COMPUTING THE TEICHMÜLLER POLYNOMIAL

ERWAN LANNEAU AND FERRÁN VALDEZ

ABSTRACT. The Teichmüller polynomial of a fibered 3-manifold, defined in [McM00], plays a useful role in the construction of mapping class having small stretch factor. We provide an algorithm that computes the Teichmüller polynomial of the fibered face associated to a pseudo-Anosov mapping class of a disc homeomorphism. As a byproduct, our algorithm allows us to derive all the relevant informations on the topology of the different fibers that belong to the fibered face.

1. Introduction

A fibered hyperbolic 3-manifold $M$ is a rich source for pseudo-Anosov mapping classes: Thurston’s theory of fibered faces tells us that integer points in the fibered cone $\mathbb{R}^+ \cdot F \subset H^1(M, \mathbb{R})$ over the fibered face $F$ of the Thurston norm unit ball correspond to fibrations of $M$ over the circle. Given that $M$ is hyperbolic, the monodromy of each such fibration is a pseudo-Anosov class $[\psi]$ with stretch factor $\lambda(\psi) > 1$. These stretch factors are packaged in the Teichmüller polynomial, defined in [McM00]. This is an element $\Theta_F = \sum_{g \in G} a_g g$ in the group ring $\mathbb{Z}[H_1(M, \mathbb{Z})/\text{Torsion}]$, which is associated to the fibered face $F$ and that is used to compute effectively the stretch factor $\lambda(\psi)$. More precisely, if $[\alpha] \in H^1(M, \mathbb{Z})$ is the integer class corresponding to $\psi$ in the fibered cone and $\xi_\alpha \in H_1(M, \mathbb{Z})$ is its dual, then the largest root of the Laurent polynomial $\Theta_F(\alpha) := \sum_{g \in G} a_g \cdot t^{\xi_\alpha(g)} \in \mathbb{Z}[t, t^{-1}]$ (in absolute value) is the stretch factor $\lambda(\psi)$. The Teichmüller polynomial has been used as a natural source of pseudo-Anosov homeomorphism having small normalized stretch factors: infinite families of pseudo-Anosov homeomorphisms $[\psi] \in \text{Mod}(\Sigma_g)$ satisfying $\lambda(\psi)^g = O(1)$ as $g \to \infty$. In particular, it has been intensively used in the papers by Hironaka [Hir10], Hironaka-Kin [HK09], Kin-Takasawa [KT13], Kin-Takasawa and Mitsuhiro [KT11], Kin-Kojima-Takasawa [KKT13]. Most of known pseudo-Anosov homeomorphisms having a small normalized stretch factor are coming from fibrations of two very particular hyperbolic manifolds: the manifold coming from the simplest hyperbolic braid [McM00] [Hir10] and the “magic manifold” see e.g. [KT11].

The Teichmüller polynomial was originally defined as the generator of the Fitting ideal of a module of transversals (defined by a lamination) over $\mathbb{Z}[H_1(M, \mathbb{Z})/\text{Torsion}]$. However, it is a result of McMullen [McM00] that this polynomial can also be defined in terms of the transition matrix of an infinite train track associated to a fibration on the fibered face $F$.

The main goal of our paper, based on this second definition, is to present an algorithm to compute explicitly the Teichmüller polynomial and to give a unified presentation of the aforementioned papers. More precisely we will denote the mapping torus of $[\psi] \in \text{Mod}(\Sigma)$ by

$$M_\psi := S \times [0, 1]/(x, 1) \sim (\psi(x), 0)$$

and we will suppose that the first Betti number of $M_\psi$ is at least 2.

Based on the results of Penner and Papadopoulos [PP87] on train tracks and elementary operations (folding operations in the present paper), we provide an algorithm that

1. computes the Teichmüller polynomial $\Theta_F$ of the fibered face $F$ of $M_\psi$ where $[\psi] \in \text{Mod}(\Sigma)$ is a pseudo-Anosov class.

2. computes the topology (genus, number of singularities and type) of the fibers of fibrations in the cone $\mathbb{R}^+ \cdot F$.

We will present our algorithm in the case where $S$ is the $n$-punctured disc $D_n$. Then $\text{Mod}(\Sigma)$ is naturally isomorphic to the braid group $B(n)$. Let $\beta \in B(n)$ and let $[f_\beta]$ be the corresponding mapping class in $\text{Mod}(D_n)$. We shall show:

Date: December 15, 2014.

Key words and phrases. Teichmüller polynomial, Pseudo-Anosov homeomorphism, Thurston norm.
**Theorem 1.1.** For any pseudo-Anosov class \([f_β] \in \text{Mod}(D_n)\) represented by a path in some automaton

\[
\tau_1 \xrightarrow{T_1} \tau_2 \xrightarrow{T_2} \cdots \xrightarrow{T_{n-1}} \tau_n \xrightarrow{T_n} \tau_{n+1},
\]

with transition matrices \(M_i = M(T_i) \in \text{GL}(\mathbb{Z}^r)\), the Teichmüller polynomial \(\Theta_F(t, u)\) of the associated fibered face \(F\) determined by \([f_β]\) is:

\[
\Theta_F(t, u) = \det(u \cdot \text{Id} - M_1D_1 \cdot M_2D_2 \cdots M_nD_nR)
\]

where the diagonal matrices \(D_i \in \text{GL}(\mathbb{Z}^r)\) are uniquely determined in terms of the path in the automaton and \(R \in \text{GL}(\mathbb{Z}^r)\) is a relabeling matrix.

For a more precise statement, in particular the nature of the variables \(u\) and \(t\), see Theorem 5.4 (see also Section 4 for the definition of the automaton). Observe that Bestvina and Handel [BH95] have introduced an effective algorithm that determines whether a given homeomorphism \(f \in \text{Mod}(D_n)\) is pseudo-Anosov. See also [Bri00] and [Hal] for implementation of the algorithm: in the pseudo-Anosov case it generates the train tracks and a path in a corresponding automaton.

**Reader’s guide.** In Section 2 we recall Thurston’s theory of fibered faces and we review basic definitions and properties of the Teichmüller polynomial and its relation with the stretch factor associated to the monodromy of a fibration \(\Sigma \rightarrow M \rightarrow S^1\). In Section 3 we describe a general strategy to compute the Teichmüller polynomial \(\Theta_F\) from a train track and a train track map (after [McM00]). In Section 4 we introduce the notion of automaton and we give several relevant examples. In particular we use the convention of labelled train-tracks (similarly to Kerckhoff and Marmi-Moussa-Yoccoz did for interval exchange transformations). Section 5 is devoted to the statement and the proof of our main theorem. Finally as a byproduct, our algorithm allows us also to derive all the relevant informations on the topology of the different fibers that belong to the face. This is the content of Section 6 (and correspond to Proposition 6.1, Corollary 6.3 and Propositions 6.4, 6.6). In Sections 7, 8 and Appendix A we apply our results to produce several examples, recovering the ones of McMullen [McM00] and Hironaka [Hir10], but also giving infinitely many new examples of Teichmüller polynomials defined by pseudo-Anosov braids in \(B_n\), for \(n \geq 4\).

**Acknowledgments.** We would like to thank Ursula Hamenstädt, Eriko Hironaka, Jérôme Los, Curt McMullen, and Jean-Luc Thiffeault for very useful and stimulating discussions.

We would also thank Centro de Ciencias Matemáticas, UNAM in Morelia and Institut Fourier in Grenoble for the hospitality during the preparation of this work. 2. **Thurston’s theory of fibered faces and the Teichmüller polynomial**

In this section we recall Thurston’s theory of fibered faces. We also review the construction of the Teichmüller polynomial and its relation with the stretch factor associated to the monodromy of a fibration \(\Sigma \rightarrow M \rightarrow S^1\).

We begin by fixing several notations. Let \(S\) be a surface (for which one might have \(\partial S \neq \emptyset\)). Let \([\psi]\) be a class in \(\text{Mod}(S)\). A deep result by Thurston (see e.g. [FM12] §13, Thm. 13.4) tell us that \(M_\psi\) admits a hyperbolic metric if and only if the mapping class \([\psi]\) is pseudo-Anosov. By Mostow’s rigidity theorem the isometry class of \(M_\psi\) does not depend on the choice of the representative or the conjugacy class of \([\psi]\) in \(\text{Mod}(S)\).

2.1. **Thurston norm and fibered faces.** Thurston introduced a very effective tool for studying essential surfaces in 3-manifolds: a norm on \(H_2(M, \mathbb{R})\). For practical reasons, we will define this norm on \(H^1(M, \mathbb{R})\). For nice references see e.g. [FLP79, exposé 14], [Cal07][Thn86].

For a compact connected surface \(S\), let \(\chi_-(S) = [\min(0, \chi(S))]\). In general, if a surface \(S\) has \(r\) connected components \(S_1, \ldots, S_r\), we define \(\chi_-(S)\) by \(\sum_{i=1}^r \chi_-(S_i)\). This determines a function \(\| \cdot \|_T : H^1(M, \mathbb{R}) \rightarrow \mathbb{N} \cup \{0\}\) as follows:

\[
\| [\alpha] \|_T := \inf \{ \chi_-(S) \mid S \text{ is a properly embedded oriented surface where } [S] \text{ is dual to } [\alpha] \},
\]
where $[S] \in H_2(M, \mathbb{Z})$ (or $H_2(M, \partial M; \mathbb{Z})$ if $\partial M \neq \emptyset$). So far this function just measures the minimal topological complexity of a surface dual to $[\alpha]$. However, if $M$ is irreducible (i.e., if every embedded sphere bounds a ball) then $\|\cdot\|$ satisfies the pseudo-norm properties. Therefore it has a unique continuous extension to a pseudo norm on $H^1(M, \mathbb{R})$. If in addition $M$ is atoroidal and $\chi(\partial M) = 0$, this continuous extension is a norm. This is the so called Thurston norm. The unit ball of this norm has a very special geometry.

**Theorem 2.1.** [Thu86] Let $M$ be an irreducible and atoroidal manifold. Then the unit ball of the Thurston norm is a convex finite sided polytope.

An avid reader can consult the proof on the preceding theorem on Calegari’s book (see [Cal07, Theorem 5.10]). The most striking aspect of the Thurston norm is that it provides a very nice picture for homology classes representing fibrations of $M$ over the circle.

### 2.2. From homology classes to fibrations.

Let $[M, S^1]$ denote the set of homotopy classes of maps from $M$ to $S^1$. Given a class $[f] \in [M, S^1]$ one can choose a smooth representative $f : M \to S^1$ and $d\theta$ the angle form on $S^1$. The pullback defines a class $[f^*d\theta]$ in $H^1(M, \mathbb{R})$. This correspondence defines a bijection between $H^1(M, \mathbb{R})$ and $[M, S^1]$. We will call $[\alpha] \in H^1(M, \mathbb{Z})$ a fibration if the corresponding class in $[M, S^1]$ is a fibration. Let us define:

$$\Phi(M) := \{[\alpha] \in H^1(M, \mathbb{Z}) \mid [\alpha] \text{ is a fibration}\}$$

and for every face $F$ of the Thurston norm ball let $\mathbb{R}^+ \cdot F$ denote the positive cone in $H^1(M, \mathbb{R})$ whose basis is $F$.

**Theorem 2.2.** [Thu86] Suppose that $b_1(M) \geq 2$. If $\Phi(M) \cap \mathbb{R}^+ \cdot F \neq \emptyset$ for some top-dimensional face $F$ of the Thurston norm unit ball, then $\Phi(M) \cap \mathbb{R}^+ \cdot F = H^1(M, \mathbb{Z}) \cap \mathbb{R}^+ \cdot F$.

When $\Phi(M) \cap \mathbb{R}^+ \cdot F \neq \emptyset$ we call $F$ a fibered face and $\mathbb{R}^+ \cdot F$ a fibered cone. A fiber of a fibration minimizes the Thurston norm in its homology class (see [Cal07, Corollary 5.13]).

### 2.3. Hyperbolic manifolds.

If the manifold $M$ is hyperbolic, then the monodromy of each fibration $\Sigma \to M \to S^1$ defines a pseudo-Anosov class in $\text{Mod}(\Sigma)$. Hence we can think of each integer point in a fibered cone $\mathbb{R}^+ \cdot F$ as a pseudo-Anosov class (on a surface that is not necessary connected). We want to compute, for a fixed fibered face $F$, the stretch factors of all pseudo-Anosov maps arising as monodromies of fibrations in the fibered cone $\mathbb{R}^+ \cdot F$. This can be done by using an invariant of the fibered face called the Teichmüller polynomial. Roughly speaking, this polynomial invariant is an element of the group ring $\mathbb{Z}[G]$, where $G = H_1(M, \mathbb{Z})/\text{Tor}$ and $\text{Tor}$ is the torsion subgroup of $H_1(M, \mathbb{Z})$. Following McMullen, let us denote it by $\Theta_F$. We will now explain how $\Theta_F$ is used to calculate stretching factors of pseudo-Anosov monodromies and we will later deal with its definition. For any $[\alpha] \in H^1(M, \mathbb{Z})$ we can associate a morphism $(\xi_\alpha : H_1(M, \mathbb{Z}) \to \mathbb{Z}) \in \text{Hom}(H_1(M, \mathbb{Z}), \mathbb{Z})$. Now $\Theta_F$ is an element of the group ring $\mathbb{Z}[G]$, thus it can be written as a formal sum:

$$\Theta_F = \sum_{g \in G} a_g g, \quad a_g \in \mathbb{Z} \text{ for all } g \in G$$

where at most a finite number of coefficients $a_g$ are different from zero. The valuation of $\Theta_F$ at $[\alpha]$ is defined as follows:

$$\Theta_F([\alpha]) := \sum_{g \in G} a_g \cdot t^{\xi_\alpha(g)} \in \mathbb{Z}[t, t^{-1}].$$

Remark that $\Theta_F(\alpha)$ is a Laurent polynomial in $\mathbb{Z}[t, t^{-1}]$. Let $\lambda(\alpha)$ be the stretch factor of the pseudo-Anosov class in $\text{Mod}(\Sigma)$ defined by the monodromy of the fibration corresponding to $[\alpha]$. The following theorem relies the Laurent polynomial $\Theta_F(\alpha)$ to $\lambda(\alpha)$.

**Theorem 2.3.** [McM00] For any fibration $[\alpha] \in \mathbb{R}^+ \cdot F$, the stretch factor $\lambda(\alpha)$ is given by the largest root (in absolute value) of the equation:

$$\Theta_F(\alpha) = \sum_{g \in G} a_g \cdot t^{\xi_\alpha(g)} = 0.$$
3. Teichmüller polynomial and train tracks.

In this section we recall the construction of the Teichmüller polynomial \( \Theta_F \) and basic facts on train tracks.

3.1. The Teichmüller polynomial of a fibered face. In the sequel \( G \) will denote \( H_1(M; \mathbb{Z})/\mathrm{Tor} \), where \( \mathrm{Tor} \) denotes the torsion subgroup of \( H_1(M; \mathbb{Z}) \). As before we assume that \( b_1(M) \geq 2 \). The pseudo-Anosov monodromy \( \psi \) of any fibration \([a]\in \mathbb{R}^+\cdot F\) with fiber \( \Sigma \) has an expanding invariant lamination \( \lambda \subset \Sigma \) which is unique up to isotopy. Let \( \mathcal{L} \) be the mapping torus of \( \psi : \lambda \to \lambda \) and \( \mathcal{L}' \) be the preimage of the lamination \( \mathcal{L} \) on the covering space

\[
\pi : \tilde{M} \to M
\]

corresponding to the kernel of the map \( \pi_1(M) \to G \). As Fried explains (see exposée 14 [FLP79]), \( \mathcal{L} \) is a compact lamination which, up to isotopy, depends only on the fibered face \( F \). Using this fact, McMullen [McM00] defines the Teichmüller polynomial of the fibered face as

\[
\Theta_F = \gcd(f : f \in I) \in \mathbb{Z}[G]
\]

where \( I \) is the Fitting ideal of the finitely presented \( \mathbb{Z}[G] \)-module of transversals of the lamination \( \mathcal{L}' \). Remark that \( \Theta_F \) is well defined up to multiplication by a unit in \( \mathbb{Z}[G] \). One of the main results of [McM00] that we exploit in this article is a formula that allows to compute explicitly \( \Theta_F \). We recall how to derive this formula in the sequel.

