To be more precise, we will uncover the dynamics of all these CA families are defined by Eq. (1), but only in the case of ECAs both \((l_0, l_1, \ldots, l_7) \in \{0, 1\}^8\)

responding to the \(r\)th time step. Moreover, we will write \(x_n^r\) to denote the value of the \(n\)th cell in \(F^r(x)\).

For a given configuration \(x \in [0, 1]^N\), we define the sum of its states and its density, respectively, by

\[
\sigma(x) = \sum_{i=0}^{N-1} x_i \quad \text{and} \quad \rho(x) = \frac{1}{N} \sigma(x).
\]

Furthermore, for \(x \in [0, 1]^N\) and \(t \in \mathbb{N}\), we denote the minimal and maximal value among \(x_0^{t}, x_1^{t}, \ldots, x_{N-1}^{t}\) by \(\min(F^t(x))\) and \(\max(F^t(x))\), respectively. The Euclidean norm in \(\mathbb{R}^N\) is denoted by the symbol \(\|\cdot\|\). For the sake of brevity, we often express configurations in a more compact form and write, for instance, \(1204101\) as a self-explanatory shorthand for \(1100010101\).

In this paper, we restrict our attention to the interesting class of affine CCAs (ACCAs), i.e., CCAs whose local rule is affine in each variable (see [9]). To define a function \(f : [0, 1]^3 \rightarrow [0, 1]\) that is affine in each variable, we start by defining the values of \(f\) on \([0, 1]^3\), i.e., we fix the values \(l_0 = f(0, 0, 0), l_1 = f(0, 0, 1), l_2 = f(0, 1, 0), l_3 = f(0, 1, 1), l_4 = f(1, 0, 0), l_5 = f(1, 0, 1), l_6 = f(1, 1, 0)\) and \(l_7 = f(1, 1, 1)\). The sequence \((l_0, l_1, \ldots, l_7) \in \{0, 1\}^8\) is called the lookup table (LUT) of \(f\). The general form of a LUT is given in Table 1.

Next, we extend the function to the entire domain \([0, 1]^3\). Obviously, the extension that is affine in each variable is unique and can be expressed as the following polynomial:

\[
f(x, y, z) = l_0(1 - x)(1 - y)(1 - z) + l_1(1 - x)(1 - y)z + l_2(1 - x)yz(1 - y) + l_3(1 - x)yz + l_4x(1 - y)(1 - z) + l_5xz(1 - y)z + l_6xy(1 - z) + l_7xyz.
\]

ACCAs are a generalization of Fuzzy CAs that are constructed from ECAs by “fuzzification” of their disjunctive normal form [29]. Thus, there are exactly 256 Fuzzy CAs, because each ECA corresponds to a unique Fuzzy CA, whose local rule is also defined by Eq. (1), where \(l_0, \ldots, l_7\) are the LUT entries of the given ECA.

To understand the difference between ECAs, Fuzzy CAs and ACCAs, it is worth emphasizing that the local rules of all these CA families are defined by Eq. (1), but only in the case of ECAs both \((l_0, l_1, \ldots, l_7) \in \{0, 1\}^8\)
and \((x, y, z) \in \{0, 1\}^3\). In the case of Fuzzy CAs, still \((l_0, l_1, \ldots, l_7) \in \{0, 1\}^8\) but \((x, y, z) \in \{0, 1\}^3\), while in the case of ACCAs both \((l_0, l_1, \ldots, l_7) \in \{0, 1\}^8\) and \((x, y, z) \in \{0, 1\}^3\).

In the investigations presented in this paper, we will further restrict our attention to legal outer-totalistic ACCAs. An outer-totalistic CA is a CA whose local rule depends only on the state of the focal cell and the sum of the states of the adjacent cells. The following theorem provides a necessary and sufficient condition for an ACCA to be outer-totalistic.

**Theorem 1** A one-dimensional ACCA is outer-totalistic if and only if the entries of the LUT of its local rule satisfy

\[
\begin{align*}
    l_0 &= a \\
    l_1 &= b \\
    l_2 &= c \\
    l_3 &= d
\end{align*}
\]

where \(a, b, c, d \in \{0, 1\}\), \(\frac{1}{2}a \leq b \leq \frac{1}{2}a + \frac{1}{2}\) and \(\frac{1}{2}c \leq d \leq \frac{1}{2}c + \frac{1}{2}\). In other words, the local rule \(f\) of an outer-totalistic ACCA is given by the following formula

\[
f(x, y, z) = (d - c - b + a)(x + z)y + (b - a)(x + z) + (c - a)y + a.
\]

**Proof** It is easy to see that if \(f\) is given by Eq. (3), with the restrictions that \(a, b, c, d \in \{0, 1\}\), \(\frac{1}{2}a \leq b \leq \frac{1}{2}a + \frac{1}{2}\) and \(\frac{1}{2}c \leq d \leq \frac{1}{2}c + \frac{1}{2}\), the corresponding ACCA is outer-totalistic. To prove that the conditions in Eq. (2) are necessary, it suffices to note that the following equalities have to hold:

\[
\begin{align*}
    f(0, 1, 0) &= f(0, 0, 1) \\
    f(1, 1, 0) &= f(0, 0, 1)
\end{align*}
\]

Hence, from Eq. (1) we get

\[
\begin{align*}
    l_4 &= \frac{1}{4}(l_0 + l_1 + l_4 + l_5) \\
    l_6 &= \frac{1}{4}(l_2 + l_3 + l_6 + l_7)
\end{align*}
\]

which yields Eq. (2). Substituting Eq. (2) into Eq. (1), we then get Eq. (3).

Let us note that for Fuzzy CAs the necessary and sufficient condition for being outer-totalistic is exactly the same as for ACCAs in Theorem 1 with the additional assumption that \(a, b, c, d \in \{0, 1\}\). As a consequence, we obtain that among the 64 outer-totalistic ECAs, only four of them are still outer-totalistic when we extend the domain of their local rule from \([0, 1]^3\) to \([0, 1]^3\). These are: ECA 0, ECA 51 (the negation), ECA 204 (the identity) and ECA 255. Thus, there are only four outer-totalistic Fuzzy CAs with the following local rules: \(f_1(x, y, z) = 0, f_2(x, y, z) = 1 - y, f_3(x, y, z) = y\) and \(f_4(x, y, z) = 1\). All of these rules give rise to a very simple dynamics.

According to Theorem 1, the set of all outer-totalistic ACCAs is parameterized by points of the four-dimensional polytope that can be obtained as the Cartesian product \(D \times D\), where the parallelepiped \(D\) has vertices \((0, 0), (0, 1), (1, 1)\) and \((0, 0.5)\).

It is easy to see that if some ACCA is outer-totalistic and its local rule \(f\) is parameterized by a point \((a, b, c, d)\), then the conjugate CA, whose local rule \(f^C\) is given by \(f^C(x, y, z) = 1 - f(1 - x, 1 - y, 1 - z)\), is also an outer-totalistic ACCA. Moreover, \(f^C\) is parameterized by the point \((a', b', c', d')\), where \(a' = 1 + c - 2d, b' = 1 - d, c' = 1 + a - 2b\) and \(d' = 1 - b\). Note that the behavior of \(f^C\) is strongly related to the behavior of \(f\). Indeed, if \(x\) is any configuration from \([0, 1]^N\) and \(y\) is the configuration given by \(yi = 1 - xi,\) for \(i \in \{0, 1, \ldots, N - 1\}\), then at each time step \(t \geq 0\) it holds that \(y^t_i = 1 - x^t_i\). For binary CAs the conjugation \(F \mapsto F^C\) is often called the white-to-black transformation.

The following theorem shows a basic property of the local rule of ACCAs.

**Theorem 2** Let \(0 \leq m \leq M \leq 1\). If a function \(f : [0, 1]^3 \mapsto [0, 1]\) is affine in each variable, then for any \(x, y, z \in [m, M]\), it holds that

\[
\min(V) \leq f(x, y, z) \leq \max(V).
\]
where the set $V$ is defined as

$$V = \{ f(x, y, z) \mid x, y, z \in \{m, M\} \}.$$

We omit the proof, as it is an immediate consequence of the monotonicity of $f$ w.r.t. each variable.

In this paper, we focus on a subclass of outer-totalistic ACCAs, known as legal ACCAs: A CA is called legal if it cannot produce anything from zeros, i.e., its local rule $f$ satisfies $l_0 = f(0, 0, 0) = 0$. According to Eqs. (2) and (3), the local rule of a legal outer-totalistic ACCA is given by

$$f(x, y, z) = (d - c - b)(x + z)y + b(x + z) + cy, \quad (4)$$

where $0 \leq b \leq \frac{1}{2}$, $0 \leq c \leq 1$ and $c \leq 2d \leq c + 1$. These restrictions on the parameters $b, c, d$ generate a parallelepiped $P$ in the Cartesian coordinate system, which is shown in Fig. 1.

As one can see, the parallelepiped $P$ has eight vertices; thus, there are exactly eight extreme points in the set of all legal outer-totalistic ACCAs (see Table 2). The local rule of any legal outer-totalistic ACCA can be written as a convex combination of the local rules listed in the last column of Table 2.

### Table 2 Analytical expressions of the local rules corresponding to the extreme points in the set of legal outer-totalistic ACCAs

| Vertex | Corresponding local rule |
|--------|--------------------------|
| $P_0 = (0, 0, 0)$ | $f(x, y, z) = 0$ (ECA 0) |
| $P_1 = (\frac{1}{2}, 0, 0)$ | $f(x, y, z) = \frac{1}{2}(x + z)(1 - y)$ |
| $P_2 = (0, 0, \frac{1}{2})$ | $f(x, y, z) = \frac{1}{2}(x + z)y$ |
| $P_3 = (\frac{1}{2}, 0, \frac{1}{2})$ | $f(x, y, z) = \frac{1}{2}(x + z)$ |
| $P_4 = (\frac{1}{2}, 1, \frac{1}{2})$ | $f(x, y, z) = y + (x + z)(\frac{1}{2} - y)$ |
| $P_5 = (0, 1, \frac{1}{2})$ | $f(x, y, z) = y - \frac{1}{2}(x + z)y$ |
| $P_6 = (\frac{1}{2}, 1, 1)$ | $f(x, y, z) = y + \frac{1}{2}(x + z)(1 - y)$ |
| $P_7 = (0, 1, 1)$ | $f(x, y, z) = y$ (ECA 204) |

### 3 Computer simulations

Our goal is to examine the dynamics of all legal outer-totalistic ACCAs; more specifically, we want to determine how these dynamics evolve when starting from binary configurations. We concentrate on such initial configurations for two reasons. Firstly, many problems concerning cellular automata are centered on binary configurations (as, for example, the density classification problem). Secondly, we want to deal with a finite set of initial configurations to be able to examine all of them using computer simulations.

