Wavelet Sparse Regularization for Manifold-Valued Data

Martin Storath, Andreas Weinmann

Abstract

In this paper, we consider the sparse regularization of manifold-valued data with respect to an
interpolatory wavelet/multiscale transform. We propose and study variational models for this task
and provide results on their well-posedness. We present algorithms for a numerical realization of
these models in the manifold setup. Further, we provide experimental results to show the potential
of the proposed schemes for applications.

Mathematical subject classification: 94A08, 90C90 65T60, 53B99, 53C35, 65K10.

Keywords: Manifold-valued Data, Sparse Regularization, Interpolatory Wavelets, Interpolatory Multiscale
Transforms, Denoising, Symmetric Spaces.

1 Introduction

In various problems of applied sciences the data take values in a manifold. Examples are circle and
sphere-valued data. They appear in interferometric SAR imaging [63], as wind directions [72], and
as orientations of flow fields [3, 75]. Further, in color image processing they appear in connection
with color spaces such as HSI, HCL, as well as in chromaticity based color spaces [27, 84, 59, 60].
Other examples are data with values in the special orthogonal group SO(3) which may express camera
positions or orientations of aircrafts [83], Euclidean motion group-valued data [70] representing,
e.g., poses as well as shape-space data [64, 20]. Another prominent manifold is the space of positive
(definite) matrices \( \text{Pos}_n \) of dimension \( n \) endowed with the Fisher-Rao metric [69]. For each \( n \in \mathbb{N} \),
\( \text{Pos}_n \) is a Cartan-Hadamard manifold which has nice differential-geometric properties. On the appli-
cation side, \( \text{Pos}_3 \) is the data space in diffusion tensor imaging [68] which allows the quantification
of diffusional characteristics of a specimen non-invasively [13, 56] and which is therefore helpful
in the context of neurodegenerative pathologies such as schizophrenia [41] and autism [6]. Another
application of positive matrices are deformation tensors; cf. [83].

There are various directions on processing manifold valued data. Manifold-valued partial differen-
tial equations have for instance been considered in [82, 29]. In particular, finite element methods
for manifold-valued data are the topic of [51, 71]. Work on statistics on Riemannian manifolds can
be found in [66, 22, 40, 23, 67, 39]. Optimization problems for manifold-valued data are for example
the topic of [2, 1, 48] and of [55] with a view towards learning in manifolds. We also mention related
work on optimization in Hadamard spaces [10, 9]. Nonsmooth variational methods for segmentation
and denoising using Potts and Mumford-Shah models for manifold-valued data were considered in
[92, 78]. TV functionals for manifold-valued data were considered in [42, 43, 44]; algorithmic
approaches for TV minimization were considered in [79, 61, 49, 91, 19, 77]. Examples of applications
of TV regularization for medical imaging tasks can be found in [15, 74, 16]. Recently, TV type reg-
ularization with indirect data terms, which in particular may be used to realize deconvolution models
in the manifold setting, has been considered in [76].

Interpolatory wavelet transforms for linear space data have been investigated by D. Donoho in [32]. Their analogues for manifold-valued data have been introduced by Ur Rahman, Donoho and their coworkers in [83]. Such transforms have been analyzed and developed further in [50, 47, 89]. Typically, the wavelet-type transforms employ an (interpolatory) subdivision scheme to predict the signal on a finer scale. The ‘difference’ between the prediction and the actual data on the finer scale is realized by vectors living in the tangent spaces of the predicted signal points which point to the actual signal values; i.e., they yield actual signal values after application of a retraction such as the exponential map. These tangent vectors then serve as detail coefficients. Subdivision schemes for manifold-valued data have been considered in [85, 45, 93, 88, 86]. Interpolatory wavelet transforms and subdivision are discussed in more detail in Section 2.1 below which deals with preliminaries. All the aforementioned approaches in this paragraph consider explicit schemes, i.e., the measured data is processed in a forward way using the analogues of averaging rules and diﬀerences on the coarsest scale. As already pointed out, the case \( q = 1 \) corresponds to the manifold analogue of the LASSO or \( l^1 \)-sparse regularization which, in the linear case, is addressed in [32].

In this paper, we consider wavelet sparse regularization for manifold-valued data. Let us brieﬂy describe the univariate situation here; details and the multivariate setup are considered in Section 2. Let \( f \in M^K \) be data living in the manifold \( M \) deﬁned on a discrete grid of length \( K \). We consider the problem (which, for \( q = 1 \), \( \alpha = 1 \), is a variant of the LASSO [80, 26] for manifold-valued data)

\[
\arg \min_{u \in M^N} \text{dist}(\mathcal{A}(u), f)^p + \mathcal{W}^{\alpha,q}_{\lambda}(u).
\]

Here, \( u \) denotes the argument to optimize for; it may be thought of as the underlying signal generating the response \( \mathcal{A}(u) \) where \( \mathcal{A} \) is a (necessarily) nonlinear operator which models for instance a system’s response. In the simplest case of pure denoising, \( \mathcal{A} \) may be implemented as the identity on \( M^N \). Further instances of \( \mathcal{A} \) are detailed in Section 2. Examples are the manifold valued analogues of convolution operators. The nearness between \( \mathcal{A}(u) \) and the data \( f \) is measured by

\[
\text{dist}(\mathcal{A}(u), f)^p = \sum_{i=1}^K \text{dist}(\mathcal{A}(u_i), f_i)^p
\]

which denotes the \( p \)-th power of the distance in \( M^K \). The parameter vector \( \lambda = (\lambda_1, \lambda_2) \) regulates the trade-oﬀ between the data fidelity, i.e., the distance to the data and the regularizing term \( \mathcal{W}^{\alpha,q}_{\lambda} \). Let us more precisely describe the term \( \mathcal{W}^{\alpha,q}_{\lambda} \) which is the central topic of the paper. We let

\[
\mathcal{W}^{\alpha,q}_{\lambda}(u) = \lambda_1 \cdot \sum_n \tilde{u}^q_{n,r}(u) \|d_{n,r}(u)\|_{\tilde{u}_{n,r}}^q + \lambda_2 \cdot \sum_n \text{dist}(\tilde{u}_{n-1,0}, \tilde{u}_{n,0})^q.
\]

Here the symbol \( \| \cdot \|_{\tilde{u}_{n,r}} \) denotes the norm induced by the Riemannian scalar product in the point \( \tilde{u}_{n,r} \), which is the point where the detail \( d_{n,r}(u) \) is a tangent vector at. The parameter \( \alpha \) is a smoothness parameter and the parameter \( q \geq 1 \) stems from a norm type term. The details \( d_{n,r} \) at scale \( r \) of the interpolatory wavelet transform for manifold valued data are given by

\[
d_{n,r} = d_{n,r}(u) = 2^{-r/2} (\tilde{u}_{n,r} \odot \tilde{u}_{n,r}), \quad \tilde{u}_{n,r} = S\tilde{u}_{n,r-1}.
\]

Here \( \tilde{u}_{n,r-1} = u_{2^{r-1}n} \) and \( \tilde{u}_{n,r} = u_{2^{r-1}n} \) (\( R \) the ﬁnest level) denote the thinned out target \( u \) at scale \( r - 1 \) and \( r \), respectively. The coarsest level is denoted by \( \tilde{u}_{n,0} = u_{2^n} \). \( S\tilde{u}_{n,r-1} \) denotes the application of an interpolatory subdivision scheme \( S \) for manifold-valued data to the coarse level data \( \tilde{u}_{n,r-1} \) evaluated at the index \( n \) which serves as prediction for \( \tilde{u}_{n,r} \). Then, \( \tilde{u}_{n,r} \odot S\tilde{u}_{n,r-1} = \exp_{\tilde{u}_{n,r-1}}^{-1} \tilde{u}_{n,r} \) denotes the tangent vector sitting in \( \tilde{u}_{n,r} = S\tilde{u}_{n,r-1} \) which points to \( \tilde{u}_{n,r} \). Here, we use the symbol \( \exp^{-1} \) to denote the inverse of the Riemannian exponential function \( \exp \). We point out that we use the normalization of the coeﬃcients \( d_{n,r} \) employed in [32] in the linear case. Details are discussed in Section 2.1. The second term addresses the coarsest scale; it measures the \( q \)-th power of the distance between the target items on the coarsest scale. As already pointed out, the case \( q = 1, \alpha = 1 \) in [1], corresponds to the manifold analogue of the LASSO or \( l^1 \)-sparse regularization which, in the linear case, is addressed
by (iterative) soft thresholding \([35]\). This choice \(q = 1, \alpha = 1\) is particularly interesting since it favors solutions \(u\) which are sparse w.r.t. the considered wavelet expansion. The manifold analogue of \(\ell^0\)-sparse regularization is obtained by using the regularizer

\[
W_0^1(u) = \lambda_1 \#\{(n, r) : d_{n,r}(u) \neq 0\} + \lambda_2 \#\{n : \tilde{u}_{n-1,0} \neq \tilde{u}_{n,0}\}.
\] (4)

The operator \(\#\) is used to count the number of elements in the corresponding set. Note that so the number of non-zero detail coefficients of the wavelet expansion is penalized. Similar to the linear case \([87, 35, 26]\), potential applications of the considered sparse regularization techniques are denoising and compression.

### 1.1 Contributions

The contributions of the paper are as follows: (i) we introduce and study a model for wavelet sparse regularization in the manifold setup; (ii) we provide algorithms for the proposed models; (iii) we show the potential of the proposed algorithms by applying them to concrete manifold-valued data. Concerning (i), we propose a variational scheme employing manifold valued interpolatory wavelets in the regularizing term. In particular, we consider a sparsity promoting \(\ell^1\) type term as well as an \(\ell^0\) type term. We obtain results on the existence of minimizers for the proposed models. Concerning (ii) we provide the details for an algorithmic realization of the proposed variational model. In particular, we apply the concepts of a generalized forward backward-scheme with Gauss-Seidel type update and a trajectory method as well as the well-established concept of a cyclic proximal point algorithm. To implement these schemes we derive expressions for the (sub)gradients and proximal mappings of the atoms of the wavelet regularizing terms. This includes the manifold analogues of \(\ell^1\) and \(\ell^0\) sparse wavelet regularization. Concerning (iii), we provide a detailed numerical study of the proposed scheme. We provide experiments with data living on the unit circle, in the two-dimensional sphere as well as in the space of positive matrices.

### 1.2 Outline of the paper

The paper is organized as follows. The topic of Section 2 is to derive a model for wavelet sparse regularization for manifold valued data and show its well-posedness. In Section 3 we consider the algorithmic realization of the proposed models. In Section 4 we provide a numerical investigation of the proposed algorithms. Finally, we draw conclusions in Section 5.

### 2 Model

In Section 2.1 we provide basic information on subdivision schemes and interpolatory multiscale transforms needed to define a variational model for wavelet sparse regularization for manifold valued data. In Section 2.2 we give a detailed formulation of the manifold analogue of the variational problem for wavelet sparse regularization. In Section 2.3 we obtain well-posedness results for the variational problem, i.e., we show that all considered problems have a minimizer.

