Homotopy Relations for Digital Images

Laurence Boxer *  P. Christopher Staecker †

Abstract

We introduce three generalizations of homotopy equivalence in digital images, to allow us to express whether a bounded and an unbounded digital image with standard adjacencies are similar with respect to homotopy.

We show that these three generalizations are not equivalent to ordinary homotopy equivalence, and give several examples. We show that, like homotopy equivalence, our three generalizations imply isomorphism of fundamental groups, and are preserved under wedges and Cartesian products.

Key words and phrases: digital topology, digital image, homotopy, fundamental group

2010 Mathematics Subject Classification: Primary 55P10; Secondary 55Q05

1 Introduction

In digital topology, we study geometric and topological properties of digital images via tools adapted from geometric and algebraic topology. Prominent among these tools are digital versions of continuous functions and homotopy. Digital homotopy can be thought of as the topology of animated digital images.

In Euclidean topology, finite and infinite spaces can have the same homotopy type. E.g., the Euclidean line $\mathbb{R}$ and a point have the same homotopy type. The analogous statement is not true in digital topology; e.g., the digital line $\mathbb{Z}$ with the $c_1$ adjacency and a single point do not have the same digital homotopy type, despite sharing homotopy properties such as having trivial fundamental groups. We introduce in this paper the notions of digital homotopy similarity, same long homotopy type, and same real homotopy type, all of which are more general than digital homotopy equivalence and whose pointed versions are less general than having isomorphic fundamental groups. These notions allow the possibility of considering a bounded and an unbounded digital image as similar with respect to homotopy.

2 Preliminaries

We say a connected digital image $X$ has *bounded diameter* if there is a positive integer $n$ such that if $x$ and $y$ are members of the same component of $X$, then there is a path in $X$ from $x$ to $y$ of length at most $n$.

Much of the material in this section is quoted or paraphrased from other papers in digital topology, such as [4].

2.1 General Properties

Let $N$ be the set of natural numbers, $N^* = \{0\} \cup N$, and let $Z$ denote the set of integers. Then $Z^n$ is the set of lattice points in Euclidean $n$–dimensional space.

Adjacency relations commonly used for digital images include the following [10]. Two points $p$ and $q$ in $Z^2$ are 8–*adjacent* if they are distinct and differ by at most 1 in each coordinate; $p$ and $q$ in $Z^2$ are 4–*adjacent* if they are 8-adjacent and differ in exactly one coordinate. Two points $p$ and $q$ in $Z^3$ are 26–*adjacent* if they are distinct and differ by at most 1 in each coordinate; they are 18–*adjacent* if they are 26-adjacent and differ in at most two coordinates; they are 6–*adjacent* if they are 18-adjacent and differ in exactly one coordinate. For $k \in \{4, 8, 6, 18, 26\}$, a $k$–*neighbor* of a lattice point $p$ is a point that is $k$–adjacent to $p$.

The adjacencies discussed above are generalized as follows. Let $u, n$ be positive integers, $1 \leq u \leq n$. Distinct points $p, q \in Z^n$ are called $c_u$–*adjacent*, or $c_u$–*neighbors*, if there are at most $u$ distinct coordinates $j$ for which $|p_j - q_j| = 1$, and for all other coordinates $j$, $p_j = q_j$. The notation $c_u$ represents the number of points $q \in Z^n$ that are adjacent to a given point $p \in Z^n$ in this sense. Thus the values mentioned above: if $n = 1$ we have $c_1 = 2$; if $n = 2$ we have $c_1 = 4$ and $c_2 = 8$; if $n = 3$ we have $c_1 = 6$, $c_2 = 18$, and $c_3 = 26$. Yet more general adjacency relations are discussed in [8].

Let $\kappa$ be an adjacency relation defined on $Z^n$. A digital image $X \subset Z^n$ is $\kappa$–*connected* [8] if and only if for every pair of points $\{x, y\} \subset X$, $x \neq y$, there exists a set $\{x_0, x_1, \ldots, x_c\} \subset X$ such that $x = x_0$, $x_c = y$, and $x_j$ and $x_{j+1}$ are $\kappa$–neighbors, $i \in \{0, 1, \ldots, c - 1\}$. A $\kappa$–*component* of $X$ is a maximal $\kappa$-connected subset of $X$.

Often, we must assume some adjacency relation for the *white pixels* in $Z^n$, *i.e.*, the pixels of $Z^n \setminus X$ (the pixels that belong to $X$ are sometimes referred to as *black pixels*). In this paper, we are not concerned with adjacencies between white pixels.
Definition 2.1. Let \( a, b \in \mathbb{Z}, a < b \). A digital interval is a set of the form \([a, b]_\mathbb{Z} = \{ z \in \mathbb{Z} | a \leq z \leq b \}\) in which 2-adjacency is assumed.

Definition 2.2. (2; see also 11) Let \( X \subset \mathbb{Z}^{n_0}, Y \subset \mathbb{Z}^{n_1} \). Let \( f : X \to Y \) be a function. Let \( \kappa_j \) be an adjacency relation defined on \( \mathbb{Z}^{n_j}, j \in \{0, 1\} \). We say \( f \) is \((\kappa_0, \kappa_1)\)-continuous if for every \( \kappa_0 \)-connected subset \( A \) of \( X \), \( f(A) \) is a \( \kappa_1 \)-connected subset of \( Y \).

See also [5, 6], where similar notions are referred to as immersions, gradually varied operators, and gradually varied mappings.

We say a function satisfying Definition 2.2 is digitally continuous. This definition implies the following.

Proposition 2.3. (2; see also 11) Let \( X \) and \( Y \) be digital images. Then the function \( f : X \to Y \) is \((\kappa_0, \kappa_1)\)-continuous if and only if for every \( \{x_0, x_1\} \subset X \) such that \( x_0 \) and \( x_1 \) are \( \kappa_0 \)-adjacent, either \( f(x_0) = f(x_1) \) or \( f(x_0) \) and \( f(x_1) \) are \( \kappa_1 \)-adjacent.

For example, if \( \kappa \) is an adjacency relation on a digital image \( Y \), then \( f : [a, b]_\mathbb{Z} \to Y \) is \((2, \kappa)\)-continuous if and only if for every \( \{c, c+1\} \subset [a, b]_\mathbb{Z} \), either \( f(c) = f(c+1) \) or \( f(c) \) and \( f(c+1) \) are \( \kappa \)-adjacent. If some function \( f : [0, k]_\mathbb{Z} \to Y \) is \((2, \kappa)\)-continuous, we say \( f \) is a \( \kappa \)-path from \( f(0) \) to \( f(k) \) of length \( k \).

We have the following.

Proposition 2.4. (2) Composition preserves digital continuity, i.e., if \( f : X \to Y \) and \( g : Y \to Z \) are, respectively, \((\kappa_0, \kappa_1)\)-continuous and \((\kappa_1, \kappa_2)\)-continuous functions, then the composite function \( g \circ f : X \to Z \) is \((\kappa_0, \kappa_2)\)-continuous.
2.2 Digital homotopy

A homotopy between continuous functions may be thought of as a continuous deformation of one of the functions into the other over a finite time period.

**Definition 2.5.** ([2]; see also [9]) Let \(X\) and \(Y\) be digital images. Let \(f, g : X \to Y\) be \((\kappa, \kappa')\)-continuous functions. Suppose there is a positive integer \(m\) and a function \(F : X \times [0, m]_{\mathbb{Z}} \to Y\) such that

- for all \(x \in X\), \(F(x, 0) = f(x)\) and \(F(x, m) = g(x)\);
- for all \(x \in X\), the induced function \(F_x : [0, m]_{\mathbb{Z}} \to Y\) defined by
  \[
  F_x(t) = F(x, t) \text{ for all } t \in [0, m]_{\mathbb{Z}}
  \]
  is \((2, \kappa')\)-continuous. That is, \(F_x(t)\) is a path in \(Y\).
- for all \(t \in [0, m]_{\mathbb{Z}}\), the induced function \(F_t : X \to Y\) defined by
  \[
  F_t(x) = F(x, t) \text{ for all } x \in X
  \]
  is \((\kappa, \kappa')\)-continuous.

Then \(F\) is a digital \((\kappa, \kappa)\)-homotopy between \(f\) and \(g\), and \(f\) and \(g\) are digitally \((\kappa, \kappa')\)-homotopic in \(Y\). If for some \(x \in X\) we have \(F(x, t) = F(x, 0)\) for all \(t \in [0, m]_{\mathbb{Z}}\), we say \(F\) holds \(x\) fixed, and \(F\) is a pointed homotopy. ■

We indicate a pair of homotopic functions as described above by \(f \simeq_{\kappa, \kappa'} g\). When the adjacency relations \(\kappa\) and \(\kappa'\) are understood in context, we say \(f\) and \(g\) are digitally homotopic to abbreviate “digitally \((\kappa, \kappa')\)-homotopic in \(Y\),” and write \(f \simeq g\).

**Proposition 2.6.** ([9, 2]) Digital homotopy is an equivalence relation among digitally continuous functions \(f : X \to Y\). ■

**Definition 2.7.** ([3]) Let \(f : X \to Y\) be a \((\kappa, \kappa')\)-continuous function and let \(g : Y \to X\) be a \((\kappa', \kappa)\)-continuous function such that

\[
f \circ g \simeq_{\kappa', \kappa'} 1_X \text{ and } g \circ f \simeq_{\kappa, \kappa} 1_Y.
\]
Then we say \(X\) and \(Y\) have the same \((\kappa, \kappa')\)-homotopy type and that \(X\) and \(Y\) are \((\kappa, \kappa')\)-homotopy equivalent, denoted \(X \simeq_{\kappa, \kappa'} Y\) or as \(X \simeq Y\) when \(\kappa\) and \(\kappa'\) are understood. If for some \(x_0 \in X\) and \(y_0 \in Y\) we have \(f(x_0) = y_0, g(y_0) = x_0\), and there exists a homotopy between \(f \circ g\) and \(1_X\) that holds \(x_0\) fixed, and a homotopy between \(g \circ f\) and \(1_Y\) that holds \(y_0\) fixed, we say \((X, x_0, \kappa)\) and \((Y, y_0, \kappa')\) are pointed homotopy equivalent and that \((X, x_0)\) and \((Y, y_0)\) have the same pointed homotopy type, denoted \((X, x_0) \simeq_{\kappa, \kappa'} (Y, y_0)\) or as \((X, x_0) \simeq (Y, y_0)\) when \(\kappa\) and \(\kappa'\) are understood. ■

It is easily seen, from Proposition 2.6, that having the same homotopy type (respectively, the same pointed homotopy type) is an equivalence relation among digital images (respectively, among pointed digital images).

For \(p \in Y\), we denote by \(\overline{p}\) the constant function \(\overline{p} : X \to Y\) defined by \(\overline{p}(x) = p\) for all \(x \in X\).

