Abstract

*Hoplitis robusta* (Nylander) is a rare and poorly known osmiine bee species occurring in the subalpine zone of the Alps. The discovery of two nests of *H. robusta* in a thin branch of a dead fallen spruce on a sunny clearing of a subalpine spruce forest allowed the investigation of the nest architecture, the analysis of the larval diet and the assessment of the nest building material. X-raying, computed tomography and subsequent dissection of the nest branch revealed that the nests were built in L-shaped pupation tunnels of cerambycid beetles, which were probably cleaned from wood debris by the female bees with the aid of their large and powerful mandibles after nest site selection. The two nests contained five and six linearly arranged brood cells separated from each other by thin partitions built from masticated green leaves (“leaf pulp”). They were sealed at their opening by a thick plug consisting of several successive layers of leaf pulp constructed immediately behind each other. Microscopical analysis of the larval provisions of eight brood cells and of 41 pollen loads of females from museum and private collections showed that *H. robusta* exhibits a strong preference for the pollen of *Potentilla* (Rosaceae). Based on field observations, DNA metabarcoding of one nest plug and stereomicroscopic analysis of the leaf pulp matrix, *Potentilla* was also identified as an important source for the leaf pulp needed for nest construction, rendering *H. robusta* one of the few bee species known to collect floral resources and nest building material from the very same plant.

Zusammenfassung

*Hoplitis robusta* (Nylander) ist eine seltene und erst unzureichend erforschte Bienenart aus der Verwandtschaft der Mauerbienen (Osmiini). Sie kommt bei uns ausschliesslich in der subalpinen Stufe der Alpen vor. Die zufällige Entdeckung von zwei Nestern, welche sich in einem dünnen Ast einer umgestürzten toten Fichte auf einer sonnigen Lichtung eines subalpinen Fichtenwaldes befanden, ermöglichte die Analyse der Nestarchitektur, der Larvenvorräte und des Nestbaumaterials. Die Untersuchung des besiedelten Astes durch Röntgen, Computertomographie und anschliessende Präparation ergab, dass beide Nester in Hakengängen von Bockkäfern (Cerambycidae) angelegt worden waren, welche die Weibchen mit Hilfe ihrer ausgesprochen kräftigen Mandibeln wahrscheinlich vorgängig besäubert hatten. Die zwei Nester enthielten fünf bzw. sechs linienförmig hintereinander angelegte Brutzellen, die durch dünne Wände aus zerkauten Laubblättern (»Pflanzenmörteln«) voneinander getrennt waren. Die Nester wurden an ihrer Öffnung mit einem dicken Propfen verschlossen, der aus mehreren direkt hintereinander liegenden Wänden...
Introduction

Bees depend on several types of resources for their reproduction (Westrich 1989). They need suitable nesting sites to hide the brood cells, flowers to collect pollen and nectar and specific materials to build the nests. In some highly specialized Palearctic osmine bees (Megachilidae), floral resources and nest building material are harvested from the very same plants. In Haetosmia vechti flowers of Heliotropium (Boraginaceae) serve as the exclusive pollen source, while masticated green leaves of the same plant are used to construct the brood cells (Gottlieb et al. 2014). Similarly, several pollen specialist Hoplitis and Osmia species of the subgenera Anthocopa and Tergosmia, respectively, each build their brood cells from petals of their exclusive pollen host, such as Centaurea (Asteraceae) in Hoplitis saundersi, Convolvulus (Convolvulaceae) in H. perezi, Linum (Linaceae) in H. mocsaryi, Malvaceae in H. cristatula and H. jakovlevi, or Hedysarum (Fabaceae) in Osmia avosetta (Ferton 1890, 1892, 1894, 1897, Westrich 1989, Rozen et al. 2010, Müller 2018a, G. Le Goff personal communication). By exploiting the same plant for different types of resources, these bees likely avoid costs incurred by searching for and exploiting alternative plants. In the present contribution, we report on the dual function of Potentilla (Rosaceae) as a source for both pollen and nest building material for Hoplitis robusta (Nylander), a rare borealpine osmine bee.