#### 2.1 Preliminaries: Subdivision schemes, interpolatory multiscale transforms

We here provide information on subdivision schemes and interpolatory multiscale transforms we need later on.
**Subdivision schemes.** We consider the multivariate setup. The purpose of a subdivision scheme is to refine a grid function. More precisely, given a function \( p = (p_i)_{i \in \mathbb{Z}^d} \) which lives on a coarser \( s \) dimensional grid, a subdivision scheme \( S \) assigns a function \( Sp \) living on a finer \( s \) dimensional grid. Here, we use the multiindex notation \( i = (i_1, \ldots, i_d) \in \mathbb{Z}^d \) to specify the points in the domain of the grid functions. In case of dyadic refinement and a linear subdivision scheme, the assignment of \( Sp \) to data \( p \) is done via the rule

\[
Sp_n = \sum_{k \in \mathbb{N}^d} a_{n-2k} p_k, \quad \text{for } n \in \mathbb{Z}^s. \tag{5}
\]

Here, \( a = (a_i)_{i \in \mathbb{Z}^d} \) is called the mask of the subdivision scheme \( S \). We always assume that \( \sum_{i \in \mathbb{Z}^d} a_i = 1 \), which means that \( S \) reproduces constants. For simplicity, we will use dyadic refinement in the following. We point out, that our approach in this paper is also amenable for refinement using general dilation matrices; references dealing with subdivision schemes for more general dilation matrices are \([53, 54, 52, 90]\). In the following we are interested in interpolatory subdivision schemes. To explain the notion of an interpolatory scheme we notice that the mask \( a \) on an \( s \)-variate domain actually encodes \( 2^s \) convolution operators \( a^{(l)} = (a_{i+2l})_{i \in \{0, 1\}^s} \). A scheme is interpolatory if the convolution operator corresponding to the coarse level grid \( l = 0 \) is the identity operator. In formulas, this means that \( a_{2i} = \delta_{i0} \), for all \( i \in \mathbb{Z}^s \), were \( \delta \) denotes the Kronecker symbol which equals one if and only if the indices are equal, and zero else. Examples of interpolatory schemes are the well-known four-point scheme \([36]\) or the schemes of Delaunay and Dubuc \([32]\) with the particular instances of the first order interpolatory scheme and the third order interpolatory Deslaurier-Dubuc scheme given by the masks

\[
a = (\ldots, 0, 1 \frac{1}{2}, 1, \frac{1}{2}, 0, \ldots), \quad \text{and} \quad a = (\ldots, 0, -\frac{1}{16}, 0, \frac{9}{16}, 1, \frac{9}{16}, 0, -\frac{1}{16}, 0, \ldots), \tag{6}
\]

respectively. These are univariate schemes which can be adapted such as to work in any multivariate domain of dimension \( s \) by a tensor product construction: the mask \( a' \) of the multivariate scheme is given by \( a' = \prod_{i=1}^s a_{n_i} \) where \( a \) is the mask of the univariate scheme, and \( n \in \mathbb{Z}^s \) is a multiindex.

In recent years, there has been a lot of interest in nonlinear subdivision schemes and in particular in subdivision schemes dealing with geometric or manifold-valued data \([85, 45, 93, 88, 86]\). For geometric data, typically geometric analogues of linear subdivision schemes are considered. This means that the coefficients stored in the mask \( a \) are used to define a geometric scheme employing a manifold construction replacing the averaging operation in affine space. Examples of such constructions include geodesic averaging \([85]\), log-exp schemes \([83]\) and intrinsic means \([88]\). The latter have turned out to be particularly suitable \([86, 46, 47]\). For this reason, and due to their variational nature, we concentrate on geometric schemes based on intrinsic means. The intrinsic mean variant of the subdivision scheme \( S \) is given by

\[
Sp_n = \text{mean}(a_{n-2n}, p). \tag{7}
\]

The intrinsic mean in the manifold \( M \) is given by

\[
\text{mean}(a_{n-2n}, p) = \arg \min_{v \in M} \sum_j a_{n-2j} \text{dist}(v, p_j)^2. \tag{8}
\]

It replaces the affine average on the right hand side of \((5)\) (which is the affine space variant.) The coefficients of the scheme are the coefficients of mask \( a \) which are the same for a linear scheme and its geometric analogue. Although the subdivision operator \( S \) is nonlinear in the general manifold setting we omit the brackets in the notation \( Sa \) since this is particularly convenient in connection with index notation.

The first definition of the intrinsic mean can be traced back to Fréchet; a lot of work has been done by Karcher \([57]\). For details including an historic overview we refer to \([4]\); see also \([58]\). Due to its use as a means of averaging in a manifold, it is employed as a basic building in various works;
The mean mean($a_i, v$) is not unique for all input constellations. However, for data living in a small enough ball uniqueness is guaranteed. For a discussion, precise bounds and an extensive list of reference concerning this interesting line of research we refer to Afsari [4]. A reasonable way to deal with the nonuniqueness is to consider the whole set of minimizers in such a case. In this paper we do so where – in case of nonuniqueness – we add an additional constraint originating from our variational formulation described in Section 2.2.

**Interpolatory wavelet transforms.** Interpolatory wavelet transforms for data living in linear spaces have been considered by D. Donoho in [34]. To explain the idea, we consider grid functions $p_{nr}, p_{nr−1}$ at the finer scale $r$ and the coarser scale $r − 1$ which are related via $p_{2nr} = p_{nr−1}$ for all multiindices $n$ and levels $r$ (which might originate from point samples of a function $f$ defined on $\mathbb{R}^3$ with values in $\mathbb{R}$). The interpolatory wavelet transforms for real valued data in [34] are then defined by mapping the signal $p$ to the details

$$d_{n,r} = d_{n,r}(p) = 2^{sr/2} \left( p_{nr} \ominus \hat{p}_{nr} \right), \quad \hat{p}_{nr} = S p_{nr−1},$$

where $n$ is a multiindex, $\ominus$ denotes the ordinary subtraction in a vector space, and $S$ denotes a linear interpolatory subdivision scheme. Please note the slight abuse of notation in the expression $S p_{nr−1}$ which represents the scheme $S$ applied to the data $p_{nr−1}$ evaluated at the multiindex $n$. The transformation then maps

$$p_{nR} \mapsto (d_{n,R}, \ldots, d_{n,1}, p_{n,0}),$$

where $p_{nR}$ is a grid function at the finest scale used as input.

Interpolatory transforms for manifold-valued data have been introduced in [83]. In the manifold situation, we interpret (9) as follows: (i) the symbol $S$ denotes a geometric subdivision scheme $S$, here concretely the intrinsic mean analog given by (8) of a linear interpolatory scheme, e.g., a multivariate tensor product Deslaurier-Dubuc scheme; (ii) the symbol $\ominus$ is interpreted via the inverse of the Riemannian exponential mapping exp, concretely, $p_{nr} \ominus S p_{nr−1} = \exp_{Sp_{nr−1}}^{-1} p_{nr}$. We note that, in contrast to the real valued situation, where the tangent spaces at all points are naturally identified, the details now are tangent vectors with $d_{n,r}$ sitting in $Sp_{nr−1}$. Concerning analytic results for these transforms we refer to [50] [47] [89].

### 2.2 Wavelet Sparse Regularization in the Manifold Setup – Variational Formulation

The previously discussed interpolatory wavelet transforms are explicit means of processing data in the sense that analogues of averaging rules and differences in the manifold setting are applied to the data directly. In contrast, we here consider an implicit approach based on a variational formulation where the interpolatory wavelet transform is used as a regularizing term.

In the following, we always consider a complete and connected Riemannian manifold $M$ (with its canonical metric connection, its Levi-Civita connection). More precisely, we consider a manifold $M$ with a Riemannian metric which is a smoothly varying inner product $\langle \cdot, \cdot \rangle_p$ in the tangent space of each point $p$. According to the Hopf-Rinow theorem, the complete manifold $M$ is geodesically complete in the sense that any geodesic can be prolonged arbitrarily. The Levi-Civita connection is the only connection which is symmetric and which is compatible with the metric. For an account on Riemannian geometry we refer to the books [73] [33].

Extending the discussion started in the introduction, we derive a model for wavelet sparse regularization for manifold-valued data in the multivariate situation. We consider data $f \in M^K$, where
\[ K = (K_1, \ldots, K_s) \in \mathbb{R}^s \] denotes a multiindex consisting of \( s \) components. We propose to consider the problem

\[
\arg \min_{u \in \mathcal{M}^N} \text{dist}(\mathcal{A}(u), f)^p + W_A^{p,q}(u).
\]  

(11)

where the target variable \( u \in \mathcal{M}^N = \mathcal{M}_1 \times \ldots \times \mathcal{M}_s \) is a multivariate function defined on a regular grid, and, in contrast to (1), \( N = (N_1, \ldots, N_s) \in \mathbb{N}^s \) denotes a multiindex consisting of \( s \) components representing the \( s \)-dimensional domain of \( u \). For instance, for a classical image \( s = 2 \), and for a volume \( s = 3 \). Further, we use the usual multiindex notation to denote

\[
\text{dist}(\mathcal{A}(u), f)^p = \sum_{i=0}^{K-1} \ldots \sum_{i_r=0}^{K_r-1} \text{dist}(\mathcal{A}(u)_{i_1, \ldots, i_r}, f_{i_1, \ldots, i_r})^p
\]

(12)

the \( p \)th power of the distance in \( \mathcal{M}^K \). The parameter vector \( \lambda = (\lambda_1, \lambda_2) \) regulates the trade-off between the data fidelity, i.e., the distance to the data and the regularizing term \( W_A^{p,q} \). Possible choices of the imaging operator \( \mathcal{A} \) are discussed below.

Our central topic is the precise definition of the wavelet sparse regularizing term \( W_A^{p,q} \) in an \( s \)-variate situation. We assume that the signal dimensions \( N = (N_1, \ldots, N_s) \) and the scale level \( R \) are related via \( N = 2^k \cdot N' \) with the scalar \( R \) and the multiindices \( N, N' \). Then, the coarsest scale \( r = 0 \) has size \( N' = (N'_{1, \ldots, N'_{s}}) \) with \( N'_{i} \) data points in the \( v \)th component, \( 1 \leq v \leq s, v \in \mathbb{N} \). We define \( \tilde{u} \) by

\[
\tilde{u}_{n,r} = u_{2^n \cdot r,n}, \quad 0 \leq r \leq R.
\]

(13)

Here, \( n \) denotes a multiindex, which, in dependence on the scale \( r \), takes values in the range \( 0 \leq n < 2N' \). With the details \( d_{n,r}(u) = 2^{-sr/2} (\tilde{u}_{n,r} \ominus \tilde{u}_{n,r}) \) where \( \tilde{u}_{n,r} = S\tilde{u}_{n,r-1} \) defined by (9) of the interpolatory wavelet transform, we have

\[
W_A^{p,q}(u) = \lambda_1 \cdot \sum_{n,r} 2^{q} \left( a + \frac{s}{2} - \frac{s}{q} \right) |d_{n,r}(u)|_{\mathcal{M}_{n,r}}^q + \lambda_2 \cdot \sum_{n,i} \text{dist}(\tilde{u}_{n-i,0}, \tilde{u}_{n,0})^q.
\]

(14)

Here, \( \| \cdot \|_{\mathcal{M}_{n,r}} \) denotes the norm induced by the Riemannian scalar product in the points \( \tilde{u}_{n,r} = S\tilde{u}_{n,r-1} \), and we recall that the symbol \( s \) denotes the spatial dimension of the domain of \( u \). Concerning the second term which addresses the coarsest level, we let \( e_i = (\delta_{ij})_{1 \leq j \leq s^v, i \in 1, \ldots, s^v} \) be the \( i \)th unit vector. The term measures the \( q \)th power of the distance between neighboring data items on the coarsest scale w.r.t. any of the coordinate directions. We note that often three parameters \( \alpha, q, q' \) are considered in connection with the linear space analogue of the regularizer in (14), cf. [26]. In this respect, we here consider the particular case of \( q = q' \). As already pointed out we are particularly interested in the case \( q = 1 \) in (14), which corresponds to the manifold analogue of \( \ell^1 \)-sparse regularization.

The manifold analogue of \( \ell^1 \)-sparse regularization is given by using the regularizer

\[
W_A^q(u) = \lambda_1 \# \{(n,r) \setminus d_{n,r}(u) \neq 0\} + \lambda_2 \# \{(n,i) : \tilde{u}_{n-i,0} \neq \tilde{u}_{n,0}\}
\]

(15)

which incorporates the number of non-zero detail coefficients \( d_{n,r} \).