**Definition 2.8.** A digital image \((X, \kappa)\) is \(\kappa\)-contractible if its identity map is \((\kappa, \kappa)\)-homotopic to a constant function \(\overline{p}\) for some \(p \in X\). If the homotopy of the contraction holds \(p\) fixed, we say \((X, p, \kappa)\) is pointed \(\kappa\)-contractible. ■

When \(\kappa\) is understood, we speak of contractibility for short. It is easily seen that \(X\) is contractible if and only if \(X\) has the homotopy type of a one-point digital image.

**2.3 Fundamental group**

Inspired by the fundamental group of a topological space, several researchers have developed versions of a fundamental group for digital images. These are not all equivalent; however, it is shown in [4] that the version of the fundamental group developed in that paper is equivalent to the version in [2].

In the following, we present the version of the digital fundamental group developed in [4].

Given a digital image \(X\), a continuous function \(f : \mathbb{N}^* \to X\) is an eventually constant path or EC path if there is some point \(c \in X\) and some \(N \geq 0\) such that \(f(x) = c\) whenever \(x \geq N\). We abbreviate the latter by \(f(\infty) = c\). The endpoints of an EC path \(f\) are the two points \(f(0)\) and \(f(\infty)\). If \(f\) is an EC path and \(f(0) = f(\infty)\), we say \(f\) is an EC loop, and \(f(0)\) is called the basepoint of this loop.

We say that a homotopy \(H : [0, k]_{\mathbb{Z}} \times \mathbb{N}^* \to X\) between EC paths is an EC homotopy when the function \(H_s : \mathbb{N}^* \to X\) defined by \(H_s(t) = H(s, t)\) is an EC path for all \(s \in [0, k]_{\mathbb{Z}}\). To indicate an
EC homotopy, we write \( f \simeq_{EC}^\kappa g \), or \( f \simeq_{EC}^\kappa g \) if it is desirable to state the adjacency \( \kappa \) of \( X \). We say an EC homotopy \( H \) holds the endpoints fixed when \( H_t(0) = f(0) = g(0) \) and there is a \( c \in \mathbb{N} \) such that \( n \geq c \) implies \( H_t(n) = f(n) = g(n) \) for all \( t \).

Given an EC loop \( f : \mathbb{N}^* \to X \), we let

\[
N_f = \min\{m \in \mathbb{N}^* | n \geq m \text{ implies } f(n) = f(m)\}.
\]

For \( x_0 \in X \), suppose \( f_0, f_1 : \mathbb{N}^* \to X \) are \( x_0 \)-based EC loops. Define an \( x_0 \)-based EC loop \( f_0 * f_1 : \mathbb{N}^* \to X \) via

\[
f_0 * f_1(n) = \begin{cases} f_0(n) & \text{if } 0 \leq n \leq N_{f_0}; \\ f_1(n - N_{f_0}) & \text{if } N_{f_0} \leq n. \\ \end{cases}
\]

3 Homotopically similar images

In Euclidean topology, it is often possible to say that a bounded space \( X \) and an unbounded space \( Y \) have the same homotopy type. For example, a single point and \( n \)-dimensional Euclidean space \( \mathbb{R}^n \) have the same homotopy type, roughly since the points of \( \mathbb{R}^n \) can be moved continuously within \( \mathbb{R}^n \) over a finite time interval to a single point. However, Definition 2.5 does not permit a digital image with unbounded diameter to have the homotopy type of an image with bounded diameter, since the second factor of the domain of a homotopy is a finite interval \([0, m] \mathbb{Z} \). In this paper, we seek to circumvent this limitation. One of the ways we do so depends on the following.

Definition 3.1. Let \( X \) and \( Y \) be digital images. We say \((X, \kappa)\) and \((Y, \lambda)\) are homotopically similar, denoted \( X \simeq_{n, \lambda}^\kappa Y \), if there exist subsets \( \{X_j\}_{j=1}^\infty \) of \( X \) and \( \{Y_j\}_{j=1}^\infty \) of \( Y \) such that:
\( \bullet \) \( X = \bigcup_{j=1}^{\infty} X_j, \ Y = \bigcup_{j=1}^{\infty} Y_j, \) and, for all \( j, \ X_j \subset X_{j+1}, \ Y_j \subset Y_{j+1}. \)

\( \bullet \) There are continuous functions \( f_j : X_j \to Y_j, \ g_j : Y_j \to X_j \) such that \( g_j \circ f_j \simeq_{\kappa, \kappa} 1_{X_j} \) and \( f_j \circ g_j \simeq_{\lambda, \lambda} 1_{Y_j}. \)

\( \bullet \) For \( v \leq w, \ f_w|_{X_v} \simeq_{\kappa, \kappa} f_v \) in \( Y_v \) and \( g_w|_{Y_v} \simeq_{\lambda, \lambda} g_v \) in \( X_v. \)

If all of these homotopies are pointed with respect to some \( x_1 \in X_1 \) and \( y_1 \in Y_1, \) we say \((X, x_1)\) and \((Y, y_1)\) are pointed homotopically similar, denoted \((X, x_1) \simeq_{s} (Y, y_1)\) when \( \kappa \) and \( \lambda \) are understood.

**Proposition 3.2.** If \( X \simeq_{\kappa, \kappa} Y, \) then \( X \simeq_{s_{\kappa, \kappa}} Y. \) If \((X, x_1) \simeq_{\kappa, \kappa} (Y, y_1), \) then \((X, x_1) \simeq_{s_{\kappa, \kappa}} (Y, y_1). \)

**Proof:** Let \( f : X \to Y \) and \( g : Y \to X \) realize a homotopy equivalence between \((X, \kappa)\) and \((Y, \lambda), \) or a pointed homotopy equivalence between \((X, \kappa, x_1)\) and \((Y, \lambda, y_1). \) Then corresponding to Definition 3.1 we can take, for all \( j, \ X_j = X, \ Y_j = Y, \ f_j = f, \ g_j = g. \)

Although Definition 3.1 does not require it, we often choose the \( X_j \) and \( Y_j \) to be finite sets. Example 6.1 has an image with bounded diameter and an image with unbounded diameter that are not homotopy equivalent but are pointed homotopically similar.

**Theorem 3.3.** Let \( X \) and \( Y \) be finite digital images. Then \( X \simeq_{s_{\kappa, \kappa}} Y \) if and only if \( X \simeq_{s_{\kappa, \kappa}} Y, \) and \((X, x_0) \simeq_{s_{\kappa, \kappa}} (Y, y_0)\) if and only if \((X, x_0) \simeq_{s_{\kappa, \kappa}} (Y, y_0). \)

**Proof:** That \( X \simeq_{s_{\kappa, \kappa}} Y \) implies \( X \simeq_{s_{\kappa, \kappa}} Y \) is shown in Proposition 3.2. To show the converse: if \( X \simeq_{s_{\kappa, \kappa}} Y, \) let \( \{X_j, Y_j, f_j, g_j\}_{j=1}^{\infty} \) be as in Definition 3.1. Since \( X \) and \( Y \) are finite, there exists a positive integer \( m \) such that \( i \geq m \) implies \( X = X_i \) and \( Y = Y_i. \) Then \( f_m : X = X_m \to Y_m = Y \) and \( g_m : Y = Y_m \to X_m = X \) satisfy

\[
g_m \circ f_m \simeq_{\kappa, \kappa} 1_X, \ f_m \circ g_m \simeq_{\lambda, \lambda} 1_Y.
\]

Thus, \( X \simeq_{s_{\kappa, \kappa}} Y. \)

A similar argument yields the pointed assertion.

In Example 6.3 we show that two digital images with unbounded diameters can be homotopically similar but not homotopy equivalent.
Theorem 3.4. Homotopic similarity and pointed homotopic similarity are reflexive and symmetric relations among digital images.

Proof. The assertion follows easily from Definition 3.1.

At the current writing, we do not have an answer for the following.

Question 3.5. Is the homotopy similarity (unpointed or pointed) of digital images a transitive relation?

This appears to be a difficult problem. We need a positive resolution to this question if we are to conclude that homotopic similarity is an equivalence relation. Notice that if \( A \simeq_s B \) via subsets \( \{A_i\}_{i=1}^{\infty} \) of \( A \) and \( \{B_i\}_{i=1}^{\infty} \) of \( B \), and \( B \simeq_s C \) via subsets \( \{B'_i\}_{i=1}^{\infty} \) of \( B \) and \( \{C_i\}_{i=1}^{\infty} \) of \( C \), we would have \( A \simeq_s C \) if \( B_i = B'_i \) for infinitely many \( i \), but one can easily construct examples for which the latter is not satisfied.

We show transitivity for the following special case.

Theorem 3.6. Let \( B \) be finite. Let \( A \simeq_s B \simeq_s C \). Then \( A \simeq_s C \). If \( (A, a_0) \simeq_s (B, b_0) \simeq_s (C, c_0) \), then \( (A, a_0) \simeq_s (C, c_0) \).

Proof. We sketch a proof for the unpointed assertion. A similar argument yields the pointed assertion.

Let \( A \simeq_s B \) via \( A = \bigcup_{i=1}^{\infty} A_i \), \( B = \bigcup_{i=1}^{\infty} B_i \), as in Definition 3.1. Let \( B \simeq_s C \) via \( B = \bigcup_{i=1}^{\infty} B'_i \), \( C = \bigcup_{i=1}^{\infty} C_i \), as in Definition 3.1. Since \( B \) is finite, there exists \( i_0 \) such that \( i \geq i_0 \) implies \( B_i = B = B'_i \). Since homotopy of continuous functions and homotopy type of digital images are transitive relations, it follows easily from Definition 3.1 that \( A \simeq_s C \).

4 Long homotopy type

In this section, we introduce long homotopy type. We obtain for this notion several properties analogous to those discussed in Section 3 for homotopic similarity.

The following definition is a step in the direction of the idea that a long homotopy is a homotopy over an infinite time interval. The following is essentially an EC version of Definition 2.5.

Definition 4.1. Let \((X, \kappa)\) and \((Y, \lambda)\) be digital images. Let \(f, g : X \to Y\) be continuous. Let \(F : X \times \mathbb{N}^* \to Y\) be a function such that
for all \( x \in X \), \( F(x, 0) = f(x) \) and there exists \( n \in \mathbb{N}^\ast \) such that \( t \geq n \) implies \( F(x, t) = g(x) \).

- For all \( x \in X \), the induced function \( F_x : \mathbb{N}^\ast \to Y \) defined by
  \[
  F_x(t) = F(x, t) \text{ for all } t \in [0, \infty] \mathbb{Z}
  \]
  is an EC-path in \( Y \).

- For all \( t \in \mathbb{N}^\ast \), the induced function \( F_t : X \to Y \) defined by
  \[
  F_t(x) = F(x, t) \text{ for all } x \in X
  \]
  is \((\kappa, \lambda)\)-continuous.