Hoplitis robusta is a holarctic megachilid bee species of 6–9 mm length distributed in the boreal zone across Europe, Asia and North America with outposts in mountainous regions of the western USA and the Alps (Müller and Mauss 2016). In the Alps, H. robusta occurs from western Switzerland over northern Italy to eastern Austria, where it mainly inhabits open forests and windfalls between 1200 m a.s.l. and the timber line (Schwarz et al. 1996, Ebmer 1997, 2001, Amiet et al. 2004, Kopf 2008, SwissBeeTeam 2018). Among the osmiine bees, H. robusta belongs to the subgenus Formicaapis, which comprises three additional species all restricted to a comparatively small area that ranges from northern Mongolia and China to southeasternmost Russia and Korea, suggesting an eastern Asian origin of the subgenus (Müller and Mauss 2016).

The biology of Hoplitis robusta is only fragmentarily known, which is likely due to the species’ rare and scattered occurrence throughout the Alpine arc. Based on observations of individuals flying around dead spruces and wooden fences, H. robusta was assumed to nest in insect burrows in dead wood (Frey-Gessner 1880, 1908–1912). This assumption was later supported by the discovery of several nests built in drilled borings of artificial trap nest blocks in the Rocky Mountains/USA (Clement and Rust 1975). Still, however, no nests of H. robusta in a natural substrate have ever been found, neither in North America nor in Europe. A similar poor knowledge pertains to the host plant choice of H. robusta, which was completely unknown until recently, when Potentilla was identified as a seemingly important host based on the microscopic analysis of pollen contained in the metasomal scopal scopa of collected females (Müller and Mauss 2016). However, the low number of pollen samples analysed in the cited study renders it difficult to evaluate the true significance of Potentilla pollen in the species’ larval diet.

Numerous attempts to find nests of Hoplitis robusta in the Swiss Alps during the past decade – including the repeated exposure of bundles of hollow bamboo stems that imitated insect burrows in dead wood – failed. In Summer 2018, however, a female of H. robusta was by chance observed sealing her nest in a branch of a dead spruce. X-raying of the branch revealed the existence of a second nest of a different female within the same branch. The discovery of these first truly natural nests of H. robusta allowed the investigation of the nest architecture, the assessment of the nest building material and the analysis of the larval diet and prompted the analysis of additional female pollen loads, all aiming at getting a more complete picture of the life history of this rare and enigmatic alpine bee species.

Methods

The nests of Hoplitis robusta were discovered in the Calfeisen valley near St. Martin/St Gallen (46°55.455N, 9°21.305E) at an elevation of 1520 m a.s.l. on 27.6.2018. The nest branch was sawed off at its base and brought to the Animal Hospital of the University of Zurich, where it was X-rayed using a Bucky Diagnost CS/TH X-Ray (Philips) combined with a Profect CS Mammo-Reader (Fujifilm). In addition, the two nests were examined by computed tomography (CT) using a 16-slice CT Brilliance scanner (Philips). Following the X-ray and CT-examination, which enabled the exact localization of the nests within the branch, the nests were dissected with the
aid of a smoothing plane and a pocket knife to analyse their architecture and the nest contents.

The pollen host spectrum of *Hoplitis robusta* was assessed by microscopic analysis of the scopal pollen contents of 41 females from museum and private collections originating from 27 different localities distributed across the Alps and from three different localities in Finland. The pollen samples from the Alps (n = 15) analysed by Müller and Mauss (2016) were included in the present study and supplemented with numerous new samples (n = 26). In addition, remains of the larval provisions in eight brood cells of two nests were microscopically analysed. The methodology for pollen removal, manufacture of pollen samples, pollen identification and data evaluation follows Müller (2018b). For each brood cell, the proportions of the different pollen types were estimated to the nearest 10%. Pollen of *Fragaria* and *Potentilla* – two closely related genera within the “Potentillaceae” in palynology (Beug 2004). As *Fragaria vesca* L. – the only *Fragaria* species occurring in the subalpine habitats of *H. robusta* – flowers early in spring when the flight period of *H. robusta* has not yet started, all pollen grains of the *Potentilla* type were invariably assigned to the genus *Potentilla*.