**Handling nonunique means.** For the definition of the details in (9) we use geometric subdivision schemes and we have defined geometric subdivision scheme using intrinsic means in (7). As explained above, intrinsic means are locally unique. (We note that it is often the case in differential geometry that the considered objects are only locally unique, e.g., geodesics.) To avoid complications, we add an additional constraint originating from our variational formulation. In case of non- uniqueness, we denote the set of all minimizers in (8) by \( S_{p,n} \) and single out those which minimize
the corresponding expression used to define \( \|d_{n,r}(u)\| \). More precisely, in such cases, we overload the previously given definition in (9) by

\[
d_{n,r}(u) = \left\{ \hat{d}_{n,r} : \hat{d}_{n,r} = 2^{-sr/2} (\hat{u}_{n,r} \otimes \hat{u}_{n,r}) , \hat{u}_{n,r} \in S \hat{u}_{n,r-1} , \hat{d}_{n,r} \in \arg \min_{d'_{n,r} \in S \hat{u}_{n,r-1}} \|d'_{n,r}\| \right\} .
\]

(16)

This means that we choose the details of smallest size (in the sense of the Riemannian metric).

**Instances of the imaging operator \( \mathcal{A} \).** We here discuss various instances of possible imaging operators to give an impression to the reader. The discussion is by no means complete. At first, letting \( \mathcal{A} \) be the identity in the manifold \( M^s \) corresponds to pure denoising. Inpainting situations can be modeled by removing the missing summands. Let us be more precise. To this end, let us consider a matrix \( A \) with real-valued entries \( a_{ij} \) given as

\[
A = \begin{pmatrix} a_{11} & \cdots & a_{1N} \\ \vdots & \ddots & \vdots \\ a_{K1} & \cdots & a_{KN} \end{pmatrix}
\]

(17)

\( i \)th positive row sums, i.e., \( \sum_j a_{ij} > 0 \) for all \( i = 1, \ldots, K \). (Note that we do not require the particular items \( a_{ij} \) to be nonnegative.) Here \( i, j, N, K \) can be read as multiindices. Using the matrix \( A \) as a kind of kernel, we may define the \( i \)th component of \( \mathcal{A}(u) \) by

\[
\mathcal{A}(u)_i = \text{mean}(a_{i,:}, u) = \arg \min_{v \in M} \sum_j a_{i,j} \text{dist}(v, u_j)^2.
\]

(18)

Then, the denoising situation corresponds to \( A \) being the identity and the inpainting situation corresponds to removing those rows of the identity matrix which correspond to missing data. But these are only special cases; actually, we can use any matrix \( A \) with positive row sums; see \([76] \). In particular, by this construction, we can realize the geometric analogue of any convolution operator which reproduces constants. Explicitly, in the bivariate situation (without multiindices), this reads

\[
\mathcal{A}(u)_{rs} = \arg \min \sum_{k,l} a'_{r-k, s-l} \text{dist}(v, u_{kl})^2,
\]

(19)

where \( a' \) denotes the bivariate convolution kernel. We further notice, that in the manifold case, where each data item can be more complex than a real number, also \( \mathcal{A} \) may denote an item/pixel-wise construction or reconstruction process. An example of such a pixel-wise construction process is the pixel-wise generation of diffusion tensor from DWI measurements in diffusion tensor imaging \([16] \). Another example in connection with shape spaces is \([74] \).

**Handling the boundary of the image or volume.** In the context of wavelets, classical means of dealing with data on a bounded domain consisting of a Cartesian product of intervals is to extend the data beyond the domain by either extending the data by 0 (zero-padding), by periodizing, or by extending the data by reflection. In the setup of interpolatory manifold valued data there is no distinguished zero-element such that the notion of zero padding does not generalize immediately. However, periodizing and extending the data by reflection are notions which directly carry over to the manifold and interpolatory setup. In the context of orthogonal and biorthogonal wavelets on the interval more sophisticated methods using tailored boundary rules have been developed. For details we refer to \([30] \) and the references therein. Inspired by these approaches for orthogonal and biorthogonal wavelets in the linear case, we use specially tailored boundary rules in experiments in this work. In particular, for a \( k \)th order linear univariate Deslaurier-Dubuc scheme, a natural boundary treatment consists of fitting a \( k \)th order polynomial to the \( k + 1 \) leftmost or rightmost data points, and evaluating these polynomials at the corresponding half-integers.
2.3 Existence of minimizers

We here derive results on the existence of minimizers for the variational problem (11) of wavelet sparse regularization using the regularizers $W^r(u)$ of (14) and $W^q(u)$ of (15). For the $W^r(u)$ regularizer with $\lambda_2 > 0$ we get the existence of minimizers without additional constraints on the measurement operator $\mathcal{A}$ and the manifold $\mathcal{M}$. This result is formulated as Theorem 3. For the $W^q(u)$ regularizer with $\lambda_2 = 0$ we need some additional constraints on $\mathcal{A}$. This result is formulated as Theorem 4. In particular, existence is guaranteed for the denoising situation with $\mathcal{A}$ being the identity. Finally, we give a corresponding existence result for wavelet sparse regularization using $\ell^0$ type regularizing terms in Theorem 6. We note that, for compact manifolds – which include the spheres in euclidean space, the rotation groups, as well as the Grassmannian manifolds – we get the existence of minimizers of the wavelet regularizers $W^r(u)$ regularizer with $\lambda_2 = 0$ and of the wavelet sparse regularizers $W^q(u)$ using $\ell^0$ type regularizing terms without additional constraints on the measurement operator $\mathcal{A}$.

We start with some preparation.

**Lemma 1.** The regularizing term $W^r(u)$ of (14) is lower semicontinuous.

*Proof.* In order to show that the sum in (14) is a lower semicontinuous function of $u$, it is enough to show that each member of the sum is a lower semicontinuous function of $u$. The members of the form $u \mapsto \text{dist}(\hat{u}_{n,-i,0}, \hat{u}_{n,0})^q$ are continuous by the continuity of the distance function dist. We show that the mappings $u \mapsto \|d_{n_i}(u)\|_{\ell^q_n}$ are lower semicontinuous functions on $\mathcal{M}^N$. To this end, we consider a sequence $(u^{(l)})_{l \in \mathbb{N}}$, each $u^{(l)} \in \mathcal{M}^N$, such that $u^{(l)} \to u$ in $\mathcal{M}^N$, as $l \to \infty$. Since the power function is increasing, it is sufficient to show that

$$\|d_{n_i}(u)\|_{\ell^q_n} \leq \liminf_l \|d_{n_i}(u^{(l)})\|_{\ell^q_n}, \quad \text{for all } n, r.$$  \hspace{1cm} (20)

Here, in case of non-unique details, we choose a realization $\hat{d}_{n_i}(u^{(l)}) \in d_{n_i}(u^{(l)})$ and a corresponding prediction $\hat{u}_{n_i}^{(l)} \in S\hat{u}_{n_i}^{(l)}$ according to (16). We note that, by (16), the value $\|d_{n_i}(u^{(l)})\|$ does not depend on the choice of $\hat{d}_{n_i}(u^{(l)})$.

Since, by assumption, $u^{(l)} \to u$ in $\mathcal{M}^N$, we find a point $x \in \mathcal{M}$ and a positive number $r$ such that all members $u^{(l)}_j$ together with all $u_j$, $j = 1, \ldots, N$, and $l \in \mathbb{N}$ are contained in a common ball $B(x, R')$ around $x$ with radius $R'$, or in other words, all members of all sequences are contained in a common bounded set. In particular, $u^{(l)}_{n_i,r-1} \in B(x, R')$, cf. (13). As explained in Section 2.1 a subdivision scheme encodes $2^s$ convolution operators with kernels given by $d^{(j)} = (a_{j+2l})$, $j \in \{0, 1\}^s$, where $a$ denotes the mask of the scheme. Each convolution operator is defined via the intrinsic mean; cf. (7) and (8). Hence, for each convolution operator defined via $d^{(j)}$, we may apply Lemma 2 to obtain a positive number $R_j$ such that all means mean($d^{(j)}_{n_i} \hat{u}_{n_i}^{(l)}$) are contained in a common ball $B(x, R_j)$. Taking the maximum of this radii $R = \max_j R_j$, w.r.t. the $2^s - 1$ averaging operators, where $s$ denotes the dimension of the domain, we have that all $\hat{u}_{n_i}^{(l)} \in S\hat{u}_{n_i}^{(l)}$ are contained in the common ball $B(x, R)$ for all $l \in \mathbb{N}$. Hence, the $\hat{u}_{n_i}^{(l)}$ form a bounded sequence. Further, the sequence $\hat{u}_{n_i}^{(l)}$ is bounded as well as a convergent sequence. As a next step, we choose a subsequence indexed by $l_k$ such that

$$\lim_k \|d_{n_i}(u^{(l_k)})\|_{\ell^q_n} = 2^{-sr/2} \lim_k \|\hat{u}_{n_i}^{(l_k)} \oplus \hat{u}_{n_i}^{(l_k)}\|_{\ell^q_n} = \liminf_l \|d_{n_i}(u^{(l)})\|_{\ell^q_n},$$  \hspace{1cm} (21)

and now invoke the boundedness of the sequences. By the Hopf-Rinow theorem, since $\mathcal{M}$ is assumed to be geodesically complete, we may extract convergent subsequences $\hat{u}_{n_i}^{(l_k)}, \hat{u}_{n_i}^{(l_k)}$ (which we, abusing notation for better readability, also denote by the indexation $n_k$) such that the limits

$$\nu_{n,r} := \lim_{k \to \infty} \hat{u}_{n_i}^{(l_k)}$$  \hspace{1cm} (22)
exist, and such that \( \tilde{u}_{n,r}^{(k)} \) converges to \( u_{n,r} \) since \( u^{(l)} \) is assumed to converge to \( u \). Since \( \| \tilde{u}_{n,r}^{(k)} \otimes \tilde{u}_{n,r}^{(l)} \|_{u_{n,r}} = \text{dist}(\tilde{u}_{n,r}^{(k)}, \tilde{u}_{n,r}^{(l)}) \), and the distance function is continuous, we have
\[
\| \tilde{u}_{n,r} \otimes v_{n,r} \|_{v_{n,r}} = \lim_{k} \| \tilde{u}_{n,r}^{(k)} \otimes \tilde{u}_{n,r}^{(l)} \|_{u_{n,r}} = 2^{sr/2} \lim_{l} \inf_{r} \| d_{n,r}(u^{(l)}) \|_{u_{n,r}},
\]
using (21) for the last identity. We next show that \( v_{n,r} \) is not in \( S \tilde{u}_{n,r-1} \). To see this, we assume towards a contradiction that \( v_{n,r} \) is not in \( S \tilde{u}_{n,r-1} = \text{mean}(a_{n-2}, \tilde{u}_{r-1}) \). Then, there is an element \( y \in \text{mean}(a_{n-2}, \tilde{u}_{r-1}) \) such that, by the definition in (8), \( \sum a_{n-r-2j} \text{dist}(y, \tilde{u}_{r-1})^2 < \sum a_{n-r-2j} \text{dist}(v_{n,r}, \tilde{u}_{r-1})^2 \).

Since \( \tilde{u}_{n,r} \rightarrow v_{n,r} \) as \( k \rightarrow \infty \) by (22), there is an index \( k_0 \) such that \( \sum a_{n-r-2j} \text{dist}(\tilde{u}_{n,r}^{(k)}, v_{n,r})^2 < \sum a_{n-r-2j} \text{dist}(\tilde{u}_{n,r}^{(k_0)}, v_{n,r})^2 \) which contradicts \( u_{n,r}^{(k_0)} \) being a minimizer of the corresponding sum. Hence \( v_{n,r} \in S \tilde{u}_{n,r-1} \). By the definition in (16) this implies \( \| \tilde{u}_{n,r} \otimes \tilde{u}_{n,r} \|_{u_{n,r}} \leq \| \tilde{u}_{n,r} \otimes v_{n,r} \|_{v_{n,r}} \) for any \( \tilde{u}_{n,r} \) as in (16). Hence, \( \| d_{n,r}(u) \|_{v_{n,r}} \leq 2^{sr/2} \| \tilde{u}_{n,r} \otimes v_{n,r} \|_{v_{n,r}} \). Together with (23), this implies
\[
\| d_{n,r}(u) \|_{v_{n,r}} \leq 2^{sr/2} \| \tilde{u}_{n,r} \otimes v_{n,r} \|_{v_{n,r}} = \lim_{l} \inf_{r} \| d_{n,r}(u^{(l)}) \|_{u_{n,r}},
\]
which means that the mappings \( u \mapsto \| d_{n,r}(u) \|_{v_{n,r}}^q \) are lower semicontinuous and, in turn, yields the assertion of the lemma.