Our investigation started with very detailed simulations, described below, whose results facilitated to formulate preliminary hypotheses (depending on the range of the parameters $b, c$ and $d$), some of which could be easily confirmed theoretically, while other ones required often very sophisticated additional simulations, revealing the underlying mechanism of a given ACCA in detail. This was essential in order to be able to choose the proper analytical tools and mathematical proof methods. As a result, it became possible to describe and theoretically confirm the dynamics of all legal outer-totalistic ACCAs. Below, we present the experimental setup for the first part of the simulations.

If the number of cells $N$ is given, then $X_N$ denotes the set of all binary configurations of length $N$, i.e., $X_N = \{0, 1\}^N$. Additionally, we use the notations $X_N^0$, $X_N^1$ and $X_N^{0,1}$ to refer to the set $X_N$ without $0^N$, $1^N$ or both of these elements, respectively, i.e.,

$$X_N^0 = X_N \setminus \{0^N\}, \quad X_N^1 = X_N \setminus \{1^N\},$$

$$X_N^{0,1} = X_N \setminus \{0^N, 1^N\}.$$
where, as mentioned earlier, $0^N$ and $1^N$ are shorthand for $0...0$ and $1...1$.

In the first part of our experiments, we sampled the set of all legal outer-totalistic ACCAs parameterized by $(b, c, d)$ by varying the parameter $c$ from 0 to 1 with a step size of 0.1 and—taking into account Theorem 1—the parameters $b, d$ from 0 to 0.5 and from 0.5$c$ to 0.5$+0.5$, respectively, with a step size of 0.05. For each such set of parameters, we defined the local rule $f$ by the expression in Eq. (4), resulting in a set $R$ containing 1331 rules.

Because we did not want to be dependent on randomly selected configurations, we chose small $N$ and examined all binary configurations of this length. As our investigations conducted in a previous work [9] showed that the behavior of an ACCA may depend on whether $N$ is odd or even, we considered two specific sizes of the grid: $N = 10$ and $N = 11$. Note that $|X_{10}| = 2^{10}$ and $|X_{11}| = 2^{11}$. For every local rule $f \in R$, we carried out the following simulations. For each $x \in X_N$, we ran the corresponding global rule $F$ for $\Lambda = 10000$ iterations and classified $x$, by checking the output configurations $F^\Lambda(x), F^{\Lambda-1}(x), F^{\Lambda-2}(x)$, to the first group $G_i^{(N)}$ with a matching condition:

$G_0^{(N)}$: all cell states are close to 0 and configurations $F^\Lambda(x)$ and $F^{\Lambda-1}(x)$ are almost the same, i.e., $\max(F^\Lambda(x)) < \varepsilon$ and $\|F^\Lambda(x) - F^{\Lambda-1}(x)\| < \eta$. In this case, we conjecture that $F^t(x)$ tends to $0^N$.

$G_1^{(N)}$: all cell states are close to 1 and configurations $F^\Lambda(x)$ and $F^{\Lambda-1}(x)$ are almost the same, i.e., $\min(F^\Lambda(x)) > 1 - \varepsilon$ and $\|F^\Lambda(x) - F^{\Lambda-1}(x)\| < \eta$. In this case, we conjecture that $F^t(x)$ tends to $1^N$.

$G_2^{(N)}$: all cell states are close to the same value and configurations $F^\Lambda(x)$ and $F^{\Lambda-1}(x)$ are almost the same, i.e., $\max(F^\Lambda(x)) - \min(F^\Lambda(x)) < \varepsilon$ and $\|F^\Lambda(x) - F^{\Lambda-1}(x)\| < \eta$. In this case, we conjecture that $F^t(x)$ tends to $c^N$, for some $c \in (0, 1)$ (the constant $c$ may depend on $x$).

$G_3^{(N)}$: all cell states are close to the same value and configurations $F^\Lambda(x)$ and $F^{\Lambda-2}(x)$ are almost the same, i.e., $\max(F^\Lambda(x)) - \min(F^\Lambda(x)) < \varepsilon$ and $\|F^\Lambda(x) - F^{\Lambda-2}(x)\| < \eta$. In this case, we conjecture that $F^t(x)$ tends to $c_1^N$ and $F^{2t+1}(x)$ tends to $c_2^N$, for some $c_1, c_2 \in [0, 1]$ (a convergence with period 2).

$G_4^{(N)}$: configurations $F^\Lambda(x)$ and $F^{\Lambda-1}(x)$ are almost the same, i.e., $\|F^\Lambda(x) - F^{\Lambda-1}(x)\| < \eta$. In this case, we assume that $F^t(x)$ tends to some fixed configuration.

$G_5^{(N)}$: all other configurations.

We will drop the upper index $(N)$ unless confusion is possible.

For the reported experiments, we chose $\varepsilon = 0.001$ and $\eta = 0.01$. As a result, for every local rule $f \in R$, we obtained 12 subsets of binary configurations: $G_0^{(10)}, \ldots, G_5^{(10)}$ and $G_0^{(11)}, \ldots, G_5^{(11)}$, satisfying $G_0^{(10)} \cup G_1^{(10)} \cup \ldots \cup G_5^{(10)} = X_{10}$ and $G_0^{(11)} \cup G_1^{(11)} \cup \ldots \cup G_5^{(11)} = X_{11}$. On this basis, we formulated the preliminary hypothesis on the dynamics of $f$.

For example, for the local rule $f(x, y, z) = 0.1(x + z)y + 0.5y$, parameterized by the point $(b, c, d) = (0, 0.5, 0.6)$, the simulations yield $G_0^{(10)} = X_{10}$ and $G_0^{(11)} = X_{11}$, (while the other subsets are empty). Thus, it is obvious that we conjecture that for each binary configuration $x \in X_N$, it holds that $F^t(x)$ tends to $0^N$.

As mentioned above, the results of these first experiments allowed to detect the nature of many legal outer-totalistic ACCAs. Moreover, it is not hard to confirm these observations theoretically (see, for example, Sect. 4.3). However, for some local rules we were forced to perform additional simulations. In particular, we varied $N, \varepsilon, \eta$, and used various data exploration techniques that allow for tracking both the positions and values of $\min(F^t(x))$ and $\max(F^t(x))$. In some cases, we relied on a visualization of the dynamics.

To visualize the dynamics of an ACCA, we use a slight modification of the radial view of CCAs—a method proposed in [30]. If the number of cells $N$ is given, we consider a circle with radius 1.1 and center $C$ divided in $N$ equal sectors by points $A_0, A_1, \ldots, A_{N-1}$. The value $x_n$ of the $n$th cell is represented by a dot lying on the line segment $CA_n$ at a distance $0.1 + x_n$ from $C$. For the sake of convenience, we connect subsequent dots using a polyline. Four examples of the radial view of some configurations from $[0, 1]^{10}$ are shown in Fig. 2.

The radial representations at subsequent time steps allow to observe the evolution of a given CCA and gain some intuition about the rules that govern it. For example, Fig. 3 shows the dynamics of the ACCA with the local rule $f(x) = -0.25(x + z)y + 0.5(x + z)$, parameterized by the point $(b, c, d) = (0.5, 0.5, 0.25)$, starting from the initial configuration $x = 1^4(10)^3$. 

\[ Springer \]
A complete description of the dynamics

Fig. 2 A radial view of sample configurations \( x \in [0, 1]^{10} \)

The simulation suggests a convergence with period 2: \( F^{2i}(x) \rightarrow (\alpha 0)^{5} \) and \( F^{2i+1}(x) \rightarrow (0\alpha)^{5} \), for some \( \alpha \in (0, 1) \). As we will see further on, Theorem 7 will confirm this observation.

4 Dynamical properties of legal outer-totalistic ACCAs

In this extensive section, we provide a detailed description of the dynamics of all legal outer-totalistic ACCAs.

4.1 General convergence results

We start with the following simple, yet crucial observation concerning local rules parameterized by points of \( P \) not lying on the left face \( (P_{0}P_{1}P_{3}P_{2}) \), back face \( (P_{0}P_{3}P_{7}P_{2}) \) and upper face \( (P_{2}P_{3}P_{6}P_{7}) \), i.e., points \( (b, c, d) \in P \) satisfying \( b, c > 0 \) and \( 2d - c < 1 \).

Lemma 1 Let \( f \) be the local rule parameterized by a point \( (b, c, d) \in P \), and let \( F \) be the corresponding global rule. Suppose that \( b, c > 0 \) and \( 2d - c < 1 \).

(p1) Let \( (x, y, z) \in [0, 1]^{3} \). Then \( f(x, y, z) = 0 \) only for \( (x, y, z) = (0, 0, 0) \) and, additionally, for \( (x, y, z) = (1, 1, 1) \) if \( c = 2d \). Furthermore, \( f(x, y, z) = 1 \) only for \( (x, y, z) = (0, 1, 0) \) if \( c = 1 \) and \( (x, y, z) = (1, 0, 1) \) if \( b = \frac{1}{2} \).

(p2) For any \( x \in X_{N}^{0,1} \) and any \( t \geq 2 \), the configuration \( F^{t}(x) \) does not contain any 1s.

(p3) For any \( x \in X_{N}^{0,1} \) (if \( (b, c, d) \not= P_{4} \) or \( N \) is odd) and for any \( x \in X_{N}^{0,1} \setminus \{ (01)^{N}, (10)^{N} \} \) (if \( (b, c, d) = P_{4} \) and \( N \) is even), if \( t > \frac{N}{2} + 2 \), then the configuration \( F^{t}(x) \) does not contain any 0s.