To assess the source of the nest building material, DNA metabarcoding of the two nest plugs consisting of masticated green leaves (= “leaf pulp”) was performed by the ISO 9001:2008 certified and ISO 17025:2005 accredited laboratory of Eurofins Medigenomix GmbH (Ebersberg, Germany). DNA of 1 g plant material from each nest plug was extracted with the Maxwell 16 FFS nucleic acid extraction kit (Promega) following the manufacturer’s manual. From the extracted DNA, barcoding sequences of the nuclear marker ITS2 and the chloroplast marker trnL were PCR amplified using target specific next-generation sequencing primers and analysed by amplicon sequencing on the Illumina MiSeq platform. For unknown reasons, the extraction of amplifiable DNA from the plug of nest 1 failed. The amplified sequences from the plug of nest 2 were sorted into sequence sets according to their similarity, each represented by a master sequence. The master sequences were identified to species or genus level by comparing them with known plant sequences made available by the NCBI database. We refrained from performing metabarcoding of the cell partitions as they were heavily contaminated with pollen of the larval provisions. Instead, the leaf pulp matrix of all cell partitions and the outermost partition of the plug of nest 1 was still available after the unsuccessful DNA amplification (see above), was stereomicroscopically examined at a magnification of 40× and compared with the leave indument of plant species collected in a radius of 15 m around the nesting site on 16.9.2018.

Data on flower visits and sources of nest building material are based on field observations in the Swiss Alps near Visperterminen/Valais (46°15.00N, 7°55.50E), St. Martin/St Gallen (46°55.50N, 9°21.30E), Curaglia/Grisons (46°40.25N, 8°50.10E), Sedrun/Grisons (46°41.20N, 8°47.50E), Sent/Grisons (46°48.55N, 10°21.10E) and Vals/Grisons (46°36.90N, 9°11.80E) from 2010 to 2018. A “flower visit” is defined as one continuous observation of a single female irrespective of the number of flowers she visited.

**Results**

**Nesting site and nest architecture**

The two nests of *Hoplitis robusta* were found on a sunny clearing of a subalpine spruce forest (Fig. 3). They were situated in a 4 cm thick and 90 cm long branch of a dead fallen spruce (*Picea abies* (L.) H. Kars.) (Figs 4, 5), the nest entrances being in a distance of 31 cm (nest 1) and 20 cm (nest 2) from the branch base. Both nests were built in L-shaped pupation tunnels of an unknown cerambycid beetle species (Figs 6, 9, 10 and Suppl. materials 1, 2). The two L-shaped tunnels had a length of 6.5 cm and 5.7 cm and were oval in shape with a mean diameter of about 6 × 3 mm and 5.5 × 3 mm. Upon discovery of the nests, the female of nest 1 was finalizing the nest seal, whereas nest 2 was already finished. As the oldest bee larva in the innermost brood cell of nest 1 was in a slightly more advanced stage than the youngest larva in the outermost brood cell of nest 2 (Figs 9, 10), the two nests must have been built by two different females.

The two nests contained six and five linearly arranged brood cells all situated in the straight horizontal part of the L-shaped tunnel (Figs 6, 9, 10 and Suppl. materials 1, 2). The brood cells, whose length ranged from 5.5–7.5 mm, were separated from each other by 0.3–0.5 mm thin partitions constructed from leaf pulp without addition of any supplementary material (Fig. 11). Neither nest was sealed by a wall of leaf pulp against its rear end, the larval provision of the innermost brood cell directly contacted the wood at the bottom of the tunnel. In both nests, the outermost brood cell was not closed at its anterior end by a cell partition (Figs 9, 10), the distance between its base and the bottom of the nest plug measured 14 mm and 17 mm.

Both nests were sealed by a thick nest plug exclusively constructed from leaf pulp (Figs 12, 13). The two nest plugs had a length of 12 mm and 11 mm and consisted of ten and eight 1–2 mm thick partitions, which were built immediately behind each other (Fig. 6 and Suppl. materials 1, 2). The outermost plug partition consisted of more finely masticated leaves than the inner partitions; its exterior side was smoothed and about 2–3 mm behind the burrow entrance (Figs 7, 8).