Lemma 2. The \( \ell^0 \) type regularizing term \( W_{\lambda}^{\ell_0}(u) \) of (15) is lower semicontinuous.

Proof. We show that the mappings
\[
f_{n,r}^1 : u \mapsto \begin{cases} 1, & \text{if } d_{n,r}(u) \neq 0, \\ 0, & \text{else,} \end{cases} \quad f_{n,r}^2 : u \mapsto \begin{cases} 1, & \text{if } \tilde{u}_{n-r,0} \neq \tilde{u}_{n,0}, \\ 0, & \text{else.} \end{cases}
\]
are lower semicontinuous functions of \( u \). This implies the assertion of the lemma since \( W_{\lambda}^{\ell_0}(u) = \lambda_1 \sum_{n,r} f_{n,r}^1(u) + \lambda_2 \sum_{n,r} f_{n,r}^2(u) \). To see the lower semicontinuity of \( f_{n,r}^1(u) \), let \( u^{(l)} \rightarrow u \) in \( M^N \), as \( l \rightarrow \infty \). If \( f_{n,r}^1(u) = 0 \) there is nothing to show, so we assume that \( f_{n,r}^1(u) = 1 \). Then, \( u_{n-r,0} \neq \tilde{u}_{n,0} \), and since \( u^{(l)} \rightarrow u \), this implies \( u^{(l)}_{n-r,0} \neq \tilde{u}_{n,0} \) for sufficiently large \( l \). Hence, for sufficiently large \( l \), \( f_{n,r}^1(u^{(l)}) = 1 \), and therefore, \( \liminf_{l} f_{n,r}^1(u^{(l)}) \geq f_{n,r}^2(u) \). We next study the lower semicontinuity of \( f_{n,r}^2(u) \), and again let \( u^{(l)} \rightarrow u \). As above, if \( f_{n,r}^2(u) = 0 \), there is nothing to show. So we may assume that \( d_{n,r}(u) \neq 0 \), which means that \( \tilde{u}_{n,r} \neq S \tilde{u}_{n,r-1} \) by (16). We show that \( u_{n,r}^{(l)} \neq S \tilde{u}_{n,r-1}^{(l)} \) for sufficiently large \( l \) which then implies that \( f_{n,r}^2(u^{(l)}) = 1 \). Assume to the contrary, that there is a subsequence \( u_{n,r}^{(k)} \) such that \( u_{n,r}^{(k)} \neq S \tilde{u}_{n,r-1}^{(k)} \). Then, \( \lim_k u_{n,r}^{(k)} \) (which exists by our assumption) is a mean for data \( \lim_k u_{n,r}^{(k)} \). But this means \( \tilde{u}_{n,r} \neq S \tilde{u}_{n,r-1} \) which is a contradiction. Hence, \( f_{n,r}^1(u^{(l)}) = 1 \) for sufficiently large \( l \), and therefore \( \liminf_{l} f_{n,r}^1(u^{(l)}) \geq f_{n,r}^1(u) \). In summary, \( f_{n,r}^1 \) and \( f_{n,r}^2 \) are lower semicontinuous which implies that \( W_{\lambda}^{\ell_0} \) is lower semicontinuous.

Theorem 3. The variational problem (11) of wavelet sparse regularization using the regularizers \( W_{\lambda}^{\alpha,q} \) of (14) with \( \alpha \neq 0 \) has a minimizer.

Proof. By Lemma 1 \( W_{\lambda}^{\alpha,q} \) is lower semicontinuous. We consider a sequence of signals \( u^{(k)} \), and use the notation \( \text{diam}(u^{(k)}) \) to denote the diameter of \( u^{(k)} \). We show that \( W_{\lambda}^{\alpha,q}(u^{(k)}) \rightarrow \infty \), as \( \text{diam}(u^{(k)}) \rightarrow \infty \). To end this consider the sums \( \sum_{n,j} \text{dist}(\tilde{u}_{n-r,0}^{(k)}, \tilde{u}_{n,0}^{(k)})^q \) in (14). An note that \( \sum_{n,j} \text{dist}(\tilde{u}_{n-r,0}^{(k)}, \tilde{u}_{n,0}^{(k)})^q \geq \left( \max_{n,j} \text{dist}(\tilde{u}_{n-r,0}^{(k)}, \tilde{u}_{n,0}^{(k)}) \right)^q \). Further, \( \text{diam}(u^{(k)}) \leq C \max_{n,j} \text{dist}(\tilde{u}_{n-r,0}^{(k)}, \tilde{u}_{n,0}^{(k)}) \) where the constant \( C \) is smaller than \( N^r \mid N^r \mid + \ldots + N^r \mid N^r \) where \( N^r \) denotes the multiindex containing the dimensions of \( u \) on the coarsest scale; cf. the description near (13). Hence, \( \text{diam}(u^{(k)}) \leq C \sum_{n,j} \text{dist}(\tilde{u}_{n-r,0}^{(k)}, \tilde{u}_{n,0}^{(k)})^q \), with \( C \) independent of \( k \). Therefore, \( W_{\lambda}^{\alpha,q}(u^{(k)}) \leq CW_{\lambda}^{\alpha,q}(u^{(k)}) \), and so \( W_{\lambda}^{\alpha,q}(u^{(k)}) \rightarrow \infty \), as \( \text{diam}(u^{(k)}) \rightarrow \infty \). Together with the lower semicontinuity of \( W_{\lambda}^{\alpha,q} \) all requirements of (16) Theorem 1] are fulfilled and we may apply this theorem to conclude the assertion. \( \square \)
We note that a statement analogous to Theorem 3 does not hold for the regularizer $W^{\alpha,q}_\lambda$ of (14) with $\lambda_2 = 0$, since then coercivity cannot be ensured in general. To account for that, we give a variant of Theorem 3 which imposes some additional constraints to $\mathcal{A}$, but then also applies to the situation $\lambda_2 = 0$.

**Theorem 4.** The variational problem (11) of wavelet regularization using the regularizers $W^{\alpha,q}_\lambda$ of (14) with $\lambda_2 = 0$ has a minimizer provided $\mathcal{A}$ is an operator such that there is a constant $C > 0$ such that, for any signal $u$, the coarsest level of $u$ may be estimated by

$$\text{dist}(u_{n-e}, u_{n}) \leq C \max(\text{diam}(\mathcal{A}(u)), R(u)),$$

for all $n, i$. In particular, the problem (11) has a minimizer for $\mathcal{A}$ being the identity. Furthermore, the problem always has a solution, when the manifold $M$ is compact.

For the proof of Theorem 4, we employ [76, Theorem 7] which we here state for the reader’s convenience.

**Theorem 5.** Let $(l_0, r_0), \ldots, (l_s, r_s)$ be $S$ pairs of (a priori fixed) indices. We assume that $R$ is lower semicontinuous. We further assume that $R$ is a regularizing term such that, for any sequences of signals $u^n$, the conditions $\text{diam}(u^n) \to \infty$ and $\text{dist}(u^n_{l_i}, u^n_{r_i}) \leq C$, for some $C > 0$ and for all $n \in \mathbb{N}$ and all $s \in [0, S]$, imply that $R(u^n) \to \infty$. If $\mathcal{A}$ is an imaging operator such that there is a constant $C' > 0$ such that, for any signal $u$, $\text{dist}(u_{l_i}, u_{r_i}) \leq C' \max(\text{diam}(\mathcal{A}(u)), R(u))$, for all $s \in [0, S]$, then the variational problem

$$\arg \min_{u \in M^N} \text{dist}(\mathcal{A}(u), f)^p + \lambda R(u), \quad \lambda > 0,$$

has a minimizer.

The proof of Theorem 5 may be found in [76].

**Proof of Theorem 4.** We apply Theorem 5. The lower semicontinuity of the $W^{\alpha,q}_\lambda$ regularizer is shown in Lemma 1. Towards the other condition of Theorem 5, let $u^{(k)}$ be a sequence such that $\text{diam}(u^{(k)}) \to \infty$, and such that $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C'$ for some $C' > 0$, all $n$, $i$ and all $k \in \mathbb{N}$. We have to show that $W^{\alpha,q}_\lambda(u^{(k)}) \to \infty$. Towards a contradiction, assume that there is a subsequence $u^{(k)}$ of $u^{(k)}$ and $C'' > 0$ such that $W^{\alpha,q}_\lambda(u^{(k)}) \leq C''$, for all $l \in \mathbb{N}$. We show that there is a constant $C'''' > 0$ such that $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C''''$, for all $n$ and $i$. Since $W^{\alpha,q}_\lambda(u^{(k)}) \leq C''$, and since $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C'$, by the definition of the details, there is a constant $C_1$ such that $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C_1$, for all $n$, $i$ and all $l \in \mathbb{N}$. Applying induction on the lever $r$ there is a constant $C_R$ such that $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C_R$, for all $n$, $i$ and all $l \in \mathbb{N}$. Letting $C'''' = C_R$ and noting that the finest level signal $u^{(k)}_{R}$ equals $u^{(k)}$, yields that $\text{dist}(u^{(k)}_{n-e}, u^{(k)}_{n}) \leq C''''$, for all $n$ and $i$. This implies that $\text{diam}(u^{(k)})$ is bounded which contradicts $\text{diam}(u^{(k)}) \to \infty$. Hence, $W^{\alpha,q}_\lambda(u^{(k)}) \to \infty$ which allows us to apply Theorem 5 and, in turn, to conclude the existence of minimizers.

Concerning the case when $\mathcal{A}$ is the identity, we notice that $\text{dist}(u_{n-e}, u_{n}) \leq \text{diam}(u)$ which implies the condition (26). Hence, we may apply the already proved assertion to conclude the existence of minimizers in case $\mathcal{A}$ is the identity.

Concerning the case when the manifold $M$ is compact we note that the condition on $R$ in Theorem 5 is trivially fulfilled since the boundedness of $M$ implies that no sequence in $M^N$ can have diameters tending to $\infty$. Hence, we may apply Theorem 5 to conclude the existence of minimizers for compact manifolds $M$.

Finally, we give an existence result for the variational problem (11) of wavelet sparse regularization using $\ell^0$ type regularizing terms $W^{\alpha}_\lambda(u)$. □
Theorem 6. The variational problem (11) of wavelet sparse regularization using the $\ell^0$ type regularizing terms $W^0_\lambda(u)$ of (15) has a minimizer provided $\mathcal{A}$ is an imaging operator such that there is a constant $C > 0$ such that
\[
\text{diam}(u) \leq C \text{diam}(\mathcal{A}(u)).
\] (28)

In particular, the problem has a minimizer for $\mathcal{A}$ being the identity. Furthermore, the problem always has a solution, when the manifold $M$ is compact.

Proof. We consider the functional $\mathcal{F}(u) := \text{dist}(\mathcal{A}(u), f)^p + W^0_\lambda(u)$. The regularizing term $W^0_\lambda(u)$ is lower semicontinuous by Lemma [1] and the data term is lower semicontinuous by [76, Lemma 3]. Together, the energy $\mathcal{F}$ is lower semicontinuous. Assuming the condition (28), we show the coercivity of $\mathcal{F}$, i.e., we show that, for $\sigma \in MN$ and any sequence $u^{(k)}$ in $MN$, $\text{dist}(u^{(k)}, \sigma) \to \infty$ as $k \to \infty$ implies $\mathcal{F}(u^{(k)}) \to \infty$ as $k \to \infty$. Towards a contradiction suppose that $\mathcal{F}$ is not coercive. Then there is $\sigma \in MN$ and a sequence $u^{(k)}$ in $MN$, such that $\text{dist}(u^{(k)}, \sigma) \to \infty$ and such that $\text{dist}(\mathcal{A}(u^{(k)}), f)^p$ is bounded (by passing to a subsequence if necessary.) Then $\text{diam}(\mathcal{A}(u^{(k)}))$ is bounded. By assumption (28), $\text{diam}(u^{(k)})$ is then bounded as well, i.e., there is a constant $C' > 0$ such that $\text{diam}(u^{(k)}) < C'$ for all $k \in \mathbb{N}$.