3.2. The setting. The formula that allows us to compute explicitly \( \Theta_F \) needs a particular splitting of the group \( G \). Fix a fiber \( \Sigma \to M \) and let \( \psi : \Sigma \to \Sigma \) be the corresponding pseudo-Anosov monodromy. We will denote by \( H = \text{Hom}(H^1(\Sigma, \mathbb{Z})^\psi, \mathbb{Z}) \cong \mathbb{Z}^{b_1(M) - 1} \) the dual of the \( \psi \)-invariant cohomology of \( \Sigma \). The natural map \( \pi_1(S) \to H_1(S, \mathbb{Z}) \to H \) determines an infinite \( \mathbb{Z}^{b_1(M) - 1} \)-covering:

\[
\tilde{\rho} : \tilde{\Sigma} \to \Sigma
\]

with deck transformation group \( H \). We can think of \( \tilde{\Sigma} \) as a component of the preimage of a fixed fiber \( \Sigma \) in the covering \( \pi : \tilde{M} \to M \) and \( H \) as the subgroup of \( \text{Deck}(\pi) = G \) fixing \( \Sigma \). For every lift

\[
(3.1) \quad \tilde{\psi} : \tilde{\Sigma} \to \tilde{\Sigma}
\]

of \( \psi \), the three manifold \( \tilde{M} \) can be easily described in terms of \( \tilde{\Sigma} \) and \( \tilde{\psi} \) as follows. For every \( k \in \mathbb{Z} \) let \( A_k \) denote a copy of \( \tilde{\Sigma} \times [0, 1] \). Then \( \tilde{M} \) is obtained from \( \bigsqcup_{k \in \mathbb{Z}} A_k \) by identifying \( (s, 1) \in A_k \) with \( (\tilde{\psi}(s), 0) \in A_{k+1} \), for every \( k \in \mathbb{Z} \). In this setting, the deck transformation group of \( \tilde{M} \) splits as:

\[
G = H \oplus \mathbb{Z}[\tilde{\psi}]
\]

where the map \( \tilde{\psi} \) acts on \( \tilde{M} \) as \( \tilde{\psi}(s, t) = (\tilde{\psi}(s), t - 1) \). Equipped with these coordinates, if \( F \subset H^1(M, \mathbb{R}) \) is the fibered face with \( [\Sigma] \in \mathbb{R}^+ \cdot F \), then we can regard \( \Theta_F \) as a Laurent polynomial \( \Theta_F(t, u) \in \mathbb{Z}[G] = \mathbb{Z}[H] \oplus \mathbb{Z}[u] \) where \( t = (t_1, \ldots, t_{b_1-1}) \) is a basis of \( H \) and \( u = \Psi \).

Remark 3.1. If \( \tilde{\psi}_1 \) and \( \tilde{\psi}_2 \) are two different lifts of \( \psi \) to \( \tilde{\Sigma} \) then \( \tilde{\psi}_1 = t \cdot \tilde{\psi}_2 \) for some \( t \in H = \text{Deck}(\rho) \). Hence, taking a different lift in \( (3.1) \) is traduced into a change of variables of the form \( u' = tu \). On the other hand, since the topology of \( \tilde{M} \) is independent of \( \psi \), the topology of the infinite surface \( \tilde{\Sigma} \) is also independent of \( \psi \).

3.3. Train tracks. A train track is a connected graph with an additional “smooth” structure. More precisely let \( \tau \) be a graph and let \( h : \tau \to \Sigma \) be an embedding so that the branches are tangent at the vertices. Since the vertices are smooth, at each vertex the edges can be partitioned into two sets, called ingoing and outgoing for convenience (the choice of the partition is arbitrary). We will also assume that at each vertex of \( \tau \) we have a cyclic order (given by \( h \)). This gives the notion of cusps at a vertex: this is a region formed by a consecutive pair (in terms of the cyclic ordering) of either two ingoing or two outgoing edges.

The pair \((\tau, h)\) (often called simply \( \tau \) if there is no confusion) is a train track if the additional following properties are fulfilled:

1. \( \tau \) has no vertex of valence 1 or 2;
2. The connected components of \( \Sigma \setminus h(\tau) \) are either polygons with at least one cusp or annuli with one boundary contained in \( \partial \Sigma \) and the other boundary with one cusp.
A (transverse) measure \( \mu \) on a train track is an assignment of a positive real number \( \mu(e) \geq 0 \) to each edge \( e \) of \( \tau \) which satisfy the switch condition at each vertex: the sum of measures of edges in the ingoing set is the same as that for the outgoing set. The train track \( \tau \) equipped with a measure \( \mu \) will be called a measured train track, and will be denoted \((\tau, h, \mu)\).

### 3.4. Measured foliations and train tracks.

We can construct a (class of) measured foliation \( F \) from a measured train track \((\tau, h, \mu)\) as follows. We replace each edge \( e \) of \( h(\tau) \) by a rectangle, of arbitrary width and height \( \mu(e) \), foliated by horizontal leaves. According to the switch condition, the rectangles glued together give a subsurface \( \hat{S} \subset \Sigma \) (with boundaries) and a measured foliation \( F \) on \( \hat{S} \). Now to define the foliation on the whole surface, one has to collapse the complementary regions. By assumption, no complementary components of \( \hat{S} \) are smooth annuli, so that we can contract each boundary component in order to obtain a well-defined measured foliation on \( \Sigma \) (see [PP87, FLP79] for details). We will call the sides of the polygons of \( \Sigma \setminus \tau \) around the punctures or around the singularities of \( F \) the infinitesimal edges.

#### Remark 3.2.

There are many arbitrary parameters in the above construction, but the equivalence class \([F] \) (up to isotopy and Whitehead moves) of \( F \) is well defined.

There is a converse to the above construction. Let \( F \) be a measured foliation representing \([F]\) and let \( p \in F \) be a singularity. Consider a polygon \( \Delta_p \) embedded into the surface \( \Sigma \), where each side \( \Delta_p \) is contained in a leaf of \( F \). We will say that the subsurface \( \Sigma \setminus \cup_{p \in \text{sing.}} \Delta_p \) has a partial foliation (still denoted by \( F \)) induced by \( F \). Since all complementary regions of this partial measured foliation have at least two cusps, we can collapse the leaves of this foliation in order to obtain a measured train track \((\tau, h, \mu)\).

By considering small segments transversal to the horizontal leaves on the rectangles used in the above procedure, we obtain a fibered neighborhood \( N(\tau) \subset \Sigma \) equipped with a retraction \( N(\tau) \to \tau \). The neighborhood \( N(\tau) \) has cusps on its boundary, and the fibers of the retraction are called ties. The train track \( \tau \) can be recovered from \( N(\tau) \) by collapsing every tie to a point. We will say that \( F \) is carried by \( \tau \) (denoted by \( F < \tau \)) if \( F \) can be represented by a partial foliation contained in \( N(\tau) \) and transverse to the ties. If in addition no leaves of \( F \) connect cusps of \( N(\tau) \), we say that \( \tau \) is suited to \( F \).

The next sections are intended to make explicit some well-known relations between pseudo-Anosov homeomorphisms and train track morphisms.

### 3.5. Invariant train tracks.

By definition, any representative of a pseudo-Anosov class \([\psi] \in \text{Mod}(\Sigma)\) leaves invariant a pair of transverse measured foliations \((F^\delta, F^\mu)\). However the action of \( \psi \) on these foliations is rather difficult to describe. A good tool to understand this action is given by train tracks (see e.g. [PP87, §4]). Let \( h: \tau \hookrightarrow \Sigma \) be suited to \( F^\mu \). Since \( F^\mu \) is invariant by \( \psi \) it follows that \( \tau \) is invariant by \( \psi \), namely:

1. The foliation \( F^\mu \) can be represented by a partial measured foliation \( F \) whose support is a fibered neighborhood \( N(\tau) \) of \( h(\tau) \).
2. The image \( \psi(h(\tau)) \) can be isotoped to a train track \( h'(\tau') \) which is contained in a fibered neighborhood \( N(h(\tau)) \) of \( h(\tau) \), is transversal to the tie foliation of \( h(\tau) \) and has switches that are disjoint from the collection of central ties of \( h(\tau) \).

If (2) holds, we will say that \( \psi(\tau) \) is carried by \( \tau \) and use the notation \( \psi(\tau) < \tau \).

#### Convention.

In this paper, we will work with labeled train tracks, that is, triples \((\tau, h, e)\), where \( e : E(\tau) \to \mathbb{A} \) is a labeling map from the set of edges of \( \tau \) into a fixed finite alphabet \( \mathbb{A} \). In the sequel we will abuse of the notation and abbreviate \((\tau, h, e)\) with \( \tau \) whenever the embedding of the graph \( h : \tau \hookrightarrow \Sigma \) and the labelling are clear from the context.

In order to make a distinction between infinitesimal edges and other edges, we make the following choice: we label the infinitesimal edges by capital letters and other edges by minuscule letters. We denote by \( \mathbb{A}_{\text{prong}} \subset \mathbb{A} \) the \( n \) letters corresponding to infinitesimal edges \( E(\tau)_{\text{prong}} \) enclosing the punctures of \( D_n \). We also denote by \( \mathbb{A}_{\text{real}} \subset \mathbb{A} \) the letters corresponding to non-infinitesimal edges \( E(\tau)_{\text{real}} \).
3.6 Incidence matrix. In the above situation, if \( \psi(\tau) = \sigma < \tau \) we naturally associate an incidence matrix \( M(\psi) \in \text{GL}(\mathbb{Z}^h) \) to \( \psi \) in the following way. For any edge \( e \) of \( \tau \) we make a choice of a tie above an interior point \( e \) (called the central tie associated to the edge \( e \)). Let \( \sigma' \) isometric to \( \sigma \) be such that \( \sigma' \subset N(\tau) \). For any edge \( f \) of \( \sigma \) we have a corresponding edge \( f' \) of \( \sigma' \) given by the isotopy. We can furthermore isotope \( \sigma' \) slightly so that it is in general position with respect to the central ties of \( \tau \). Now for any pair \((e, f)\) with labels \((\alpha, \beta)\) (i.e. \( \varepsilon(e) = \alpha \) and \( \varepsilon(f) = \beta \)) we define \( M_{\beta, \alpha}(\psi) \) as the geometric intersection between \( f' \) with the central tie associated to the edge \( e \) of \( \tau \).

A classical theorem (see [PP87, Theorem 4.1]) asserts that in the pseudo-Anosov case, the leading eigenvalue of this matrix equals the stretch factor of the pseudo-Anosov class \([\psi]\) (if one restricts to a good set of edges, the corresponding matrix is a Perron-Frobenius matrix).

The determinant formula. Now consider \( \tilde{\tau} \subset \tilde{\Sigma} \) a component of \( \rho^{-1}(\tau) \) lying in the infinite surface \( \tilde{\Sigma} \), as defined in [3.2]. This is an infinite train track whose set of edges and vertices can be identified with \( E \times H \) and \( V \times H \) respectively. Since \( \tau \) is \( \psi \)-invariant, \( \tilde{\tau} \) is \( \tilde{\psi} \)-invariant. This means that \( \tilde{\psi}(\tilde{\tau}) \) can be isotoped to a train track \( \tilde{\tau}' \) which lies in a tie neighborhood of \( N(\tilde{\tau}) \) of \( \tilde{\tau} \), is transverse to \( \tilde{\tau}' \)'s ties and whose switches are disjoint from the collection of central ties of \( \tilde{\tau} \). As with the train track \( \tau \) and the map \( \psi \), we can associate to \( \tilde{\tau} \) and \( \tilde{\psi} \) an incidence matrix \( P_E(t) \in \text{GL}(\mathbb{Z}[H]^h) \) with entries in \( \mathbb{Z}[H] \). Analogously, there is a matrix \( P_V(t) \) with entries in \( \mathbb{Z}[H] \) associated to the set of vertices of \( \tilde{\tau} \). The next theorem states that the Teichmüller polynomial associated to the fibered face \( F \) can be recovered from the matrices \( P_E(t) \) and \( P_V(t) \).

**Theorem 3.3** ([McM00]). The Teichmüller polynomial of the fibered face \( F \) is given by:

\[
\Theta_F(t, u) = \frac{\det(u \cdot \text{Id} - P_E(t))}{\det(u \cdot \text{Id} - P_V(t))}.
\]

3.7 Train track morphisms. We begin with a classical definition (see e.g. [Los10]).

**Definition 3.4.** A map \( T \) between two train tracks \( (\tau, h) \) and \( (\tau', h') \) is a train-track morphism if it is cellular and preserves the smooth structure. If in addition \( (\tau, h) \) and \( (\tau', h') \) are isomorphic as train tracks we call \( T \) a train track map.

A train-track morphism \( T : \tau \rightarrow \tau' \) is a representative of \([f] \in \text{Mod}(\Sigma)\) if in addition

1. The diagram

\[
\begin{array}{ccc}
\tau & \xrightarrow{h} & \Sigma \\
\downarrow{\tau'} & & \downarrow{f} \\
\tau' & \xrightarrow{h'} & \Sigma
\end{array}
\]

commutes, up to isotopy, and

2. \( f \circ h(\tau) \subset N(h'(\tau')) \) and \( f \circ h(\tau) \) is transverse to the tie foliation of \( h'(\tau') \).

To any train track morphism \( T \) one can associate an incidence matrix \( M(T) \in \text{GL}(\mathbb{Z}^h) \) in the following way: for any pair \((e, e')\) with labels \((\alpha, \beta)\) i.e. \( \varepsilon(e) = \alpha \) and \( \varepsilon(e') = \beta \) we define \( M(T)_{\beta, \alpha} \) as the number of occurrences of \( e' \) in the edge path \( T(e) \). It is clear from the definitions that if \( T : \tau \rightarrow \tau' \) is the representative map of a homeomorphism \( f : \Sigma \rightarrow \Sigma \) and if \( f(\tau) < \tau \) then the incidence matrix \( M(f) \) defined in the preceding section and the incidence matrix \( M(T) \) are equal.

**Theorem 3.5.** ([PP87]) Let \( \psi \) be pseudo-Anosov homeomorphism and let \( \mathcal{F}^u \) be in the class of its unstable foliation. There exists a train track \( \tau \) suited to \( \mathcal{F}^u \) so that \( \psi(\tau) \subset \tau \). Furthermore \( \psi(\tau) \) is isotopic to a train track \( \tau' \subset N(\tau) \) which is transverse to the ties so that the matrix describing the linear map from the space of weights on real edges of \( \tau' \) to the space of weights on real edges of \( \tau \) is primitive irreducible (i.e. some iterate all of whose entries are strictly positive).

3.8 Elementary operations. One of the main difficulties to use the aforementioned formulas (computing matrix \( M(\psi) \) and Formula (3.2)) is that \( \psi(\tau) \) (or \( \tilde{\psi}(\tilde{\tau}) \)) might look very complicated so that the isotopy needed to embed this train track in a tie neighborhood of \( \tau \) transverse to the ties might be difficult to find. There is a general strategy that will simplify calculation, involving two natural (dual) operations defined on a train track and usually called folding and splitting.
Roughly speaking, they are defined by folding or splitting a fibered neighborhood $N(\tau)$ along a cusp. For a more precise definition, see [Los10,PP87] (for splitting operation) and [SKL02] (for folding operation). In this paper we shall make use of folding operation which will produce from a train track $\tau$ a new train track $\tau'$ with the property that $\tau \prec \tau'$. We now describe briefly the combinatorial folding operations. Observe that these operations first appear as (dual) right/left splits described in [PP87].