Proof(p1) Let \( 0 < b \leq \frac{1}{2}, 0 < c \leq 1 \) and \( c \leq 2d < c + 1 \). Note that according to Eq. (4), it holds that

\[
\begin{align*}
&f(0, 0, 0) = 0, \\
&f(0, 0, 1) = f(1, 0, 0) = b, \\
&f(0, 1, 1) = f(1, 1, 0) = d, \\
&f(1, 1, 1) = 2d - c.
\end{align*}
\]

Among the values different from \( f(0, 0, 0) \), only \( f(1, 1, 1) \) may be zero if \( 2d - c = 0 \). Moreover, the vertices \( (0, 0, 0) \) and \( (1, 1, 1) \) do not lie on a common edge in \([0, 1]^{3}\); thus, it is not possible to get \( f(x, y, z) = 0 \) if \( (x, y, z) \) is neither \( (0, 0, 0) \) nor \( (1, 1, 1) \). This follows directly from the fact that \( f \) is affine w.r.t. each variable and the minimal value of \( f \) on \([0, 1]^{3}\) is zero. Similarly, \( f(x, y, z) \) only takes value 1 for \( (0, 1, 0) \) if \( c = 1 \), or \( (1, 0, 1) \) if \( b = \frac{1}{2} \).

(p2) Suppose that \( x \in X_{N}^{0,1}, t \geq 2 \), but \( F^{t}(x) \) contains 1. If so, then according to (P1), \( F^{t-1}(x) \) has to contain a string 01 and, consequently, \( F^{t-2}(x) \) contains a string \( xyz\bar{u} \) such that \( f(x, y, z) = 0 \) and \( f(y, z, u) = 1 \). However, the first equality implies \( y = z \), while the second one is possible only when \( y \neq z \). This contradiction shows that \( F^{t}(x) \) cannot contain any 1s if \( t - 2 \geq 0 \).

(p3) Suppose that \( x \in X_{N}^{0,1} \). From (P2) we know that \( F^{t}(x) \) does not contain any 1s. According to (P1), if \( F^{2}(x) = 0^{N} \), then \( F^{3}(x) = 0^{N} \), or \( F^{1}(x) = 1^{N} \) and \( c = 2d \). As the first case is impossible (since \( x \neq 0^{N} \) and \( x \neq 1^{N} \)), it has to hold that \( F^{1}(x) = 1^{N} \) and \( c = 2d \). However, \( F^{1}(x) = 1^{N} \) only when \( N \) is even, \( x = (01)^{\frac{N}{2}} \) or \( x = (10)^{\frac{N}{2}} \), and both \( b = \frac{1}{2} \) and \( c = 1 \). Thus, if \( (b, c, d) \neq P_{4} \) or \( N \) is odd, then \( F^{2}(x) \neq 0^{N} \). The same holds when \( (b, c, d) = P_{4}, N \) is even but \( x \neq (01)^{\frac{N}{2}} \) and \( x \neq (10)^{\frac{N}{2}} \). If so, then in each subsequent
Fig. 3 Visualization of the dynamics of an ACCA with the local rule parameterized by the point \((b, c, d) = (0.5, 0, 0.25)\) starting from the initial configuration \(x = 1111101010\). The subsequent radial views show \(F_t(x)\) for given \(t\) time step, the length of every string of 0s in \(x\) is reduced by one on each side; hence, \(F_t^{k+} (x)\) has no 0 for \(s > \frac{N}{2}\).

Since we consider legal ACCAs, it holds that \(F_t(0^N) = 0^N\) for any \(t > 0\). Moreover, as we will see, for many \((b, c, d) \in \mathcal{P}\) and many \(x \in X_N\), it holds that \(F_t(x) \to 0^N\). The following lemma characterizes the homogeneous configurations \(s^N \in X_N\) that may be the limit of some sequence \((F_t(x))_{t \in \mathbb{N}}\) when \(b + c - d \neq 0\).

**Lemma 2** Let \(f\) be the local rule parameterized by a point \((b, c, d) \in \mathcal{P}\) and let \(F\) be the corresponding global rule. Suppose that \(b + c - d \neq 0\). If for some \(x \in X_N\) it holds that \(\lim_{t \to \infty} F_t(x) = s^N\), then \(s = 0\) or \(s = \frac{2b + c - 1}{2(b + c - d)}\).

**Proof** If \(\lim_{t \to \infty} F_t(x) = s^N\), then \(f(s, s, s) = s\). Hence, according to Eq. (4) we obtain

\[
2(d - c - b)s^2 + (2b + c)s = s. \tag{6}
\]

Since \(b + c - d \neq 0\), Eq. (6) has only two solutions: \(s = 0\) or \(s = \frac{2b + c - 1}{2(b + c - d)}\), which proves our claim.

Note that although \(\frac{2b + c - 1}{2(b + c - d)}\) is bounded from above by 1, it still might be negative, in which case the only possible homogeneous limit of \(F_t(x)\) is \(0^N\).

4.2 The case \(2d - c = 1\): the upper face

We start our investigation with local rules that satisfy both \(l_0 = f(0, 0, 0) = 0\) and \(l_1 = f(1, 1, 1) = 2d - c = 1\), i.e., double-legal local rules. These rules
are parameterized by points lying on the upper face $P_2P_3P_6P_7$ of the parallelepiped $P$ (see Fig. 4a).

In this case, the expression of the local rule $f$ reduces to

$$f(x, y, z) = (1 - b - d)(x + z)y + b(x + z) + (2d - 1)y,$$

where $0 \leq b \leq \frac{1}{2}$ and $\frac{1}{2} \leq d \leq 1$. Thus, the set of double-legal outer-totalistic ACCAs can also be parameterized by the points of the square $P_2P_3P_6P_7$ shown in Fig. 4b and denoted in the remainder by $S$. Note that if $f$ is double-legal, then also $f^C$ is double-legal. Moreover, the points that parameterize $f$ and $f^C$ are symmetric w.r.t. the diagonal $P_2P_7$. As the behavior of $F^C$ is strongly related to the behavior of $F$, it is sufficient to consider the case $b + d \leq 1$.

In Table 3, we list a few points $(b, c, d)$ corresponding to double-legal outer-totalistic ACCAs with distinct dynamics and indicate the corresponding groups of initial configurations identified through simulation. These distinct dynamics will be discussed analytically further on.

**Theorem 3** Let $f$ be the local rule parameterized by a point $(b, d) \in S$ and let $F$ be the corresponding global rule.

(s1) If $b + d < 1$, then for any initial configuration $x \in X_N^1$, it holds that

$$\lim_{t \to \infty} F^t(x) = 0^N,$$

while $F^t(1^N) = 1^N$ for each $t > 0$. 

---

Table 3 Examples of points $(b, c, d)$ representing five distinct dynamics observed in the simulation of double-legal outer-totalistic ACCAs lying on the upper face $P_2P_3P_6P_7$ of the parallelepiped $P$

| $(b, c, d)$ | $N = 10$ | $N = 11$ |
|-------------|----------|----------|
| $(0.2, 0.4, 0.7)$ | $G_0 = X_1^0$ | $G_0 = X_1^1$ |
|             | $G_1 = \{1^{10}\}$ | $G_1 = \{1^{11}\}$ |
| $(0.2, 0.4, 0.9)$ | $G_0 = \{0^{10}\}$ | $G_0 = \{0^{11}\}$ |
|             | $G_1 = \{1^{10}\}$ | $G_1 = \{1^{11}\}$ |
| $(0.2, 0.6, 0.8)$ | $G_0 = \{0^{10}\}$ | $G_0 = \{0^{11}\}$ |
|             | $G_1 = \{1^{10}\}$ | $G_1 = \{1^{11}\}$ |
| $(0.0, 1.0, 1.0)$ | $G_0 = \{0^{10}\}$ | $G_0 = \{0^{11}\}$ |
|             | $G_1 = \{1^{10}\}$ | $G_1 = \{1^{11}\}$ |
| $(0.5, 0.0, 0.5)$ | $G_0 = \{0^{10}\}$ | $G_0 = \{0^{11}\}$ |
|             | $G_1 = \{1^{10}\}$ | $G_1 = \{1^{11}\}$ |
|             | $G_2 \neq \emptyset$ | $G_2 = X_1^0$ |
|             | $G_5 \neq \emptyset$ | $G_5 = X_1^1$ |
Moreover, from the above calculations, it is obvious that if at least one variable $x, y, z$ is strictly smaller than 1, then also $f(x, y, z) < 1$. This means that for some $t_0 \in \mathbb{N}$ the configuration $F^{t_0}(x)$ does not contain any 1s, i.e., $M = \max_i(F^{t_0}(x)) < 1$, then for each $t \geq t_0$ and $0 \leq n \leq N - 1$, it holds that $x_n^t \leq M$.

Hence,

\[
\sigma(F^{t+1}(x)) = \sum_{n=0}^{N-1} x_n^{t+1}
\]

\[
= \sum_{n=0}^{N-1} \left( (1 - b - d)(x_{n-1}^t + x_{n+1}^t)x_n^t + b(x_{n-1}^t + x_{n+1}^t) + (2d - 1)x_n^t \right)
\]

\[
\leq \left( \sum_{n=0}^{N-1} (1 - b - d)2Mx_n^t \right)
\]

\[
+ (2b + 2d - 1)\sigma(F^t(x))
\]

\[
= (1 - b - d)2M\sigma(F^t(x))
\]

\[
+ (2b + 2d - 1)\sigma(F^t(x))
\]

\[
= (1 - 2(1 - b - d)(1 - M))\sigma(F^t(x)).
\]

This means that $\sigma(F^t(x))$ tends to zero (since $1 - 2(1 - b - d)(1 - M) < 1$), which concludes the proof of statement (s1). As mentioned before, statement (s2) is a direct consequence of (s1), since local rules parameterized by points $(b, d) \in S$ with $b + d > 1$ are conjugate to those with $b + d < 1$.

If $b + d = 1$, then $f(x, y, z) = b(x + z) + (1 - 2b)y$ and $f$ is density-conserving, i.e., for any $x \in X_N$, it holds that

\[
\rho(x) = \rho(F(x)) = \rho(F^2(x)) = \rho(F^3(x)) = \ldots.
\]

The dynamics of such ACCAs is described in [9], including the proof of statements (s3) and (s5). Statement (s4) is obvious.