Since $\text{dist}(u^{(k)}, \sigma) \to \infty$ and $\text{diam}(u^{(k)})$ is bounded we find for any given (ball radius) $C'' > C'$ a subsequence (indexed by $k_l$) of closed, disjoint balls $B_l$ such that all members of $u^{(k_l)}$ are contained in $B_l$, i.e.,
\[
\{ u_l^{(k_l)} : i = 1, \ldots, N \} \subset B_l, \quad B_l \cap B_{l'} = \emptyset \quad \text{for all } l, l' \in \mathbb{N}.
\] (29)

We next define a suitable (ball radius) $C''$. By [76, Lemma 2], since $u^{(k_l)}$ is contained in a ball of radius $C'$, then there is a constant $L \geq 1$ (which depends on the weights in $\mathcal{A}$) such that $\mathcal{A}(u^{(k_l)})$ is contained in in a ball of radius $LC'$. Accordingly, we choose $C'' := LC'$ and consider the balls $B_l$ of (30) of radius $C''$. Then,
\[
\{ \mathcal{A}(u_l^{(k_l)}) : j = 1, \ldots, K \} \subset B_l, \quad B_l \cap B_{l'} = \emptyset \quad \text{for all } l, l' \in \mathbb{N}.
\] (30)

As a result, $\text{dist}(\mathcal{A}(u^{(k_l)}), f)^p \to \infty$ which contradicts the assumption. Hence, the energy is coercive which, together with its lower semicontinuity, yields the existence of minimizers.

If $\mathcal{A}$ is the identity, the condition (28) is obviously fulfilled. Hence, we may apply the already proved assertion to conclude the existence of minimizers. If the manifold $M$ is compact, the functional is automatically coercive which together with its lower semicontinuity already observed above, yields the existence of minimizers for compact manifolds.

\section{3 Algorithms}

In the following we derive algorithms for the manifold valued variational problem (11) of wavelet regularization using the regularizers $W_{\lambda}^{\alpha,\sigma}(u)$ of (14) and $W_{\lambda}^{0}(u)$ of (15). We consider generalized forward-backward as well as cyclic proximal point algorithms. These basic algorithmic structures are presented and applied to the considered variational problems in Section 3.1. The differential geometric details to implement these structures for the present problems are given in Section 3.2. In particular, we there explain how to compute the derivatives and proximal mappings of the atoms of the involved wavelet regularizers.

\subsection{3.1 Algorithmic Structures}

We denote the functional in (11) by $\mathcal{F}$ and decompose both the data term $D$ and the regularizer $W_{\lambda}(u) = W_{\lambda}^{\alpha,\sigma}(u)$ or $W_{\lambda}^{0}(u)$ into atoms $D_i$ and $W_{n,r}$, i.e., we let
\[
\mathcal{F}(u) = D(u) + W_{\lambda}(u) = \sum_{i=1}^{K} D_i(u) + \lambda \sum_{r=0}^{R} \sum_{n\in\mathbb{N}} W_{n,r}(u)
\] (31)
with
\[ D_i(u) := \text{dist}(\mathcal{A}(u), f_i)^p, \] (32)
and, for level \( r \geq 1, \)
\[ W_{n,r}(u) = \begin{cases} \lambda_1 \cdot 2^{-q \left( \alpha + \frac{\alpha - 2}{2} \right)} \| d_{n,r}(u) \|_{\mathbf{a},r}, & \text{if } q \geq 1, \\ \lambda_1 \# \{ d_{n,r}(u) \neq 0 \}, & \text{if } q = 0. \end{cases} \] (33)

For level \( r = 0, \) we consider extended multiindices \( \tilde{n} = (n, i) \) and use the notation
\[ W_{\tilde{n},0}(u) = W_{(n,i),0}(u) = \begin{cases} \lambda_2 \cdot \text{dist}(\tilde{a}_{n-i,0}, \tilde{a}_{n,0})^q & \text{if } q \geq 1 \\ \lambda_2 \# \{ \tilde{a}_{n-i,0} \neq \tilde{a}_{n,0} \} & \text{if } q = 0. \end{cases} \] (34)

We note that the meaning of the employed symbols is explained near (14) and (15). We will omit the tilde notation of (34) in the following keeping in mind that the index \( n \) in \( W_{n,0} \) encodes a zeroth level index together with a direction whereas the \( n \) in \( W_{n,r}, r \geq 1, \) encodes an \( r \)th level index.

In the following we will employ the above decomposition into atoms within the proposed algorithms. More precisely, for each atom we will either apply a gradient step (which is possible for differentiable terms) or its proximal mapping within an iterative scheme. Here, the proximal mappings of a function \( f \) on a manifold \( M^N \) is given by
\[ \text{prox}_{\mu f} x = \arg \min_y f(y) + \frac{1}{2\mu} \| x - y \|_2^2, \quad \mu > 0. \] (35)

For general manifolds, the proximal mappings (35) are not globally defined, and the minimizers are not unique in general, at least for possibly far apart points; cf. [37, 8]. This is a general issue in the context of manifolds that are – in a certain sense – a local concept involving objects that are locally well defined. In case of ambiguities, a possibility is to consider the above objects as set-valued quantities.

**Generalized Forward Backward Scheme.** In [16], we have proposed a generalized forward backward algorithm for DTI data with a voxel-wise indirect data term. In [76], we have employed these schemes for the variational regularization of inverse problems for manifold-valued signals. To improve the method, we have proposed a variant based on a trajectory method together with a Gauß-Seidel type update strategy as well as a stochastic variant of the generalized forward-backward scheme there. We explain the ideas and apply the schemes to our regularizers.

The basic approach using a generalized forward-backward scheme is to decompose the considered functional \( \mathcal{F} \) into two summands \( \mathcal{F}(u) = \mathcal{F}^1(u) + \mathcal{F}^2(u) \) where the one summand \( \mathcal{F}^1 \) is differentiable, and the other summand \( \mathcal{F}^2 \) is further decomposed into atoms via \( \mathcal{F}^2(u) = \sum_k \mathcal{F}_k^2(u) \). The purpose is to find a decomposition such that, for each of these atoms \( \mathcal{F}_k^2 \), one has rather simple means to compute the proximal mappings. A generalized forward-backward scheme then performs an (explicit) gradient step for the differentiable term \( \mathcal{F}^1 \), as well as an (implicit) proximal mapping step for each atom \( \mathcal{F}_k^2 \) of the term \( \mathcal{F}^2 \). One instantiation in our situation of wavelet regularization is
\[ \mathcal{F}^1 = \mathcal{D} \quad (\text{with } p > 1), \quad \text{and} \quad \mathcal{F}^2 = \begin{cases} W^p_{\alpha,d}(u), & q \geq 1, \quad \text{or} \quad W^p_{\alpha,0}(u), \quad \text{with atoms } W_{n,r}, \end{cases} \] (36)

where the \( W_{n,r} \) are given by (33) and (34), respectively. We note that, for \( p > 1, \) the data terms \( \mathcal{D} \) are differentiable. Another possible instantiation in our situation is
\[ \mathcal{F}^1 = W^p_{\alpha,d}(u), \quad (\text{with } q > 1), \quad \text{and} \quad \mathcal{F}^2 = \mathcal{D} \quad (\text{with } p \geq 1), \quad \text{with atoms } D_i, \] (37)
where the $D_l$ are given by (32).

If the differentiable term $F^1$ also allows for an additive decomposition of the form $F^1(u) = \sum_k F^1_k(u)$ (which is the case in our examples above) the computation of the gradient of $F^1$ may be interpreted as computing the gradients of the atoms $F^1_k(u)$ and then to apply a Jacobi type update. Instead, one may use a Gauß-Seidel type update strategy instead of the Jacobi type update. This means that the result of computing the gradient of $F^1_k$ is already used as an iterate when computing the gradient of $F^1_{k+1}$. The advantage of the Gauß-Seidel type update strategy is that it is amenable for a trajectory method which is crucial for avoiding unreasonably small step sizes of the overall algorithm which limits its performance. (For a detailed discussion of these step size issues and its resolution we refer to the authors’ previous work [76].) Instead of computing only one (potentially large) gradient step, the trajectory method applied to an atom $F^1_k$ computes several smaller steps. More precisely, we define the trajectory operator $\text{traj}_\mu F^1_k$ applied to the atom $F^1_k$ for input $x_0$ (which may be thought of as the result for $F^1_{k-1}$) as the output $x$ of the following algorithm, i.e., $x = \text{traj}_\mu F^1_k(x_0)$ is given by

\begin{equation}
\text{Iterate w.r.t. } r \text{ until } \tau \geq 1:
\begin{align*}
x_r & := x_{r-1} + \tau_{r-1} \mu \nabla F^1_k(x_{r-1}); \quad \tau := \sum_{l=0}^{r-1} \tau_l \\
x & := x_{r-1} + \left(1 - \sum_{l=0}^{r-2} \tau_l\right) \mu \nabla F^1_k(x_{r-1})
\end{align*}
\end{equation}

Here, $\tau_{r-1}$ is a predicted step size for the gradient step at $x_{r-1}$ (which may be realized by a line search yielding a parameter with minimal functional value along the line.) Further $\mu > 0$ is a parameter. This scheme is inspired by solving initial value problems for ODEs. Instead of using a straight line we follow a polygonal path normalized by evaluating it at “time” $\tau = 1$. Using this trajectory method instead of a gradient step, we obtain the following generalized forward backward algorithm with Gauß-Seidel type update scheme.

\begin{equation}
\text{Iterate w.r.t. } n:
\begin{align*}
1. \text{ Compute } u^{(n+k'/2K')} & = \text{traj}_\mu F^1_k \left(u^{(n+(k'-1)/2K')}ight) \quad \text{for all } k' = 1, \ldots, K' ; \\
2. \text{ Compute } u^{(n+0.5+k/2K'')} & = \text{prox}_{\mu_n \nabla F^2_k} u^{(n+0.5+(k-1)/2K'')}, \quad \text{for all } k = 1, \ldots, K''.
\end{align*}
\end{equation}

As explained above $\text{traj}_\mu F^1_k(\cdot)$ denotes the application of the trajectory method defined by (38). During the iteration, the positive parameter $\mu_n$ is decreased in a way such that $\sum_n \mu_n = \infty$ and such that $\sum_n \mu_n^2 < \infty$.

We get the generalized forward backward algorithm for wavelet regularization (including wavelet sparse $\ell^0$ and $\ell^1$ regularization) for data terms with $p > 1$ by the scheme (39) with

\begin{equation}
F^1_k = D_{k'} \quad \text{(with } p > 1), \quad \text{and } F^2_k = F^2_{k(n,r)} = W_{n,r},
\end{equation}

where the $D_{k'}$ are given by (32), and where the $W_{n,r}$ are given by (33) and (34), respectively. The index mapping $k = k(n, r)$ serializes the pyramid like data of the wavelet scheme. Equation (40) is an adaption of the instantiation (36) above. The corresponding adaption (37) above is to apply the scheme (39) with

\begin{equation}
F^1_k = F^1_{k(n,r)} = W_{n,r}, \quad \text{(with } q > 1), \quad \text{and } F^2_k = D_k \quad \text{(with } p \geq 1).
\end{equation}

As above, where the $D_k$ are given by (32), the $W_{n,r}$ are given by (33) and (34), and $k' = k'(n, r)$ is the index mapping which serializes the pyramid like data of the wavelet scheme.
The Cyclic Proximal Point Scheme. Further, we consider proximal point algorithms which may also be used in the case \( p = 1 \) and \( q = 1 \). A reference for cyclic proximal point algorithms in vector spaces is \([21]\). In the context of Hadamard spaces, the concept of CPPAs was developed by \([11]\), where it is used to compute means and medians. In the context of variational regularization methods for nonlinear, manifold-valued data, they were first used in \([91]\) and then later in various variants in \([18, 12, 25]\). The basic idea of CPPAs is to compose the considered functional \( F \) into basic atoms and then to compute the proximal mappings of each of the atoms in a cyclic, iterative way. In the above notation we have the algorithm

Iterate w.r.t. \( n \) :

1. Compute \( u^{(n+k'/2K')} = \text{prox}_{\mu_n F^1_k} u^{(n+(k'-1)/2K')} \) for all \( k' = 1, \ldots, K' \); \hspace{1cm} (42)

2. Compute \( u^{(n+0.5+k/2K'')} = \text{prox}_{\mu_n F^2_k} u^{(n+0.5+(k-1)/2K'')} \), for all \( k = 1, \ldots, K'' \).