Let $\tau$ be a train track. Let $e_1, e_2$ be two edges of $\tau$ that are issued from the same vertex $v_1$ and that form a cusp $C$. We assume that one of the two edges is not infinitesimal (say it is $e_1$). We describe the folding where edge $e_1$ is folded onto edge $e_2$ (the other case being similar). The edge $e_2$ (respectively, $e_1$) is incident to two vertices $v_1$ and $v_2$ (respectively, $v_1$ and $v_3$). The orientation around $v_1$ determines an edge $e$ attached to $v_2$ (see Figure 1). If the cusp determined by $e$ is on the same side as the cusp $C$ then we cannot fold $e_1$ onto $e_2$. In the other case we form a new graph $\tau'$ in the following way: we identify the edges $e_2$ and $e_1$ so that the new graph we obtain has a new edge: $\epsilon'$ from $v_3$ to $v_2$. If $e$ is an infinitesimal edge we then fold again $\epsilon'$ on $e$. The new train track $(\tau', h')$ naturally inherits a labelling $\epsilon'$ induced from the one of $\tau$: every edge of $\tau'$ share the same label than the corresponding edge of $\tau$.

**Figure 1.** The folding operation: edge $e_1$ folded onto $e_2$ produces a new train track.

**Definition 3.6.** We will say that a train track $\tau$ refines to a train track $\sigma$ if there exists a sequence

$$\sigma = \tau_1 \prec \tau_2 \prec \cdots \prec \tau_k = \tau$$

where $\tau_i$ is obtained from $\tau_{i-1}$ by a folding operation.

**Proposition 3.7.** [PP87] Suppose that $F \prec \sigma \prec \tau$ where $\sigma$ is contained in a fibered neighborhood $N(\tau)$ and $\tau$ is suited to $F$. Then $\tau$ refines to $\sigma$.

**Sketch of the proof of Proposition 3.7.** We prove the proposition by using splitting instead of folding, it is easier to explain and the corresponding sequence of foldings easy to derive.

Up to making an isotopy, one can find a fibered neighborhood $N(\sigma)$ contained in the interior of $N(\tau)$ whose tie foliation is formed by sub arcs of the tie foliation of $N(\tau)$. The number of cusps of $N(\sigma)$ and $N(\tau)$ is the same and one can define a pairing between these two sets of cusps with a family of disjointly embedded arcs $\{\Gamma_i\}_{i=1}^n$ contained in $N(\tau) \setminus \text{Int}(N(\sigma))$ which are transverse to the ties ([PP87, Lemma 2.1]). The sequence of splittings that defines the refinement is obtained by cutting $N(\sigma)$ along $\Gamma_i$, $i = 1, \ldots, n$. Each time the arc $\Gamma_i$ crosses a singular tie of $N(\tau)$, the cutting along $\Gamma_i$ defines a splitting operation on $\tau$. The concatenation of these operations produces the sequence (3.3).
The previous proposition has a simple but important consequence: the refinement of \( \tau \) to \( \psi(\tau) \) allows us to factorize the incidence matrix \( M(\psi) \) as a product of matrices associated to folding operations. In the sequel we explain how this can be done.

3.9. **Folding operations and train track morphisms.** Each folding operation from a train track \( (\tau, h, e) \) to a train track \( (\tau', h', e') \) produces a train track morphism \( T : \tau \rightarrow \tau' \) that represents some \([f] \in \text{Mod}(\Sigma)\) such that \( f(h(\tau)) < h'(\tau') \). Hence our preceding discussions can be reformulated as follows.

**Lemma 3.8** (Penner-Papadoupoulos [PP87]). Every (labeled) train track map representing a class \([f] \in \text{Mod}(\Sigma)\) is obtained by a finite sequence of train track maps induced by folding operations and then followed by a relabeling operation.

Hence to any pseudo-Anosov class \([\psi]\) and any invariant train track \( \tau \), one can define a (non unique) sequence of folding operations defined by the refinement sequence

\[
\psi(\tau) = \tau_1 < \tau_2 < \cdots < \tau_{k-1} < \tau_k = \tau
\]

The sequence of folding operations defines a sequence of train track maps:

\[
\psi(\tau) = (\tau_1, \epsilon_1) \xrightarrow{T_1} (\tau_2, \epsilon_2) \xrightarrow{T_2} \cdots \xrightarrow{T_{k-1}} (\tau_k, \epsilon_k) \xrightarrow{T_k} (\tau_1, \epsilon_{k+1}) \xrightarrow{R} (\tau_1, \epsilon_1)
\]

Here \( R \) is just a relabeling map. Therefore Lemma 3.8 in this context implies that \( T = R \circ T_k \circ T_{k-1} \circ \cdots \circ T_2 \circ T_1 \). We draw the incidence matrix \( M(\psi) \) or \( M(T) \) as

\[
M(T) = M(R \circ T_k \circ T_{k-1} \circ \cdots \circ T_2 \circ T_1) = M(T_1)M(T_2)\cdots M(T_k)M(R).
\]

**Remark 3.9.** Observe that since we work with labelled train tracks, all the transition matrices \( M(T_i) \) have the form \( \text{Id} + E \) where \( E \) is a non negative matrix.

To summarize, to each pseudo-Anosov homeomorphisms, one can associate a train track and a sequence of folding operations such that the corresponding product of matrices is irreducible i.e. it has some power such that every entry has positive coefficients (Theorem 3.5). In general the converse is not true, however under mild assumption one has:

**Theorem 3.10.** Let \( \tau = \tau_1 < \tau_2 < \cdots < \tau_{k-1} < \tau_k = \tau \) be a refinement sequence defined by folding operations such that the corresponding incidence matrix is irreducible and the Perron-Frobenius eigenvector satisfies the switch conditions of the train track \( \tau \). Then the train track map \( T \) associated to this sequence is the representative of a pseudo-Anosov homeomorphism.

3.10. **Elementary operations and standardness.** As we have seen in the preceding paragraphs, every train track map \( T : \tau \rightarrow \tau' \) representing a class in \( \text{Mod}(\Sigma) \) is the product of train track maps defined by elementary operations. When \( \Sigma \) is the \( n \)-punctured disc \( D_n \) this product can be refined by asking that every train track in \( \Sigma \) is **standardly embedded**. Since all the calculations that we present in the present paper are described in this context, we will discuss these notions in detail.

In §3.5 we made the convention that the \( n \)-letters in \( \mathcal{A}_{\text{prong}} \) label the infinitesimal edges enclosing punctures of \( D_n \), hence any labeling using these letters defines a labeling of the punctures of \( D_n \). We consider \( D_n \) to be modeled on the unit disc \( \mathbb{C} \) with \( n \) punctures along the real line \( \mathbb{R} \). Let \( l_\alpha \) be a vertical segment joining the puncture labeled by \( \alpha \in \mathcal{A}_{\text{prong}} \) to the boundary of the disc. Now consider a train track \( h : \tau \hookrightarrow D_n \). If all the edges except these infinitesimal edges are embedded in the upper (or lower) half disc, then we say that \( (\tau, h) \) is standard. If only one open real edge of \( h(\tau) \) intersects only once \( \cup l_\alpha \), and all the other real edges are embedded in the upper (or lower) half disc, then we say that \( (\tau, h) \) is almost standard. These notions were first introduced in [SKL02].

We consider \( B_n \) the \( n \)-th braid group with standard generators \( \sigma_1, \ldots, \sigma_{n-1} \) and consider the natural map \( B_n \rightarrow \text{Mod}(D_n) \) which associates to each braid \( \beta \) the mapping class \( f_\beta \). If \( (\tau, h) \) is standard and we perform a folding operation on \( h(\tau) \), then the resulting train track \( (\tau_1, h_1) \) is either standard or almost standard. In the latter situation we can easily turn \((\tau_1, h_1)\) into a standard marking.

**Lemma 3.11.** [SKL02] Let \( (\tau, h) \) be an almost standard train track in \( D_n \). Then there exist some \( n \)-braid of the form \( \delta_{[1,m]}^h = (\sigma_{m-1}\sigma_{m-2} \cdots \sigma_1)^\pm \) (called standardizing braid) such that \( (\tau_1, f_\beta \circ h_1) \) is standard.
In this context we say that $f_\beta$ is a standardizing homeomorphism for $(\tau_1, h_1)$.

**Definition 3.12.** Any infinitesimal edge around a puncture determines a cusp (enclosing a puncture). Any standardizing homeomorphism $f_\beta$ acts on those edges by a permutation $\pi \in \mathbb{A}_{\text{prong}}$. Moreover if $e, f$ are two infinitesimal edges (with labeling $\alpha, \beta$ respectively) and if $\pi(\alpha) = \beta$ then $f_\beta$ acts as a rotation whose support is contained in a small neighborhood of the punctures. We encode this action by the rotation number of $\pi(\alpha) = \beta^k$.

**Example 3.13.** In Figure 11 the two standardizing homeomorphisms corresponding to $\sigma_1^{-1}$ and $\sigma_2$ act on the punctures as follows (we identify punctures and infinitesimal edges enclosing punctures for the labelling):

\[
\pi(\sigma_2) = \begin{pmatrix} A & B & C \\
A & C+1 & B \end{pmatrix} \quad \text{and} \quad \pi(\sigma_1^{-1}) = \begin{pmatrix} A & B & C \\
A & B^{-1} & C \end{pmatrix}.
\]

In particular, for any $k \in \mathbb{Z}$, $k > 0$, the permutation associated to $\sigma_2^k$ is $\pi(\sigma_2^k) = \begin{pmatrix} A & Bk & C \\
A & B & Ck \end{pmatrix}$.

### 4. Construction of the Automaton

In this section, for simplicity, we specify to the case of the punctured disc. However all the discussion can be done for surfaces of higher genera. Let us fix $n > 2$, the number of punctures, and the singularity data of train tracks (i.e. the number and type of prongs). We fix an alphabet $\mathbb{A}$.

**4.1. Graphs of foldings.** We start with the following observation: the number of labelled train tracks $(\tau, h, e)$ of $D_n$ where

- $(\tau, h)$ is standard,
- $\tau$ has prescribed singularity data and labelling $e : E(\tau) \to \mathbb{A}$

(up to isotopy of $D_n$ fixing the punctures) is finite.

Moreover this set is also (set-wise) invariant by folding operations followed by standardness operations. Finally, given a tuple $(\tau, h, e)$ into this finite set, since the number of cusps and edges is finite, there are only finitely many possible folding operations on $h(\tau)$. These three finiteness ingredients allow us to construct a graph in the following way.

1. Vertices are tuples $(\tau, h, e_{E(\tau)_{\text{hol}}})$ where $h : \tau \to D_n$ is standard (up to isotopy fixing the punctures).
2. There is an edge between $(\tau_1, h_1, e_1)$ and $(\tau_2, h_2, e_2)$ if there is a folding operation from $(\tau_1, h_1, e_1)$ to $(\tau_2, h'_1, e_2)$ and either:
   - (a) $h'_1(\tau_2)$ is standard: then $h_2 = h'_1$, or
   - (b) $h'_1(\tau_2)$ is almost standard: $h_2 = f_\beta \circ h'_1$ where $f_\beta$ is a standardizing braid.
3. There is an edge between $(\tau, h, e)$ and $(\tau, f_\beta \circ h_\tau, e)$ where $\beta \in B_n$ and $f_\beta \circ h(\tau)$ is also standard.

The resulting directed graph is called the folding automaton associated to the number of marked points of $D_n$ and the type of singularities. Observe that this graph is not necessarily strongly connected (even not connected). It would be nice to have a description of the topology of these graphs in general.

For any train track $(\tau, h, e)$ we will denote by $N^{\text{lab}}(\tau, h, e)$ the connected component of the folding automaton containing $(\tau, h, e)$. One can also perform the same construction without labelling: the connected components containing $(\tau, h)$ are then denoted by $N(\tau, h)$.

**Example 4.1.** See Figures 12, 16, 20 for examples of automata.

**4.2. Closed loops in $N(\tau, h)$ and pseudo-Anosov homeomorphisms.** The labelling allows us to define for each edge of $N^{\text{lab}}(\tau, h, e)$ a train track map and its associate transition matrix. Hence given a path $\eta$ in $N^{\text{lab}}(\tau, h, e)$ (not necessarily closed) represented by

\[(\tau_1, e_1) \xrightarrow{T_1} (\tau_2, e_2) \xrightarrow{T_2} \cdots \xrightarrow{T_{k-1}} (\tau_k, e_k) \xrightarrow{T_k} (\tau_1, e_{k+1})\]

one defines the matrix $M(\eta)$ by using the formula (3.4):

\[M(\eta) = M(T_k \circ T_{k-1} \circ \cdots \circ T_2 \circ T_1) = M(T_1)M(T_2) \cdots M(T_k).\]
Now if $\gamma$ is a loop in $N(\tau, h)$ starting at some point $(\tau_i, h_i)$ we can lift $\gamma$ to some path $\tilde{\gamma}$ in $N^{lab}(\tau, h, e)$ starting at $(\tau_i, h_i, e_i)$. Here $e$ is any labelling of $(\tau, h)$. The end point of $\tilde{\gamma}$ (that is $(\tau_i, h_i, e'_i)$) defines a train track map

$$R : (\tau_i, h_i, e'_i) \rightarrow (\tau_i, h_i, e_i).$$

The associated matrix $M(R) \in \text{GL}(\mathbb{Z}^h)$ is induced by a permutation, namely $R_{\alpha, \beta} = 1$ if $\pi(\alpha) = \beta$ and 0 otherwise, where $\pi = e'_i \circ (e_i)^{-1} \in \text{Sym}(\mathbb{A})$. We then define:

$$M(\gamma) := M(\tilde{\gamma}) \cdot M(R).$$

Obviously the conjugacy class of the matrix $M(\gamma)$ does not depend on the choice of the labelling $e$.

**Remark 4.2.** The above discussion allows us to reformulate Theorem 3.5 and Lemma 3.8 as follows: any pseudo-Anosov homeomorphism is obtained from a closed loop in some graph $N(\tau, h)$ by using the above construction. The converse is almost true: this is Theorem 3.10.

We end this section with a useful description of the train track map representing lift of homeomorphism to $D_n$.

### 4.3. Lifting train tracks.

We denote by $\rho : \tilde{D}_n \rightarrow D_n$ the $H = \mathbb{Z}^{h(M)-1}$-covering of the punctured disc (see Section 3.1). The infinite surface $\tilde{D}_n$ can be constructed by gluing $H$ copies of the simply connected domain obtained by cutting the base $D_n$ along $n$ disjoint segments from the punctures to the exterior boundary. The way one should glue is dictated by the monodromy of the covering. We call each of these simply connected domains a leaf of the covering $\rho : \tilde{D}_n \rightarrow D_n$. Henceforth, we choose a leaf in $\tilde{D}_n$ and we label it with $e_H$, the identity element in $H$. We call it the leaf at level zero.

For each standard $(\tau, h, e)$, there is a natural way to define an infinite train track $\tilde{h} : \tilde{\tau} \rightarrow \tilde{D}_n$ by $\tilde{h}(\tilde{\tau}) := \rho^{-1}(h(\tau))$. The edges and vertices of $\tilde{\tau}$ are in bijection with $E(\tau) \times H$ and $V(\tau) \times H$ respectively and there are several ways to label the edges of $\tilde{\tau}$.

Every permutation $\eta \in \text{Sym}(A_{\text{prong}})$ defines a labeling of the edges of $\tilde{\tau}$ as follows. For every edge $e$ of $\tilde{\tau}$ whose image under $\tilde{h}$ is properly contained in the leaf at level zero we define $\tilde{e}(e) = e(e)$, where $\rho(e) = e$. Now by the way we defined the leaves of the covering, and given that we are working with standardly embedded train tracks, there are exactly $2n$ edges of $\tilde{\tau}$ whose image under $\tilde{h}$ are not properly contained in the leaf of level zero. Moreover, these edges can be grouped in pairs $\{e^1, e^2\}$ where $\rho(e^1) = \rho(e^2) = e$, and $e$ is an infinitesimal edge of $\tau$ around a puncture. For every such edge $e$ we define $\tilde{e}(e^1) = \eta(e(e))$ where $e(e) \in A_{\text{prong}}$. Finally, we extend $\tilde{e}$ to the remaining edges of $\tilde{\tau}$ by using the $H$-monodromy action of the covering.