4.3 The case $2b + c < 1$ and $2d - c < 1$

The points of $\mathcal{P}$ satisfying $2b + c < 1$ and $2d - c < 1$ are shown in Fig. 5.

The dynamics of ACCAs whose local rules are parameterized by these points is very simple. The state of each cell tends to zero, irrespective of the initial configuration. The following theorem formally characterizes the behavior of such CAs.

**Theorem 4** Let $f$ be the local rule parameterized by a point $(b, c, d) \in \mathcal{P}$ and let $F$ be the corresponding global rule. If $2b + c < 1$ and $2d - c < 1$, then for any initial configuration $x \in X_N$, it holds that $\lim_{t \to \infty} F^t(x) = 0^N$. 

\[ \]
A complete description of the dynamics

**Proof** Let us choose \( N \in \mathbb{N} \) and \( x \in X_N \). For any \( t \geq 0 \), it holds that

\[
\sigma \left( F^{t+1}(x) \right) = \sum_{n=0}^{N-1} x_n^{t+1} \\
= \sum_{n=0}^{N-1} \left[ (d-c-b)(x_{n-1}^t + x_{n+1}^t)x_n^t \\
+ b(x_{n-1}^t + x_{n+1}^t) + cx_n^t \right] \\
= \left( \sum_{n=0}^{N-1} (d-c-b)(x_{n-1}^t + x_{n+1}^t)x_n^t \right) \\
+ (2b + c)\sigma \left( F^t(x) \right) .
\]

Hence, if \( d - c - b < 0 \), then

\[
\sigma \left( F^{t+1}(x) \right) \leq (2b + c)\sigma \left( F^t(x) \right) .
\]

If \( d - c - b \geq 0 \), then

\[
\sum_{n=0}^{N-1} (d-c-b)(x_{n-1}^t + x_{n+1}^t)x_n^t \\
\leq \sum_{n=0}^{N-1} (d-c-b)(x_{n-1}^t + x_{n+1}^t) \\
= 2(d-c-b)\sigma \left( F^t(x) \right) ;
\]

thus, in this case,

\[
\sigma \left( F^{t+1}(x) \right) \leq 2(d-c-b)\sigma \left( F^t(x) \right) \\
+ (2b + c)\sigma \left( F^t(x) \right) \\
= (2d-c)\sigma \left( F^t(x) \right) .
\]

Since \( 2b + c < 1 \) and \( 2d - c < 1 \), we see that, in both cases, \( \sigma \left( F^t(x) \right) \) tends to zero, which concludes the proof. \( \square \)

4.4 The case \( 2b + c \geq 1 \) and \( 2d - c < 1 \)

To conclude our investigation, we explore the dynamics of the local rules parameterized by points belonging to the polyhedron \( P_1 P_2 P_3 P_4 P_5 P_6 P_7 \) without the upper face \( P_5 P_6 P_7 \), denoted by \( \mathcal{P}_0 \) and shown in Fig. 6. This set is explicitly given as

\[
\mathcal{P}_0 = \{ (b, c, d) \in \mathcal{P} \mid 2b + c \geq 1 \text{ and } 2d - c < 1 \} .
\]

In this subsection, the expression \( \frac{2b+c-1}{2(b+c-d)} \) will be denoted by \( \lambda \) and will turn out to be a key parameter. Note that if \( (b, c, d) \in \mathcal{P}_0 \), then it holds in particular that \( b + c - d > 0 \), hence \( \lambda \) is well defined and lies in \([0, 1]\).

This section is organized as follows. We start with some technical lemmata. Then we describe the dynam-
ics of the rules parameterized by points belonging to \( \mathcal{P}_0 \), except for the three edges \( P_1 P_3, P_4 P_6 \) and \( P_5 P_7 \). Next, we consider the edges \( P_4 P_6, P_1 P_3 \) and \( P_5 P_7 \) one by one. The latter case is the most complicated one, since the rules parameterized by points from \( P_5 P_7 \) exhibit the most surprising behavior.

### 4.4.1 Some technical lemmata

In order to prove the main theorems in this section, we introduce a few lemmata.

**Lemma 3** Let \( f \) be the local rule parameterized by a point \((b, c, d) \in \mathcal{P}_0\). The function \( g : [0, 1] \to \mathbb{R} \) defined by

\[
g(s) := f(s, s, s) = -2(b + c - d)s^2 + (2b + c)s
\]

has the following two properties:

I. If \( 0 \leq s \leq s_* \), then \( 0 \leq g(s) \leq s_* \).

II. If \( 0 < s < 1 \), then \( \lim_{t \to \infty} g^t(s) = \lambda \), where \( g^t(s) = g \circ g \circ \ldots \circ g(s) \) \( t \) times.

**Proof** Assume first that \( 2b + c > 1 \), then the graph of the function \( g \) is shown in Fig. 7a (under the proviso that \( s_* \) may lie to the right of 1 or \( s_2 \) may be equal to 1). Indeed, the function \( g \) is a quadratic function with roots \( s_1 = 0 \) and \( s_2 = \frac{2b + c}{2(d + c + d)} \), restricted to the domain \([0, 1]\). It has two fixed points, namely 0 and \( \lambda \). Since \( c \leq 2d \leq c + 1 \), it holds that \( \lambda \leq 1 \leq s_2 \). Directly from the graph of \( g \), we can conclude that (I) holds, since for \( s \geq \lambda \) we have \( g(s) \leq s \). Moreover, the fixed point \( s_1 = 0 \) is a repeller, while \( \lambda \) is an attractor with basin including \((0, 1)\). This implies (II).

Next, assume that \( 2b + c = 1 \). In that case, it holds that \( \lambda = 0 \) and the line \( y = s \) is tangent to the graph of \( g \) at \( s_1 = 0 \) (see Fig. 8) and one can see that 0 is an attractor with basin \([0, 1]\). \( \square \)

As a simple consequence of Lemma 3, we get the following description of the orbits for the initial configuration \( 1^N \).

**Lemma 4** Let \( f \) be the local rule parameterized by a point \((b, c, d) \in \mathcal{P}_0\) and let \( F \) be the corresponding global rule. If \( c = 2d \) (i.e., \((b, c, d) \in \mathcal{P}_0\)), then \( F^t(1^N) = 0^N \), for each \( t \geq 1 \); otherwise, \( F^t(1^N) \xrightarrow{t \to \infty} \lambda^N \).

\( \square \) Springer
A complete description of the dynamics configuration

In the remainder we will only consider initial configurations.

Proof

Lemma 5

Let $f$ be the local rule parameterized by a point $(b, c, d) \in \mathcal{P}_0$ and let $F$ be the corresponding global rule. For each $\varepsilon > 0$, for each $t_0 \in \mathbb{N}$, and for any initial configuration $x \in X_N$, there exists $t_\varepsilon \geq t_0$ such that

$$\min(F^t(x)) < \lambda - \varepsilon.$$  

Proof We give a proof by contradiction. Let $\varepsilon > 0$ and $t_0 \in \mathbb{N}$ be given and assume that for some initial configuration $x$ it holds for each $t \geq t_0$ that

$$\min(F^t(x)) \geq \lambda + \varepsilon.$$  

For every $t \geq t_0$ and any $n \in \{0, 1, \ldots, N-1\}$, it holds that

$$x_n^{t+1} = f(x_{n-1}^t, x_n^t, x_{n+1}^t)$$

$$= - (b + c - d)(x_{n-1}^t + x_n^t + x_{n+1}^t) + b(x_{n-1}^t + x_{n+1}^t) + cx_n^t$$

$$\leq - (b + c - d)(x_{n-1}^t + x_{n+1}^t)(\lambda + \varepsilon)$$

$$+ b(x_{n-1}^t + x_{n+1}^t) + cx_n^t$$

$$= \left(\frac{1}{2} - \frac{1}{b + c - d}\right) \lambda + \varepsilon$$

$$+ \frac{1}{2}(b + c - d)\varepsilon.$$  

since $b + c - d > 0, x_n^t \geq \lambda + \varepsilon$ and $\lambda = \frac{2b+c-1}{2(b+c-d)}$.

Hence, for each $t \geq t_0$ we find

$$0 \leq \sigma(F^{t+1}(x)) \leq \sum_{n=0}^{N-1}$$

$$\times \left[\left(\frac{1}{2} - \frac{1}{b + c - d}\right) \lambda + \varepsilon\right] (x_{n-1}^t + x_{n+1}^t) + c x_n^t$$

$$= (1 - 2(b + c - d)\varepsilon) \sigma(F^t(x)).$$

Note that $1 - 2(b + c - d)\varepsilon < 1$, so the above inequality implies $\sigma(F^t(x)) \to 0$ as $t \to \infty$, contrary to the assumption in Eq. (7).

The following lemma lists some dependencies between the elements of the set $\mathcal{V}$ introduced in Theorem 2. Note that if $f$ is a local rule defined by Eq. (4), then the set $\mathcal{V}$ contains at most six different numbers:

$$V_1 = f(m, m, m) = -2(b + c - d)m^2 + (b + c)m;$$

$$V_2 = f(M, m, m) = -(b + c - d)Mm - (b + c - d)m^2$$

$$+ bM + (b + c)m;$$

$$V_3 = f(m, M, m) = -(b + c - d)Mm + 2bm + cM;$$

$$V_4 = f(M, M, m) = -(b + c - d)Mm + 2bM + cm;$$

$$V_5 = f(M, M, M) = -(b + c - d)Mm - (b + c - d)M^2$$

$$+ bm + (b + c)M;$$

$$V_6 = f(m, M, M) = -(b + c - d)M^2 + (2b + c)M.$$  

Moreover, $V_2$ always lies between $V_1$ and $V_4$, while $V_5$ always lies between $V_3$ and $V_6$ (since $f$ is affine also w.r.t. $x + z$). The following lemma presents some dependencies between $V_1, V_3, V_4$ and $V_6$.