**Pollen hosts**

*Hoplitis robusta* harvested the pollen of five plant families (Tab. 1). However, it exhibited a strong preference for *Potentilla* (Rosaceae) (Fig. 1), as revealed by the composition of both the female scopal loads and the brood cell provisions (Tab. 1, 2). In the scopal loads, pollen of *Potentilla* constituted 77.1% of the total pollen grain volume and it was recorded in 37 out of 41 loads, 26 of which

were pure loads. In the cell provisions, pollen of Potentilla was the exclusive constituent in six out of eight provisions, while two provisions additionally contained moderate amounts of pollen of Helianthemum (Cistaceae). Pollen collection by females of H. robusta at six different localities in the Swiss Alps (see Methods) was invariably observed on flowers of Potentilla erecta (L.) Raeusch. (n = 27 flower visits), except for two females that visited the flowers of Potentilla aurea L. and Ranunculus lanuginosus L., respectively. Pollen collecting females worked the Potentilla flowers in a rapid and efficient way (Fig. 1): they embraced the anthers below their body and – while turning slowly around the flower centre – picked up the pollen directly into the scopa by rapidly seesawing the underside of the metasoma against the anthers (Fig. 1); simultaneously, they sucked nectar from the base of the androecium.

**Nest building material**

Four females of Hoplitis robusta were observed in the Grisons near Sedrun on 1.8.2013, near Sent on 5.7.2016 and near Curaglia on 29.6.2018 harvesting material for nest construction from green leaves of Potentilla erecta. DNA metabarcoding revealed that the plug of nest 2 was constructed from masticated leaves of three rosaceous herb species including Potentilla erecta (Tab. 3).

**Table 1.** Pollen composition of female pollen loads of Hoplitis robusta. n = total number of pollen loads, N = number of pollen loads from different localities. Countries: A = Austria, CH = Switzerland, FIN = Finland. Plant families: AST = Asteraceae, CIS = Cistaceae, FAB = Fabaceae, RAN = Ranunculaceae, ROS = Rosaceae. Definition of bee host range after Müller and Kuhlmann (2008).

| Origin | n | N | % pollen grain volume | Preferred host | % pollen grain volume | % pure loads | % loads with preferred host | Host range |
|--------|---|---|-----------------------|----------------|-----------------------|-------------|-----------------------------|------------|
| A (2), CH (35), FIN (4) | 41 | 30 | 30% | Potentilla | 77.1% | 63.4% | 90.2% | polylectic (5 plant families) with strong preference for Potentilla (Rosaceae) |

**Table 2.** Pollen composition of larval provisions in eight brood cells of Hoplitis robusta from two nests owned by different females; in brood cells 1–3 of nest 2, the larvae had already devoured all provisions.

|       | Potentilla | Helianthemum |
|-------|------------|--------------|
| nest 1 | brood cell 1 | 90% | 10% |
|        | brood cell 2 | 100% | |
|        | brood cell 3 | 100% | |
|        | brood cell 4 | 90% | 10% |
|        | brood cell 5 | 100% | |
|        | brood cell 6 | 100% | |
| Nest 2 | brood cell 4 | 100% | |
|        | brood cell 5 | 100% | |
| Total  | 97.5% | 2.5% |

**Table 3.** Origin of the masticated green leaves used by Hoplitis robusta to build the plug of nest 2 based on DNA metabarcoding.

| Plant taxon          | % sequence reads |
|----------------------|------------------|
| Fragaria vesca (Rosaceae) | 50.9 |
| Potentilla erecta (Rosaceae) | 43.6 |
| Alchemilla spec. (Rosaceae) | 5.5 |

Figs. 14–16. 14) Leaf of Potentilla erecta. 15) Close-up view of leaf of Potentilla erecta with indumental hairs along the leaf margins and on the leaf surface. 16) Leaf pulp matrix of uppermost partition of the plug of nest 1 with numerous indumental hairs possibly originating from Potentilla and/or Fragaria.
North American nests were built in borings with a diameter of 4–5 mm and contained 3–14 linearly arranged and 5.5–11 mm long brood cells; the 0.3–1 mm thin cell partitions were constructed from masticated leaves and the 10–14 mm long nest plugs consisted of 8–13 successive layers of leaf pulp. However, in contrast to the findings of the present study, three North American nests contained 3–18 mm long vestibule cells following the last brood cell and some cell partitions had small pieces of wood embedded in the leaf pulp matrix. Whether the construction of vestibule cells and the combination of leaf pulp with additional material also occurs in European populations of *H. robusta* is unknown. Interestingly, nests of *Hoplitis maritima* (Romankova) – an eastern Asian representative of the subgenus *Formicapis* – were discovered in cerambycid beetle burrows in 4–5 cm thick branches of dead fallen conifers (Romankova 1985), exactly corresponding to the nesting sites of the two females of *H. robusta* in the Swiss Alps; these nests contained 2–6 linearly arranged brood cells and leaf pulp served as material for the construction of both cell partitions and nest plug. The identical nesting biologies of *H. robusta* and *H. maritima* suggest that the use of beetle burrows in dead wood as nesting site and of masticated leaves as nest building material are subgeneric traits of the subgenus *Formicapis*.