### 4.4. Lifting train track maps.

Let us consider $(\tau, h)$ and $(\tau', h')$ two train tracks in $D_n$ and let $T : \tau \rightarrow \tau'$ be a train track map representing a class $[f] \in \text{Mod}(D_n)$. Now consider: $\tilde{f} : \tilde{D}_n \rightarrow \tilde{D}_n$ a lift of $[f]$ to the $H = \mathbb{Z}^{h(M)-1}$-covering of the punctured disc $\rho : \tilde{D}_n \rightarrow D_n$, $(\tilde{\tau}, \tilde{h})$ and $(\tau', \tilde{h}')$ lifts of $(\tau, h)$ and $(\tau', h')$ to this covering respectively. As with finite train tracks, a cellular map $\tilde{T} : \tilde{\tau} \rightarrow \tilde{\tau}'$ that preserves the smooth structure will be called a train track morphism. If in addition the domain and image train tracks of the morphism are isomorphic as train tracks we speak of a train track map. A train track morphism $\tilde{T} : \tilde{\tau} \rightarrow \tilde{\tau}'$ is a representative of the lift $\tilde{f}$ if:

1. The diagram

$$
\begin{array}{ccc}
\tilde{\tau} & \xrightarrow{\tilde{h}} & \tilde{D}_n \\
\downarrow{\tilde{f}} & & \downarrow{\tilde{f}} \\
\tilde{\tau}' & \xrightarrow{\tilde{h}'} & \tilde{D}_n
\end{array}
$$

commutes, up to isotopy, and

2. $\tilde{f} \circ \tilde{h}(\tilde{\tau}) \subset N(\tilde{h}'(\tilde{\tau}'))$ and $\tilde{f} \circ \tilde{h}(\tilde{\tau})$ is transverse to the tie foliation of $\tilde{h}'(\tilde{\tau}')$. 

It is clear that for every lift \( \tilde{f} \) of \( f \) there is a train track map representing it.

Let \( \eta \in \text{Sym}(A_{\text{prong}}) \) be any permutation and \( \pi \in \text{Sym}(A_{\text{prong}}) \) be the permutation defined by \( f \). These permutations define labelings \((\tilde{\tau}, \tilde{h}, \tilde{e})\) and \((\tilde{\tau}', \tilde{h}', \tilde{e}')\) respectively, by \( \eta \) and \( \pi \circ \eta \). As in the case of finite train tracks we can associate to the train track map \( \tilde{T} : \tilde{\tau} \rightarrow \tilde{\tau}' \) representing \( \tilde{f} \) an incidence matrix. The matrix \( M(\tilde{T}) \in \text{GL}(\mathbb{Z}[H]^{A}) \) records how the edges of \( \tilde{f} \circ \tilde{h} \) intersect the central ties of \( \tilde{h}' \). Obviously by construction one has \( M(\tilde{T}) = M(T) \cdot \text{Diag}(v) \) for a suitable vector \( v \in \mathbb{Z}[H]^{A} \). In the next section we explain how to compute this vector in the particular situation where \( T : \tau \rightarrow \tau' \) is an edge of the folding automaton.

5. Computing the Teichmüller Polynomial

In this section we shall prove our main result. The statement uses what we call the decorated folding automaton. The idea is to enrich the folding automaton by adding additional information to each of its edges so that the computation of the Teichmüller polynomial can be carried out using just the decorated folding automaton. This represents a simplification of the problem of computing \( \Theta_F \), for with the method we propose there is no need to pass to an abelian infinite cover.

5.1. The decorated folding automaton. In the next paragraphs we define the extra piece of information needed to obtain the decorated folding automaton. Roughly speaking, this extra piece of information is a vector \( v \) with entries in \( \mathbb{Z}[H] \) that encodes the incidence matrix \( M(T) \) of the lift of a train track map \( T \) coming from a folding operation, see §4.4.

Recall that when defining the folding automaton in §1.1, the labelling map \( e \in (\tau, h, e) \) is restricted to the set of real edges \( E(\tau) \) of \( \tau \). We will often choose the convention that, for any train track, the infinitesimal edges enclosing punctures are labeled by \( \{A, B, C, \ldots\} = A_{\text{prong}} \) where the alphabetical order is set to match the order on the punctures of \( D_n \) induced by the natural order of \( \mathbb{R} \).

Let \((\tau, h, e) \xrightarrow{\tilde{f}} (\tau', h', e')\) be a train track map associated to an edge in the folding automaton which corresponds to a folding operation \( \tilde{f} \) and that represents a standardizing homeomorphism \( f_{\beta} \), where \( \beta \) is a braid in \( B_n \). If \( h' \) is standardly embedded we say that the folding \( F \) is standard. For every edge in the folding automaton corresponding to a standard folding we define \( v \in \mathbb{Z}[H]^{A_{\text{real}}} \) as the constant vector on which each entry is equal to 1.

Henceforth we assume that the folding \( F \) is not standard. There are two real edges \( \{e, e'\} \subset E(\tau) \) and three vertices \( \{v_0, v_1, v_2\} \subset V(\tau) \) involved when performing \( \tilde{f} \). We observe that:

1. there is a unique edge \( f \in \{e, e'\} \) in \( f_{\beta}(h(\tau)) \) which is not properly embedded, i.e. that traverses to the lower half of the punctured disc \( D_n \),
2. there exists a unique vertex \( v_{\text{fix}} \in \{v_0, v_1, v_2\} \) which is fixed by \( f_{\beta} \), and
3. after performing the folding operation on \( F \), a new cusp in \((\tau', h', e')\) appears. This cusp is incident to a vertex \( v_{\text{end}} \in \{v_0, v_1, v_2\} \). Let \( \tilde{X} \in A_{\text{prong}} \) be the label of the unique infinitesimal edge of \( \tau \) enclosing a puncture that is incident to \( v_{\text{end}} \).

**Definition 5.1.** We denote by \( N(T) \) the connected component of \( \tau \setminus f \) which does not contain the vertex \( v_{\text{fix}} \) (possibly \( N(T) = \emptyset \)). We define \( f' \in \{e, e'\} \) by \( f' \neq f \). There are two cases to consider:

- **Case 1:** \( f' \notin N(T) \). We define \( v \in \mathbb{Z}[H]^{A_{\text{real}}} \) as:
  \[
  \begin{cases}
  v_{\alpha} = X_{\pm}^{\pm} & \text{if } e(\alpha) = \alpha \in A_{\text{real}} \text{ and } e \in N(T) \cup f, \\
  v_{\alpha} = 1 & \text{otherwise}.
  \end{cases}
  \]

- **Case 2:** \( f' \in N(T) \). We define \( v \in \mathbb{Z}[H]^{A_{\text{real}}} \) as:
  \[
  \begin{cases}
  v_{\alpha} = X_{\pm}^{\pm} & \text{if } e(\alpha) = \alpha \in A_{\text{real}} \text{ and } e \in N(T), \\
  v_{\alpha} = 1 & \text{otherwise}.
  \end{cases}
  \]

The sign of the exponent in \( X_{\pm}^{\pm} \) is determined by the choice of the counterclockwise direction as positive direction for rotations on the disc. The decorated folding automaton \( N^{\text{aug}}(\tau, h) \) is \( \text{A}_{\tau}(\tau, h, e) \) where we add the information \((\tau, e)\) at each edge.
Remark 5.2. A priori one would expect the vector $v$ encoding the matrix $M(T)$ to be larger, that is, $v \in \mathbb{Z}[H]^\delta$. However, as we will see in the next section, the contribution of infinitesimal edges to the determinant formula\(^3\) cancels out with the contribution of the matrix $P_\nu(t)$, and hence one can restrict the computation of the Teichmüller polynomial to the subset of $\mathbb{A}_{\text{real}} \subset \mathbb{A}$ formed by real edges.

If there is an edge between $(\tau, h, e)$ and $(\tau, f_\beta \circ h, e)$ where $\beta \in B_n$ and $f_\beta \circ h(\tau)$ is also standard then the vector $v \in \mathbb{Z}[H]^\delta$ is defined by $v = (X^{\pm 1}, X^{\pm 1}, \ldots, X^{\pm 1})$ depending on the orientation of the braid $\beta$, and $X$ is the label associated to the first, respectively last, prong of $D_n$.

Example 5.3. We consider the folding automaton for the train track depicted in Figure 2. We have depicted only real edges. Infinitesimal edges enclosing punctures are labeled by $[A, B, C] = \mathbb{A}_{\text{prong}}$, where the alphabetical order is set to match the order on the punctures of $\mathbb{A}$. This automaton has two edges. To the right the one corresponding to the non standard folding $F_{ab}$ that folds the real edge labeled with $a$ over the real edge labeled with $b$. The standardizing homeomorphism in this case is given by $f_{r_2}$, and a direct computation shows that:

- $v_{bx}$ is the vertex on which the infinitesimal edge $A$ is incident and $v_{end}$ is the vertex on which the infinitesimal edge $C$ is incident. Therefore the label of the unique infinitesimal edge of $\tau$ enclosing a puncture that is incident to $v_{end}$ is given by $X = C$.
- The edge $f$ in definition $5.1$ is the edge labeled with $a$. Therefore $N(T_{ab})$ is the graph containing the infinitesimal edges $B$ and $C$, the vertices to which they are incident and the real edge $b$. Therefore, according to definition $5.1$ we are in case 2.

Hence we deduce that the vector corresponding to this edge of the automaton is given by $v_{ab} = (1, C^{\pm 1})$. We leave to the reader the rest of the computations. To deduce the signed permutations corresponding to the edges of the automaton it is useful to look at Figure 11.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure11.png}
\caption{The decorated folding automaton for $B_3$. The two edges represent $\sigma_1^{-1}$ (left) and $\sigma_2$ (right).}
\end{figure}

5.2. Main result. A pseudo-Anosov class $[f_\beta] \in \text{Mod}(D_n)$ leaving invariant a train track $(\tau, h)$ defines a map

\[(5.5) \quad t : \mathbb{A}_{\text{prong}} \to H = \text{Hom}(H^1(D_n, \mathbb{Z}), \mathbb{Z})\]

in the following way. We have a collection of cycles $s_\alpha = [\partial U_\alpha]$, $\alpha \in \mathbb{A}_{\text{prong}}$, that form a basis for $H_1(D_n, \mathbb{Z})$. Moreover $f_\beta$ acts on this basis, indeed for every $\alpha \in \mathbb{A}_{\text{prong}}$ we have $f_\beta(s_\alpha) = s_{\beta(\alpha)}$, where $\beta \in \text{Sym}(\mathbb{A}_{\text{prong}})$ is the permutation that $\beta$ defines on the punctures. For each cycle $\sigma$ of $\beta$ let $l_\sigma = \sum_{\alpha \in \text{Supp}(\sigma)} s_\alpha$. This defines a multiplicative basis for $H$, that we denote by $t_1, \ldots, t_r$, for simplicity. The map $t : \mathbb{A}_{\text{prong}} \to H$ is given by $t(\alpha) = l_\sigma$ provided that $\alpha \in \text{Supp}(\sigma)$.

Convention. Let $\mathbb{A}_{+}^{\pm 1}_{\text{prong}} := \{ \alpha^{\pm 1}, \alpha^{-1} \}_{\alpha \in \mathbb{A}_{\text{prong}}}$. We extend the function $t : \mathbb{A}_{\text{prong}} \to H$ (respectively, $\pi \in \text{Sym}(\mathbb{A}_{\text{prong}})$) to a function $\{ 1 \} \cup \mathbb{A}_{+}^{\pm 1}_{\text{prong}} \to H$ (respectively, permutation of $\{ 1 \} \cup \mathbb{A}_{+}^{\pm 1}_{\text{prong}}$) by $t(\alpha^{\pm 1}) = t(\alpha)^{\pm 1}$ if $\alpha \in \mathbb{A}_{\text{prong}}$ and $t(1) = 1$ (respectively, $s(\alpha^{\pm 1}) = (s(\alpha))^{\pm 1}$ and $s(1) = 1$).

Finally, if $v$ is a vector with entries in $\{ 1, \alpha^{\pm 1} \} \alpha \in \mathbb{A}_{\text{prong}}$, we define $t(v)$ (respectively, $\pi(v)$) as the vector that results from the evaluation $t$ (respectively, $\pi$) on each coordinate.

Theorem 5.4. Let $[f_\beta]$ be a pseudo-Anosov class given by the loop

\[
(\tau_1, e_1) \xrightarrow{T_1} (\tau_2, e_2) \xrightarrow{T_2} \cdots \xrightarrow{T_{k-1}} (\tau_k, e_k) \xrightarrow{T_k} (\tau_1, e_{k+1}) \xrightarrow{R} (\tau_1, e_1)
\]
in the decorated folding automaton. We assume that the matrix describing the linear map on the space of weights on real edges is primitive irreducible. Then the Teichmüller polynomial $\Theta_F(t, u)$ of the associated fibered face $F$ determined by $\beta$ is:

\begin{equation}
\Theta_F(t_1, \ldots, t_k, u) = \det(u \cdot \Id - M)
\end{equation}

where

\begin{equation}
M = M(T_1)D_1 \cdot M(T_2)D_2 \cdots M(T_k)D_k \cdot M(R).
\end{equation}

and, for $i = 1, \ldots, k$:

\begin{equation}
\left\{ \begin{array}{l}
D_i = \text{Diag}(t(w_i)) \in \text{GL}(\mathbb{Z}[H]^{\text{real}}), \\
w_i = \eta_i(v_i), \\
\eta_i = \text{Id}_{\text{prong}} \text{ and for } i \geq 2 : \eta_i = \pi_{i-1} \circ \eta_{i-1}.
\end{array} \right.
\end{equation}

Proof of Theorem 5.4 We first observe that the assumption on real edges implies that the contribution of infinitesimal edges to the numerator in the determinant formula (5.2) cancels out with the denominator. This fact, together with the discussion we did in sections 4.2 and 4.4, imply formulas (5.6) and (5.7). We need then to show that each diagonal matrix $D_i$ is given by formula (5.8). We will prove first that given an edge

\begin{equation}
(\tau_i, \epsilon_i, h_i) \xrightarrow{T_i} (\tau_{i+1}, \epsilon_{i+1}, h_{i+1})
\end{equation}

of the decorated automaton representing a standardizing homeomorphism $f_\beta$, the incidence matrix $M(\tilde{T}_i)$ with entries in $\mathbb{Z}[H]$ associated to a lift of $T_i$ to $\tilde{D}_n$ is of the form $M(T_i)\text{Diag}(t(\eta_i(v_i)))$. This is the longest part of the proof and is done by cases that depend on the train track $(\tau_i, \epsilon_i, h_i)$. We deal with the recursive nature of formula (5.8) at the end. In order to present the list of cases, we observe that

1. No train track of the decorated folding automaton defines a polygon whose sides are real edges. More precisely, if $(\tau, h, e) \in N^{\text{ab}}(\tau, h, e)$, then there is no connected component of $D_n \setminus h(\tau)$ homeomorphic to a disc whose boundary is formed by real edges of $\tau$.

2. All standardizing homeomorphisms are 'simple' in the sense of Ko-Los-Song [SKL02]. More precisely, let $\delta_{[\ell, m]} := \sigma_{m-1} \sigma_{m-2} \cdots \sigma_{\ell}$, where the $\sigma_j$'s are the standard Artin generators of the braid group $B_n$. Then we can suppose that all the homeomorphism used to standardize train tracks in the augmented folding automaton are of the form $\delta_{[\ell, m]}$.

It will be useful to understand the proof to describe more precisely the covering $\tilde{D}_n$ discussed in section 4.5. Let $D$ be the leaf of this covering obtained by cutting the base $D_n$ along $n$ disjoint vertical segments that go from the punctures to the lower part of the exterior boundary. Any labelling by elements of $\mathcal{A}$ of the infinitesimal edges surrounding punctures defines a natural labelling of these vertical segments. Let us denote them by $\iota_{\alpha}$ where $\alpha \in \mathcal{A}$. The infinite covering $\tilde{D}_n$ is obtained by gluing the disjoint family of copies of $D$ in the family $\{D_h\}_{h \in H}$ as follows: for every $h \in H$, crossing in $D_h$ the segment $\iota_{\alpha}$ in the counter clockwise direction takes you to $D_{h(\alpha)}$, where $\iota_{\alpha}$ is the map defined in (5.3). From this detailed description we deduce that if the train track map corresponding to the edge (5.9) comes from a standard folding $F_i$ then $M(\tilde{T}_i) = M(T_i)$. Indeed, it is sufficient to remark that no real edge of $\tilde{f}_\beta(\tilde{T}_i)$ intersects a vertical segment $\iota_{\alpha}$.