Then \( F \) is an \( l \)-homotopy from \( f \) to \( g \). If for some \( x_0 \in X \) and \( y_0 \in Y \) we have \( F(x_0, t) = y_0 \) for all \( t \in \mathbb{N}^\ast \), we say \( F \) is a pointed \( l \)-homotopy. We write \( f \simeq^l_{\kappa, \lambda} g \), or \( f \simeq^l_g \) when the adjacencies \( \kappa \) and \( \lambda \) are understood, to indicate that \( f \) and \( g \) are \( l \)-homotopic functions. □

Note that the definition above generalizes EC homotopy of paths: if two EC paths \( f, g : [0, \infty] Z \to Y \) are EC homotopic, then the EC homotopy from \( f \) to \( g \) is an \( l \)-homotopy of \( f \) to \( g \).

**Proposition 4.2.** Let \( f, g : X \to Y \) be (unpointed or pointed) continuous functions between digital images. If \( f \) and \( g \) are (unpointed or pointed) homotopic in \( Y \), then \( f \) and \( g \) are (unpointed or pointed, respectively) \( l \)-homotopic in \( Y \). The converse is true if \( X \) is finite.

**Proof.** We give a proof for the unpointed assertions. The pointed assertions are proven similarly.

If \( f \simeq g \), there is a homotopy \( h : X \times [0, m] Z \to Y \) such that \( h(x, 0) = f(x) \) and \( h(x, m) = g(x) \). Then the function \( H : X \times [0, \infty] Z \to Y \) defined by \( H(x, t) = h(x, \min\{m, t\}) \) is an \( l \)-homotopy from \( f \) to \( g \).

Suppose \( X \) is finite and \( f \simeq^l g \). Then there is an \( l \)-homotopy \( H : X \times [0, \infty] Z \to Y \) such that \( H(x, 0) = f(x) \) and, for all \( x \in X \), there exists

\[
  t_x = \min\{t \in \mathbb{N}^\ast \mid s \geq t \text{ implies } H(x, s) = H(x, t)\}.
\]

Let \( m = \max\{t_x \mid x \in X\} \). Then the function \( h : X \times [0, m] Z \to Y \) defined by \( h(x, t) = H(x, t) \) is a homotopy from \( f \) to \( g \). □

At the current writing, we have not found answers to the following.
Question 4.3. (Unpointed and pointed versions:) Is l-homotopy a symmetric relation among continuous functions between digital images?

Question 4.4. (Unpointed and pointed versions:) Is l-homotopy a transitive relation among continuous functions between digital images?

Positive answers to Questions 4.3 and 4.4 are necessary for l-homotopy to be an equivalence relation. In the absence of such results, we proceed with the following definition.

Definition 4.5. Let $(X, \kappa)$ and $(Y, \lambda)$ be digital images. Let $f, g : X \to Y$ be continuous. Let $F : X \times Z \to Y$ be a function such that

- for all $x \in X$, there exists $N_{F,x} \in \mathbb{N}$ such that $t \leq -N_{F,x}$ implies $F(x, t) = f(x)$ and $t \geq N_{F,x}$ implies $F(x, t) = g(x)$.

- For all $x \in X$, the induced function $F_x : Z \to Y$ defined by
  \[ F_x(t) = F(x, t) \text{ for all } t \in Z \]
  is $(c_1, \lambda)$-continuous.

- For all $t \in Z$, the induced function $F_t : X \to Y$ defined by
  \[ F_t(x) = F(x, t) \text{ for all } x \in X \]
  is $(\kappa, \lambda)$-continuous.

Then $F$ is a long homotopy from $f$ to $g$. If for some $x_0 \in X$ and $y_0 \in Y$ we have $F(x_0, t) = y_0$ for all $t \in \mathbb{N}^*$, we say $F$ is a pointed long homotopy. We write $f \sim^L_{\kappa, \lambda} g$, or $f \sim^L g$ when the adjacencies $\kappa$ and $\lambda$ are understood, to indicate that $f$ and $g$ are long homotopic functions. ■

It is easy to show that the existence of an l-homotopy implies a long homotopy:

Proposition 4.6. Let $f, g : (X, \kappa) \to (Y, \lambda)$ be continuous functions between digital images. If $f \sim^l g$ then $f \sim^L g$. If the l-homotopy between $f$ and $g$ is pointed, then the long homotopy between $f$ and $g$ is pointed.
Proof. Clearly, if \( F : X \times \mathbb{N}^* \to Y \) is a (pointed) \( l \)-homotopy from \( f \) to \( g \), then the function \( F' : X \times \mathbb{Z} \to Y \) defined by
\[
F'(x,t) = \begin{cases} 
F(x,t) & \text{if } t \geq 0; \\
F(x,0) & \text{if } t < 0,
\end{cases}
\]
is a (pointed) long homotopy from \( f \) to \( g \).

The same argument used in Proposition 4.2 proves the corresponding assertion for long homotopy:

**Proposition 4.7.** Let \( f, g : X \to Y \) be (unpointed or pointed) continuous functions between digital images. If \( f \) and \( g \) are (unpointed or pointed) homotopic in \( Y \), then \( f \) and \( g \) are (unpointed or pointed, respectively) long homotopic in \( Y \). The converse is true if \( X \) is finite.

Unlike with \( l \)-homotopy, it is easy to see that long homotopy is symmetric.

**Theorem 4.8.** Long homotopy and pointed long homotopy are reflexive and symmetric relations.

Proof. We state a proof for the unpointed assertion. The same argument works for the pointed assertion.

For the reflexive property, we note the following. Given a continuous function \( f : (X, \kappa) \to (Y, \lambda) \), it is clear that the function \( F : X \times \mathbb{Z} \to Y \) given by \( F(x,t) = f(x) \) is a long homotopy from \( f \) to \( f \).

For the symmetric property, we note that if \( F : X \times \mathbb{Z} \to Y \) is a long homotopy from \( f \) to \( g \), where \( f, g : (X, \kappa) \to (Y, \lambda) \) are continuous, then \( F' : X \times \mathbb{Z} \to Y \), defined by \( F'(x,t) = F(x,-t) \), is a long homotopy from \( g \) to \( f \).

At the current writing, we lack an answer to the following.

**Question 4.9.** Is long homotopy (pointed or unpointed) between continuous functions a transitive relationship?

This seems to be a difficult problem. If \( X \) is finite and \( f, g, h : X \to Y \) with \( f \simeq^L g \simeq^L h \), then \( f \simeq^L h \) since it follows from Proposition 4.2 that in this case, long homotopy coincides with homotopy, which is transitive. To demonstrate the difficulty involved in the general case, we will prove transitivity for another special case.

It is easy to see that if \( c, d : X \to Y \) are two different constant maps whose constant values \( c = c(x) \) and \( d = d(x) \) are in the same component of \( X \), then \( c \) and \( d \) are homotopic, and thus long
homotopic. Thus the following theorem is a very special case of transitivity, but the proof is already somewhat involved.

Say that a digital image $X$ is \textit{locally finite} when each point $x \in X$ is adjacent to only finitely many other points of $X$. E.g., if $X$ is finite, or if $X$ has a $c_n$-adjacency, then $X$ is locally finite.

\textbf{Theorem 4.10.} Let $X$ be locally finite, and let $f : X \to Y$ be a continuous function, and let $c, d : X \to Y$ be two constant functions with constant values $c$ and $d$ in the same component of $Y$. If $f \simeq^L c$, then $f \simeq^L d$.

\textit{Proof.} Let $\sigma : [0, k]Z \to Y$ be a path from $c$ to $d$. Our proof is by induction on $k$. If $k = 0$, then $c = d$ and there is nothing to prove. Letting $c' = \sigma(k - 1)$, for our induction case we may assume that $f \simeq^L c'$, and we will show that $f \simeq^L d$. (Note that $c'$ and $d$ are adjacent.)

Let $H : X \times Z \to Y$ be a long homotopy of $f$ to $c'$. Then for each $x \in X$, there is a number $N_x$ such that, whenever $t \geq N_x$, we have $H(x, t) = c'$. Since $X$ is locally finite, there is a number $N'_x \geq N_x$ such that, whenever $t \geq N'_x$, we have $H(x', t) = c'$ for every $x'$ adjacent to $x$.

Then we define $G : X \times Z \to Y$ as:

$$G(x, t) = \begin{cases} H(x, t) & \text{if } t \leq N'_x; \\ d & \text{if } t > N'_x. \end{cases}$$

We claim that $G$ is a long homotopy of $f$ to $d$. It is clear that for all $x \in X$ there exists $n_x \in \mathbb{N}$ such that $t \leq -n_x$ implies $G(x, t) = H(x, t) = f(x)$ and $t \geq n_x$ implies $G(x, t) = d$. Furthermore, the induced function $G_x(t)$ is given by:

$$G_x(t) = \begin{cases} H_x(t) & \text{if } t \leq N'_x; \\ d & \text{if } t > N'_x, \end{cases},$$

which is continuous since $H(x, N'_x) = c'$ is adjacent to $d$.

Lastly we show that the induced function $G_t(x)$ is continuous: take any point $y$ adjacent to $x$, and we will show that $G_t(x)$ is adjacent or equal to $G_t(y)$.

- When $t \leq N'_x$, we have $G_t(x) = H_t(x)$, which is adjacent or equal to $H_t(y)$ because $H$ is a homotopy.

  - If $H_t(y) = G_t(y)$, we have the desired conclusion that $G_t(x)$ is adjacent or equal to $G_t(y)$.
  - Otherwise, $G_t(y) = d \neq H_t(y)$, so $t > N'_y$, which implies $H(x, t) = c'$. Thus, $G_t(x) \in \{c', d\}$, so $G_t(x)$ is adjacent or equal to $G_t(y)$.
• If \( t > N_x' \) then \( G_t(x) = d \). For \( G_t(y) \) there are two cases. If \( t \geq N_y' \) then \( G_t(y) = d = G_t(x) \). If \( t < N_y' \) we still must have \( t \geq N_y \) since \( t > N_x' \) and \( y \) is adjacent to \( x \). Thus in this case \( G_t(y) = H_t(y) = c' \), and thus \( G_t(x) = d \) and \( G_t(y) = c' \) are adjacent as desired.

\[ \]

**Definition 4.11.** Let \( f : (X, \kappa) \to (Y, \lambda) \) and \( g : (Y, \lambda) \to (X, \kappa) \) be continuous functions. Suppose \( g \circ f \simeq^L 1_X \) and \( f \circ g \simeq^L 1_Y \). Then we say \((X, \kappa)\) and \((Y, \lambda)\) have the same long homotopy type, denoted \( X \simeq^L_{\kappa, \lambda} Y \) or simply \( X \simeq^L Y \). If there exist \( x_0 \in X \) and \( y_0 \in Y \) such that \( f(x_0) = y_0 \), \( g(y_0) = x_0 \), the long homotopy \( g \circ f \simeq^L 1_X \) holds \( x_0 \) fixed, and the long homotopy \( f \circ g \simeq^L 1_Y \) holds \( y_0 \) fixed, then \((X, x_0, \kappa)\) and \((Y, y_0, \lambda)\) have the same pointed long homotopy type, denoted \((X, x_0) \simeq^L_{\kappa, \lambda} (Y, y_0) \) or \((X, x_0) \simeq^L (Y, y_0) \).