Females of *Hoplitis robusta* possess unusually large and powerful mandibles (Fig. 2). As such mandibles do not appear to be adaptive in collecting floral resources nor in harvesting and masticating green leaves, their function remains enigmatic. We hypothesize that these powerful mandibles have evolved as a tool to clean L-shaped pupation tunnels of cerambycid beetles immediately following nest site selection. After emergence, adults of cerambycid beetle species, which gnaw L-shaped tunnels in the last larval instar for pupation, use to leave behind substantial amounts of densely packed wood chips and fibres in the straight horizontal part of the tunnel (Fig. 17). The strong female mandibles might provide the needed strength to remove the wood debris out of the tunnel. A similar cleaning function has been hypothesized for the huge female mandibles of *H. maritima* (Romankova 1985, Müller and Mauss 2016).

**Pollen hosts**

The composition of the female scopal loads, the pollen content of the brood cells, field observations of flower visiting females and the highly efficient pollen collecting behaviour all suggest that *Hoplitis robusta* is strongly dependent on *Potentilla* (Rosaceae) for its reproduction. Since the pollen of *Potentilla* could not reliably be distinguished from that of *Fragaria* by the method used in the present study (see Methods), it cannot be excluded that *H. robusta* occasionally also exploits flowers of *Fragaria vesca*. However, as the flowering period of *F. vesca* and the flight period of *H. robusta* at most marginally overlap, *Fragaria* is not expected to be a regular pollen host of *H. robusta* in the Alps. A preference for the pollen of herbaceous Rosaceae has also been recorded for eastern Asian *Hoplitis* species of the subgenus *Formicapis: H.*

**Discussion**

**Nesting site and nest architecture**

The nest architecture of the two nests of *Hoplitis robusta* from the Swiss Alps corresponds well with that of nests found in drilled borings of artificial trap nest blocks in the Rocky Mountains/USA (Clement and Rust 1975). The six

Figure 17. L-shaped pupation tunnel of *Tetropium castaneum* (Cerambycidae) after emergence of the adult beetle with densely packed wood chips and fibers in the straight horizontal part of the tunnel (photo B. Wermelinger).
maritima is oligoelectic on Fragaria and Potentilla (Ro-
mankova 1985, Proshchalykin in Quest 2009), and sev-
eral pollen loads of H. excisa (Morawitz) were composed
of Rosaceae pollen, mainly of the Potentilla type (Müller
and Mauss 2016). This suggests that the preferential or
exclusive use of herbaceous Rosaceae as pollen hosts is a
subgeneric trait of Formicapis.

The larval provision of a single brood cell of Hoplitis
robusta from the Rocky Mountains/USA contained pollen
possibly from a legume, such as Astragalus or Trifolium
(Clement and Rust 1975). However, given the uncertainty
in pollen identification admitted by the authors and the
negligible amount of Fabaceae pollen in the larval diet of H.
robusta in the Alps (see Tab. 1), the larval provision might
possibly have consisted of pollen of the Potentilla type,
which – albeit distinctly smaller – has a similar morphology
and shape as pollen grains of Astragalus and Trifolium. This
assumption is in line with flower records of H. robusta from
North America, which originate mainly from herbaceous
Rosaceae, primarily Potentilla (Ascher and Pickering 2018).