Now let us suppose that the edge (5.9) comes from a non standard folding $F_i$. We justify in detail the equality $M(\tilde{T}_i) = M(T_i)\text{Diag}(t(\eta_i(v_i)))$ in two illustrative cases. Then we explain how to proceed with all the cases that remain, see Appendix C.

Case A.1. This case is formed by an infinite family of train tracks arising from a graph $\Gamma$ embedded in $D_n$. This graph $\Gamma$ will be called a basic type and consists of: two real edges $\{e, e'\}$, three vertices $\{v_0, v_1, v_2\}$ and at most three infinitesimal edges, each of which encloses a puncture of $D_n$ and is incident to a vertex in $\{v_0, v_1, v_2\}$. For the particular situation of case A.1, the graph $\Gamma$ is depicted in figure 3.

The idea now is to add edges and vertices to $\Gamma$ to form vertices $(\tau_i, \epsilon_i, h_i)$ of the folding automaton in $D_n$. There are many ways to do this, some of which are depicted in figure 3. In fact, given that the vertices of the automaton are properly embedded train tracks, there are only finitely many types of train tracks that can be obtained this way. To illustrate what we mean by a type of a train track we display in figure 4 all possible
types of train tracks arising from the basic type $\Gamma$ in figure 3\footnote{For this particular case we depict $\Gamma$ embedded in $D_n$.}. In figure 4 each one of the small boxes represents a subgraph of $(\tau_t, \varepsilon_t, h_t)$.

Now let us consider an edge of the automaton (5.9) where $(\tau_t, h_t, \varepsilon_t)$ is the type A.1.1 depicted in figure 4 and the train track map $T_t$ represents the homeomorphism $f_{\beta}$ that standardizes the train track $F_{e'c}(\tau_t)$ that arises when folding edge $e$ over edge $e'$. In figure 5 we depict this edge of the automaton in detail. The numbers 0, 1, 2 in this figure represent vertices $[v_0, v_1, v_2]$ respectively. Remark that for this edge of the automaton we have $v_\text{fix} = v_0$ and $v_\text{end} = v_1$. Moreover, edges $f, f'$ from definition 5.1 are given by $f = e, f' = e'$ and the subgraph $N(T_t)$ is highlighted in bold. We observe that $f' \notin N(T_t)$, hence we are in case 1 presented in the same definition.

![Figure 3. Basic type A.1 and some train tracks that arise from it.](image1.png)

![Figure 4. Types A.1.1 and A.1.2 arising from simple type A.1.](image2.png)
In figure 5 we depict this edge of the automaton in detail. Remark that $v_{\text{fix}} = v_2$, $v_{\text{end}} = v_1$, $f = e$, $f' = e'$ and the subgraph $N(T_i)$ is highlighted in bold. We remark that $f \in N(T_i)$, hence we are in case 2 from definition 5.1. This is the main difference with the case we treated in case A.1.

Now consider the lift $\widetilde{D_n} \xrightarrow{\tilde{f}_0} \widetilde{D_n}$ which fixes the point in the fiber over $v_{\text{fix}}$ contained in $D_{v_H}$. To compute $M(\tilde{T}_i)$ we present figure 8 where $\tilde{f}_\beta(\tilde{T}_i)$ and $\tilde{h}_{i+1}(\tilde{T}_{i+1})$ are both depicted at the leaf $D_{v_H}$ of level zero. Remark
that at the leaf of level zero, except for real edges in \( \tilde{f}_β(\tilde{T}) \) depicted in bold, all real edges in \( \tilde{f}_β(\tilde{T}) \) are labeled by \( \tilde{e}_i \) with letters in \( \mathbb{A} \). Labels given to the edges in bold by \( \tilde{e}_i \) are of the form \( t_β^1t \), where \( t \) ranges among labels in \( \mathbb{A} \) reserved for real edges in \( N(T_i) \cup \tilde{f} \) and \( t(X) = t_i \). Here, \( X \in \mathbb{A}_{\text{prong}} \) is the label (given by \( e_i \)) of the unique infinitesimal edge of \( τ_i \) enclosing a puncture and that is incident to \( v_{\text{end}} \). Now remark that the projection of the real edges depicted in bold in figure 9 to the base \( \mathbb{D}_n \) are precisely the edges in \( fβ(τ_i) \) contained in \( N(T_i) \). From this data we can perform a straightforward calculation which shows that in this case \( M(\tilde{T}_i) = M(T_i)\text{Diag}(t(\tilde{η}_i(v_{i}))) \), where all entries in the diagonal matrix \( \text{Diag}(t(\tilde{η}_i(v_{i}))) \) different from 1 are equal to \( t_i \). The case when \( T_i \) represents the homeomorphism \( fβ \) that standardizes the train track \( F_{e\epsilon'}(τ_i) \) that arises when folding \( e \) over \( e' \) is treated in the same way.

\[ \text{Figure 9. Lifting an edge of the automaton in case B.1.1.} \]

The rest of the cases are treated as follows:

1. Pick a basic type \( Γ \) from the list presented in Appendix C and consider \( (τ_i, h_i, e_i) \) one of the finitely many possible types of train tracks that can be constructed from \( Γ \).

2. Consider an edge (5.9) of the folding automaton starting from the train track chosen in the preceding step and where \( T_i \) comes from either the folding \( F_{e\epsilon'} \) or \( F_{e'e} \), and represents a standardizing homeomorphism \( \tilde{D}_n \xrightarrow{fβ} D_n \).

3. Pick the lift \( \tilde{D}_n \xrightarrow{fβ} \tilde{D}_n \) which fixes the point in the fiber over \( v_{\text{fix}} \) contained in \( D_{e\epsilon'} \) and the corresponding train track map of the form (5.10) representing it. Then, depending on the case of definition (5.1), perform analogous calculations to the ones presented in cases A.1 and B.1.

To finish the proof consider any edge (5.9) in the decorated folding automaton with extra information \( (π_i, v_i) \). If \( e \) is an infinitesimal edge in \( τ_{i+1} \), then we can define \( ε_{i+1}(e) := π_i(ε_i(e)) \). Hence \( w_{i+1} = π_i \circ \cdots \circ π_1(v_{i+1}) \). This implies the recursive nature of formula (5.3).

**Remark 5.5.** Let \( t \) be the variable of \( H \) and \( u \) corresponds to the lift \( \tilde{Ψ} \). Then

\[ Θ_F(t, u) = \mathbb{Z}[G] = \mathbb{Z}[t] \oplus \mathbb{Z}[u]. \]

From Remark 5.1 we conclude that picking different lifts of the standardizing homeomorphism \( fβ \) results in multiplying \( M(\tilde{T}) \) by some \( t_0 \in H \). This does not affect the expression for the Teichmüller polynomial since \( Θ_F(t, u) = \text{det}(uI - t_0M(\tilde{T})) = t_0^0 \text{det}(t_0^{-1}uI - M(\tilde{T})) = t_0^{(α-1)}Θ_F(u', t) \), where \( u' = t_0^{-1}u \) is the coordinate corresponding to the other lift.

**Remark 5.6.** Observe that we can formally apply above theorem to any isotopy class (not necessary pseudo-Anosov). See the example below.

**Example 5.7.** Let us consider the class \( [fβ] \) where \( β = σ_2^2 \) is a braid in \( B_3 \). (see Figure 2). The corresponding loop is

\[ (\tau, e) \xrightarrow{T_1} (\tau, e) \xrightarrow{T_2} (\tau, e) \]

In this example the map \( t : \{A, B, C\} \to H \) is given by \( t(α) = t_0 \) for all \( α \in \mathbb{A}_{\text{prong}} = \{A, B, C\} \) since the permutation on punctures defined by \( fβ \) is the identity. In other words, \( H \) is isomorphic to \( \mathbb{Z}^3 \). A direct calculation shows that \( w_1 = \eta_1(1, C^+) = (1, C^+) \) since \( \eta_1 = \text{Id}_{\mathbb{A}_{\text{prong}}} \). Hence \( t(w_1) = (1, 1, C) \). On the other

\^2Remark that for some simple types only one of these two foldings is possible.
hand \( w_2 = \eta_2(1, C^+) = (1, B^+) \) since \( \eta_2(A, B, C) = (A, C, B) \). Hence \( t(w_2) = (1, t_B) \). A direct calculation also shows that the matrix associated to \( T_i \) is \( \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right) \) for \( i = 1, 2 \). Theorem 5.4 then gives
\[
M(\sigma_2^i) = \left( \begin{array}{cc} 1 & 1 \\ 0 & 1 \end{array} \right) \cdot \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) = \left( \begin{array}{cc} 1 & t_B + t_B c_t \\ 0 & t_B c_t \end{array} \right).
\]

Similarly for \( \beta = \sigma_1^2 \) we have \( t(\alpha) = t_A \) and \( H \) isomorphic to \( \mathbb{Z}^3 \). A direct calculation shows that \( w_1 = \eta_1(A^{-1}, 1) = (A^{-1}, 1) \). Hence \( t(w_1) = (t_B, 1) \). On the other hand \( w_2 = \eta_2(A^{-1}, 1) = (B^{-1}, 1) \) with \( \eta_2(A, B, C) = (B, A, C) \). Hence \( t(w_2) = (t_B, 1) \). A direct calculation also shows that the matrix associated to \( T_i \) is \( \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) \) for \( i = 1, 2 \). Theorem 5.4 then gives
\[
M(\sigma_1^2) = \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) \cdot \left( \begin{array}{cc} r_1^1 & 0 \\ 0 & r_1^2 \end{array} \right) \cdot \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) = \left( \begin{array}{cc} r_1^1 r_2^1 + r_1^2 & 0 \\ 0 & r_1^2 \end{array} \right).
\]

**Remark 5.8.** Compare with formula in [McM90, §11] (here the presentation of the group \( H \) is different):
\[
M(\sigma_2^2) = \left( \begin{array}{cc} r_2^1 + r_2^1 r_2^1 & 0 \\ r_2^1 & r_2^1 \end{array} \right) \quad \text{and} \quad M(\sigma_1^2) = \left( \begin{array}{cc} t^1 & t^2 + t^2_1 \\ 0 & 1 \end{array} \right).
\]

For instance our algorithm applied to \( \sigma_1^2 \sigma_2^2 \) given by the loop
\[
\left( (\tau, \epsilon) \xrightarrow{T_1} (\tau, \epsilon) \right)^3 \xrightarrow{T_2} (\tau, \epsilon),
\]
(where \( T_1 \) represents \( \sigma_2^2 \) and \( T_2 \) represents \( \sigma_1^2 \)) gives that the Teichmüller polynomial is
\[
\Theta_F(t_A, t_B, c_C, u) = \det \left( u \cdot \text{Id} - \left( \begin{array}{cc} t_B - c_C & 0 \\ 0 & t_B c_C \end{array} \right) \right)^3 \cdot \left( \begin{array}{cc} r_2^1 r_2^1 & 0 \\ 0 & r_2^1 \end{array} \right).
\]

### 6. Topology of a Fiber

In this section we provide a way to compute the topology (genus, number and type of singularities) of a fiber. We begin by introducing some notation that will be used throughout the sequel. As usual we will consider a mapping torus \( M_\psi = D_n \times [0, 1]/(x, 1) \sim (\psi(x), 0) \) induced by a pseudo-Anosov braid \( \psi \in B_n \).

It turns out that there is a natural model for \( M_\psi \) as a link complement \( S^3 \setminus N(L) \) where \( N(L) \) is a regular neighborhood of a link \( L \) in the 3-sphere. To construct the link \( L = L_\partial \), simply close the braid \( \psi \) representing \( \psi \) while passing it through an unknot \( \alpha \) (representing the boundary of the disc \( D_n \)). Let \( \Sigma \to M \to S^1 \) be a fibration with monodromy \( \psi : \Sigma \to \Sigma \). Recall that, if \( \Sigma \) has genus \( g \) and \( b \) boundary components, then \( \chi(\Sigma) = 2g + b - 2 \). Hence the Thurston norm does not determine completely the topology of \( \Sigma \). To achieve this we have to determine one of the numbers \( g \) or \( b \) (the surface \( \Sigma \) is orientable).

#### 6.1. Computing the number of boundary components

Since \( M_\psi \) is homeomorphic to the link complement \( S^3 \setminus N(L) \) we can describe its homology group easily. First there is an embedding \( i : D_n \hookrightarrow M \) such that the image of the exterior boundary of \( D_n \) spans \( \alpha \) and \( i(D_n) \) is punctured by the \( n \) strands of \( \beta \). The boundary of \( M \) is a union of tori \( T_1, \ldots, T_r \), where \( r = b_1(M) \) (viewed as the boundary of a regular neighborhood of link components \( \partial N(L_i) \)). Let \( \{S_1, \ldots, S_r\} \) be a basis of \( H_2(M, \partial M; \mathbb{R}) \) (e.g. take Seifert surfaces whose boundary is \( T_i \)). By convention we normalize so that \( S_r = \partial D_n \). This normalization implies that \( T_r \) comes from the unknot \( \alpha \). The meridians of components of \( \partial D_n \) give a natural basis for \( H_1(M, \mathbb{Z}) \) \[ Hi22 \].

Now let \( \{[m_i], [l_i]\} \) be a meridian and longitude basis for \( H_1(T_i; \mathbb{R}) \), where the orientation of \( l_i \subset \partial S_i \) is induced by the orientation of \( [S_i] \). We consider the long exact sequence of the homology groups of the pair \( (M, \partial M) \). We write the boundary map:
\[
\partial : H_2(M, \partial M; \mathbb{R}) \to H_1(\partial M; \mathbb{R}).
\]

On the chosen basis, for any \( i = 1, \ldots, r \), one has
\[
\partial_i[S_i] = \sum_{j=1}^r (a_{ij}[m_j] + b_{ij}[l_j])
\]
with \( a_{ij}, b_{ij} \in \mathbb{Z} \). We set \( A = (a_{ij})_{i,j=1,\ldots,r} \) and \( B = (b_{ij})_{i,j=1,\ldots,r} \).
Proposition 6.1. Let $\kappa = \sum_{i=1}^r c_i [S_i]$, where $c = (c_1, \ldots, c_r) \in \mathbb{Z}^r$, be an integral homology class (not necessarily primitive). Then for any embedded surface $S \subset M_\phi$ (not necessarily minimal representative) such that $[S] = \kappa$, and for any $j = 1, \ldots, r$, the number of connected components of $S \cap T_j$ is $\gcd(a_j, b_j)$ where $(a_1, \ldots, a_r) = cA$ and $(b_1, \ldots, b_r) = cB$.

Proof of Proposition 6.1. Writing $[S] = \sum_{i=1}^r c_i [S_i] \in H_2(M, \partial M; \mathbb{R})$, elementary linear algebra gives

$$\partial_s([S]) = \sum_{i=1}^r \left( r \sum_{j=1}^r c_i a_{ij} [m_j] + c_i b_{ij} [l_j] \right).$$

Now $S \cap T_j \subset \partial S$ is a union of oriented parallel simple closed curves. Hence its homology class is given by

$$\left( \sum_{i=1}^r c_i a_{ij} [m_j] + \sum_{i=1}^r c_i b_{ij} [l_j] \right) \in H_1(T_j; \mathbb{R})$$

Thus the number of connected components of $S \cap T_j$ is given by

$$\gcd(\sum_{i=1}^r c_i a_{ij}, \sum_{i=1}^r c_i b_{ij}).$$

The proposition is proved.

Remark 6.2. In our situation, since $S_i$ is a Seifert surface whose boundary is the torus $T_j$ one has:

$$\partial_s [S_i] = [l_i] - \sum_{j=1}^r \text{Lk}(L_i, L_j) [m_j],$$

where $\text{Lk}(L_i, L_j)$ is the linking number of the two closed curves $L_i$ and $L_j$ with orientations given by the orientations of $[l_i]$ and $[l_j]$. In other words: $B = \text{Id}$ and $A = (\text{Lk}(L_i, L_j))_{i,j = 1, \ldots, r}$.

We end this section with the following corollary on the connected components of $\Sigma \cap T_i$.