Lemma 6

Let $f$ be the local rule parameterized by a point $(b, c, d) \in \mathcal{P}_0$ and let $0 \leq m < M \leq 1$. Then it holds that

(d1) $V_1 \leq V_4$ if and only if $m \leq \frac{b}{b+c-d}$;

(d2) $V_3 \leq V_6$ if and only if $M \leq \frac{b}{b+c-d}$;

(d3) $V_1 \leq V_3$ if and only if $m \leq \frac{c}{2(b+c-d)}$;

(d4) $V_4 \leq V_3$ if and only if $c \geq 2b$;

(d5) $V_4 \leq V_6$ if and only if $M \leq \frac{c}{2(b+c-d)}$.

Proof Statements (d1)–(d5), respectively, follow from

$$V_4 - V_1 = 2(M - m)(b - (b + c - d)m),$$

$$V_6 - V_3 = 2(M - m)(b - (b + c - d)M),$$

$$V_3 - V_1 = (M - m)(c - 2(b + c - d)),$$

$$V_5 - V_4 = (M - m)(c - 2b),$$

$$V_4 - V_6 = (M - m)(2(b + c - d)M - c),$$

$\Box$ Springer
4.4.2 The case

Let \( (b, c, d) \in \mathcal{P}_0 \setminus (P_1 P_3 \cup P_4 P_6 \cup P_5 P_7) \).

In this subsection, we uncover the dynamics of local rules parameterized by points \( (b, c, d) \) that belong to \( \mathcal{P}_0 \) but do not lie on any of the edges \( P_1 P_3, P_4 P_6 \) and \( P_5 P_7 \), i.e., \( 0 < b < \frac{1}{2} \) or \( 0 < c < 1 \). In this case, the dynamics turns out to be very simple: Each initial configuration \( x \in X_{N}^{0,1} \) tends to the same homogeneous one, as stated in the following theorem.

**Theorem 5** Let \( f \) be the local rule parameterized by a point \( (b, c, d) \in \mathcal{P}_0 \) and let \( F \) be the corresponding global rule. If \( 0 < b < \frac{1}{2} \) or \( 0 < c < 1 \), then for any initial configuration \( x \in X_{N}^{0,1} \), it holds that

\[
\lim_{t \to \infty} F^t(x) = \lambda^N.
\]

**Proof** Let \( (b, c, d) \in \mathcal{P}_0 \), where \( 0 < b < \frac{1}{2} \) or \( 0 < c < 1 \), and \( x \in X_{N}^{0,1} \). We consider the case \( c \geq 2b \), the case \( c < 2b \) being analogous. Suppose that \( b = \frac{1}{2} \), then it would also hold that \( c = 1 \), a contradiction. Hence, it holds that \( b < \frac{1}{2} \), which implies that \( \varepsilon = \frac{1-2b}{2(b+c-d)} > 0 \). Since \( 2d - c < 1 \), according to Lemma 1(P2)–(P3) and Lemma 5, there exists \( t_\varepsilon \geq 2 \) such that \( 0 < m_0 < \lambda + \varepsilon \) and \( M_0 < 1 \), where

\[
m_0 = \min(F^{t_\varepsilon}(x)) \quad \text{and} \quad M_0 = \max(F^{t_\varepsilon}(x)).
\]

If \( m_0 = M_0 \), i.e., \( F^{t_\varepsilon}(x) \) is a homogeneous configuration \((m_0)^N\), then according to Lemma 3, it holds that \( F^t(x) \) tends to \( \lambda^N \). Therefore, we can assume that \( m_0 < M_0 \).

Consider the following two sequences \((m_t)_{t \geq 0}\) and \((M_t)_{t \geq 0}:\)

\[
m_{t+1} = \min\{f(x, y, z) \mid x, y, z \in \{m_t, M_t\}\}, \quad M_{t+1} = \max\{f(x, y, z) \mid x, y, z \in \{m_t, M_t\}\}.
\]

According to Theorem 2, it holds that

\[
F^{t_{\varepsilon}+t}(x) \in [m_t, M_t]^N.
\]

We will show that the sequence of \( N \)-dimensional cubes \([m_t, M_t]^N\) collapses to a single point \( \lambda^N \). We consider two cases.

Case one. Assume that for some \( t_0 \geq 0 \), it holds that \( M_{t_0} \leq \frac{b}{b+c-d} \). Then obviously \( m_{t_0} \leq \frac{b}{b+c-d} \) and from Lemma 6 it follows that

\[
M_{t_0+1} = f(M_{t_0}, M_{t_0}, M_{t_0}) = g(M_{t_0})
\]

and

\[
m_{t_0+1} = f(m_{t_0}, m_{t_0}, m_{t_0}) = g(m_{t_0}).
\]

Note that \( c \geq 2b \) implies that \( \lambda \leq \frac{b}{b+c-d} \leq s_\varepsilon \). Thus,

\[
M_{t_0+1} = g(M_{t_0}) \leq g\left(\frac{b}{b+c-d}\right) \leq \frac{b}{b+c-d}.
\]

By simple induction, we get \( M_t \leq \frac{b}{b+c-d} \) for \( t \geq t_0 \), and consequently, \( M_{t+1} = g(M_t) \) and \( m_{t+1} = g(m_t) \). Therefore, according to Lemma 3(g2), we have

\[
\lim_{t \to \infty} M_t = \lim_{t \to \infty} g(M_t) = \lim_{t \to \infty} g^t(M_{t_0}) = \lambda,
\]

and

\[
\lim_{t \to \infty} m_t = \lim_{t \to \infty} g(m_t) = \lim_{t \to \infty} g^t(m_{t_0}) = \lambda.
\]

which concludes the proof in the first case.

Case two. Assume that for all \( t \geq 0 \), it holds that \( M_t > \frac{b}{b+c-d} \). Let us note that for all \( t \geq 0 \) it holds that \( m_t < \lambda + \varepsilon \). Indeed, from Lemma 3(g1), it follows that

\[
m_{t+1} \leq f(m_t, m_t, m_t) = g(m_t) < \lambda + \varepsilon
\]

\[
= \frac{c}{2(b+c-d)}.
\]

It follows from Lemma 6(d2), (d3) and (d4) that for all \( t \geq 0 \) it holds that

\[
M_{t+1} = f(m_t, M_t, m_t) = cM_t + 2m_t(b - (b+c-d)M_t) \leq cM_t,
\]

(8)

which is only possible for \( c = 1 \), as otherwise the sequence \((M_t)_{t=0}^\infty\) would decrease exponentially to zero, contradicting the assumption that \( M_t > \frac{b}{b+c-d} > 0 \), for all \( t \geq 0 \). Note that if \( c = 1 \), then \( \frac{b}{b+c-d} = \lambda < M_t \) and the sequence \((M_t)_{t=0}^\infty\) is decreasing. Again, we consider two cases.
(a) Assume that for all \( t \geq 0 \), it holds that also \( m_t \geq \lambda \). It then holds that \( \lambda \leq m_t \leq M_t \). Using Eq. (8), it follows that

\[
M_{t+1} - \lambda = M_t + 2m_t(b + 1 - d)(\lambda - M_t) - \lambda \\
= (M_t - \lambda)(1 - 2m_t(b + 1 - d)) \\
\leq (1 - 2b)(M_t - \lambda).
\]

Since \( 0 < b < \frac{1}{2} \), the above upper bound shows that the difference between \( M_t \) and \( \lambda \) decreases exponentially to 0, i.e., \( \lim_{t \to \infty} m_t \) and \( \lim_{t \to \infty} M_t = \lambda \), which implies that also \( \lim_{t \to \infty} m_t = \lambda \).

(b) Assume that for some \( \tau \geq 0 \), it holds that \( m_\tau < \lambda \). Of course, then due to Lemma 3(g1), it holds that \( m_t \leq \lambda \), for all \( t \geq \tau \). It follows from Lemma 6(d1) and (d2) that for all \( t \geq \tau \), it holds that

\[
m_{t+1} = \min(g(m_t), g(M_t)).
\]  

Let \( \delta = \min(m_{\tau}, g(M_{\tau})) \). On the one hand, it holds that \( 0 < m_{\tau} \leq \lambda \). On the other hand, \( \lambda < M_{\tau} < 1 \) implies \( g(M_{\tau}) > 0 \). This yields \( 0 < \delta \leq \lambda \). We will show that \( m_t \geq \delta \) for all \( t \geq \tau \) (it holds for \( t = \tau \)). The following reasoning is based on Fig. 7a. Since \( \lambda < M_{\tau} \leq M_t \), it holds that \( g(M_t) \geq \min(\lambda, g(M_{\tau})) \geq \delta \). Moreover, since \( m_t \leq \lambda \), it holds that \( g(m_t) \geq m_t \geq \delta \). Together, according to Eq. (9), we obtain \( m_{t+1} \geq \delta \).

Now, let us compare the differences \( M_{t+1} - m_{t+1} \) and \( M_t - m_t \) for \( t \geq \tau \). If \( m_{t+1} = g(M_t) \), then it follows from Eq. (8) and Lemma 3 that

\[
M_{t+1} - m_{t+1} = (M_t - m_t)(2b + 1 - d)M_t - 2b \\
\leq (M_t - m_t)2(1 - d)M_t \\
\leq (M_t - m_t)2(1 - d)M_t.
\]

Similarly, if \( m_{t+1} = g(m_t) \), then

\[
M_{t+1} - m_{t+1} = (M_t - m_t)(1 - 2(b + 1 - d)m_t) \\
\leq (M_t - m_t)(1 - 2(b + 1 - d)\delta).
\]

In both cases, we have

\[
M_{t+1} - m_{t+1} \leq \alpha(M_t - m_t)
\]

for all \( t \geq \tau \), where

\[
\alpha = \max(2(1 - d)M_t, 1 - 2(b + 1 - d)\delta).
\]

Note that \( c = 1 \) implies that \( \frac{1}{2} \leq d < 1 \). Together with \( \delta > 0 \) and \( b < \frac{1}{2} \), it then follows that \( \alpha < 1 \). This means hat

\[
\lim_{t \to \infty} m_t = \lim_{t \to \infty} M_t = \lambda,
\]

as \( m_t \leq \lambda \leq M_t \), for all \( t \geq \tau \).