Nest building material

The use of green leaves of Potentilla erecta as nest build-
ing material by Hoplitis robusta is documented both by
field observations and DNA metabarcoding and is also
suggested by the stereomicroscopic analysis of the leaf
pulp matrix, clearly indicating that Potentilla leaves play
an important role for the construction of cell partitions
and nest plugs in H. robusta. However, Potentilla was
not the exclusive source, two other rosaceous herbs were
also confirmed as suppliers of nest building material, i.e. 
Fragaria vesca and possibly to a lesser and only margin-
al degree Alchemilla spec. The fact that these three taxa
all belong to the Rosaceae is surprising and suggests that
the selection of leaves for manufacturing leaf pulp is far
from accidental and that the leaves of Rosaceae species
might possess particularly favourable properties as nest
building material. In fact, eight Central European osmi-
ine bee species belonging to two genera and six subgenera
were recorded to harvest leaf material for nest construction
from rosenaceous genera, such as Fragaria, Potentilla, Rosa
and/or Sanguisorba, i.e. Hoplitis (Alcidaeaea) claviventris
(Thomson), Osmia (Erythrosmia) andrenoides Spinola, O. (Helicosmia) aurulenta (Panzer), O. (Helicosmia) leatiana
(Kirby), O. (Hoplopsis) spinulosa (Kirby), O. (Melanos-
oria) parietina Curtis, O. (Melanosoria) pilicornis Smith
and O. (Neosmia) bicolor (Schrank) (Müller 1994, 2018a
and references therein, Prosi et al. 2016). Although the
very poor knowledge on the plant spectra exploited by
leaf masticating megachilid bees for nest construction ren-
ders any conclusions premature, it is well conceivable that
some species including H. robusta might be specialized
with respect to the plants they use for manufacturing leaf
pulp. Interestingly, experiments with the North American
Osmia bruneri Cockerell in flight cages recently revealed
that leaves of Malva neglecta and Sphaeralcea ambiguus
(both Malvaceae) as well as of Oenothera elata (Ona-
graceae) were readily accepted by the females as leaf pulp
sources, whereas those of Callirhoe involucrata and Hi-
biscus syriacus (Malvaceae) as well as of Cercis canadensis
(Fabaceae) were ignored, suggesting strong preferenc-
es for the plants exploited for leaf pulp (Cane submitted).

Conclusions

Among the Central European megachilid bees, Hoplitis
robusta is an exception in that it harvests floral resources
and nest building material from the very same plant tax-
on, i.e. Potentilla. Though the dependence on Potentilla
is not complete, neither for collecting floral resources nor
for harvesting nest building material, Potentilla plays a key
role in the life history of H. robusta. The findings of the
present study suggest that large stands of Potentilla erecta
in close neighbourhood to sun-exposed dead wood fulfill
all requirements for population survival of H. robusta in
the subsample zone of the Alps. Pollen of Potentilla is also
crucial for the reproduction of other alpine bee species.
Andrena tarsata Nylander and Panurginus herzi Moraw-
itz are strictly specialized on Potentilla, while in several
polylectic species, such as Andrena amieti Praz, Müller &
Genoud, Andrena coitana (Kirby) or Panurginus montanus
Giraud, pollen of Potentilla often represents a considerable
proportion of the collected pollen (Westrich 1989, Müller
2018b, Praz et al. submitted). Thus, species of Potentilla
and particularly P. erecta play a significant role in sustain-
ing populations of numerous bee species in alpine habitats.

Acknowledgements

We gratefully acknowledge the help of the following
colleagues who generously permitted pollen remov-
aland from Hoplitis robusta specimens of their collections
or under their curation: F. Amiet (Solothurn), H. Baur
(Naturhistorisches Museum Bern), R. Eastwood (ETH
Zürich), K. Hirt (Menziken), A. Freitag (Musée de Zo-
ologie Lausanne), F. Gusenleitner and M. Schwarz (Bi-
ologiezentrum Linz) and S. Liersch (Bündner Naturmu-
seum Chur). B. Wermelinger (WSL Birmensdorf) and U.
Bense (Mössingen) provided information on the biology
of Cerambycidae. J. Cane (Utah State University) made
a still unpublished manuscript on the leaf pulp sources of
Osmia bruneri available to us. T. Janke (Eurofins, Ebers-
berg) provided technical information on metabarcoding.
B. Wermelinger kindly provided the photo of figure 17.
Comments by Jack Neff, Stefan Dötterl and Jessica Lit-
man improved the manuscript.