Corollary 6.3. For any $[\Sigma] = \sum_{i=1}^r c_i [S_i] \in H_2(M, \partial M; \mathbb{R})$ where $c = (c_1, \ldots, c_r) \in \mathbb{Z}^r$ we let $a = cA$ and $b = cB$ as above. Then each connected component of $\Sigma \cap T_j$ is identified to a curve (well defined up to isotopy):

$$c_{\Sigma} = p[m_j] + q[l_j] \in H_1(T_j; \mathbb{R}), \quad \text{with} \quad p = \frac{a_j}{\gcd(a_j, b_j)}, \quad q = \frac{b_j}{\gcd(a_j, b_j)}.$$

From the last corollary we make the following definition. If $T$ is a torus, and if $H_1(T, \mathbb{Z})$ is equipped with its preferred basis given by meridian and longitude (denoted by $[m]$ and $[l]$) then the slope of an essential simple closed curve $[c] = p[m] + q[l]$ (with $\gcd(p, q) = 1$) is $\frac{p}{q}$. Conversely for any slope $r \in \mathbb{Q} \cup \{\infty\}$ one defines the (isotopy class) $c_r$ of the corresponding simple closed curve.

6.2. Computing the number and type of singularities of the fiber. Let $\Sigma \to M_\psi \to S^1$ be a fibration in $\mathbb{R}^+ \cdot F$ with pseudo-Anosov monodromy $\phi$. In this section we explain how to compute the singularity data of the stable measured foliation of $\Sigma$ that is invariant by $\phi$ using the singularity data of the stable measured foliation of $\psi$. The arguments are based on work by Fried.

In the sequel we denote by $\mathcal{F}$ the stable measured foliation invariant by $\psi$. Up to isotopy one can assume that $\psi(\mathcal{F}) = \mathcal{F}$. This determines a 2-dimensional lamination $\mathcal{L}_\phi = \mathcal{F} \times \mathbb{R} / \{(s, t) \sim (\psi(s), t+1)\}$ obtained as the mapping torus of $\psi : \mathcal{F} \to \mathcal{F}$. The “vertical flow lines” $\{s\} \times \mathbb{R} \subset \Sigma \times \mathbb{R}$ descend to the leaves of a 1-dimensional foliation whose leaves will be called the flow lines of $\psi$. Hence $\mathcal{L}_\phi$ is swept out by the leaves of the flow lines passing through $\mathcal{F}$.

We distinguish two cases: $\mathcal{F}$ has no singularities in the interior of $D_n$ (see Proposition 6.4) or $\mathcal{F}$ has some singularities in the interior of $D_n$ (see Proposition 6.6). Any singularity $s$ of $\mathcal{F}$ in the boundary of $D_n$ determines a closed curve $\gamma_s$ of slope $\frac{a_j}{q}$ on the torus $T_s \subset \partial M$, given by the flow line passing throughout $s$. See for example figures 4 and 5 in [KT13].
Proposition 6.4 (\(\mathcal{F}\) has no singularities in the interior of \(D_n\)). For any \([\Sigma] \in \mathbb{R}^+ \cdot F \subset H_2(M, \partial M; \mathbb{R})\) with monodromy \(\phi : \Sigma \to \Sigma\), the singularity data of the stable foliation \(\mathcal{F}_\phi\) of the pseudo-Anosov map \(\phi\) is given by:

1. \(\mathcal{F}_\phi\) has no singularities in the interior of \(\Sigma\).
2. At each connected component of \(\partial\Sigma \cap T_i\) (of slope \(\frac{b}{a}\) given by Corollary 6.3), there is a singularity of \(\mathcal{F}_\phi\) of type \(k \cdot [p_s q - q_s p]\)-prong if \(s\) is a \(k\)-prong singularity.

Remark 6.5. In all examples that we will be treating in this article, every singularity of \(\mathcal{F}\) in a boundary of \(D_n\) that does not intersect \(T_i\) is a 1-prong. Except for the example treated in section 3 in \(B_4\), \(\mathcal{F}_\phi\) has no singularities in the interior of \(\Sigma\) and for each \(1 \leq i \leq r\), writing \(\partial\Sigma \cap T_i = a[m_i] + b[l_i] \in H_1(T_i; \mathbb{R})\), \(\mathcal{F}_\phi\) has \(\gcd(a, b)\) singularities in \(T_i\), each of which is a \([p_s q - q_s p]\)-prong, where \(p = \frac{a}{\gcd(a, b)}\), \(q = \frac{b}{\gcd(a, b)}\) and \(\gamma_i\) is the slope of the curve \(\gamma_i \subset T_i\). The type of the remaining singularity can be determined using the Euler-Poincaré formula.

Proof of Proposition 6.4. Let \([\Sigma] \in \mathbb{R} \cdot F \subset H_2(M_\phi, \partial M_\phi; \mathbb{R})\) be a fiber of \(M\), with monodromy \(\phi : \Sigma \to \Sigma\). We will use the following result of Fried (see [Fri82, McM00]): After an isotopy we have that

1. The fiber \(\Sigma\) is transverse to the flow lines of \(\psi\), and
2. The monodromy of the fibration determined by \([\Sigma]\) coincides with the first return map of the foliation \(\mathcal{F}\).

Hence the monodromies of any two points in \(\mathbb{R} \cdot F \subset H_2(M_\phi, \partial M_\phi; \mathbb{R})\) determine, up to isotopy, the same lamination \(L_\phi\). Let \(\tau \leftarrow D_n\) be a train track invariant by our given pseudo-Anosov homeomorphism \(\psi\). Up to isotopy we assume that \(\psi(\tau)\) is contained in a fibered neighborhood of \(\tau\) and transverse to the tie foliation. We assume that \(\tau\) carries the measured foliation \(\mathcal{F}\). Let \(L_\tau\) be the mapping torus of \(\tau\), namely \(L_\tau = \tau \times [0, 1]/(x, 1) \sim (\psi(x), 0))\).

The aforementioned result of Fried implies that the intersection \(\mathcal{F}_\phi = \Sigma \cap L_\phi\) defines an invariant measured foliation for \(\phi\) and \(\mathcal{F}_\phi\) is carried by the train track \(\tau_\phi = \Sigma \cap L_\tau\). By construction \(L_\phi\) is carried by the branched surface \(L_\tau\). For any singularity \(s\) of \(\mathcal{F}\), one obtains a simple closed curve \(\gamma_s \subset M\) which is the closed orbit of the flow line passing throughout \(s\). Notice that the union of all \(\gamma_s\) is the branched loci of \(L_\tau\). Since \(\mathcal{F}\) has no singularities in the interior of \(D_n\) all curves \(\gamma_s\) lies in \(T_i\) for some \(i\). Hence all the singularities of \(\mathcal{F}_\phi\) lies in \(\partial\Sigma \cap T_i\) which proves the first point of the proposition.

Now we determine the number and type of prongs of \(\tau_\phi\). For that we consider the number of prongs of \(\mathcal{F}_\phi\) at each component of \(\partial\Sigma \cap T_j\) for each \(j\) (clearly for a given \(j\) the type of the singularity at the component is the same). Let \(c[p/q] = p[m_j] + q[l_j] \in H_1(T_j; \mathbb{R})\) be the corresponding curve representing a connected component of \(\partial\Sigma \cap T_j\) (see Corollary 6.3). By the aforementioned result of Fried, each intersection between \(c[p/q]\) and \(\gamma_s\) contributes to \(k\)-infinitesimal edges (if \(s\) is a \(k\)-prong singularity). Hence total number of prongs of \(\mathcal{F}_\phi\) at \(\partial\Sigma \cap T_j\) is equal to

\[k \cdot i(c[p/q] \cdot \gamma_s)\]

Since the slope of \(\gamma_s\) is \(p_s/q_s\) one draws:

\[i(c[p/q] \cdot \gamma_s) = |p_s q - q_s p|\]

This ends the proof of Proposition 6.4. \(\square\)

We now address the case when \(\mathcal{F}\) has singularities in the interior of \(D_n\). Roughly speaking, the idea is to remove the interior singularities of \(\mathcal{F}\) to be in the context of the preceding case.

Note that in the definition of pseudo-Anosov homeomorphism we can remove or add punctures while keeping the “same” map \(\psi : S \to S\). More precisely when \(\{\psi^i(x)\}\) is a periodic orbit of unpunctured points, puncturing at \(\{\psi^i(x)\}\) refers to adding them to the puncture set \(\{p_i\}\). Conversely, when \(\{\psi^i(p)\}\) is a periodic orbit of \(k\)-prong punctured singularities for \(k > 1\), capping them off refers to removing them from the puncture set. For pseudo-Anosov braids, puncturing or capping off corresponds to adding or removing some strands.

Proposition 6.6 (\(\mathcal{F}\) has singularities in the interior of \(D_n\)). Puncturing at \(\{\psi^i(s)\}\) for any singularity \(s\) of \(\mathcal{F}\) in the interior of \(D_n\) gives rise to a pseudo-Anosov \(\tilde{\psi} : D_m \to D_m\) where \(m > n\). By construction \(\mathcal{F}_{\tilde{\psi}}\) has
no interior singularities. Moreover the injection $D_n \to D_m$ induces a map $M_φ \to M_\bar{φ}$ = $\bar{M}$ and each class $[Σ] \in \mathbb{R}^+ \cdot F \subset H_2(M, \partial M; \mathbb{R})$ (with with monodromy $φ$) determines a class $[\tilde{Σ}] \in \mathbb{R}^+ \cdot F \subset H_2(\tilde{M}, \partial \tilde{M}; \mathbb{R})$ with monodromy $\bar{φ}$.

The map $φ$ is obtained by capping the singularities of $\tilde{φ}$ that lie in the interior of $D_n$. In particular $T_φ$ and $T_\bar{φ}$ share the same number and type of singularities.

**Proof of Proposition 6.6.** The proof is clear from the definition of capping off and puncturing at singularities. □

6.3. **Orientability of singular foliation.** In this section we determine whether or not the measured foliation $T_φ$ is orientable. For that we will use the following well known theorem of Thurston:

**Theorem.** For any pseudo-Anosov homeomorphism $φ$ on a surface $Σ$ the following are equivalent:

1. The stretch factor of $φ$ is an eigenvalue of the linear map $φ_*$ defined on $H_1(Σ, \mathbb{Z})$.
2. The invariant measured foliation $T_φ$ of $φ$ is orientable.

To compute the homological dilatation we will make use of the Alexander polynomial. As the Teichmüller polynomial, the Alexander polynomial of $Σ$:

$$Δ_Σ = \sum_{g \in G} b_g \cdot g$$

is an element of the group ring $\mathbb{Z}[G]$, where $G = H_1(Σ, \mathbb{Z})/\text{Tor}$. For a precise definition see [McM02, §2]. The Alexander polynomial can be evaluated in an homology class $[Σ] \in H_2(M, \partial M; \mathbb{R})$ using Poincaré-Lefschetz duality and then proceeding as with the Teichmüller polynomial in the corresponding dual cohomology class. We have the following classical result (see e.g. [Mil68]):

**Theorem 6.7.** Let $[α] \in \mathbb{R}^+ \cdot F \subset H^1(M, \mathbb{R})$ with monodromy $φ : Σ \to Σ$. Then the characteristic polynomial of $φ_*$ acting on $H_1(Σ, \mathbb{Z})$ is given by the Alexander polynomial $Δ_Σ$ evaluated in $[α]$.

7. **First examples in $B_3$**

The goal of this section is to revisit classical examples, first studied by Hironaka [HK06], Kin-Takasawa [KT13] and McMullen [McM00]. We stress that the novelty in this section are the methods presented to perform calculations, and not the results of these. In the next sections we will address examples in $B_n$ for $n \geq 4$.

**Convention.** The natural order on $\mathbb{R}$ induces an order on the punctures of $D_n$ and thus a labeling. We label the infinitesimal edges enclosing punctures in $D_n$, from left to right, by $A, B, C$ so that $κ_{\text{prong}} = \{A, B, C\}$. Hence the standard generators $σ_1, σ_2$ (induced by left Dehn half-twists around loops enclosing the punctures) define the permutations $(A, B, C) \to (B, A, C)$ and $(A, B, C) \to (A, C, B)$ respectively.

7.1. **The simplest’s pseudo-Anosov braid.** We consider first the homeomorphism $ψ = f_{σ_1^{-1}σ_2}$ and treat this example in detail.

7.1.1. **Invariant train track.** It is well known that the isotopy class of $ψ$ is pseudo-Anosov. Indeed the homeomorphism $ψ$ leaves invariant the train track $τ_0$ presented in Figure 10 The map $f_{σ_1^{-1}σ_2}$ is then represented by the train track map $T : τ_0 \to τ_0$, defined by $a \to aab$ and $b \to ab$. The incidence matrix, $\left( \begin{array}{c} 1 \\ 1 \end{array} \right)$, is irreducible.

**Figure 10.** An invariant train track $τ_0$ for $f_{σ_1^{-1}σ_2}$.
We now quickly review how one can find a sequence of foldings discussed in the previous sections. For this purpose, consider the folding automaton and the two folding maps $F_{ba}, F_{ab}$ corresponding to the two standardizing homeomorphisms $f_{\sigma^{-1}}$ and $f_{\sigma^2}$ depicted in Figure 11.

![Figure 11. The folding automaton for $B_3$. The map $f_{\sigma^{-1}}$ is an isotopy (rotation in the neighborhood near punctures). Observe that the folding $F_{ba}$ induces a train track map $T_{ab}$ that represents $f_{\sigma^{-1}}$. The same is true for $F_{ba}$ with $f_{\sigma^2}$.

Remark 7.1. In the sequel, we will encode the folding automaton by representing the isotopy near the punctures by a permutation (see Definition 3.12 and Example 3.13). This defines a simpler automaton: see Figure 12.

![Figure 12. The folding automaton for $B_3$]. Note that the graphs $N_{lab}(\tau, h, \varepsilon)$ and $N(\tau, h)$ coincide: it has only one vertex and two edges represented by the two folding maps $F_{ab}$ and $F_{ba}$. For each edge we have represented the action of the standardizing braids on the punctures.

The two foldings $F_{ba}$ and $F_{ab}$ define two train track maps $T_{ba}$ and $T_{ab}$ (representing the two homeomorphisms $f_{\sigma^{-1}}$ and $f_{\sigma^2}$, respectively):

\[
\begin{align*}
\tau_0 &\xrightarrow{T_{ba}} \tau_0 \\
 a &\rightarrow a \\
 b &\rightarrow ba \\
\tau_0 &\xrightarrow{T_{ab}} \tau_0 \\
 a &\rightarrow ab \\
 b &\rightarrow a
\end{align*}
\]

whose incidence matrices are $M_{ba} := M(T_{ba}) = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ and $M_{ab} := M(T_{ab}) = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. To be more precise, one sees that in this very particular example $\tau_0$ is both invariant by $f_{\sigma^2}$ and $f_{\sigma^{-1}}$ and the associated train track
maps are given by $T_{ab}$ and $T_{ba}$. Hence the path in the automaton representing $f_{\sigma_1^{-1}\sigma_2} = f_{\sigma_1^{-1}} \circ f_{\sigma_2}$ has the train track map given by $T_{ba} \circ T_{ab}$. Therefore the incidence matrix is

$$M(T_{ba} \circ T_{ab}) = M_{ab} \cdot M_{ba} = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}.$$  

Observe that in this case the relabeling map involved is equal to the identity map. In the above situation, matrices belong to $\text{GL}(\mathbb{Z}^{ab\text{real}}) = \text{GL}(\mathbb{Z}^{a,b})$.

7.1.2. The Teichmüller polynomial. We now compute the Teichmüller polynomial of the fibered face containing the fibration defined by the suspension of $f_{\sigma_1^{-1}\sigma_2}$. Recall that $D_3$ is the complement of 3 round discs $D_A$, $D_B$ and $D_C$ lying along a diameter of the closed unit disc. The rank of the group $H$ is given by the number of cycles of the permutation induced by the action of $f_{\sigma_1^{-1}\sigma_2}$ on the boundary $[[\partial D_3]]_{\sigma \in \text{prong}}$. Since the braid $\beta = \sigma_1^{-1}\sigma_2$ permutes 3 strands cyclically, $H$ is isomorphic to $\mathbb{Z}$. Therefore $\pi : \tilde{D}_3 \to D_3$ is a $\mathbb{Z}$-covering. The infinite surface $\tilde{D}_3$ can be constructed by glueing $\mathbb{Z}$ copies of the simply connected domain obtained by cutting $D_3$ along three disjoint segments going from $D_A$ to the exterior boundary of $D_3$. These are the so called leaves of the covering $\pi : \tilde{D}_3 \to D_3$ (see §4.3). For our computations, we fix a labeling by $t \in \mathbb{Z}$ of the set of leaves forming $\tilde{D}_3$ that is coherent with the action of $\text{Deck}(\pi)$. This labeling induces a labeling for the edges and vertices of the infinite train track $(\tilde{\tau}_0, \tilde{h})$.