4.4.3 The case \((b, c, d) = (\frac{1}{2}, 1, d) \) for \( \frac{1}{2} \leq d < 1 \).

In this subsection, we discuss the dynamics of local rules parameterized by points belonging to the edge \( P_{4}P_{6} \). In this case, \( \lambda = \frac{1}{2} - \frac{2\epsilon}{\lambda} \) and the local rule is given by

\[
f(x, y, z) = -\left(\frac{3}{2} - d\right)(x + z)y + \frac{1}{2}(x + z) + y.
\]

An interesting observation is the following bifurcation: For any even \( N \in \mathbb{N} \), it holds that

\[
\lim_{d \to \frac{1}{2}^+} F^d\left((01)^\frac{N}{2}\right) = \lambda^N \text{ if } \frac{1}{2} < d < 1, \text{ and}
\]

\[
\lim_{d \to \frac{1}{2}^+} F^d\left((01)^\frac{N}{2}\right) = 0^N \text{ if } d = \frac{1}{2}, \text{ while}
\]

\[
\lim_{d \to \frac{1}{2}^-} \lambda = \lim_{d \to \frac{1}{2}^-} \frac{1}{2 + \frac{2\epsilon}{\lambda} - 2d} = \frac{1}{2} \neq 0.
\]

**Theorem 6** Let \( f \) be the local rule parameterized by a point \((\frac{1}{2}, 1, d) \) \( \in P_{4}P_{6} \) and let \( F \) be the corresponding global rule. If \( \frac{1}{2} < d < 1 \), then for any initial configuration \( x \in X_{N}^{0,1} \), it holds that

\[
\lim_{t \to \infty} F^t(x) = \lambda^N.
\]

If \( d = \frac{1}{2} \), then

- if \( N \) is odd, then for any \( x \in X_{N}^{0,1} \), it holds that

\[
\lim_{t \to \infty} F^t(x) = \lambda^N = \left(\frac{1}{2}\right)^N;
\]

- if \( N \) is even, then for any \( x \in X_{N}^{0,1} \setminus \{(01)^\frac{N}{2}, (10)^\frac{N}{2}\} \), it holds that

\[
\lim_{t \to \infty} F^t(x) = \lambda^N = \left(\frac{1}{2}\right)^N.
\]
while \( F^t \left( (01)^N \right) = F^t \left( (10)^N \right) = 0^N \) for \( t \geq 2 \).

**Proof.** Let \( x \in X_N^0 \). For any \( t \geq 0 \), let \( \mu_t \) denote the maximal absolute difference between \( x^t_n \) and \( \lambda \), i.e.,

\[
\mu_t = \max_{0 \leq n \leq N-1} |x^t_n - \lambda|.
\]

As \( \frac{1}{2} \leq \lambda < 1 \), it holds that \( \mu_t \leq \lambda \). Additionally,

\[
f(x, y, z) - \lambda = (\lambda - y) \left( \frac{3}{2} - d \right) (x - \lambda + z - \lambda),
\]

implies

\[
|f(x, y, z) - \lambda| \leq |y - \lambda| \left( \frac{3}{2} - d \right) (|x - \lambda| + |z - \lambda|),
\]

which means that

\[
\mu_{t+1} \leq \mu_t \left( \frac{3}{2} - d \right) 2 \mu_t = (3 - 2d) \mu_t^2.
\]  

(10)

In particular, since \( \mu_t \leq \lambda = \frac{1}{3 - 2d} \), it holds that \( \mu_{t+1} \leq \mu_t \).

Lemma 1(P2) implies that there exists \( \tau \geq 2 \) such that \( m = \min \left( F^\tau(x) \right) > 0 \). Similarly, Lemma 1(P3) implies that there exists some \( \tau > \frac{N}{2} + 2 \) such that \( M = \max \left( F^\tau(x) \right) < 1 \) in the following cases: (i) \( \frac{1}{2} < d < 1 \), (ii) \( d = \frac{1}{2} \) and \( N \) is odd, or (iii) \( d = \frac{1}{2} \), \( N \) is even and \( x \in X_N^0 \setminus \{ (01)^N, (10)^N \} \). Hence, there exists some \( \tau > 0 \) such that

\[
m = \min \left( F^\tau(x) \right) > 0 \quad \text{and} \quad M = \max \left( F^\tau(x) \right) < 1.
\]

This implies that \( \mu_\tau \) is strictly smaller than \( \lambda \). Indeed,

\[
\mu_\tau = \max_{0 \leq n \leq N-1} |x^\tau_n - \lambda| = \max \left( |M - \lambda|, |m - \lambda| \right) < \lambda.
\]

Therefore, according to Eq. (10), for any \( t \geq \tau \) it holds that

\[
\mu_{t+1} \leq \left( 3 - 2d \right) \mu_t^2 \mu_t,
\]

where \( (3 - 2d) \mu_t < 1 \). As a consequence, we get that \( \mu_t \xrightarrow{t \to \infty} 0 \), which means that \( \lim_{t \to \infty} F^t(x) = \lambda^N \).

Note that if \( d = \frac{1}{2} \), then \( \lambda = \frac{1}{2} \) and

\[
f(x, y, z) = -(x + z) y + \frac{1}{2} (x + z) + y.
\]

One easily verifies that in this case

\[
F^t \left( (01)^N \right) = F^t \left( (10)^N \right) = 0^N
\]

for each \( t \geq 2 \).

4.4.4 The case \((b, c, d) = \left( \frac{1}{2}, 0, d \right)\) for \( 0 \leq d < \frac{1}{2} \).

In this subsection, we discuss the dynamics of local rules parameterized by points belonging to the edge \( P_1 P_3 \). In this case, the local rule is given by

\[
f(x, y, z) = \frac{1}{2} (x + z) (1 - (1 - 2d) y),
\]

which yields

\[
f(x, y, z) \leq \frac{1}{2} (x + z) \leq \max(x, z).
\]

Moreover, the alternating sum of states, i.e.,

\[
(-1)^j x_0^j + (-1)^{j+1} x_1^j + (-1)^{j+2} x_2^j + \ldots + (-1)^{j+N-1} x_{N-1}^j,
\]

is an invariant of this dynamical system. Indeed,

\[
\sum_{j=0}^{N-1} (-1)^{j+1+j} x_j^{j+1} = \sum_{j=0}^{N-1} (-1)^{j+1+j} \left[ \frac{1}{2} x_{j-1}^j + \frac{1}{2} x_{j+1}^j + \frac{1}{2} (1 - 2d) (x_{j-1}^j x_j^j + x_j^j x_{j+1}^j) \right].
\]

Due to the periodic boundary conditions, we have

\[
\sum_{j=0}^{N-1} (-1)^j x_{j-1}^j = \sum_{j=0}^{N-1} (-1)^j x_{j+1}^j = \sum_{j=0}^{N-1} (-1)^{j+1} x_j^j
\]

and

\[
\sum_{j=0}^{N-1} (-1)^j x_{j-1}^j x_j^j = \sum_{j=0}^{N-1} (-1)^{j+1} x_j^j x_{j+1}^j = - \sum_{j=0}^{N-1} (-1)^j x_j^j x_{j+1}^j,
\]
which implies
\[
\sum_{j=0}^{N-1} (-1)^{i+j} x_j^{t+1} = \sum_{j=0}^{N-1} (-1)^{i+j} x_j^t . \tag{13}
\]

The following theorem describes the dynamics of such CAs.

**Theorem 7** Let \( f \) be the local rule parameterized by a point \((\frac{1}{2}, 0, d) \in \mathcal{P}_0\), where \( 0 \leq d < \frac{1}{2} \), and let \( F \) be the corresponding global rule.

(i) If \( N \) is even, then for any \( x \in X_N \), it holds that
\[
\lim_{t \to \infty} F^{2t}(x) = (\alpha 0)^{\frac{N}{2}} \quad \text{and} \quad \lim_{t \to \infty} F^{2t+1}(x) = (\alpha 0)^{\frac{N}{2}}
\]
if \( \alpha = \frac{2}{N}(x_0 - x_1 + x_2 - x_3 + \ldots - x_{N-1}) \geq 0 \),
while
\[
\lim_{t \to \infty} F^{2t}(x) = (0\alpha)^{\frac{N}{2}} \quad \text{and} \quad \lim_{t \to \infty} F^{2t+1}(x) = (0\alpha)^{\frac{N}{2}}
\]
if \( \alpha < 0 \).

(ii) If \( N \) is odd, then for any \( x \in X_N \), it holds that
\[
\lim_{t \to \infty} F^t(x) = 0^N .
\]

**Proof** Let \( x \in X_N \). First, we consider even \( N \). For each \( t \geq 0 \), we consider the following two sets
\[
E_t = \left\{ j \in \{ 0, 1, \ldots, N-1 \} \mid j \equiv t \ (\text{mod} \ 2) \right\} ,
\]
\[
O_t = \left\{ j \in \{ 0, 1, \ldots, N-1 \} \mid j \not\equiv t \ (\text{mod} \ 2) \right\} = \{ 0, 1, \ldots, N-1 \} \setminus E_t .
\]

Note that
\[
E_0 = E_2 = E_4 = \ldots = \{ 0, 2, \ldots, N-2 \} ,
\]
\[
E_1 = E_3 = E_5 = \ldots = \{ 1, 3, \ldots, N-1 \} ,
\]
\[
O_0 = O_2 = O_4 = \ldots = \{ 1, 3, \ldots, N-1 \} ,
\]
\[
O_1 = O_3 = O_5 = \ldots = \{ 0, 2, \ldots, N-2 \} .
\]

Let \( \alpha_t = \max_{j \in E_t} x_j^t \) and \( \beta_t = \max_{j \in O_t} x_j^t \). According to Eq. (12), for any \( t \geq 0 \) it holds that \( \alpha_{t+1} \leq \alpha_t \) and \( \beta_{t+1} \leq \beta_t \). This means that both sequences \( (\alpha_t)_{t \geq 0} \) and \( (\beta_t)_{t \geq 0} \) are convergent. Hence, \( \alpha = \lim_{t \to \infty} \alpha_t \) and \( \beta = \lim_{t \to \infty} \beta_t \). Now consider \( \delta > 0 \), then there exists \( \tau \geq 0 \) such that for any \( t \geq \tau \), it holds that
\[
\alpha \leq \alpha_t < \alpha + \delta .
\]
We will show that for any \( t \geq \tau \) and any \( j \in E_t \), it holds that
\[
x_j^t \geq \alpha - \left( \frac{N}{2} - 1 \right) \delta . \tag{14}
\]