As above, the parameters \( \mu_n \) are chosen such that \( \sum_n \mu_n = \infty \) and such that \( \sum_n \mu_n^2 < \infty \).

We implement the cyclic proximal point algorithm for wavelet regularization by using \([40]\) in \([42]\). We note that we in particular use \([12]\) when both the exponent \( p \) of the power of the distance in the data term \( D \) equals one and the exponent \( q \) in \( W_p^p(u) \) of \([14]\) equals one, or when we consider \( p = 1 \) together with the regularizer \( W_0^0(u) \) of \([15]\), i.e., when we consider the analogues of wavelet \( \ell^1 \) or \( \ell^0 \) sparse regularization with an \( \ell^1 \) type data term.

Often the considered functionals are not convex; hence the convergence to a globally optimal solution cannot be ensured. Nevertheless, as will be seen in the numerical experiments section, we experience a good convergence behavior in practice. This was also observed in previous works such as \([18, 12]\) where the involved manifold valued functionals are not convex either.

Potential for Parallelization. We note that the algorithms given by the application of \([40]\) and \([41]\) in \([39]\) and \([42]\) are in many situations massively parallelizable with minor modifications. Concerning the wavelet terms \( W_p^p(u) \) of \([14]\) and \( W_0^0(u) \) of \([15]\) which the \( W_{n,r}(u) \) are based on, we notice that each item \( u \) directly contributes to at most two scales \( r \), and \( r + 1 \). On the finer scale \( r + 1 \), it only contributes to one member \( d_{n,r+1} \). Further, on the coarser scale \( r \) it directly contributes to at most \( A \) members \( d_{n,r} \), where \( A \) is the number of elements in the support of the mask \( a \) of the subdivision scheme \( S \) given in \([5]\). Hence, any two \( W_{n,r}, W_{n',r'} \) with \( |r - r'| > 1 \) may be computed in parallel. Further, \( W_{n,r}, W_{n',r'} \) (which corresponds to the case \( r' = r \)) can be computed in parallel whenever \( |n - n'| \geq A' \) where \( A' \) is the smallest integer such the the support of the mask \( a \) is contained in \( \{a', \ldots, A\}' \), where \( s \) is the dimension of the multivariate domain. Finally, \( W_{n,r}, W_{n',r+1} \) (which corresponds to the case \( r' = r + 1 \)) can be computed in parallel whenever \( |n' - 2n| \geq A' \), with the same \( A' \) as in the previous line. The computations for the data term \( D \) is parallelizable as well; for details we refer to the corresponding discussion in \([76]\). The resulting minor modification in the algorithms resulting from the parallelization of the wavelet term and the data term then consists of another order of applying the operations \( \text{traj}_{\mu_n F^1_k} \) and \( \text{prox}_{\mu_n F^2_k} \), or the operations \( \text{prox}_{\mu_n F^1_k} \) and \( \text{prox}_{\mu_n F^2_k} \), within the cycle \( n \).

3.2 Differential geometric derivation of the relevant gradients and the proximal mappings.

We here provide differential geometric expressions for the gradients and proximal mappings of the atoms derived and employed in the algorithms of Section 3.1. In particular, we provide a derivation of the gradients and proximal mappings of the atoms of the wavelet regularizers \( \mathcal{W}_p^p(u) \) of \([14]\) including the analogue of \( \ell^1 \) sparse wavelet regularization. Further, for the atoms of \( \mathcal{W}_0^0(u) \) of \([15]\).
Glischs of the atoms of the wavelet regularizers \( W^{α,δ}(u) \). We here derive expressions for the gradients of the atoms \( W^{α,δ}(u) \) of Equation (14) given in [33] and [34].

We first consider the zeroth level \( n = 0 \), and see how to compute the gradient of the corresponding mappings given by

\[
    u' \mapsto W_{n,0}(u') = W_{(n,i),0}(u') = λ_2 \cdot \text{dist}(\tilde{u}_{n-e_i,0}', \tilde{u}_{n,0})^q.
\]

Hence, we have to compute the gradient of the \( p \)-th power of the distance mapping \( d : y \mapsto \text{dist}(y, f)^p \), \( f \in M \). This gradient is given by (cf. [4]) \( \nabla d(y) = \frac{1}{p}||\exp_y^{-1}(f)||^{q-2} \exp_y^{-1}(f) \). Applied to our situation in [43], we have

\[
    \nabla W_{α,δ}(u)_{n',0} = \begin{cases} 
    \frac{1}{q} ||\exp^{-1}_{α_{n,0}}(\tilde{u}_{n,0})||^{q-2} \exp^{-1}_{α_{n,0}}(\tilde{u}_{n,0}), & \text{if } n' = n - e_i, \\
    \frac{1}{q} ||\exp^{-1}_{α_{n,0}}(\tilde{u}_{n-e_i,0})||^{q-2} \exp^{-1}_{α_{n,0}}(\tilde{u}_{n-e_i,0}), & \text{if } n' = n, \\
    0, & \text{else.}
    \end{cases}
\]

Concerning a general level \( r \neq 0 \), according to [33], we have to compute the gradients of the mappings

\[
    u \mapsto W_{n,r}(u) = λ_1 \cdot 2^{rq} \left(\frac{r+\frac{q-2}{2}}{q}\right) ||d_{n,r}(u)||^q_{\tilde{u}_{n,r}}.
\]

\( q \geq 1 \). By the definition of \( d_{n,r} \) in (16) and the properties of the exponential mapping we have that

\[
    ||d_{n,r}(u)||^q_{\tilde{u}_{n,r}} = 2^{-sr/2} \text{dist}(\tilde{u}_{n,r-1}, \tilde{u}_{n,r})^q = 2^{-sr/2} \text{dist}(\text{mean}(a_{n-2}, \tilde{u}_{r,j-1}), \tilde{u}_{n,r})^q.
\]

Hence, in order to obtain the gradient of the mapping in (45) w.r.t. the argument \( u \), we have to derive the gradients of the mappings

\[
    u_l \mapsto W_{n,r}(u) = λ_1 \cdot 2^{rq} \left(\frac{r+\frac{q-2}{2}}{q}\right) 2^{-sr/2} \text{dist}(\text{mean}(a_{n-2}, \tilde{u}_{r,j-1}), \tilde{u}_{n,r})^q,
\]

for all indices \( l \) of \( u \). For the index corresponding to \( \tilde{u}_{n,r} \), i.e., the index \( l_0 \) for which \( u_{l_0} = \tilde{u}_{n,r} \), we get by applying the above formula for the gradient of the distance function that

\[
    \nabla W_{n,r}(u)_{n,r} = \frac{λ_1}{q} \cdot 2^{rq} \left(\frac{r+\frac{q-2}{2}}{q}\right) \exp^{-1}_{α_{n,r}} \text{mean}(a_{n-2}, \tilde{u}_{r,j-1}) ||^{q-2} \exp^{-1}_{α_{n,r}} \text{mean}(a_{n-2}, \tilde{u}_{r,j-1}),
\]

Here, the lower index \( n, r \) denotes the component of the gradient corresponding to the variable \( \tilde{u}_{n,r} \) which corresponds to the \( l_0 \)th index of \( u \).

As the major task, we have to compute the gradient of \( W_{n,r} \) w.r.t. the variables \( \tilde{u}_{r,j-1} \). To this end, we notice that the mapping \( \tilde{u}_{k_0,r-1} \mapsto W_{n,r}(u) \) is the concatenation of the mean mapping

\[
    M : \tilde{u}_{k_0,r-1} \mapsto \text{mean}(a_{n-2}, \tilde{u}_{r,j-1}) = \arg \min_{x \in M} \sum_k a_{n-2k} \text{dist}(x, \tilde{u}_{k,r-1})^2
\]

and the \( q \)-th power of the distance mapping. Hence, by the chain rule and the rules of transposition, the gradient of \( W_{n,r} \) w.r.t. \( \tilde{u}_{k_0,r-1} \) is given by the application of the adjoint of the differential of the mapping \( M \) of (49) to the gradient of the distance function already presented above. So, let us consider the adjoint of the differential of the mapping \( M \) of (49). The point here is that the mapping \( M \) may not be written down explicitly, since the function value itself is the minimizer of a corresponding minimization problem which cannot be explicitly solved. However, we have found a rather explicit
representation of the differential of the mean mapping (and its adjoint) as a function of the points in $\mathcal{M}$. We here provide some explanation and notation and recall the corresponding statement in the notation of the present work then. We use the fact that every (weighted) mean $M(x_1, \ldots, x_K)$ of $K$ points $x_1, \ldots, x_K$, is a zero of the mapping $\mathcal{W}$, i.e.,

$$\mathcal{W}(x_1, \ldots, x_K, M(u_1, \ldots, u_K)) = 0,$$  \hspace{1cm} (50)

where the mapping $\mathcal{W} : \mathcal{M}^{K+1} \to \mathcal{TM}$ is defined as $\mathcal{W}(x_1, \ldots, x_K, m) = \sum_{j=1}^{K} a_{i-2j}exp_m^{-1}(x_j)$. Here, $\mathcal{TM}$ denotes the tangent bundle of $\mathcal{M}$. As a mapping of the argument $m$, $\mathcal{W}$ is a tangent vector field. (If there is a unique mean $M(x_1, \ldots, x_K)$ of $x_1, \ldots, x_K$, \hspace{1cm} (49) it is characterized by (50). In case of non-uniqueness, the characterization holds at least locally.) In $[76]$, we use the notation $\mathcal{W}$ for the function

$$\mathcal{W} : (x_1, \ldots, x_K) \mapsto \mathcal{W}(x_1, \ldots, x_K, M(x_1, \ldots, x_K)).$$ \hspace{1cm} (51)

and calculate the derivative of $\mathcal{W}$, which equals zero in view of (50) and so obtain a representation of the derivative of $M$. To formulate this representation we need the linear mappings $R_{k_0}$ and $L$, which are defined in terms of Jacobi fields. For defining $R_{k_0}$ we consider the Jacobi fields along the geodesic $\gamma$ connecting $\gamma(0) = m = \text{mean}(a_{n-2}, \tilde{u}, \ldots, \tilde{u})$ and $\gamma(1) = \tilde{u}_{k_0, r-1}$. As intermediate step, the mapping $R_{k_0}$ is given by the boundary to initial value mapping

$$r_{k_0} : \mathcal{TM}_{\tilde{u}_{k_0, r-1}} \to \mathcal{TM}_m, \hspace{0.5cm} J(1) \mapsto \frac{D}{dt}J(0),$$ \hspace{1cm} (52)

where the $J$ are the Jacobi fields with $J(0) = 0$ which parametrize $\mathcal{TM}_{\tilde{u}_{k_0, r-1}}$ via the point evaluation mapping $J \mapsto J(1)$. We note that this mapping is well-defined for non conjugate points which is the case for close enough points. We then let

$$R_{k_0}w := a_{n-2k_0}r_{k_0}w,$$ \hspace{1cm} (53)

for tangent vectors $w$ sitting at the point $\tilde{u}_{k_0, r-1}$. Next, we define the mapping $L$. To this end, let $\gamma_k$ be the geodesic connecting $\gamma_k(0) = m = \text{mean}(a_{n-2}, \tilde{u}, \ldots, \tilde{u})$ and $\gamma_k(1) = \tilde{u}_{k, r-1}$, for the indices $k$ in the $r-1$th level for which the weight is nonzero. For each geodesic $\gamma_k$, we consider the Jacobi fields $J_k$ with $J_k(1) = 0$ and the mappings

$$l_k : \mathcal{TM}_m \to \mathcal{TM}_m, \hspace{0.5cm} J_k(0) \mapsto \frac{D}{dt}J_k(0)$$ \hspace{1cm} (54)

where the Jacobi fields $J_k$ (with $J_k(1) = 0$) parametrize $\mathcal{TM}_m$ via the evaluation map $J_k \mapsto J_k(0)$. Again, we note that this mapping is well-defined for non conjugate points which is the case for close enough points. Then, we let

$$Lv := \sum_k a_{n-2k} l_k v,$$ \hspace{1cm} (55)

for tangent vectors $v$ in the point $m = \text{mean}(a_{n-2}, \tilde{u}, \ldots, \tilde{u})$. We have now gathered all information to formulate $[76]$ Theorem 11 adapted to the notation of the present work.