As noted before, the path in the automaton $\mathcal{N}(h, \tau_0)$ representing $f_{\sigma_1^{-1}\sigma_2}$ is $T_{ba} \circ T_{ab}$. In Figure 13 we depict the lift of each factor in this path to $\tilde{D}_3$.

![Figure 13. The lift of homeomorphisms induced by folding operations.](image)

The first train track map $T_{ab}$ corresponds to the homeomorphism $f_{\sigma_2}$. We choose the lift $\tilde{f}_{\sigma_2}$ of $f_{\sigma_2}$ that fixes the vertex $v_{fix}$, which in figure 13 is the vertex to the left. Equipped with this choice we get a train track map $\tilde{T}_{ab} : \tilde{\tau}_0 \to \tilde{\tau}_0$ induced by $\tilde{f}_{\sigma_2}(\tilde{\tau}_0) < \tilde{\tau}_0$. Similarly the train track map $T_{ba}$ represents the homeomorphism $f_{\sigma_1^{-1}}$ and we choose the lift $\tilde{f}_{\sigma_1^{-1}}$ of $f_{\sigma_1^{-1}}$ that fixes $v_{fix}$, which in figure 13 is the vertex to the right. This lift is represented by train track map $\tilde{T}_{ba} : \tilde{\tau}_0 \to \tilde{\tau}_0$. As we did in Example (5.7), a direct calculation shows that

$$w_1 = \eta_1(1, C^+) = (1, C^+), \text{ since } \eta_1(A, B, C) = (A, B, C),$$
$$w_2 = \eta_2(A^{-1}, 1) = (A^{-1}, 1) \text{ since } \eta_2(A, B, C) = \pi_1 \circ \eta_1(A, B, C) = (A, C, B),$$

In the particular case of this example, all punctures are permuted cyclically, hence $t(w_1) = (1, t)$ and $t(w_2) = (t^{-1}, 1)$. Theorem 5.4 then gives that the incidence matrix of the train track map $\tilde{T}$ representing $\tilde{f}_{\sigma_1^{-1}\sigma_2}$ is

$$M(\tilde{T}) = M(\tilde{T}_{ba} \circ \tilde{T}_{ab}) = \begin{pmatrix} 1 & 1 \\ 0 & t \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 + t^{-1} & t \\ 1 & t \end{pmatrix}.$$  

Therefore the characteristic polynomial is

$$\Theta_F(t, u) = u^2 - (1 + t + t^{-1})u + 1.$$  

Remark 7.2. From the preceding calculations it is easy to compute the Teichmüller polynomials associated to braids in $B_3$ that permute the strands cyclically (by considering products of $M(\tilde{T}_{ba})$ and $M(\tilde{T}_{ab})$, compare with [McM00] §11).
7.1.3. Evaluating the Teichmüller polynomial of $\sigma_1^{-1} \sigma_2$. First given a class $f_\beta \in \text{Mod}(D_n)$ we explain how to assign coordinates on $H^1(M; \mathbb{Z})$ such that the cohomology class corresponding to the fibration defined $f_\beta$ is $(0, \ldots, 0, 1)$. Following Section 6.1 we choose an ordered basis $B = \{[m_1], \ldots, [m_r]\}$ of $H_1(M; \mathbb{Z})$ formed by the meridians of the tori $T_1, \ldots, T_r$, respectively. Given that $H_1(M; \mathbb{Z})$ is torsion free, the base $B$ defines a base $B' = \{[s_1], \ldots, [s_{r-1}], [y]\}$ for $H^1(M; \mathbb{Z}) \cong \text{Hom}(H_1(M, \mathbb{Z}), \mathbb{Z})$ by duality. Here $s_i = m_i^*$ for $i = 1, \ldots, r - 1$ and $m_r = y$. Let $[S_i] = i(D_n)$ denote the class of the fiber of the fibration defined by $f_\beta$. The intersection of $[S_i]$ with $[m_i]$ is given by $\delta_{ij}$ and hence, using the Universal Coefficient Theorem and Poincaré duality, we deduce that the coordinates of $[S_i]^* \in H^1(M; \mathbb{Z}) \cong H_2(M, \partial M; \mathbb{Z})$ for the basis $B'$ are precisely $(0, \ldots, 0, 1)$. In the rest of the examples presented in this text we always choose the ordered basis $B'$. Remark that $\{[m_1], \ldots, [m_{r-1}]\}$ generate the $f_\beta$-invariant homology of the $r - 1$ punctured disc and $[m_r]$ corresponds to the natural lifting $\tilde{f}_\beta$ of $f_\beta$, hence we can identify $\{[m_1], \ldots, [m_{r-1}], [m_r]\}$ with the variables $\{t_1, \ldots, t_{r-1}, u\}$ of the Teichmüller polynomial (see Section 5.1). In the following figure we depict the link complement defined by $\sigma_1^{-1} \sigma_2$.

**Figure 14.** The link $\delta_2^1$ and the fiber of the fibration defined by $\sigma_1^{-1} \sigma_2$.

We now determine the Thurston norm for the case $\beta = \sigma_1^{-1} \sigma_2$. We achieve this by computing first the Alexander norm of $M = M_{f_\beta}$. Direct computation shows that the Alexander polynomial of $\beta$ is

$$
\Delta_M(t, u) = u + u^{-1} - (-t^{-1} + 1 - t)
$$

(7.11) well defined up to multiplication by a unit in $\mathbb{Z}[G]$ (see [McM02]). The Newton polygon $N(\Delta_M)$ of this polynomial is the symmetric diamond formed by the convex hull of the points $(0, \pm 1), (\pm 1, 0), (0, 0)$; its Newton polytope is the square of vertices $\{(\pm \frac{1}{2}, \pm \frac{1}{2})\}$. By Remark B.3 the unit ball of the Alexander norm is the square of vertices $\{(\pm \frac{1}{2}, \pm \frac{1}{2})\} \subset H^1(M; \mathbb{Z})$. Hence

$$
||\langle s, y \rangle||_A = \max(2s, 2y)
$$

for all $(s, y) \in H^1(M; \mathbb{Z})$. By theorems B.1, B.2 we conclude that the segment joining the points $(-\frac{1}{2}, \frac{1}{2})$ and $(\frac{1}{2}, \frac{1}{2})$ is the fiber face $F$ of the Thurston norm ball whose cone $\mathbb{R}^+ \cdot F$ contains the fibration defined by $\sigma_1^{-1} \sigma_2$. Hence

$$
||\langle s, y \rangle||_T = \max(2s, 2y)
$$

for all fibrations $(s, y) \in \mathbb{R}^+ \cdot F \cap H^1(M; \mathbb{Z})$.

We finally explain how to evaluate $\Theta_F$ in a point $(s, y) \in H^1(M; \mathbb{Z})$. Let $f_s, f_y : H_1(M; \mathbb{Z}) \to \mathbb{Z}$ be the duals of $[s]$ and $[y]$ respectively. Hence, the dual of a point $(s, y) \in H^1(M; \mathbb{Z})$ is given by $f_{(s,y)} := sf_y + yf_y$. Since by definition $f_{(s,y)}(u) = y$ and $f_{(s,y)}(t) = s$ one has

$$
\Theta_F(s, y) = X_{f_{(s,y)}(u)} - (1 + X_{f_{(s,y)}(t)} + X_{f_{(s,y)}(t^{-1})})X_{f_{(s,y)}(u)} + 1 = X^{2y} - (1 + X^s + X^{-s})X^y + 1
$$

7.1.4. The topology of the fiber. Let $\Sigma$ be the fiber of the fibration determined by the point $(s, y) \in \mathbb{R}^+ \cdot F$, where $F$ is the segment joining the points $(-\frac{1}{2}, \frac{1}{2})$ and $(\frac{1}{2}, \frac{1}{2})$. Since every fiber is (Thurston) norm minimizing in its homology class, we have:

$$
||\langle s, y \rangle||_T = |y| = -\chi(\Sigma) = 2\text{genus}(\Sigma) - 2 + \#\{\text{boundary components of } \Sigma\}.
$$
We calculate now the number of boundary components of $\Sigma$ as follows. We choose a basis $\{[S_1],[S_2]\}$ of $H_2(M, \partial M; \mathbb{Z})$ by taking two Seifert surfaces of the components of the $6_2$ link shown in Figure 14. By Remark 6.2, we have that

$$\partial_1[S_1] = l_1 - \text{Lk}(L_1, L_2)m_2 \quad \partial_1[S_2] = l_2 - \text{Lk}(L_2, L_1)m_1.$$  

A straightforward computation shows that $|\text{Lk}(L_1, L_2)| = |\text{Lk}(L_2, L_1)| = 3$. Letting $A = \left( \begin{smallmatrix} 0 & 3 \\ 1 & 0 \end{smallmatrix} \right)$, Proposition 6.1 implies that the number of connected components of $\partial \Sigma \cap T_j$ is $\text{gcd}(a_j, b_j)$ where $a = (s, y)A = (3y, 3s)$ and $b = (s, y)$. Therefore the total number of connected components of $\partial \Sigma$ is $\text{gcd}(3, s) + \text{gcd}(3, y) = \text{gcd}(3, s) + \text{gcd}(3, y)$. Plugging this data into (7.12), we get

$$\text{genus}(\Sigma) = |y| + 1 - \frac{\text{gcd}(3, s) + \text{gcd}(3, y)}{2}.$$  

With notations of Corollary 6.3, the slope of the boundary components are $3/s$ and $3/y$.

7.1.5. The singularities of the fiber. We already observed that $\Sigma$ has $\text{gcd}(3, s)$ boundary components at $T_1$ and $\text{gcd}(3, y)$ boundary components at $T_2$.

For any singularity $s$ of $F$ one needs to determine the slope of $\gamma_s \subset M$ where $\gamma_s$ is the closed orbit of the flow line passing throughout $s$. Since $F$ has no singularities in the interior of $D_n$, all curves $\gamma_s$ lie in $T_i$ for some $i$. We label the prongs with the capital letters $A, B, C$. One sees that the braid $\beta$ permutes the prongs $(A, B, C)$ to $(C, A, B)$. We denote the corresponding permutation $\pi(\beta)$. Since $\pi(\beta)$ has only one cycle, there is only one torus component (see Figure 15). Now when performing the pseudo-Anosov braid and isotopy, one needs to understand the rotation in the neighborhood near punctures (see Definition 3.12 and Example 3.12).

As usual one can obtain the permutation $\pi(\beta)$ as follows: for each elementary step we have a permutation encoding how the isotopy (rotation) acts in the neighborhood near punctures. More precisely:

$$\pi(\sigma_2) : (A, B, C) \to (A, C^+, B) \quad \text{and} \quad \pi(\sigma_1^{-1}) : (A, B, C) \to (B, A^-, C).$$

Composition gives the desired slope:

$$\pi(\beta) = \pi(\sigma_1^{-1}\sigma_2) = \pi(\sigma_2) \circ \pi(\sigma_1^{-1}).$$

Hence $\pi(\beta) : (A, B, C) \to (C^+, A^-, B)$ and so $\gamma = [l]$ i.e. its slope is $0/1$ (no Dehn twist around the meridian).

![Figure 15. Computing the slope of the curve $\gamma_p$](image)

Concretely the slope of $\gamma_p$ is $p/q = 0/1$. The slope for the other component $T_2$ is $1/0$. We apply Proposition 6.4 at each connected component of $\partial \Sigma \cap T_j$ as follows.

1. For $T_1$ (coordinate $t$): one has $(a_1, b_1) = (3y, s)$. Thus at each connected component (of the $\text{gcd}(3y, s)$ components) there is a singularity of $F_{\phi}$ of type $3y/\text{gcd}(3, s)$-prong.

2. For $T_2$ (coordinate $t$): one has $(a_2, b_2) = (3s, y)$. Thus at each connected component (of the $\text{gcd}(3s, y)$ components) there is a singularity of $F_{\phi}$ of type $y/\text{gcd}(3, y)$-prong.
7.1.6. Orientability of singular foliation. To compute the homological dilatation we will use the Alexander polynomial \( \Delta_M(t, u) = u^2 - u(1 - 1 - t) + 1 \) (up to a factor). By Theorem 6.7, the homological dilatation is the maximal root of \( \Delta_M \) (in absolute value) evaluated in \((s, y)\), namely it is the maximal root (in absolute value) of the polynomial:

\[
Q(X) = X^{2y} - (1 - X^s - X^{-s})X^y + 1, \quad y > s
\]

Recall that the stretch factor is the maximal root of

\[
P(X) = X^{2y} - (1 + X^s + X^{-s})X^y + 1.
\]

Since \( Q(-X) = P(X) \) when \( s \) is odd and \( y \) is even, we draw that the invariant measured foliation is orientable if \( s \) is odd and \( y \) is even.

In the rest of this paper we will focus only on computing the Teichmüller polynomials, for the rest (Thurston norm, topology of fibers and type of singularities) can be performed using the methods presented for the simplest pseudo-Anosov braid.

7.2. The Teichmüller polynomial of \( \sigma_2\sigma_1^{-1}\sigma_2 \in B_3 \). The link complement \( M = S^3 \setminus L(\beta) \) of the braid \( \beta = \sigma_2\sigma_1^{-1}\sigma_2 \) is homeomorphic to the magic manifold (see [KT13] for more details). This braid fixes one strand and permutes the other two, hence the \( H \)-covering \( \widetilde{D}_1 \) is a \( \mathbb{Z}^2 \)-covering. Let us denote by \((t_A, t_B)\) the variables of the deck transformation group of \( \pi: \widetilde{D}_3 \to D_3 \) corresponding to the permuted and fixed strands, respectively. From the automaton presented in Figure 12 one sees that the path in the automaton \( N(h, \tau_0) \) representing \( f_{\sigma_2\sigma_1^{-1}\sigma_2} \) is the composition of three folding maps. By Theorem 5.4 one has

\[
w_1 = \eta_1(1, C^+) = (1, C^+), \quad \text{since} \quad \eta_1(A, B, C) = (A, B, C),
\]

\[
w_2 = \eta_2(1, A^{-1}) = (A^{-1}, 1), \quad \text{since} \quad \eta_2(A, B, C) = \pi_1 \circ \eta_1(A, B, C) = (A, C, B),
\]

\[
w_3 = \eta_3(1, C^+) = (1, B^+), \quad \text{since} \quad \eta_3(A, B, C) = \pi_2 \circ \eta_1(A, B, C) = (C, A, B).
\]

Hence \( t(w_1) = (1, t_A) \), \( t(w_2) = (t_A^{-1}, 1) \) and \( t(w_3) = (1, t_B) \) and the incidence matrix of the train track map \( M(\widetilde{T}) \) representing a lift of \( f_{\sigma_2\sigma_1^{-1}\sigma_2} \) is

\[
M(\widetilde{T}) = \begin{pmatrix}
1 & t_A \\
0 & t_A
\end{pmatrix}
\begin{pmatrix}
t_A^{-1} & 0 \\
\end{pmatrix}
\begin{pmatrix}
1 & t_B \\
0 & t_B
\end{pmatrix}
= \begin{pmatrix}
t_A^{-1} + 1 & t_A t_B + t_B + t_B t_A^{-1} \\
1 & t_A t_B + t_B
\end{pmatrix}.
\]

Taking the characteristic polynomial we get

\[
\Theta_F(t_A, t_B, u) = u^2 - (t_A t_B + t_B + 1 + t_A^{-1})u + t_B.
\]

8. The Teichmüller polynomial of \( \sigma_1^{-1}\sigma_2\sigma_3 \in B_4 \)

8.1. Invariant train track. The homeomorphism \( f_{\tau_1^{-1}\tau_2\tau_3} \) is a pseudo-Anosov homeomorphism: it leaves invariant the train track \( \tau_1 \) (see Figure 16) and the train track map \( T : \tau_1 \to \tau_1 \) induced by \( f_{\tau_1^{-1}\tau_2\tau_3}(\tau_1) < \tau_1 \) is given by

\[
\begin{align*}
  a &\to cbaa \\
b &\to c \\
c &\to d \\
d &\to ba
\end{align*}
\]

Its incidence matrix \( M(T) = \begin{pmatrix}
2 & 1 & 1 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
1 & 1 & 0 & 0
\end{pmatrix} \) is irreducible. In Figure 16 we depict part of the folding automaton \( N(\tau_1, h) \).