Indeed, suppose that this is not true, i.e., there exist \( t_0 \geq \tau \) and \( j_0 \in E_{t_0} \) such that \( x_{j_0}^{t_0} < \alpha - \varepsilon \), where \( \varepsilon = \left( \frac{N}{2} - 1 \right) \delta \). According to Eq. (12) we have
\[
x_{j_0+1}^{t_0+1} < \frac{1}{2}(\alpha + \delta + \alpha - \varepsilon) = \alpha - \frac{1}{2}\varepsilon + \frac{1}{2} \delta
\]
\[
x_{j_0+2}^{t_0+2} < \frac{1}{2}(\alpha + \delta + \alpha - \varepsilon) = \alpha - \frac{1}{2}\varepsilon + \frac{1}{2} \delta
\]
\[
= \alpha - \frac{1}{4}\varepsilon + \frac{3}{4} \delta
\]
and so on. Thus, after \( \frac{N}{2} - 1 \) steps, we get that for each \( j \in E_{t_0 + \frac{N}{2} - 1} \)
\[
x_j^{t_0 + \frac{N}{2} - 1} < \alpha - \frac{1}{2} \frac{N-1}{2} \varepsilon + \frac{2}{2^\frac{N}{2} - 1} \delta = \alpha ,
\]
which contradicts the fact that \( \alpha _{t_0 + k} \geq \alpha \), which implies \( \min_{j \in E_t} x_j^t \to \alpha \). In the same way, we can prove that \( \min_{j \in O_t} x_j^t \to \beta \). It then holds that
\[
\lim_{t \to \infty} F^{2t}(x) = (\alpha \beta)^{\frac{N}{2}} \quad \text{and} \quad \lim_{t \to \infty} F^{2t+1}(x) = (\beta \alpha)^{\frac{N}{2}} .
\]

According to Eqs. (11) and (13), the numbers \( \alpha \) and \( \beta \) satisfy the following equations:
\[
\begin{cases}
\alpha = \alpha (1 - (1 - 2d) \beta) \\
\beta = \beta (1 - (1 - 2d) \alpha)
\end{cases}
\]
\[
\frac{N}{2}(\alpha - \beta) = x_0 - x_1 + x_2 - x_3 + \ldots - x_{N-1} .
\]

The first two imply that if \( \alpha \neq 0 \), then \( \beta = 0 \) and vice versa. Therefore, if \( x_0 - x_1 + x_2 - x_3 + \ldots - x_{N-1} \leq 0 \), then \( \alpha = \frac{2}{\sqrt{N}}(x_0 - x_1 + x_2 - x_3 + \ldots - x_{N-1}) \). Otherwise, \( \alpha = 0 \) and \( \beta = -\frac{2}{\sqrt{N}}(x_0 - x_1 + x_2 - x_3 + \ldots - x_{N-1}) \). This concludes the proof for even \( N \).

Second, we consider odd \( N \). Consider the following concatenation:
\[
(x x) = x_0 x_1 \ldots x_{N-1} x_0 x_1 \ldots x_{N-1} \in X_{2N} .
\]
Due to the periodic boundary conditions, it holds for each \( t \geq 0 \) that

\[
F^t(x) = F^t(x) F^t(x).
\]

However, for the initial configuration \( xx \), the alternating sum equals 0 and the first part of the theorem implies that

\[
\lim_{t \to \infty} F^{2t}(xx) = \lim_{t \to \infty} F^{2t+1}(xx) = 0^{2N}.
\]

This concludes the proof for odd \( N \).

4.4.5 The case \((b, c, d) = (0, 1, d)\) for \( \frac{1}{2} \leq d < 1 \)

In this subsection, we discuss the dynamics of local rules parameterized by points belonging to the edge \( P_bP_c \). In this case, \( \lambda = 0 \) and the local rule is given by

\[
f(x, y, z) = y(1 - (1 - d)(x + z)).
\]

In particular, \( f(x, 0, z) = 0 \) and \( f(0, y, 0) = y \). This means that any binary configuration \( x \in X_N \) not containing two neighboring 1s is a fixed point of \( f \). Furthermore, each substring of \( x \in X_N \) starting and ending with 0 and not containing two neighboring 1s remains unchanged in \( F^t(x) \) for every \( t \geq 0 \). Additionally, according to Lemma 4, we have \( F^t(1^N) \xrightarrow{t \to \infty} 0^N \).

For these reasons, to uncover the behavior of \( f \), it suffices to consider strings of the type 011...110, where the number of 1s equals \( K \) with \( 2 \leq K < N \). W.l.o.g., let us assume that \( x^0_0 = 0, x^0_1 = x^0_2 = \ldots = x^0_K = 1, x^0_{K+1} = 0 \). The dynamics of \( f \) on

\[
x^0_0 x^0_1 \ldots x^0_K x^0_{K+1} = 011 \ldots 110
\]

is then described by the system of recurrence relations:

\[
\begin{align*}
x^{t+1}_n &= x^{t+1}_{K+1} = 0, \\
x^{t+1}_n &= x^n_n (1 - (1 - d)(x^{t}_{n+1} + x^{t}_{n+1})), \quad n \in \{1, \ldots, K\},
\end{align*}
\]

(15)

where \( \frac{1}{2} \leq d < 1 \). Since \( 0 \leq 1 - (1 - d)(x^{t}_{n+1} + x^{t}_{n+1}) \leq 1 \), the sequence \( (x^n_n)_{t=0}^{\infty} \) is decreasing for every \( n \in \{1, 2, \ldots, K\} \) and thus converges. We denote this limit as \( q_n = \lim_{t \to \infty} x^n_n \in [0, 1] \). According to Eq. (15), it holds that

\[
q_n = q_n (1 - (1 - d)(q_{n+1} + q_{n+1})).
\]

for any \( n \in \{1, 2, \ldots, K\} \), where \( q_0 = q_{K+1} = 0 \). Since \( f \) is outer-totalistic, it holds that

\[
x^n_n = x^{t}_{K+1} - n
\]

(17)

for any \( n \in \{1, 2, \ldots, K\} \) and any \( t \geq 0 \), and thus,

\[
q_n = q_{K+1} - n
\]

(18)

for any \( n \in \{1, 2, \ldots, K\} \).

We start with some technical lemmata.

**Lemma 7** For each \( n \in \{1, 2, \ldots, K - 1\} \), it holds that \( q_n q_{n+1} = 1 \). Moreover, if \( K \) is even, then \( q_{\frac{K}{2}} = q_{\frac{K}{2}+1} = 0 \). In particular, if \( K = 2 \), then \( q_1 = q_2 = 0 \).

**Proof** Since, \( \frac{1}{2} \leq d < 1 \), it follows from Eq. (16) that

\[
q_{a-1}q_a + q_0q_{n+1} = 0, \quad \text{for any} \; n \in \{1, 2, \ldots, K - 1\}.
\]

Since \( q_0 = 0 \), we get \( q_1q_2 = 0 \). A simple induction yields the first part of the claim. If \( K \) is even, then, according to Eq. (18), it holds for \( n = \frac{K}{2} \) that \( q_{\frac{K}{2}} = q_{\frac{K}{2}+1} = 0 \). Hence, \( q_{\frac{K}{2}} q_{\frac{K}{2}+1} = 0 \) implies \( q_{\frac{K}{2}} = q_{\frac{K}{2}+1} = 0 \), which concludes the proof.

The above lemma states that regardless of \( d \in \left[\frac{1}{2}, 1\right]\), the string 0110 goes to 0000:

\[
\ldots 0110 \xrightarrow{t \to \infty} \ldots 0000 \ldots .
\]

From here on, we can assume that \( K \geq 3 \).

**Lemma 8** If \( K \geq 3 \), then \( q_1 \geq 1 - d \). Moreover, if \( d = \frac{1}{2} \), then the string 011...110 in \( x \) turns into the string 010...010 in \( F(x) \), which then remains unchanged in \( F^t(x) \) for any \( t \geq 1 \).

**Proof** According to Eq. (15), for any \( t \geq 0 \), it holds that

\[
x^n_1 - x^n_2 = x^n_1 - x^n_2 + (1 - d)x^n_0 x^n_3.
\]

Hence, also using \( x^n_1 = x^n_2 = 1 \), we have

\[
x^n_1 - x^n_2 = x^n_1 - x^n_0 (1 - d) \sum_{l=0}^{t-1} x^n_2 x^n_3 = (1 - d) \sum_{l=0}^{t-1} x^n_2 x^n_3.
\]
Since $x^0_2 x^0_3 = 1$ and $x^l_2 x^l_3 \geq 0$, for any $l \geq 0$, it then follows that

$$q_1 \geq q_1 - q_2 = (1 - d) \sum_{l=0}^{\infty} x^l_2 x^l_3 \geq 1 - d .$$

Further, if $d = \frac{1}{2}$, then the local rule is given by $f(x, y, z) = y(1 - \frac{1}{2}(x + z))$, and the second part of the lemma readily follows. \hfill \Box

Finally, we consider the case $\frac{1}{2} < d < 1$ and $K \geq 3$. The following theorem describes the dynamics of $F$ on strings $011 \ldots 110$, where the number of 1s is even.

**Theorem 8** Let $\frac{1}{2} < d < 1$ and $K \geq 4$ be even. For any $t \geq 0$, it holds that

$$x^l_1 \geq x^l_3 \geq \ldots \geq x^K_{K-3} \geq x^K_{K-1}$$

(19)

and, as a consequence,

$$q_1 \geq q_3 \geq \ldots \geq q_{K-3} \geq q_{K-1} .$$

(20)

Moreover, $q_{2j} = q_{K+1-2j} = 0$, for $2j \leq \frac{K}{2}$.