**Theorem 7.** The derivative of the intrinsic mean mapping w.r.t. the input variable $\tilde{u}_{k_0, r-1}$ in direction $w$ at $\mathcal{TM}_{\tilde{u}_{k_0, r-1}}$ is given by

$$\partial_{\tilde{u}_{k_0, r-1}}\partial M(u)w = -L^{-1}R_{k_0}w$$ \hspace{1cm} (56)

where the linear mapping $L$ is given by (55), and the linear mappings $R_{k_0}$, is given by (53).
Combining these results with (57) we can describe the gradients of the mappings \( W_{n,r} \) rather explicitly. We have

\[
\nabla W_{n,r}(u)_{n',r'} = \begin{cases} 
  s \exp_{\hat{a}_{n,r}}^{-1} \text{mean}(a_{n-2,r-1}) & \text{if } r' = r, n' = n, \\
  s R_{n'}^* L^{-1} \cdot \frac{\exp_{\text{mean}(a_{n-2,r-1})}^{-1} \hat{a}_{n,r}}{\|\exp_{\text{mean}(a_{n-2,r-1})}^{-1} \hat{a}_{n,r}\|^2}, & \text{if } r' = r - 1, n - 2n' \in \text{supp } a, \\
  0 & \text{else},
\end{cases}
\]

where

\[
s = \frac{\lambda_1}{q} \cdot 2^r \left( \frac{n - \frac{q}{2}}{2^r} \right)^{2^{r}/2}.
\]

(58)

Here, \( R_{n'}^* \) denotes the adjoint of \( R_{n'} \) given by (53). \( L^{-1} \) denotes the adjoint of \( L^{-1} \) given by (55), the symbol \( \text{supp} \) is used to denote the support of the mask \( a \) of the subdivision scheme, and the condition \( n - 2n' \in \text{supp } a \) means that \( u_{n-1,n'} \) contributes to the computation of \( \hat{a}_{n,r} \), i.e., the corresponding weight \( a_{n-2,n'} \) for averaging is nonzero.

If the manifold \( M \) is a Riemannian symmetric space, the Jacobi fields needed to compute the mappings \( R_{\gamma_0} \), and \( L \) in the above theorem can be made more explicit. This is as well discussed in [76], and we here only state the corresponding results for completeness. In particular, we observe that basically a series of low dimensional eigenvalue problems (instead of ODEs) has to be solved. As a reference on symmetric spaces we refer to [28]. We consider the geodesic \( \gamma \) and the Jacobi fields \( J \) with \( J(0) = 0 \) along \( \gamma \). Then the numerical task is to compute an orthonormal basis \( (w_i) \) of eigenvectors together with corresponding eigenvalues \( (\lambda_i) \) of the self-adjoint Jacobi operator \( J \mapsto R((\gamma(0), J)(\gamma'(0))) \), where \( R \) denotes the Riemannian curvature tensor. In terms of this eigen-decomposition the adjoint \( R_{\gamma}^* \) can then be written using the functional calculus together with a spectral mapping theorem, i.e., \( R_{\gamma}^* \) is given by

\[
w = \sum_i \alpha_i w^i \mapsto R_{\gamma}^* w = a_{n-2} \sum_i \alpha_i f_1(\lambda_i) pt_{\mu,\tilde{u}_{k,r-1}} w^i,
\]

(59)

where \( f_1(\lambda_i) = 1 \) if \( \lambda_i = 0 \), \( f_1(\lambda_i) = \frac{\sqrt{\lambda_i} d}{\sinh(\sqrt{\lambda_i} d)} \), if \( \lambda_i > 0 \), and \( d < \pi / \sqrt{\lambda_i} \), and where \( f_1(\lambda_i) = \frac{\sqrt{-\lambda_i} d}{\sinh(\sqrt{-\lambda_i} d)} \), if \( \lambda_i < 0 \), with \( d = \text{dist}(m, \tilde{u}_{k,r-1}) \). Here, \( pt_{\mu,\tilde{u}_{k,r-1}} w^i \) denotes the parallel transport of the basis vector \( w^i \) from the point \( m = \text{mean}(a_{n-2}, \tilde{u}_{r-1}) \) to the point \( \tilde{u}_{k,r-1} \). (For the parallel transport, there are typically closed form expressions in a symmetric space.) Similarly, but even without parallel transport, we may compute the adjoints \( \ell_{\gamma}^* \) defined by (54) which yield the adjoint \( L^* \) via \( L^* v := \sum_k a_{n-2} \ell_{\gamma}^* v \), cf. (55).

We consider the geodesics \( \gamma_k \) we used above for (54) to connect \( m = \gamma(0) \) and \( \tilde{u}_{k,r-1} = \gamma(1) \), and the orthonormal basis \( (w^\alpha) \) of eigenvectors of the self-adjoint Jacobi operator \( R \) w.r.t. the geodesic \( \gamma_k \) and the above Jacobi fields \( J \) with \( J(1) = 0 \). We get, for \( \ell_{\gamma}^* : \mathcal{T} \mathcal{M}_n \rightarrow \mathcal{T} \mathcal{M}_n \),

\[
\ell_{\gamma}^* : w = \sum_i \alpha_i w^i \mapsto \ell_{\gamma}^* w = \sum_i f_2(\lambda_i) \alpha_i w^i,
\]

(60)

where \( f_2(\lambda_i) = -1 \), if \( \lambda_i = 0 \), where \( f_2(\lambda_i) = -d \sqrt{-\lambda_i} \frac{\cos(\sqrt{-\lambda_i} d)}{\sinh(\sqrt{-\lambda_i} d)} \), if \( \lambda_i > 0 \), and \( d < \pi / \sqrt{-\lambda_i} \), and where \( f_2(\lambda_i) = -d \sqrt{-\lambda_i} \frac{\cos(\sqrt{-\lambda_i} d)}{\sinh(\sqrt{-\lambda_i} d)} \), if \( \lambda_i < 0 \).

**Proximal mappings of the atoms of the wavelet regularizers \( W_{\lambda}^{a,q}(u) \).** We here explain how to compute the proximal mappings of the atoms \( W_{n,r} \) of the wavelet regularizer \( W_{\lambda}^{a,q} \) of (14) given in (53) and (54).

For the zeroth level \( n = 0 \), we notice that, by (54), we have to compute the proximal mapping of (43). This essentially corresponds to computing the proximal mapping of the \( q \)th power of the
distance function as a joint function of both arguments. The proximal mapping can be explicitly computed in terms of geodesics as shown in [91]. It is given by

$$\text{prox}_{W_n}(u_{n'}) = \begin{cases} [\bar{u}_{n,e_i,0}, \bar{u}_{n,0}], & \text{if } n' = n - e_i, \\ [\bar{u}_{n,0}, \bar{u}_{n,e_i,0}], & \text{if } n' = n, \\ u_{n'}, & \text{else.} \end{cases}$$

(61)

Here, $[\bar{u}_{n,e_i,0}, \bar{u}_{n,0}]$ denotes the unit speed geodesic connecting $\bar{u}_{n,e_i,0}$ and $\bar{u}_{n,0}$ evaluated at time parameter $t$, with $t$ dependent on $q$. For $q = 1, 2$ we can explicitly calculate $t$ as

$$t = \begin{cases} \frac{\lambda_2}{(2+1.2)} \text{dist}(\bar{u}_{n,e_i,0}, \bar{u}_{n,0}) & \text{for } q = 2, \\ \frac{\lambda_2}{1.2} \text{dist}(\bar{u}_{n,e_i,0}, \bar{u}_{n,0}) & \text{for } q = 1. \end{cases}$$

(62)

Concerning a general level $r \neq 0$, according to (33), we have to compute the proximal mappings of (45). This means, for given iterate $u \in M^N$, we have to find a minimizer of the functional

$$u' \mapsto \frac{1}{2\mu} \text{dist}(u, u')^2 + W_{n,r}(u') = \frac{1}{2\mu} \text{dist}(u, u')^2 + \lambda_1 \cdot 2^q \left(\alpha + \frac{3}{2} \cdot 2^q \|d_{n,r}(u')\|_q^q\right).$$

(63)

$q \geq 1$. This is particularly interesting if the exponent $q$ equals one since then the distance mapping is not differentiable on the diagonal. Since for a general level $r$, no closed form expression of the proximal mapping of (45) seems available, we use a gradient descent scheme for $q > 1$, and a subgradient descent for $q = 1$. Subgradient descent has already been used to compute the proximal mappings in the context of higher order total variation type regularization [12] [23]. Let us explain the (sub)gradient descent scheme to compute the proximal mapping of (45). We first recall that the gradients of the mapping $u_k' \mapsto \text{dist}(u_k, u_k')^2$ are given by $-\log_{u_k} u_k$. The gradient of the summand $W_{n,r}$ in (63) is given by (57). Using these gradients we compute the gradient of the mapping (63) and then apply a standard gradient descent scheme for $q > 1$. If $q = 1$, we apply subgradient descend with an iteration dependent damping factor, i.e., for the $l$th iteration the subgradient of the $(l-1)$th iterate is scaled by a factor $\tau_l$. The sequence $(\tau_l)$ is chosen to be square-summable but not summable for convergence reasons. For the computation of the subgradient of the summands $W_{n,r}$ for $q = 1$, we notice that the mapping is differentiable whenever mean$(u_{n-2}, \bar{u}_{n-1}) \neq \bar{u}_{n,r}$. For the degenerate case of point constellations where $W_{n,r}$ is not differentiable we notice that the at least 0 is contained in the subdifferential of $W_{n,r}$.

**Proximal mappings for the analogue of $l_0$ sparse wavelet regularization.** We here consider the atoms of $W_n(u)$ of (15) which we also denote by $W_{n,r}$ as in (33) and (34).