**Proposition 4.12.** If \( X \simeq_{\kappa, \lambda} Y \), then \( X \simeq^L_{\kappa, \lambda} Y \). If \((X, x_0) \simeq_{\kappa, \lambda} (Y, y_0) \), then \((X, x_0) \simeq^L_{\kappa, \lambda} (Y, y_0) \).

The converses of both statements hold when \( X \) and \( Y \) are both finite.

**Proof.** The assertions follow from Definition 4.11 and Proposition 4.7.

**Theorem 4.13.** Long homotopy type, and pointed long homotopy type, are reflexive and symmetric relations among digital images.

**Proof.** The assertions follow easily from Definition 4.11.

At the current writing, we lack an answer to the following.

**Question 4.14.** Is long homotopy type (unpointed or pointed) a transitive relation among digital images?

This appears to be a difficult problem. A positive resolution to this question is necessary in order for us to conclude that long homotopy type is an equivalence relation. Since homotopy equivalence is an equivalence relation, Proposition 4.12 implies (for both the pointed and unpointed questions) that if there exists an example of non-transitivity for long homotopy type, i.e., images \( A, B, C \) such that \( A \simeq^L B \simeq^L C \) with \( A \) and \( C \) not long homotopically equivalent, then at least one of \( A, B, C \) must be infinite.

In the next result, we prove transitivity for a special case. The following resembles Theorem 3.6 for homotopic similarity, but requires that the intermediate image be a single point. It does not seem easy to generalize to finite sets as in Theorem 3.6.
Theorem 4.15. Let $X \simeq^L \{a\} \simeq^L Y$. Then $X \simeq^L Y$. If $(X, x_0) \simeq^L (\{a\}, a) \simeq^L (Y, y_0)$, then $(X, x_0) \simeq^L (Y, y_0)$.

Proof. We state a proof for the pointed assertion; the unpointed assertion is handled similarly.

By hypothesis, there are pointed functions $f : (X, x_0) \to (\{a\}, a)$ and $g : (\{a\}, a) \to (X, x_0)$ and a pointed long homotopy $H : X \times \mathbb{Z} \to X$ from $1_X$ to $g \circ f = x_0$. Similarly, there are pointed functions $h : (Y, y_0) \to (\{a\}, a)$ and $k : (\{a\}, a) \to (Y, y_0)$ and a pointed long homotopy $K : Y \times \mathbb{Z} \to Y$ from $1_Y$ to $k \circ h = y_0$. Let $x_0'$ be the constant function from $X$ to $Y$. Let $y_0'$ be the constant function from $Y$ to $X$. Then $H$ is a pointed long homotopy from $1_X$ to $x_0 = x_0' \circ y_0'$, and $K$ is a pointed long homotopy from $1_Y$ to $y_0 = y_0' \circ x_0'$. The assertion follows.

A digital image with bounded diameter and an image with infinite diameter cannot have the same homotopy type, but Example 6.1 shows that such a pair of images can have the same long homotopy type. Example 6.3 gives two digital images with unbounded diameters that have the same long homotopy type but not the same homotopy type.

5 Real homotopy type

In this section we present another generalization of digital homotopy that we call real homotopy. As in the case of long homotopy, we will allow the time interval to be infinite, this time using the real interval $[0, 1]$. Though nondiscrete sets are not typically used in digital topology, we will see as in the other sections that real homotopy and digital homotopy are equivalent when the images under consideration are finite. The advantage in using the real interval rather than the integer interval $[0, \infty)$ is that two copies of $[0, 1]$ can be concatenated in a natural way, which allows us to prove that real homotopy is transitive.

It also turns out that long homotopy can tell us a lot about real homotopy.

We begin with a preliminary definition that is a kind of continuity property for a function from a real interval into a digital image. Informally we want to require that such a function be locally constant with jump discontinuities only between adjacent points.

Definition 5.1. Let $(X, \kappa)$ be a digital image, and $[0, 1] \subset \mathbb{R}$ be the unit interval. A function $f : [0, 1] \to X$ is a real [digital] $[\kappa]$-path in $X$ if:
• there exists $\varepsilon_0 > 0$ such that $f$ is constant on $(0, \varepsilon_0)$ with constant value equal or $\kappa$-adjacent to $f(0)$,

• there exists $\varepsilon_1 > 0$ such that $f$ is constant on $(1-\varepsilon_1, 1)$ with constant value equal or $\kappa$-adjacent to $f(1)$,

• for each $t \in (0, 1)$ there exists $\varepsilon_t > 0$ such that $f$ is constant on each of the intervals $(t-\varepsilon_t, t)$ and $(t, t+\varepsilon_t)$, and these two constant values are equal or $\kappa$-adjacent, with at least one of them equal to $f(t)$.

If $t = 0$ and $f(0) \neq f((0, \varepsilon_0))$, or $0 < t < 1$ and the two constant values $f((t-\varepsilon_t, t))$ and $f((t, t+\varepsilon_t))$ are not equal, or $t = 1$ and $f(1) \neq f((1-\varepsilon_1, 1))$, we say $t$ is a jump of $f$.

In fact such a real path can only have finitely many jumps, as the following Proposition shows.

**Proposition 5.2.** Let $p, q \in (X, \kappa)$. Let $f : [a, b] \to X$ be a real $\kappa$-path from $p$ to $q$. Then the number of jumps of $f$ is finite.

**Proof.** Suppose $f$ has an infinite set of jumps in the domain $[a, b]$. By the Bolzano-Weierstrass Theorem this set of jumps has an accumulation point. Thus there exists $t_0 \in [a, b]$ and a sequence of distinct jumps $\{t_j\}_{j=1}^{\infty}$ such that $\lim_{j \to \infty} t_j = t_0$. Then for every $\varepsilon > 0$, at least one of the intervals $(t_0 - \varepsilon, t_0)$ and $(t_0, t_0 + \varepsilon)$ has infinitely many members of $\{t_j\}_{j=1}^{\infty}$, contrary to the requirement of Definition 5.1 that there be $\varepsilon > 0$ such that $f$ is constant on each of the intervals $(t_0 - \varepsilon, t_0)$ and $(t_0, t_0 + \varepsilon)$.

Now we can define real digital homotopy of functions. The following is a “real” version of Definitions 2.5 and 4.1.

**Definition 5.3.** Let $(X, \kappa)$ and $(Y, \kappa')$ be digital images, and let $f, g : X \to Y$ be $(\kappa, \kappa')$ continuous. Then a real [digital] homotopy of $f$ and $g$ is a function $F : X \times [0, 1] \to Y$ such that:

• for all $x \in X$, $F(x, 0) = f(x)$ and $F(x, 1) = g(x)$

• for all $x \in X$, the induced function $F_x : [0, 1] \to Y$ defined by

$$F_x(t) = F(x, t)$$

is a real $\kappa$-path in $X$. 15
• for all \( t \in [0, 1] \), the induced function \( F_t : X \to Y \) defined by
  \[
  F_t(x) = F(x, t) \text{ for all } x \in X
  \]
  is \((\kappa, \kappa')\)-continuous.

If such a function exists we say \( f \) and \( g \) are real homotopic and write \( f \simeq^R g \). If there are points \( x_0 \in X \) and \( y_0 \in Y \) such that \( F(x_0, t) = y_0 \) for all \( t \in [0, 1] \), we say \( f \) and \( g \) are pointed real homotopic.

Unlike long homotopy, real homotopy is easily shown to be an equivalence relation.

**Theorem 5.4.** Real homotopy and pointed real homotopy are equivalence relations among continuous functions between digital images.

**Proof.** We give the proof for the unpointed assertion. A similar argument can be used to establish the pointed assertion.

Reflexivity is clear: for any digitally continuous function \( f : X \to Y \), the function \( F(x, t) = f(x) \) is a real homotopy from \( f \) to \( f \).

For symmetry, let \( f, g : X \to Y \) be digitally continuous with \( f \simeq^R g \), and let \( F : X \times [0, 1] \to Y \) be a real homotopy from \( f \) to \( g \). Then define \( G : X \times [0, 1] \to Y \) by \( G(x, t) = F(x, 1 - t) \). It is easy to verify that \( G \) is a real homotopy from \( g \) to \( f \), and so \( g \simeq^R f \).

For transitivity, let \( f, g, h : X \to Y \) with \( f \simeq^R g \) and \( g \simeq^R h \). Let \( F, G : X \times [0, 1] \to Y \) be homotopies from \( f \) to \( g \) and \( g \) to \( h \), respectively. Then define \( H : X \times [0, 1] \to Y \) by
  \[
  H(x, t) = \begin{cases} 
  F(x, 2t) & \text{if } t \leq 1/2, \\
  G(x, 2t - 1) & \text{if } t \geq 1/2.
  \end{cases}
  \]
Again it is routine to check that \( H \) is a real homotopy from \( f \) to \( h \), and so \( f \simeq^R h \) as desired. \( \square \)

Next we show that long homotopy of functions implies real homotopy.

**Theorem 5.5.** Let \( X \) and \( Y \) be digital images, and let \( f, g : X \to Y \) be continuous. If \( f \simeq^L g \) then \( f \simeq^R g \). If \( f \) and \( g \) are pointed long homotopic, then they are pointed real homotopic.

**Proof.** Let \( h : (0, 1) \to \mathbb{R} \) be a homeomorphism with \( \lim_{x \to 0} h(x) = -\infty \) and \( \lim_{x \to 1} h(x) = \infty \). For example \( h \) can be taken to be a rescaled version of the tangent function. Let \( H : X \times \mathbb{Z} \to Y \) be a
long homotopy from \( f \) to \( g \), and define \( F : X \times [0,1] \to Y \) by:

\[
F(x,t) = \begin{cases} 
  f(x) & \text{if } t = 0, \\
  H(x, \lfloor h(t) \rfloor) & \text{if } t \in (0,1), \\
  g(x) & \text{if } t = 1.
\end{cases}
\]

We claim that \( F \) is a real homotopy from \( f \) to \( g \). We have defined \( F \) so that \( F(x,0) = f(x) \) and \( F(x,1) = g(x) \) for all \( x \). Observe also that each induced function \( F_t(x) \) is continuous - for \( t \in \{0,1\} \) this is true because \( f \) and \( g \) are continuous, and for other \( t \) because \( H_s \) is continuous for any \( s \in \mathbb{Z} \).