**Proof** To prove Eq. (19), we apply induction w.r.t. $t$. For $t = 0$, these inequalities are obvious. Assume that they are satisfied for some $t \geq 0$. Using the symmetry relationships in Eq. (17), we have

$$x^t_{2j} \leq x^t_{j+1}$$

for any $j \in \{1, 2, \ldots, \frac{K}{2} - 1\}$. Using the induction hypothesis, it then follows that

$$x^{t+1}_{2j-1} = x^t_{2j-1}(1 - (1 - d)(x^t_{2j-2} + x^t_{2j}))$$

$$\geq x_{2j-1}(1 - (1 - d)(x_{2j} + x_{2j+2})) = x^{t+1}_{2j+1} ,$$

for any $j \in \{1, 2, \ldots, \frac{K}{2} - 1\}$, which yields Eq. (19) and thus Eq. (20). According to Lemma 7, it holds that $q_{\frac{K}{2}} = q_{\frac{K}{2}+1} = 0$, so Eq. (20) implies that $q_{2j+1} = 0$, for any $2j + 1 \geq \frac{K}{2}$. Thus,

$$q_{2j} = q_{K+1-2j} = 0 ,$$

for any $2j \leq \frac{K}{2}$, which concludes the proof. \hfill \Box

The above theorem can be illustrated as follows. Suppose that in a string $011 \ldots 110$ the number of 1s is even, then

$$0 \ 1 \ 1 \ 1 \ldots 1 \ \hat{1} \ldots 1 \ 1 \ 1 \ 1 \ 0$$

$$t \rightarrow \infty$$

$$0 \ q_1 \ 0 \ q_3 \ 0 \ 0 \ \ldots \ 0 \ q_3 \ 0 \ q_1 \ 0$$

where $q_1 \geq q_3 \geq \ldots$ and $q_1 \geq 1 - d$.

For an odd number $K \geq 3$, we introduce the following notations: $s = \frac{K+1}{2}, 2n_o - 1$ is the largest odd number not greater than $s$ and $2n_e$ is the largest even number not greater than $s$.

**Lemma 9** Let $K \geq 3$ be odd. For any $t \geq 0$, it holds that

$$x^t_1 \geq x^t_3 \geq \ldots \geq x^{2n_o-1}_t$$

(21)

$$x^t_2 \leq x^t_4 \leq \ldots \leq x^{2n_e}_t .$$

Additionally,

$$x^{2n_o-1}_t \geq x^{2n_e}_t .$$

(22)

Moreover, if $t > s$, then the inequalities in Eqs. (21) and (22) are strict.

**Proof** One can prove Eq. (21) using induction in a similar way as in the proof of Theorem 8. We can also prove Eq. (22) using induction. Note that for $t = 0$ the inequality is trivially fulfilled and assume that it is satisfied for some $t \geq 0$. If $s$ is odd, then $2n_o - 1 = s$ and $2n_e = s - 1$; thus, Eq. (21) and the induction hypothesis imply

$$x^{t+1}_{2n_e} = x^{t+1}_{s-1} = x^t_{s-1}(1 - (1 - d)(x^t_{s-2} + x^t_{s}))$$

$$\leq x^t_{s}(1 - (1 - d)(x^t_{s} + x^t_{s}))$$

$$\leq x^t_{s}(1 - (1 - d)(x^t_{s-2} + x^t_{s-1}))$$

$$= x^t_{s}(1 - (1 - d)(x^t_{s-1} + x^t_{s-2}))$$

$$= x^{t+1}_{s} = x^{t+1}_{2n_o-1} .$$

Similarly, if $s$ is even, then $2n_e = s$ and $2n_o - 1 = s - 1$, and it follows using Eq. (21), the induction hypothesis and the fact that $x^{t+1}_{s-1} = x^{t}_{s+1}$ according to Eq. (17), that
Lemma 10 Let $K \geq 3$ be odd. For any $t \geq 0$, it holds that
\[ x_{2n_e}^{t+1} - x_{2n_e}^t \geq x_{2n_e}^{s+1} - x_{2n_e}^s. \] (23)

Proof For odd $s$, we have $x_{2n_e}^t = x_{2n_e}^{t+1}$; thus,
\[
x_{2n_e}^{t+1} - x_{2n_e}^t = x_{2n_e}^{s+1} - x_{2n_e}^s = x_{2n_e}^{s+1} - x_{2n_e}^s - (1 - (1 - d)(x_{2n_e}^t + x_{2n_e}^s)) - x_{2n_e}^t (1 - (1 - d)(x_{2n_e}^s + x_{2n_e}^{s-1}))) = x_{2n_e}^{s+1} - x_{2n_e}^s - (1 - d)x_{2n_e}^s (x_{2n_e}^{s-1} - x_{2n_e}^s) \geq x_{2n_e}^{s+1} - x_{2n_e}^s.
\]

For even $s$, we have $x_{2n_e}^{s+1} = x_{2n_e}^{s+1}$; thus,
\[
x_{2n_e}^{t+1} - x_{2n_e}^t = x_{2n_e}^{s+1} - x_{2n_e}^s = x_{2n_e}^{t+1} - x_{2n_e}^t - (1 - d)(x_{2n_e}^{s+1} - x_{2n_e}^s) = x_{2n_e}^{t+1} - x_{2n_e}^t - (1 - d)x_{2n_e}^s (x_{2n_e}^{s-1} - x_{2n_e}^s) \geq x_{2n_e}^{t+1} - x_{2n_e}^t.
\]

Theorem 9 Let $K \geq 3$ be odd. For any $2j - 1 \leq s$, it holds that $q_{2j-1} > 0$, while for any $2j \leq s$, it holds that $q_{2j} = 0$. Moreover, $q_1 + q_3 + \ldots + q_K = 1$.

Proof If $t > s$, then for $2j - 1 \leq s$ Lemmata 9 and 10 imply that
\[
x_{2n_e}^{t+1} - x_{2n_e}^t \geq x_{2n_e}^{t+1} - x_{2n_e}^s \geq x_{2n_e}^{t+1} - x_{2n_e}^t.
\]
Thus, \( q_{2j-1} \geq x_{2n_{o}-1}^{t+1} - x_{2n_{c}}^{t+1} > 0 \), since for \( t = s + 1 \) inequality Eq. (22) is strict. Furthermore, since \( q_{2j-1} > 0 \), Lemma 7 implies that \( q_{2j} = 0 \). To prove the last part of the theorem, note that since \( x_0^t = x_K^t = 0 \), it holds that

\[
\sum_{j=1}^{K} (-1)^{j+1} x_j^t = \sum_{j=1}^{K} (-1)^{j+1} x_j^{t-1} = \ldots = \sum_{j=1}^{K} (-1)^{j+1} x_0^t = 1.
\]

This implies that \( \sum_{j=1}^{K} (-1)^{j+1} q_j = 1 \). Since \( q_j = 0 \) for even \( j \), the proof is complete. \( \square \)

The above theorem can be illustrated as follows. For even \( s \), we have

\[
\begin{array}{cccccccccccccccc}
0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 \\
\downarrow & t \rightarrow \infty & & & & & & & & & & & & & & \\
0 & q_1 & 0 & q_3 & 0 & \ldots & q_{2n_{o}-1} & 0 & q_{2n_{o}-1} & \ldots & 0 & q_3 & 0 & q_1 & 0
\end{array}
\]

while for odd \( s \), we have

\[
\begin{array}{cccccccccccccccc}
0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 \\
\downarrow & t \rightarrow \infty & & & & & & & & & & & & & & \\
0 & q_1 & 0 & q_3 & 0 & \ldots & 0 & q_{2n_{o}-1} & 0 & \ldots & 0 & q_3 & 0 & q_1 & 0
\end{array}
\]

5 Conclusions

In this paper, we have provided a complete description of the dynamics of legal outer-totalistic ACCAs. On the one hand, such CAs are the simplest generalization of elementary cellular automata, while on the other hand, they are dynamical systems that exhibit some properties that do not occur in the binary case. Thanks to massive numerical simulations, we have been able to partition the rule space in a number of classes with a distinct behavior. Through the use of a panoply of proof techniques and oftentimes tedious proofs, we have been able to provide undeniable analytical evidence for the dynamics observed.

Table 4 summarizes the results obtained. In order to keep the presentation manageable, we focus on initial configurations from \( X_N^{0,1} \) only and add a short explanation for the other configurations separately below the table.

Since we only consider legal outer-totalistic ACCAs, it always holds that \( F^t(0^N) = 0^N \). For the configuration \( x = 1^N \), the dynamics is as follows: If \( 2d - c = 0 \) or \( 2d - c = 1 \), then \( F^t(1^N) = 0^N \) or \( F^t(1^N) = 1^N \), respectively, while if \( 0 < 2d - c < 1 \), then \( F^t(1^N) \) tends to the homogeneous configuration \( 0^N \) (if \( 2b + c \leq 1 \)) or \( \lambda^N \) (if \( 2b + c > 1 \)).

The results obtained show that in the set of ACCAs considered, one can observe various types of sensitivity:

- Sensitivity to the change of a single value in an initial configuration. This kind of sensitivity may concern all initial configurations, as, for example, for \( f(x, y, z) = 0.4(x + z) + 0.2y \) (see (s3) in Theorem 3) or only some initial configurations, as for example, for \( f(x, y, z) = 0.2(x + z)y + 0.4(x + z) - 0.2y \) (see (s1) in Theorem 3).

- Sensitivity to the change of the number of cells in the grid. Note that if we add one cell to the considered grid, then the parity of \( N \) will change. For example, the local rule \( f(x, y, z) = -0.1(x + z)y + 0.5(x + z) \) is not immune to such interference in the grid structure (see Theorem 7).

- Sensitivity to slight changes in the parameters of a local rule. Perhaps the best example of this sensitivity are local rules parameterized by points lying on the edge \( P_1P_3 \), i.e., local rules given by the following expression:

\[
f(x, y, z) = -\left(\frac{1}{2} - d\right)(x + z)y + \frac{1}{2}(x + z),
\]

where \( 0 \leq d \leq \frac{1}{2} \). The dynamics of such ACCAs for \( 0 \leq d < \frac{1}{2} \) (see Theorem 7) is completely different than for \( d = \frac{1}{2} \) (see (s3) in Theorem 3).

Although we limited our investigation to binary initial configuration only, nearly all results can be readily extended to all configurations from \([0, 1]^N\). However, the case described in Sect. 4.4.5 would require a more substantial effort.

Acknowledgements The computations were carried out at the Academic Computer Centre in Gdańsk (TASK KDM).

Funding The authors have not disclosed any funding.
Data availability Data sharing is not applicable to this article as any datasets were generated by presented formulas and analyzed during the current study.