In this part of the automaton we see three vertices \((\tau_i \mid i = 1, 2, 3, \) bolder train tracks). More precisely the (standard) folding \( F_{ab} \) induces a train track map \( T_1 : \tau_1 \to \tau_2 \) that represents \([\text{Id}] \in \text{Mod}(D_4)\). On the other hand the folding \( F_{cd} \) induces a train track map \( T_2 : \tau_2 \to \tau_1 \) that represents \([f_{\sigma_2\sigma_1}] \in \text{Mod}(D_4)\). Finally \( F_{bc} \) induces a train track map \( T_3 : \tau_1 \to \tau_1 \) that represents \([f_{\sigma_1^{-1} \sigma_2}] \in \text{Mod}(D_4)\). Hence the closed path representing \( f_{\tau_1^{-1}\tau_2\tau_3} \) is given by the sequence of train track maps in the labelled automaton

\[
(\tau_1, e_1) \xrightarrow{T_1} (\tau_2, e_2) \xrightarrow{T_2} (\tau_1, e_3) \xrightarrow{T_3} (\tau_1, e_3) \xrightarrow{R} (\tau_1, e_1)
\]
with the relabeling $R : (\tau_1, \varepsilon_3) \mapsto (\tau_1, \varepsilon_1)$. Direct computations gives (in the ordered basis $(a, b, c, d)$):

$$M(T_1) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad M(T_2) = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad M(T_3) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad M(R) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

We recover our incidence matrix $M(T)$ as $M(R \circ T_3 \circ T_2 \circ T_1) = M(T_1)M(T_2)M(T_3)M(R)$.

8.2. Teichmüller polynomial. We now calculate the Teichmüller polynomial of the fibered face containing the fibration defined by the suspension of $f_{\sigma_1^{-1} \sigma_2 \sigma_3}$. Since the braid permutes all the strands cyclically, $\pi : \tilde{D}_4 \to D_4$ is a $\mathbb{Z}$-covering. We now apply Theorem 5.4 step by step.

1. The folding $F_{ab}$ is standard, hence $v_1 = (1, 1, 1, 1)$ and this implies that $D_1$ is the identity matrix.
2. The folding $F_{ad}$ is not standard. Following definition 5.1 in $(\tau_2, \varepsilon_2)$ we have $f = a, f' = d \in N(T_2)$ hence we are in case 2. We conclude that $v_2 = (1, D, D, D)$. Since $\sigma_1^{-1} \sigma_2 \sigma_3$ permutes the strands cyclically, we have that $w_2 = (1, t, t, t)$. Therefore the matrix $D_2 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & t & 0 \\ 0 & 0 & 0 & t \end{pmatrix}$. 

![Figure 16](image1.png)

**Figure 16.** Detail of foldings and standardizing braids in the automaton in $B_4$.

![Figure 17](image2.png)

**Figure 17.** Detail of the labeled folding automaton in $B_4$. 

26 ERWAN LANNEAU AND FERRÁN VALDEZ
(3) The folding $F_{b_2}$ is not standard. Following definition \[S.1\] in$(\tau_3, \varepsilon_3)$ we have $f = b, f' = a \notin N(T_2)$ hence we are in case 1. We conclude that $v_3 = (A^{-1}, 1, 1, 1)$. Since $\sigma_1^{-1} \sigma_2 \sigma_3$ permutes the strands cyclically, we have that $w_2 = (r^{-1}, 1, 1, 1)$. Therefore the matrix $D_3$ is:

$$D_3 = \begin{pmatrix} r^{-1} & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Hence, the matrix whose characteristic polynomial is $\Theta_F$ is given by:

$$M(\tilde{T}) = M(T_1) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} M(T_2) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} M(T_3) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} M(R) = \begin{pmatrix} 1 + r^{-1} & t & t & 0 \\ 0 & 0 & t & 0 \\ 0 & 0 & 0 & t \\ 1 & t & 0 & 0 \end{pmatrix}$$

We conclude that the Teichmüller polynomial of $f_{\sigma_1^{-1} \sigma_2 \sigma_3}$ is:

$$\Theta_F(t, u) = u^4 - (1 + r^{-1})u^3 - (r^2 + r^3)u + r^2.$$ This calculation can also be performed without the use of elementary operations: $\tilde{T}_1$ is $f_{\sigma_1^{-1} \sigma_2 \sigma_3}$-invariant and the corresponding incidence matrix is precisely $M(\tilde{T})$ (see Figure 18).

![Diagram](image.png)

**Figure 18.** The lift of $f_{\sigma_1^{-1} \sigma_2 \sigma_3}$ to $\tilde{D}_4$

### APPENDIX A. AN INFINITE FAMILY OF BRAIDS.

We consider, for each $n \in \mathbb{N}$, $n > 0$, the braid $\beta_n \in B_{n+4}$ given by

$$\beta_n = \delta_n \delta_3 \sigma_1$$

where $\delta_n = (\sigma_1 \sigma_2 \cdots \sigma_{n+3})^{-1}$. Consider the train track $(\tau_1, \varepsilon_1)$ given by Figure [19] We have a train track map $(\tau_1, \varepsilon_1) \rightarrow (\tau_1, \varepsilon_1)$ representing $f_{\beta_n}$. The loop

$$(\tau_1, \varepsilon_1) \overset{T_1}{\rightarrow} (\tau_2, \varepsilon_2) \overset{T_2}{\rightarrow} \cdots \overset{T_{n+1}}{\rightarrow} (\tau_{n+1}, \varepsilon_{n+1}) \overset{T_{n+2}}{\rightarrow} (\tau_{n+1}, \varepsilon_{n+1}) \overset{R}{\rightarrow} (\tau_1, \varepsilon_1)$$

where:

1. The train track map $T_1$ is induced by folding the edge labelled $a_1$ onto the edge labelled $a_2$: It represents the braid $\sigma_1$.
2. For every $i = 2, \ldots, n + 1$ the train track morphism $T_i$ is induced by folding the edge labelled $a_{n+5-i}$ onto the edge labelled $a_1$ and then applying a standardizing braid, and
3. $T_{n+2}$ is induced by the braid $\delta_n$ since $\delta_n^{-1} \circ h(\tau_1)$ is standard, represents the train track map $T$, that is, $T = R \circ T_{n+2} \circ T_{n+1} \circ \cdots \circ T_2 \circ T_1$.

We easily obtain:

$$M(T_1) = \text{Id}_{b_{n+3}} + E_{a_1a_2},$$
$$M(T_i) = \text{Id}_{b_{n+3}} + E_{a_{n+5-i}a_1} \text{ for } i = 2, \ldots, n + 1,$$
$$M(T_{n+2}) = \text{Id}_{b_{n+3}}.$$
Since $T$ is a labeling by $\alpha, \beta$ we can draw (in the ordered basis $\{a_1, a_2, \ldots, a_{n+3}\}$):

$$M(R) = \begin{pmatrix}
1 & 0 & 0 & 0 & \cdots & \cdots & 0 \\
0 & 0 & 0 & 0 & \cdots & \cdots & 1 \\
0 & 1 & 0 & 0 & \cdots & \cdots & 0 \\
0 & 0 & 1 & 0 & \cdots & \cdots & 0 \\
\vdots & \vdots & \vdots & 0 & \cdots & \cdots & 0 \\
\vdots & \vdots & \vdots & \vdots & \cdots & \cdots & 0 \\
0 & 0 & 0 & 0 & \cdots & \cdots & 1 \\
\end{pmatrix}_{(a_1, a_2, \ldots, a_{n+3})}.$$

Therefore the incidence matrix $M(T)$ of the train track map $T$ is $M(T_1)M(T_2) \cdots M(T_{n+1})M(T_{n+2})M(R)$, whose characteristic polynomial is:

$$P(X) = X^{n+3} - X^{n+2} - \cdots - X + 1.$$

We now calculate the Teichmüller polynomial of the fibered face $F$ containing the fibration defined by the suspension of $f_{\beta}$. Since the braid permutes all the strands cyclically, $\pi : \widetilde{D}_n \to D_n$ is a $\mathbb{Z}$-covering and we fix a labeling by $t \in \mathbb{Z}$ of the set of leaves forming $D_n$ that is coherent with the action of $\text{Deck}(\pi)$.

One needs to compute the vectors $w_i = \eta(v_i)$ for $i = 1, \ldots, n+1$. The first case is similar to the situation discussed in other examples: $w_1 = v_1 = (1, B, 1, \ldots, 1)$. Hence $t(w_1) = (1, t, 1, \ldots, 1)$.

For the map $T_2$ one has $f = a_{n+3}$ and $f' = a_1$. On the other hand $f' \in N(T_2)$ thus we are in case 2 hence $v_2 = (X^{-1}, X^{-1}, 1)$. For the others vectors, for each $i = 3, \ldots, n+1$, we have $f = a_{n+5-i}$ and $f' = a_1$. Since $N(T_i) = 0$, $f' \notin N(T_i)$ and we are in case 1. Hence $(v_i)_{a_{n+5-i}} = X$ and $(v_i)_a = 1$ otherwise. Finally for $T_{n+2}$, one has $(v_{n+2})_t = X^{-1}$ for every $a$. In conclusion, a straightforward computation shows:

$$t(w_i) = (1, t, 1, \ldots, 1),$$

where the entry $t$ in $(w_i)$ occurs at position $n + 5 - i$.

We can apply Equation (5.6) to obtain $\Theta_F(t, u) = \det(u \cdot \text{Id} - M)$ where $M = M(T_1)D_1 \cdots M(T_{n+2})D_{n+2}M(R)$ where $D_i = \text{Diag}(t(w_i))$. Therefore we obtain

$$M = \begin{pmatrix}
\tau^{-2} & 0 & 0 & 0 & \cdots & \cdots & \tau^{-1} \\
0 & 0 & 0 & 0 & \cdots & \cdots & \tau^{-1} \\
0 & \tau^{-2} & 0 & 0 & \cdots & \cdots & 0 \\
\tau^{-2} & 0 & \tau^{-1} & 0 & \cdots & \cdots & 0 \\
\vdots & \vdots & 0 & \tau^{-1} & \cdots & \cdots & 0 \\
\vdots & \vdots & \vdots & 0 & \cdots & \cdots & 0 \\
\tau^{-2} & 0 & 0 & 0 & \cdots & \cdots & \tau^{-1} \\
\end{pmatrix}_{(a_1, a_2, \ldots, a_{n+3})}.$$

and its associated characteristic polynomial, that is the Teichmüller polynomial of $f_{\beta}$:

$$\Theta_F(t, u) = u^{n+3} - \tau^{-2} u^{n+2} - \tau^{-3} u^{n+1} - \cdots - \tau^{-(n+3)} u + \tau^{-(n+5)}.$$

**Remark A.1.** In figure 20 we depict lifts of the maps $f_{\sigma_1}$ and $f_{\delta_1}$, that we denote by $\widetilde{f}_{\sigma_1}$, $\widetilde{f}_{\delta_1}$, respectively.
The Thurston norm of a link complement can be computed directly in some simple examples (see for example [Thu86]). Our calculations will make use of the Alexander norm. The definition of this norm makes use of the Alexander polynomial. As the Teichmüller polynomial, the Alexander polynomial $\Delta_M = \sum_{g \in G} b_g \cdot g$ of $M$ is an element of the group ring $\mathbb{Z}[G]$, where $G = H_1(M, \mathbb{Z})/\text{Tor}$. The Alexander norm is defined on $H^1(M; \mathbb{R})$ by

\begin{equation}
\|\alpha\|_A := \sup_{b \neq 0 \neq b_0} \alpha(g - h)
\end{equation}

The next two theorems explain how the Alexander norm and Thurston norm are related.

**Theorem B.1** ([McM02]). Let $M$ be a compact, orientable 3-manifold whose boundary, if any, is a union of tori. If $b_1(M) \geq 2$ then for all $[\alpha] \in H^1(M, \mathbb{Z})$:

$$
\|\alpha\|_A \leq \|\alpha\|_T.
$$

Moreover, equality holds when $\alpha : \pi_1(M) \to \mathbb{Z}$ is represented by a fibration $\Sigma \to M_\psi \to S^1$, where $\Sigma$ has non-positive Euler characteristic.

**Theorem B.2** ([McM00]). Let $F$ be a fibered face in $H^1(M, \mathbb{R})$ with $b_1(M) \geq 2$. Then we have:

1. $F \subset A$ for a unique face $A$ of the Alexander unit norm ball, and
2. $F = A$ and $\Delta_M$ divides $\Theta_F$ if the lamination $L$ associated to $F$ is transversally orientable.

In particular, the Thurston and Alexander norms agree on integer classes in the cone over a fibered face of the Thurston norm ball. The condition “the lamination $L$ associated to $F$ is transversally orientable” is equivalent the following condition: there exist a fibration $\Sigma \to M_\psi \to S^1$ whose pseudo-Anosov monodromy fixes a projective measured lamination $[(l, \mu)] \in P\mathcal{ML}(\Sigma)$ which is transversally orientable. Equivalently, this last condition is equivalent to the orientability of a train track $\tau$ carrying $l$. From these theorems we can deduce the following simple fact: if $b_1(M) = 2$ and all faces of $B_T$ are fibered, then the Thurston and Alexander norms coincide. The effective calculation of the Alexander norm is possible thanks to the following obvious remark:

**Remark B.3.** Since the Alexander polynomial of a 3-manifold is symmetric the Alexander norm ball is dual to the scale by of factor of 2 of the Newton polytope of the Alexander polynomial.

For the sake of completeness we end this section discussing the Teichmüller norm and how it can also be used to calculate the Thurston norm. Fix a fibered face $F \subset H^1(M, \mathbb{R})$ and let $\Theta_F = \sum_{g \in G} a_g \cdot g$ be the corresponding Teichmüller polynomial. The Teichmüller norm (relative to $F$) is defined by:

\begin{equation}
\|\alpha\|_{\Theta_F} := \sup_{a_g \neq 0 \neq a_0} \alpha(g - h)
\end{equation}

**APPENDIX B. COMPUTING THE THURSTON NORM**

Figure 20. The lifts $\tilde{f}_{r_1}$, $\tilde{f}_{r_3}$ and $\tilde{f}_{r_5}$. Dotted lines indicate the action of $\tilde{f}_{r_3}$ and $\tilde{f}_{r_5}$.
Compare with [B.13]. The unit ball $\mathcal{B}_\Theta$ of the Teichmüller norm is dual to the Newton polytope $N(\Theta_F)$ of the Teichmüller polynomial [McM00]. Moreover,

**Theorem B.4 ([McM00]).** For any fibered face $F$ of the Thurston norm ball, there exists a face $D$ of the Teichmüller norm ball,

$$D \subset \{ [\alpha] \mid ||\alpha||_{\Theta_F} = 1 \}$$

such that $\mathbb{R}^+ \cdot F = \mathbb{R}^+ \cdot D$.

**APPENDIX C. BASIC TYPES**

In figure 21 we present the basic types that remain to complete the proof of theorem 5.4. To understand the picture it is important to consider:

1. For each basic type depicted in the figure we omit the basic type obtained by performing a reflection with respect to a vertical line. We have to take this ‘reflected’ basic types into consideration for the proof.
2. At most three infinitesimal edges are depicted, nevertheless the types presented can live in any punctured disc.
3. The little black dot on which in some basic types the real edges are incident needs to be changed, when constructing a train track from the basic type, by either a vertex or a multigon formed by infinitesimal edges.