It remains to show that the induced function \( F_x : \mathbb{R}_+ \to Y \) is a real path for every \( x \). Note that the value of \( H_x(t) = H(x, \lfloor h(t) \rfloor) \) changes only when \( h(t) \) is an integer. When \( h(t) \) is an integer, the value of \( H_x \) can only change from one point of \( Y \) to an adjacent point. Thus for any \( t \in (0,1) \), there is some \( \epsilon \) such that \( H_x \) is constant on \( (t-\epsilon,t) \) and \( (t,t+\epsilon) \), and these constant values are adjacent, and one of them equals \( F_x(t) \).

It remains to show the existence of \( \epsilon_0 \) and \( \epsilon_1 \) as in Definition 5.3. Because \( H \) is a long homotopy, there is a natural number \( N \) such that \( H(x,t) = g(x) \) whenever \( t > N \) and \( H(x,t) = f(x) \) whenever \( t < -N \). Then choose \( \epsilon_0 \) with \( 0 < \epsilon < h^{-1}(-N) \), and then \( F_x \) will be constant on \([0,\epsilon] \) as required. Choose \( \epsilon_1 \) such that \( h^{-1}(N) < \epsilon_1 < 1 \), and \( F_x \) will be constant on \((1-\epsilon,1) \), as required. Thus \( F_x \) is a real path and so \( F \) is a real homotopy.

Next we show that real homotopy is weaker than digital homotopy, and that the two notions are equivalent when the domain is finite. This result is analogous to Proposition 5.7 for long homotopy.

**Theorem 5.6.** Let \((X,\kappa)\) and \((Y,\kappa')\) be digital images, and let \( f, g : X \to Y \) be \((\kappa,\kappa')\)-continuous. Then \( f \simeq g \) implies \( f \simeq^R g \), and the converse is true when \( X \) is finite. If \( f \) and \( g \) are pointed homotopic, then they are pointed real homotopic, and the converse is true when \( X \) is finite.

**Proof.** We give the proof for the unpointed assertion. A similar argument can be used to establish the pointed assertion.

First we assume that \( f \simeq g \). This implies, by Proposition 4.3, that \( f \simeq^L g \). Hence by Theorem 5.5 \( f \simeq^R g \).

Now for the converse we assume that \( f \simeq^R g \) and \( X \) is finite, and show that \( f \simeq g \). Let \( F \) be a real homotopy from \( f \) to \( g \). Since \( X \) is finite and each real path \( F_x(t) \) has finitely many jumps, there are only finitely many values of \( t \in [0,1] \) which can be jumps for any of the paths \( F_x(t) \). Let
be these jump points, and choose \( t_1, \ldots, t_{k-1} \) so that \( j_i < t_i < j_{i+1} \) for each \( i \). Also let \( t_0 = 0 \) and \( t_{k+1} = 1 \). Since jumps in real paths only move to adjacent points, \( F_x(t_i) \) is adjacent or equal to \( F_x(t_{i+1}) \) for each \( i \).

Now define \( G : X \times [0, k+1] \rightarrow Y \) by \( G(x, i) = F(x, t_i) \). We will show that \( G \) is a homotopy from \( f \) to \( g \). We have \( G(x, 0) = F(x, t_0) = F(x, 0) = f(x) \) and \( G(x, k+1) = F(x, t_{k+1}) = F(x, 1) = g(x) \). Since \( f_i(x) \) is \((\kappa, \kappa')\)-continuous for each \( t_i \in [0, 1] \), we have \( G_i(x) \) \((\kappa, \kappa')\)-continuous for each \( i \in [0, k+1] \) as required.

It remains to show that the induced function \( G_x : [0, k+1] \rightarrow Y \) is \((2, \kappa')\)-continuous for each \( x \in X \). Equivalently, we must show that \( G_x(i) \) is \( \kappa' \)-adjacent or equal to \( G_x(i+1) \) for each \( i \). But we have already stated that \( F_x(t_i) = G_x(i) \) is adjacent or equal to \( F_x(t_{i+1}) = G_x(i+1) \) for each \( i \), as desired.

In the case when \( X \) is finite, the converse above shows that a real homotopy implies an ordinary (finite) homotopy, which by Proposition 4.7 implies a long homotopy. Combining all these results gives:

**Corollary 5.7.** Let \( X \) be a finite digital image, \( Y \) be any digital image, and \( f, g : X \rightarrow Y \) be continuous. Then the following three statements are equivalent: \( f \simeq_R g \), \( f \simeq_L g \), and \( f \simeq_R g \). Similar equivalences hold for pointed relations.

The following simple question seems hard to answer:

**Question 5.8.** Is Corollary 5.7 true without the finiteness assumption?

With our real homotopy relation we can make the obvious definition for real homotopy type of digital images.

**Definition 5.9.** We say digital images \((X, \kappa)\) and \((Y, \kappa')\) have the same real homotopy type, denoted \( X \simeq_R^{\kappa, \kappa'} Y \) or \( X \simeq_R Y \) when \( \kappa \) and \( \kappa' \) are understood, if there are continuous functions \( f : X \rightarrow Y \) and \( g : Y \rightarrow X \) such that \( g \circ f \simeq_R 1_X \) and \( f \circ g \simeq_R 1_Y \). If there exist \( x_0 \in X \) and \( y_0 \in Y \) such that \( f(x_0) = y_0 \), \( g(y_0) = x_0 \), and the real homotopies implicit above are pointed with respect to \( x_0 \) and \( y_0 \), we say \( X \) and \( Y \) have the same pointed real homotopy type, denoted \( (X, x_0) \simeq_R^{\kappa, \kappa'} (Y, y_0) \) or \( (X, x_0) \simeq_R (Y, y_0) \).

Having the same real homotopy type is also easily seen to be an equivalence relation.
Theorem 5.10. Having the same real homotopy type or pointed real homotopy type is an equivalence relation among digital images.

Proof. We prove the unpointed assertion. Simple modifications to the argument give the pointed assertion.

For the reflexive property it is easy to see that an identity map $1_X$ shows that $X \simeq^R X$. The symmetric property follows from the symmetry in Definition 5.9. It remains to prove transitivity.

Suppose $X \simeq^R Y \simeq^R W$. Then there are continuous functions $f : X \to Y$, $f' : Y \to X$, $g : Y \to W$, and $g' : W \to Y$, and real homotopies $F : X \times [0, 1] \to X$ from $f' \circ f$ to $1_X$, $F' : Y \times [0, 1] \to Y$ from $f \circ f'$ to $1_Y$, $G : Y \times [0, 1] \to Y$ from $g' \circ g$ to $1_Y$, and $G' : W \times [0, 1] \to W$ from $g \circ g'$ to $1_W$. We will show that $X \simeq^R W$ using the functions $g \circ f : X \to W$ and $f' \circ g' : W \to X$.

Consider the function $H : X \times [0, 1] \to X$ defined by $H(x, t) = f'(G(f(x), t))$. We will show that $H$ is a real homotopy from $f' \circ g' \circ g \circ f$ to $f' \circ f$. First observe that

$$H(x, 0) = f'(G(f(x), 0)) = f'(g'(g(f(x)))) = f' \circ g' \circ g \circ f(x)$$

and

$$H(x, 1) = f'(G(f(x), 1)) = f'(f(x)) = f' \circ f(x).$$

Also observe that $H_t = f' \circ G_t \circ f$, and thus $H_t$ is continuous by Theorem 2.4. For $H_x$, we have $H_x = f' \circ G_{f(x)}$. Since $G_{f(x)}$ is a real path and $f'$ is continuous, it is easy to see that $H_x$ is a real path.

Thus we have shown that $f' \circ g' \circ g \circ f \simeq^R f' \circ f$. By our assumption we have $f' \circ f \simeq^R 1_X$, and thus by transitivity of real homotopy (Theorem 5.4) we have $f' \circ g' \circ g \circ f \simeq^R 1_X$. A similar argument shows that $g \circ f \circ f' \circ g' \simeq 1_W$, and thus $X \simeq^R W$ as desired. □

Because of the theorem above, when $X \simeq^R Y$, we say $X$ and $Y$ are real homotopy equivalent.

Corollary 5.11. If $X \simeq Y$ then $X \simeq^R Y$. If $(X, x_0) \simeq (Y, y_0)$ then $(X, x_0) \simeq^R (Y, y_0)$. If both $X$ and $Y$ are finite, then the converses hold.

Proof. This follows easily from Theorem 5.6 □

Corollary 5.12. If $X \simeq^b Y$, then $X \simeq^R Y$. If $(X, x_0) \simeq^b (Y, y_0)$, then $(X, x_0) \simeq^R (Y, y_0)$.

Proof. This follows from Definitions 4.11 and 5.9 and Theorem 5.6 □
Note that in light of Corollary 5.12, Example 6.3 below shows it is possible for two digital images to be pointed real homotopy equivalent without being pointed homotopy equivalent.

6 Examples

A finite set and an infinite set cannot have the same digital homotopy type. In particular the set \( \mathbb{Z} \) is not the same digital homotopy type as a single point, even though the continuous objects they represent (\( \mathbb{R} \) and a point) are classically homotopy equivalent. In the following example we show that \( \mathbb{Z} \) is homotopically similar to a point, and also of the same long homotopy type (and thus the same real homotopy type).

Example 6.1. Let \( x = (x_0, x_1, \ldots, x_{n-1}) \in \mathbb{Z}^n \) and let \( u, v \in \{1, n\}_\mathbb{Z} \). Then \((\{x\}, x)\) and \((\mathbb{Z}^n, x)\) are \((c_u, c_v)\)-pointed homotopically similar and have the same \((c_u, c_v)\)-pointed long homotopy type.

Proof: Corresponding to Definition 3.1, let \( X_j = \{x\} \), let \( Y_j = \Pi_{i=0}^{n-1} [x_i - j, x_i + j]_\mathbb{Z} \), let \( f_j \) be the inclusion map, and let \( g_j \) be the constant map with image \( \{x\} \). Since a digital cube is pointed \((c_u, c_v)\)-contractible with respect to any of its points \([1]\), the assertion of pointed homotopic similarity follows.

Let \( H : \mathbb{Z}^n \times \mathbb{N}^* \to \mathbb{Z}^n \) be the map defined as follows. Let \( H(y, 0) = y \). For \( t > 0 \), let \( q \) be the reduction of \( t \) modulo \( n \), and we bring the \( q \)-th coordinate of \( H(y, t) \) one unit closer to the \( q \)-th coordinate of \( x \), i.e., if \( H((y_0, \ldots, y_{n-1}), t - 1) = (z_0, \ldots, z_{n-1}) \) then

\[
H((y_0, \ldots, y_{n-1}), t) = \begin{cases} 
(z_0, \ldots, z_{q-1}, z_q - 1, z_{q+1}, \ldots, z_{n-1}) & \text{if } z_q > x_q; \\
(z_0, \ldots, z_{n-1}) & \text{if } z_q = x_q; \\
(z_0, \ldots, z_{q-1}, z_q + 1, z_{q+1}, \ldots, z_{n-1}) & \text{if } z_q < x_q.
\end{cases}
\]

Since, in a single time step, \( H \) changes only one coordinate, it is easily seen that this map holds \( x \) fixed and, for all \( u, v \in [1, n]_\mathbb{Z} \), is a \((c_u, c_v)\)-l-homotopy from \( 1_{\mathbb{Z}^n} \) to the map \( i_x \circ \pi \), where \( \pi : \mathbb{Z}^n \to \{x\} \) is a constant map and \( i_x : \{x\} \to \mathbb{Z}^n \) is the inclusion function. From Proposition 4.6 we have that \( 1_{\mathbb{Z}^n} \) and \( i_x \circ \pi \) are pointed long homotopic. Since \( 1_{\{x\}} = \pi \circ i_x \), the assertion of the same pointed long homotopy type follows. \( \blacksquare \)

Recall that a tree is an acyclic graph in which every pair of points is connected by a unique injective path. We consider both finite and infinite trees.

Example 6.2. Let \( (X, \kappa) \) be a digital image that is a tree. Let \( x_0 \in X \). Then \( (X, x_0) \) is pointed homotopically similar to, and has the same pointed long homotopy type, as \( (\{x_0\}, x_0) \).
Proof. In the following, for $x \neq x_0$ we use $\text{parent}(x)$ to denote the unique vertex in $X$ adjacent to $x$ along the unique path in $X$ from $x$ to $x_0$; and, by $\text{dist}(x, y)$ (the distance between vertices $x$ and $y$) we mean the length of the path in $X$ from $x$ to $y$. Note if $\text{dist}(x, x_0) = n > 0$, then $\text{dist}(\text{parent}(x), x_0) = n - 1$.

Corresponding to the notation of Definition 3.1 let $X_j = \{x \in X | \text{dist}(x, x_0) \leq j\}$. Let $Y = Y_j = \{x_0\}$. Let $f_j : X_j \to Y_j$ be the function $f_j(x) = x_0$. Let $g_j : Y_j \to X_j$ be the function $g(x_0) = x_0$. Let $H_j : X_j \times [0, j] \to X_j$ be the function

$$H_j(x, t) = \begin{cases} x & \text{if } t = 0; \\ x_0 & \text{if } t > 0 \text{ and } H(x, t - 1) = x_0; \\ \text{parent}(H(x, t - 1)) & \text{if } t > 0 \text{ and } H(x, t - 1) \neq x_0. \end{cases}$$

Then $H_j$ is a pointed homotopy from $1_{X_j}$ to $g_j \circ f_j$. Further, $f_j \circ g_j = 1_{Y_j}$. It follows easily that $(X, x_0)$ and $(\{x_0\}, x_0)$ are pointed homotopically similar.

Let $H : X \times N^* \to X$ be the function

$$H(x, t) = \begin{cases} x & \text{if } t = 0; \\ x_0 & \text{if } t > 0 \text{ and } H(x, t - 1) = x_0; \\ \text{parent}(H(x, t - 1)) & \text{if } t > 0 \text{ and } H(x, t - 1) \neq x_0. \end{cases}$$

Then $H$ is a pointed l-homotopy from $1_X$ to $\pi_0$. From Proposition 4.6, $1_X$ and $i_{\{x_0\}} \circ \pi_0$ are pointed long homotopic, where $i_{\{x_0\}}$ is the inclusion function of $\{x_0\}$ into $Z^n$. Since $\pi_0 \circ i_{\{x_0\}} = 1_{\{x_0\}}$, it follows that $(X, x_0)$ and $(\{x_0\}, x_0)$ have the same pointed long homotopy type.

Example 6.3. Let $X = Z \times \{0\} \subset Z^2$ and let $Y = X \cup (\{0\} \times N) \subset Z^2$ (see Figure 4). Then $(X, (0, 0)) \simeq_{c_1, c_1} (Y, (0, 0))$, and $(X, (0, 0)) \simeq_L (Y, (0, 0))$. But $(X, (0, 0))$ and $(Y, (0, 0))$ do not have the same $(c_1, c_1)$-pointed homotopy type.

Proof: It follows from Example 6.2 and Theorems 3.6 and 4.6 that $(X, (0, 0)) \simeq_{c_1, c_1} (Y, (0, 0))$, and $(X, (0, 0)) \simeq_L (Y, (0, 0))$.

Suppose $(X, (0, 0)) \simeq_{c_1, c_1} (Y, (0, 0))$. Then there are pointed continuous functions $f : X \to Y$, $g : Y \to X$, and pointed homotopies $H : X \times [0, k] \to X$ and $H' : Y \times [0, m] \to Y$ such that $H(x, 0) = x$ and $H(x, k) = g \circ f(x)$ for all $x \in X$, and $H'(y, 0) = y$ and $H'(y, m) = f \circ g(y)$ for all $y \in Y$.

We show $f$ is a surjection. Note if $A = N^* \times \{0\}$, $B = \{(n, 0) | n \in Z, (-n, 0) \in A \}$, and $C = \{0\} \times N^*$, we have $Y = A \cup B \cup C$. Suppose there exists $p = (u, v) \in Y \setminus f(X)$.  

21
Figure 1: The image $Y$ of Example 6.3, with the subsets $A, B, C$ of its proof marked by arrows

- If $p \in A$ then, since $f(X)$ is $c_1$-connected and contains $(0, 0)$, $A_1 = \{(x, 0) \mid x \geq u\} \subset Y \setminus f(X)$. In particular,

$$A_2 = [u, u + 2m] \times \{0\} \subset Y \setminus f(X). \quad (1)$$

Since $u > 0$, $A_2$ is the set of all points in $Y$ within $m$ steps of $(u + m, 0)$, so we have a contradiction of the assumption that $1_Y$ and $f \circ g$ are homotopic in $m$ steps, as statement (1) implies no point of $(f \circ g)(X)$ is within $m$ steps of $(u + m, 0)$. Therefore, we cannot have $p \in A$.

- The cases $p \in B$ and $p \in C$ yield contradictions similarly.

Thus, we must have that $f$ is a surjection, since assuming otherwise yields a contradiction.

Since $Y \setminus \{(0, 0)\}$ is disconnected and each of $A, B,$ and $C$ is infinite, the fact that $f$ is a continuous surjection implies there exist infinitely many $x \in X$ such that $f(x) = (0, 0)$. Therefore, there exist $p_0 = (a, 0), p_1 = (b, 0) \in X$ with $b > a + 2k$ such that $f(p_0) = f(p_1) = (0, 0)$. Then $g \circ f(p_0) = g \circ f(p_1) = g(0, 0)$. Therefore, at least one of $p_0$ or $p_1$ is carried by $g \circ f$ more than $k$ steps away from itself, contrary to the assumption that $g \circ f$ and $1_X$ are homotopic within $k$ steps. The assertion that $(X, (0, 0))$ and $(Y, (0, 0))$ do not have the same pointed homotopy type follows from this contradiction. ■

**Example 6.4.** There exist digital images $(X, \kappa)$ and $(Y, \lambda)$ that are homotopically similar but not pointed homotopically similar, and that have the same long homotopy type but not the same pointed long homotopy type, and that have the same real homotopy type but not the same pointed real homotopy type.

22
Proof: By [7, 4], there exist finite digital images $X$ and $Y$ that are homotopically equivalent but not pointed homotopically equivalent. By Theorem 3.3, $X$ and $Y$ are homotopically similar but not pointed homotopically similar. By Proposition 4.12, $X$ and $Y$ have the same long homotopy type but not the same pointed long homotopy type. By Theorem 5.6, $X$ and $Y$ have the same real homotopy type but not the same pointed real homotopy type. ■

7 Fundamental groups

In this section, we show that digital images that are pointed homotopically similar, or that have the same pointed real homotopy type, or that have the same pointed long homotopy type, have isomorphic fundamental groups.

Theorem 7.1. Let $(X, x_1) \simeq^* (Y, y_1)$. Let $\{X_j, Y_j, f_j, g_j\}_{j=1}^\infty$ be as in Definition 3.1, and let $x_1 \in X_1$, $y_1 \in Y_1$. Then there is an isomorphism $F : \Pi_1^*(X, x_1) \rightarrow \Pi_1^*(Y, y_1)$.

Proof. By hypothesis, for all indices $j$ we have that $g_j \circ f_j$ is pointed homotopic in $X_j$, hence in $X$, to $1_{X_j}$ and $f_j \circ g_j$ is pointed homotopic in $Y_j$, hence in $Y$, to $1_{Y_j}$.

We define a function $F : \Pi_1^*(X, x_1) \rightarrow \Pi_1^*(Y, y_1)$ as follows. Let $f$ be an $x_1$-based EC loop in $X$. There is a smallest positive integer $j$ such that the image of $f$ is contained in $X_j$. Then $f_j \circ f$ is a $y_1$-based loop in $Y_j$. Define $F([f]) = [f_j \circ f]$.

Suppose $f' \in [f]_X$. For some smallest indices $j$, $j'$, the images of $f$, $f'$ lie in $X_j$, $X_{j'}$, respectively. Further, there is some $a > j, j'$ such that $f$ and $f'$ are EC-homotopic in $X_a$. We have:

$$F([f]) = [f_j \circ f] = [(f_a | X_j) \circ f] = [f_a \circ f] = [f_a \circ f'] = [(f_a | X_{j'}) \circ f'] = [f_{j'} \circ f'] = F([f']) .$$

Therefore, $F$ is well defined.

Suppose $f$ is an $x_1$-based EC loop in $X$ such that $F([f]) = [y_1]$, the identity element of $\Pi_1^*(Y, y_1)$. If $j$ is the minimal index such that the image of $f$ is contained in $Y_j$, then

$$F([f]) = [y_1] = [f_j \circ f] ,$$

so

$$[f] = [(g_j \circ f_j) \circ f] = [g_j \circ (f_j \circ f)] = [g_j \circ y_1] = [x_1] ,$$

the identity element of $\Pi_1^*(X, x_1)$. Therefore, $F$ is one-to-one.
Given a $y_1$-based EC loop $g$ in $Y$, the image of $g$ is contained in some $Y_j$ for some smallest $j$. If $j’ \leq j$ is such that $j’$ is the minimal index such that the image of $g_j \circ g$ is contained in $X_j$, then

$$[g] = [f_j \circ g_j \circ g] = [f_j' \circ (g_j \circ g)] = F((g_j \circ g)).$$

Thus, $F$ is onto.

Let $L_i$ be $x_1$-based EC loops in $X$, $i \in \{0, 1\}$. Suppose the minimal indices for the $X_j$ containing the images of the $L_i$ are $j_0, j_1$ respectively, where, without loss of generality, $j_0 \leq j_1$. Then $j_1$ is the minimal index of the $X_j$ containing $L_0 \ast L_1$. Then

$$F([L_0 \ast L_1]) = [f_{j_1} \circ (L_0 \ast L_1)] = [f_{j_1}(L_0) \ast f_{j_1}(L_1)] = [(f_{j_1}, X_{j_0})(L_0) \ast f_{j_1}(L_1)]$$

$$= [f_{j_1}(L_0)] \cdot [f_{j_1}(L_1)] = F(L_0) \cdot F(L_1).$$

Therefore, $F$ is a homomorphism. This completes the proof. \qed

**Theorem 7.2.** Let $(X, x_0) \simeq_{\kappa, \lambda}^R (Y, y_0)$. Then $\Pi^1_\kappa(X, x_0)$ and $\Pi^1_\lambda(Y, y_0)$ are isomorphic.

**Proof.** The hypothesis implies that there exist pointed continuous functions $f : (X, x_0) \to (Y, y_0)$ and $g : (Y, y_0) \to (X, x_0)$, and pointed long homotopies $H : X \times [0, 1] \to X$ from $g \circ f$ to $1_X$ and $G : Y \times [0, 1] \to Y$ from $f \circ g$ to $1_Y$.

Given an $x_0$-based EC loop $L$ in $X$, define $f_* : \Pi^1_\kappa(X, x_0) \to \Pi^1_\lambda(Y, y_0)$ by $f_*([L]) = [f \circ L]$. This function $f_*$ is the homomorphism induced by $f : X \to Y$ (see \[1\] for a proof that $f_*$ is a well-defined homomorphism). It remains to show that $f_*$ is one-to-one and onto.

Suppose $f_*([L]) = [f \circ L] = [y_0]$, the identity element of $\Pi^1_\lambda(Y, y_0)$. Since $g \circ f \simeq_R 1_X$, we have $g \circ f \circ L \simeq_R L$. Since the image of $L$ is finite, an argument similar to that used in the proof of Theorem 5.6 shows that $g \circ f \circ L \simeq L$ by a pointed homotopy, and thus by a pointed EC homotopy. Thus,

$$[L] = [g \circ f \circ L] = [g \circ (f \circ L)] = [g \circ y_0] = [y_0],$$

the identity element of $\Pi^1_\kappa(X, x_0)$. Hence, $f_*$ is one-to-one.

Suppose $M$ is a $y_0$-based EC loop in $Y$. Then there is a real homotopy in $Y$ between $M$ and $f \circ g \circ M$ that holds the endpoints fixed. As above, since the image of $M$ is finite, the argument from Theorem 5.6 gives a homotopy between $M$ and $f \circ g \circ M$ that holds the endpoints fixed. Therefore,

$$[M] = [f \circ g \circ M] = f_*([g \circ M]).$$

24
Thus, $f_*$ is onto.

**Theorem 7.3.** Let $(X, x_1) \simeq^{r}_{\kappa, \lambda} (Y, y_1)$. Then $\Pi^r_1(X, x_0)$ and $\Pi^r_1(Y, y_0)$ are isomorphic.

**Proof.** By Theorem 7.2, $(X, \kappa, x_0)$ and $(Y, \lambda, y_0)$ have the same real homotopy type. Then Theorem 7.2 gives the result.

---

**8 Wedges and Cartesian products**

In this section we show that the wedge and Cartesian product operations preserve pointed homotopic similarity, pointed long homotopy type, and pointed real homotopy type.

Recall that if $X_1, X_2$ are digital images in $Z^m$ with the same adjacency relation $\kappa$ such that $X_1 \cap X_2 = \{x_0\}$ for some point $x_0$, and such that $x_0$ is the only point of $X_1$ adjacent to any point of $X_2$, and also the only point of $X_2$ adjacent to any point of $X_1$, then $X = X_1 \cup X_2$, with the $\kappa$ adjacency, is the wedge of $X_1$ and $X_2$, denoted $X = X_1 \wedge X_2$, and $x_0$ is the wedge point of $X$. Also, if $X = X_1 \wedge X_2$, $Y = Y_1 \wedge Y_2$, $x_0$ is the wedge point of $X$, $y_0$ is the wedge point of $Y$, and $f_i : (X_1, x_0) \to (Y_i, y_0)$ are $(\kappa, \lambda)$-pointed continuous for $i \in \{1, 2\}$, then the function $f_1 \wedge f_2 : X \to Y$ defined by

$$ (f_1 \wedge f_2)(x) = \begin{cases} f_1(x) & \text{if } x \in X_1; \\ f_2(x) & \text{if } x \in X_2, \end{cases} $$

is easily seen to be $(\kappa, \lambda)$-continuous.

**Theorem 8.1.** Suppose $X_1, X_2$ are digital images in $Z^m$, and $Y_1$ and $Y_2$ are digital images in $Z^n$. If $(X_1, x_0) \simeq^s_{\kappa, \lambda} (Y_1, y_0)$ and $(X_2, x_0) \simeq^s_{\kappa, \lambda} (Y_2, y_0)$, and $X = X_1 \wedge X_2$ has wedge point $x_0$ and $Y = Y_1 \wedge Y_2$ has wedge point $y_0$, then $(X, x_0) \simeq^s_{\kappa, \lambda} (Y, y_0)$.

**Proof.** By hypothesis, there are subsets $X_{j, n}$ of $X_j$ and $Y_{j, n}$ of $Y_j$, such that $X_{j, n} \subset X_{j+1, n}$ and $Y_{j, n} \subset Y_{j+1, n}$, for $j \in \{1, 2\}$, $n \in \mathbb{N}$, $X_j = \bigcup_{n=1}^\infty X_{j, n}$, $Y_j = \bigcup_{n=1}^\infty Y_{j, n}$, and pointed continuous functions $f_n : (X_{1, n}, x_0) \to (Y_{1, n}, y_0)$, $g_n : (Y_{1, n}, y_0) \to (X_{1, n}, x_0)$, $f'_n : (X_{2, n}, x_0) \to (Y_{2, n}, y_0)$, $g'_n : (Y_{2, n}, y_0) \to (X_{2, n}, x_0)$, such that $g_n \circ f_n$ is pointed homotopic in $X_{1, n}$ to $1_{X_{1, n}}$, $f_n \circ g_n$ is pointed homotopic in $Y_{1, n}$ to $1_{Y_{1, n}}$, $g'_n \circ f'_n$ is pointed homotopic in $X_{2, n}$ to $1_{X_{2, n}}$, and $f'_n \circ g'_n$ is pointed homotopic in $Y_{2, n}$ to $1_{Y_{2, n}}$. Also, $x_0$ is the wedge point for each $X_{1, n} \wedge X_{2, n}$, and $y_0$ is the wedge point for each $Y_{1, n} \wedge Y_{2, n}$.

Then it is easily seen that $(g_n \wedge g'_n) \circ (f_n \wedge f'_n)$ is pointed homotopic in $X_1 \wedge X_2$ to $1_{X_1 \wedge X_2}$ and $(f_n \wedge f'_n) \circ (g_n \wedge g'_n)$ is pointed homotopic in $Y_1 \wedge Y_2$ to $1_{Y_1 \wedge Y_2}$. The assertion follows. □
Theorem 8.2. Suppose \(X_1, X_2\) are digital images in \(\mathbb{Z}^m\), and \(Y_1\) and \(Y_2\) are digital images in \(\mathbb{Z}^n\). If \((X_1, x_0) \simeq_{k,\lambda} (Y_1, y_0)\), and \((X_2, x_0) \simeq_{k,\lambda} (Y_2, y_0)\), and \(X = X_1 \land X_2\) has wedge point \(x_0\) and \(Y = Y_1 \land Y_2\) has wedge point \(y_0\), then \((X, x_0) \simeq_{k,\lambda} (Y, y_0)\).

Proof. By hypothesis, for \(i \in \{1, 2\}\) there exist pointed continuous functions \(f_i : (X_i, x_0) \rightarrow (Y_i, y_0)\) and \(g_i : (Y_i, y_0) \rightarrow (X_i, x_0)\), long pointed homotopies \(H_i : (X_i, x_0) \times \mathbb{Z} \rightarrow (X_i, x_0)\) from \(1_{X_i}\) to \(g_i \circ f_i\) in \(X_i\), and long pointed homotopies \(K_i : (Y_i, y_0) \times \mathbb{Z} \rightarrow (Y_i, y_0)\) from \(1_{Y_i}\) to \(f_i \circ g_i\) in \(Y_i\).

Then the function \(H : (X_1 \land X_2, x_0) \times \mathbb{Z} \rightarrow (X_1 \land X_2, x_0)\) defined by
\[
H(x, t) = \begin{cases} 
H_1(x, t) & \text{if } x \in X_1; \\
H_2(x, t) & \text{if } x \in X_2,
\end{cases}
\]
is a pointed long homotopy in \(X\) from \(1_{X_1 \land X_2}\) to \((g_1 \land g_2) \circ (f_1 \land f_2)\). Similarly, the function \(K : (Y_1 \land Y_2, x_0) \times \mathbb{Z} \rightarrow (Y_1 \land Y_2, x_0)\) defined by
\[
K(y, t) = \begin{cases} 
K_1(y, t) & \text{if } y \in Y_1; \\
K_2(y, t) & \text{if } y \in Y_2,
\end{cases}
\]
is a pointed long homotopy in \(Y\) from \(1_{Y_1 \land Y_2}\) to \((f_1 \land f_2) \circ (g_1 \land g_2)\). The assertion follows. \(\blacksquare\)

Arguments similar to those above demonstrate the following.

Theorem 8.3. Suppose \(X_1, X_2\) are digital images in \(\mathbb{Z}^m\), and \(Y_1\) and \(Y_2\) are digital images in \(\mathbb{Z}^n\). If \((X_1, \kappa, x_0) \simeq_{R,\lambda} (Y_1, \lambda, y_0)\) and \((X_2, x_0) \simeq_{R,\lambda} (Y_2, y_0)\), and \(X = X_1 \land X_2\) has wedge point \(x_0\) and \(Y = Y_1 \land Y_2\) has wedge point \(y_0\), then \((X, x_0) \simeq_{R,\lambda} (Y, y_0)\). \(\blacksquare\)

Now we consider Cartesian products. For our pointed assertions in the following, we assume
\[
x_i = (x_{i,1}, x_{i,2}, \ldots, x_{i,n_i}) \in X_i \subset \mathbb{Z}^{n_i}, \quad y_i = (y_{i,1}, y_{i,2}, \ldots, y_{i,n_i}) \in Y_i \subset \mathbb{Z}^{n_i},
\]
\[
x_0 = (x_1, x_2, \ldots, x_n) = (x_{1,1}, x_{1,2}, \ldots, x_{1,n_1}, x_{2,1}, x_{2,2}, \ldots, x_{2,n_2}, \ldots, x_{k,1}, x_{k,2}, \ldots, x_{k,n_k}) \in \prod_{i=1}^k X_i \subset \mathbb{Z}^D,
\]
\[
y_0 = (y_1, y_2, \ldots, y_n) = (y_{1,1}, y_{1,2}, \ldots, y_{1,n_1}, y_{2,1}, y_{2,2}, \ldots, y_{2,n_2}, \ldots, y_{k,1}, y_{k,2}, \ldots, y_{k,n_k}) \in \prod_{i=1}^k Y_i \subset \mathbb{Z}^D,
\]
where \(D = \sum_{i=1}^k n_i\).

Theorem 8.4. Let \(X_i\) and \(Y_i\) be digital images in \((\mathbb{Z}^{n_i}, c_{n_i})\), \(i \in \{1, 2, \ldots, k\}\). Let \(x_i \in X_i, y_i \in Y_i\). Let \(D = \sum_{i=1}^k n_i\).

- If \(X_i \simeq_{c_{n_i},c_{n_i}} Y_i\) for \(i \in \{1, 2, \ldots, k\}\), then \(\prod_{i=1}^k X_i \simeq_{c_{D,c_D}} \prod_{i=1}^k Y_i\). If \((X_i, x_i) \simeq_{c_{n_i},c_{n_i}} (Y_i, y_i)\) for \(i \in \{1, 2, \ldots, k\}\), then \((\prod_{i=1}^k X_i, x_0) \simeq_{c_{D,c_D}} (\prod_{i=1}^k Y_i, y_0)\).
• If \( X_i \simeq_{c_{n_i}, c_{n_i}} Y_i \) for \( i \in \{1, 2, \ldots, k\} \), then \( \Pi^k_{i=1} X_i \simeq_{c_{D}, c_{D}} \Pi^k_{i=1} Y_i \). If \( (X_i, x_i) \simeq_{c_{n_i}, c_{n_i}} (Y_i, y_i) \) for \( i \in \{1, 2, \ldots, k\} \), then \( (\Pi^k_{i=1} X_i, x_0) \simeq_{c_{D}, c_{D}} (\Pi^k_{i=1} Y_i, y_0) \).

• If \( X_i \simeq_{c_{(n_i, c_{n_i})}} Y_i \) for \( i \in \{1, 2, \ldots, k\} \), then \( \Pi^k_{i=1} X_i \simeq_{c_{D}, c_{D}} \Pi^k_{i=1} Y_i \). If \( (X_i, x_i) \simeq_{c_{(n_i, c_{n_i})}} (Y_i, y_i) \) for \( i \in \{1, 2, \ldots, k\} \), then \( (\Pi^k_{i=1} X_i, x_0) \simeq_{c_{D}, c_{D}} (\Pi^k_{i=1} Y_i, y_0) \).

• If \( X_i \simeq_{c_{n_i}, c_{n_i}} Y_i \) for \( i \in \{1, 2, \ldots, k\} \), then \( \Pi^k_{i=1} X_i \simeq_{c_{D}, c_{D}} \Pi^k_{i=1} Y_i \). If \( (X_i, x_i) \simeq_{c_{(n_i, c_{n_i})}} (Y_i, y_i) \) for \( i \in \{1, 2, \ldots, k\} \), then \( (\Pi^k_{i=1} X_i, x_0) \simeq_{c_{D}, c_{D}} (\Pi^k_{i=1} Y_i, y_0) \).

**Proof.** We give proofs for the unpointed assertions. In all cases, the proof of the pointed assertion is virtually identical to that for its unpointed analog. Let \( X = \Pi^k_{i=1} X_i \subset \mathbb{Z}^D, Y = \Pi^k_{i=1} Y_i \subset \mathbb{Z}^D \).

First we prove the statement about ordinary homotopy equivalence. Suppose \( X_i \simeq_{c_{n_i}, c_{n_i}} Y_i \) for \( i \in \{1, 2, \ldots, k\} \). Then there exist \((c_{n_i}, c_{n_i})\)-continuous functions \( f_i : X_i \to Y_i \) and \( g_i : Y_i \to X_i \), and homotopies \( H_i : X_i \times [0, u_i] \to X_i \) from \( 1_{X_i} \) to \( f_i \circ g_i \), and \( K_i : Y_i \times [0, v_i] \to Y_i \) from \( 1_{Y_i} \) to \( g_i \circ f_i \).

Without loss of generality, we can replace each \( u_i \) and each \( v_i \) with \( U = \max\{u_1, v_1, \ldots, u_k, v_k\} \), since if \( u_i < U \) then we can extend \( H_i \) by defining \( H_i(x, t) = H_i(x, u_i) = g_i \circ f_i(x) \) for \( u_i \leq t \leq U \), and similarly for \( K_i \).

For \( a_i \in X_i \), let \( f : X \to Y \) be defined by

\[
 f(a_1, a_2, \ldots, a_k) = (f_1(a_1), f_2(a_2), \ldots, f_k(a_k)).
\]

For \( b_i \in Y_i \), let \( g : Y \to X \) be defined by

\[
 g(b_1, b_2, \ldots, b_k) = (g_1(b_1), g_2(b_2), \ldots, g_k(b_k)).
\]

Let \( H : X \times [0, U] \to X \) be defined by

\[
 H(a_1, a_2, \ldots, a_k, t) = (H_1(a_1, t), H_2(a_2, t), \ldots, H_k(a_k, t)).
\]

Let \( K : Y \times [0, U] \to Y \) be defined by

\[
 K(b_1, b_2, \ldots, b_k, t) = (K_1(b_1, t), K_2(b_2, t), \ldots, K_k(b_k, t)).
\]

It is easy to see that \( H \) is a \((c_{D}, c_{D})\)-homotopy from \( 1_X \) to \( g \circ f \), and \( K \) is a \((c_{D}, c_{D})\)-homotopy from \( 1_Y \) to \( f \circ g \).

Minor modifications in the argument given above allow us to demonstrate the claims for long homotopy type and real homotopy type.
It remains to prove the statement about homotopic similarity. Suppose \( X_i \simeq_{c_n, c_n, Y_i} \) for \( i \in \{1, 2, \ldots, k\} \). Then there exist \( \{X_{i,j}\}_{j=1}^{\infty} \subset X_i \) such that \( X_{i,j} \subset X_{i,j+1} \) and \( \bigcup_{j=1}^{\infty} X_{i,j} = X_i \), \( \{Y_{i,j}\}_{j=1}^{\infty} \subset Y_i \) such that \( Y_{i,j} \subset Y_{i,j+1} \) and \( \bigcup_{j=1}^{\infty} Y_{i,j} = Y_i \), continuous functions \( f_{i,j} : X_{i,j} \to Y_{i,j} \) and \( g_{i,j} : Y_{i,j} \to X_{i,j} \), and homotopies \( H_{i,j} : X_{i,j} \times [0, U_{i,j}] \to X_{i,j} \) from \( g_{i,j} \circ f_{i,j} \) to \( 1_{X_{i,j}} \) and \( K_{i,j} : Y_{i,j} \times [0, U_{i,j}] \to Y_{i,j} \) from \( f_{i,j} \circ g_{i,j} \) to \( 1_{Y_{i,j}} \). As above, for each \( j \) we can replace each \( u_{i,j} \) and each \( v_{i,j} \) by \( U_j = \max\{u_{i,j}, v_{i,j}\}_{i=1}^{k} \).

Notice that for all \( j \), \( \Pi_{i=1}^{k} X_{i,j} \subset \Pi_{i=1}^{k} X_{i,j+1} \) and \( \Pi_{i=1}^{k} Y_{i,j} \subset \Pi_{i=1}^{k} Y_{i,j+1} \). Also, \( \bigcup_{j=1}^{\infty} \Pi_{i=1}^{k} X_{i,j} = X \) and \( \bigcup_{j=1}^{\infty} \Pi_{i=1}^{k} Y_{i,j} = Y \).

Let \( f_j : \Pi_{i=1}^{k} X_{i,j} \to \Pi_{i=1}^{k} Y_{i,j} \) be defined by
\[
f_j(a_1, \ldots, a_k) = (f_{1,j}(a_1), \ldots, f_{k,j}(a_k))
\]
for \( a_i \in X_{i,j} \). Let \( g_j : \Pi_{i=1}^{k} Y_{i,j} \to \Pi_{i=1}^{k} X_{i,j} \) be defined by
\[
g_j(b_1, \ldots, b_k) = (g_{1,j}(b_1), \ldots, g_{k,j}(b_k))
\]
for \( b_i \in Y_{i,j} \). Let \( H_j : \Pi_{i=1}^{k} X_{i,j} \times [0, U_j] \to \Pi_{i=1}^{k} X_{i,j} \) be defined by
\[
H_j(a_1, \ldots, a_k, t) = (H_{1,j}(a_1, t), \ldots, H_{k,j}(a_k, t)),
\]
for \( a_i \in X_{i,j} \). Let \( K_j : \Pi_{i=1}^{k} Y_{i,j} \times [0, U_j] \to \Pi_{i=1}^{k} Y_{i,j} \) be defined by
\[
K_j(b_1, \ldots, b_k, t) = (K_{1,j}(b_1, t), \ldots, K_{k,j}(b_k, t)),
\]
for \( b_i \in Y_{i,j} \). Then it is easily seen that \( H_j \) is a homotopy from \( f_j \circ g_j \) to \( 1_{X_j} \), and \( K_j \) is a homotopy from \( g_j \circ f_j \) to \( 1_{Y_j} \). Therefore, \( X \simeq^* Y \).

9 Further remarks and open questions

We have introduced three notions of digital images having homotopic resemblance - homotopic similarity, having the same long homotopy type, and having the same real homotopy type - in both unpointed and pointed versions. Unlike the usual definition of digital homotopy equivalence, these let us consider two digital images \( X \) and \( Y \) as similar with respect to homotopy properties even if one of them has a component with infinite diameter and the other does not. We have shown that two digital images that are homotopy equivalent are homotopically similar, have the same long homotopy
type, and have the same real homotopy type, and that the converses hold when both images are finite; however, we have shown the converses to be false if one of the images has infinite diameter. We have shown that two digital images that share any of these three pointed homotopy resemblances have isomorphic fundamental groups. We have also shown that wedges preserve pointed homotopy similarity, pointed long homotopy type, and pointed real homotopy type; as do finite Cartesian products when we use relaxed adjacencies.

In addition to several questions stated earlier that we have not answered at this writing, we have the following.

**Question 9.1.** *(Unpointed and pointed versions:) Which, if any, of homotopic similarity, having the same long homotopy type, and having the same real homotopy type, implies either of the others?*

Corollary 5.12 is our only result concerning Question 9.1 that having the same long homotopy type implies having the same real homotopy type.

**Question 9.2.** *(Unpointed and pointed versions:) Which, if any, of these relations are equivalent?*

As above, a negative example for Question 9.2 would require a pair of digital images \((X, Y)\) in which at least one of the members is infinite.

**10 Acknowledgment**

The suggestions of an anonymous reviewer were quite helpful and are much appreciated.