For the zeroth level $n = 0$, we notice that, by (34), we have to compute the proximal mapping of

$$u' \mapsto W_{0,0}(u') = W_{(n,j),0}(u') = \lambda_2 \#\{\bar{u}_{n,e_i,0}' \neq \bar{u}_{n,0}'\}.$$

(64)

We first notice that both $\bar{u}_{n-e_i,0}'$, $\bar{u}_{n,0}'$ correspond to data items of $u'$ whose indices we denote by $i(0), i(1)$, i.e., $\bar{u}_{n-e_i,0}' = u_{i(0)}'$ and $\bar{u}_{n,0}' = u_{i(1)}'$. Then the computation of the proximal mapping of $W_{0,0}(u)$ amounts to minimizing, for given $u$, the functional

$$u' \mapsto \frac{1}{2\mu} \text{dist}(u, u')^2 + \lambda_2 \#\{\bar{u}_{n,e_i,0}' \neq \bar{u}_{n,0}'\}.$$

(65)

A short application of calculus shows that, if $\text{dist}(u_{i(0)}, u_{i(1)}) > 2 \sqrt{\mu \lambda_2}$, then $u^* := u$ minimizes (68). If $\text{dist}(u_{i(0)}, u_{i(1)}) > 2 \sqrt{\mu \lambda_2}$, it follows that choosing both components $i(0)$ and $i(1)$ of $u'$ by the geodesic
midpoint of \( u_{l(0)} \) and \( u_{l(1)} \) and setting the other components to the corresponding values of \( u \) yields a minimizer of (68), i.e., a minimizer \( u^* \) is given by its components

\[
(u^*)_l = \begin{cases} 
\text{mean} ((0.5, 0.5), (u_{l(0)}, u_{l(1)})), & \text{if } l \in \{0, 1\}, \\
u_l, & \text{else.}
\end{cases}
\]  

(66)

For a general level \( r \neq 0 \), we have to compute the proximal mappings of

\[
u' \mapsto W_{n,r}(u') = \lambda_1 \# \{ d_{n,r}(u) \neq 0 \}
\]  

(67)

where the right hand side equals zero if and only if \( \tilde{u}_{n,r} \in S\tilde{u}_{n',r-1}', \) i.e., \( \tilde{u}_{n,r}' \) is a mean of the \( \tilde{u}_{n',r-1}' \) with the weights given by the subdivision scheme; see (16) and (7). Else, the right hand side equals \( \lambda_1 \). The computation of the proximal mapping of \( W_{n,r}(u) \) amounts to minimizing, for given \( u \), the functional

\[
u' \mapsto W'(u') = \frac{1}{2n} \text{dist}(u, u')^2 + \lambda_1 \# \{ d_{n,r}(u') \neq 0 \}.
\]  

(68)

We distinguish two cases depending on whether \( \# \{ d_{n,r}(u') \neq 0 \} \) equals one or zero. Given that \( \# \{ d_{n,r}(u') \neq 0 \} = 1 \), the optimal solution of (68) subject to this constraint is given by

\[
u^# = u, \quad W'(u^#) = \lambda_1.
\]  

(69)

Given that \( \# \{ d_{n,r}(u') \neq 0 \} = 0 \), we have by the discussion preceding (68) that

\[
u^{##} = \arg \min_{u, \# \{ d_{n,r}(u') \neq 0 \} = 0} W'(u') = \arg \min_{u' : \tilde{u}_{n',r-1} \in S\tilde{u}_{n',r-1}'} W'(u')
\]  

(70)

For minimizing the right hand side of (70), we set all the components of \( u^{##} \) to the corresponding components of \( u \) which do not correspond to \( u_{n,r}^{##} \) or to \( u_{n',r-1}^{##} \) with \( n - 2n' \in \text{supp } a \). The components of \( u^{##} \) corresponding to \( \tilde{u}_{n,r}^{##} \) are given by minimizing the functional

\[
u' \mapsto V(u') := \frac{1}{2n} \sum_{n' : n - 2n' \in \text{supp } a} \text{dist}(\tilde{u}_{n',r-1}', \tilde{u}_{n',r-1})^2 + \text{dist}(\text{mean}(a_{n-2}, \tilde{u}_{n,r}'), \tilde{u}_{n,r}'')^2.
\]  

(71)

Then, the component \( u_{n,r}^{##} \) of \( u^{##} \) is given by the point mean(\( a_{n-2}, \tilde{u}_{n',r-1}' \)) of (71) for the minimizing arguments \( \tilde{u}_{n',r-1}' \) of (71). For minimizing (71), we observe that (71) just states the minimization problem for the proximal mapping of the mean mapping already discussed before. We note that the gradient of the first summands are just the gradients of the distance map as discussed above. Further, we notice that the last summand of the functional \( V \) equals the second line of (57). Then we use gradient descent for computing the \( \tilde{u}_{n',r-1}' \). Summing up, we have

\[
\text{prox}_{\mu W_{n,r}}(u) = \begin{cases} 
u^# & \text{if } V(u^{##}) > \lambda_1, \\
u^{##} & \text{if } V(u^{##}) \leq \lambda_1,
\end{cases}
\]  

(72)

where \( V \) is given by (71).

**Gradients and proximal mappings for the atoms of the data term.** Methods for deriving the gradients and proximal mappings of the decomposition of the data term \( D \) into its atoms \( D_i \) according to (12) have been derived in (76). For the data term, we employ the schemes derived there and refer to this reference for details. (There, similar as above, the gradients of the intrinsic mean mapping are employed for the computations.)
Figure 1: Results of the proposed $\ell^1$ wavelet regularization for manifold-valued signals. The given noisy data is shown on the left, the result using the manifold analogue of the first order interpolatory wavelet and the third order Deslaurier-Dubuc (DD) wavelet along with the corresponding signal-to-noise-ratio improvement are shown in the center and on the right, respectively.
Figure 2: Wavelet coefficients of the first signal in Figure 1 at the start (noisy data) and the end (reconstruction) of the iteration using the manifold analogue of the first order interpolatory wavelet (first and second row) and the third order Deslaurier-Dubuc (DD) wavelet (third and fourth row). Only a few coefficients remain significantly larger than zero after the iterations.

4 Experimental Results

We carry out experiments for data with values in the circle $S^1$, the sphere $S^2$ and the manifold $\text{Pos}_3$ of positive definite matrices equipped with the Fisher-Rao metric. $S^1$ valued data is visualized by the phase angle, and color-coded as hue value in the HSV color space when displaying image data. We visualize $S^2$-valued signal by points on the unit sphere. The abscissa is represented by a color varying continuously from the start of signal (blue) to the end of the signal (purple). Data on the $\text{Pos}_3$ manifold is visualized by the isosurfaces of the corresponding quadratic forms. More precisely, the ellipse visualizing the point $f_p$ at voxel $p$ are the points $x$ fulfilling $(x - p)^\top f_p^{-1}(x - p) = c$, for some $c > 0$. The $S^1$-valued data are corrupted by Von Mises noise with concentration parameter $\kappa$ [62].

The $S^2$-valued data are created from the original image $g$ by $f_{ij} = \exp_{g_{ij}} \eta_{ij}$ where $\eta_{ij}$ is a tangent vector at $g_{ij}$ and both its components are Gaussian distributed with standard deviation $\sigma$. The $\text{Pos}_3$ valued signal are corrupted by Rician noise with noise parameter $\eta$ [14]. To quantitatively measure the quality of a reconstruction, we use the manifold variant of the signal-to-noise ratio improvement $\Delta \text{SNR} = 10 \log_{10}((\sum_{ij} d(g_{ij}, f_{ij})^2)/(\sum_{ij} d(g_{ij}, u_{ij})^2))$ dB, see [21]. Here $f$ is the noisy data, $g$ is the ground truth, and $u$ is a regularized reconstruction. A higher $\Delta \text{SNR}$ value means better reconstruction quality. We have implemented the presented methods in Matlab 2017b. We used functions of the toolboxes CircStat [17], Manopt [24], MVIRT [12], and implementations from the authors’ prior works [91, 25]. All examples were computed using 200 iterations. The cooling sequence $(\mu^k)_{k \in \mathbb{N}}$ used as stepsize in the gradient descent for computing the non-explicit proximal mappings was chosen as $\lambda^k = \mu^k \lambda_0^{-\tau}$ with $\tau = 1$. For the spherical data we used a stagewise cooling similar to the one in [25], i.e., letting the sequence fixed to $\lambda_0$ for 50 iterations in the first stage, use the moderate cooling
Figure 3: Results of the $\ell^0$-variant of the propose method for the same data as given in Figure 1. The given noisy data is shown on the left, the result using the manifold analogue of the first order interpolatory wavelet and the third order Deslaurier-Dubuc (DD) wavelet along with the corresponding signal-to-noise-ratio improvement are shown in the center and on the right, respectively.
\[ \tau = 0.35 \] in the second stage until iteration 100 and then the cooling \( \tau = 0.55 \) afterwards. For the secondary regularization parameter, we used \( \lambda_2 = 0 \) in all denoising experiments, and \( \lambda_2 = 0.0001 \) in all deconvolution experiments. The primary regularization parameter \( \lambda_1 \) was adjusted empirically and is reported in the following.

Figure 1 shows the results of the proposed \( \ell^1 \) wavelet regularization for noise signal using the first order interpolatory wavelet and the third order Deslaurier-Dubuc (DD) wavelet for manifold valued data given by the masks in (6). The noise parameters were chosen as \( \kappa = 5, \sigma = \) and \( \eta = 80 \), for the \( S^1 \)-valued, the \( S^2 \)-valued and the \( \text{Pos}_3 \)-valued signals, respectively. The regularization parameters, \( \lambda_1 = 4 \) for the spherical data and \( \lambda_1 = 8 \) for the \( \text{Pos}_3 \) data, were chosen empirically. We observe that the noise is reduced significantly with a signal-to-noise-ratio improvement of up to around 8.9 dB by both the first order interpolatory wavelet and the third order Deslaurier-Dubuc (DD) wavelet. Both schemes yield comparable reconstruction results.

Figure 2 displays the wavelet coefficients of the first signal in Figure 1 before the first iteration (noisy data) and after the final iteration (reconstruction) for the first order interpolatory wavelet and the third order DD wavelet. We observe that also in the manifold setup the method has a shrinkage effect on the coefficients: only a few coefficients remain significantly larger than zero after the final iteration.

In Figure 3 the \( \ell^0 \) variant of the proposed method is applied to the same signals as in Figure 1. We observe that the noise is reduced significantly with a signal-to-noise-ratio improvement which is comparable to the \( \ell^1 \) variant. We observe that \( \ell^0 \) regularization and the \( \ell^1 \) variant perform equally well with only slight differences depending on the particular signal under consideration.

Figure 4 shows the results of a deconvolution experiment. Here the original signal was convolved with the manifold analogue of a Gaussian kernel with standard deviation 2 (set to zero outside a window of length 13) before corrupting it with noise. Then the signal was reconstructed using the proposed wavelet sparse regularization method with the data term including the manifold-valued convolution operator as forward operator. Here, we use generalized forward backward algorithm with Gauß-Seidel type update scheme (39). As the point deconvolution and denoising task is more involved than pure denoising we used lower noise levels for these experiments; more precisely, for the noise generation, we used the parameters \( \kappa = 20, \sigma = 0.1, \) and \( \eta = 60 \) for the \( S^1 \), the \( S^2 \), and the \( \text{Pos}_3 \) data, respectively. The first regularization parameter \( \lambda_1 \) was set equal to 6, 4 and 2, respectively. As in the direct measurement case, the first order interpolatory wavelet and the third order DD wavelet yield comparably reconstruction results.

We proceed with experiments considering bivariate data. We focus on denoising using \( \ell^1 \) wavelet regularization based on the manifold analogue of the tensor product third order DD wavelet. In Figure 5 a synthetic \( S^1 \)-valued image was corrupted by von Mises noise (\( \kappa = 10 \)) and reconstructed using \( \lambda_1 = 32 \). In Figure 6 a synthetic \( \text{Pos}_3 \)-valued image was corrupted by Rician noise of level \( \eta = 40 \) and reconstructed using \( \lambda_1 = 8 \). As in the univariate case, the proposed method reduces the noise significantly. We observe some block artifacts at the roundish structures which can be attributed to the tensor product structure. Eventually we show the results on a real diffusion tensor image of a human brain provided by the Camino project [31]. The original tensors were computed from the diffusion weighted images by a least squares fit based on the Stejskal-Tanner equation, and invalid tensors were filled by averages of their neighboring pixels. The image shows a cutout of the axial slice number 20. Figure 7 shows the smoothing effect of the proposed method using \( \lambda_1 = 12 \).

5 Conclusion

In this paper we have introduced and studied a variational model for wavelet sparse regularization in the manifold setup. We have proposed a variational scheme using manifold valued interpolatory wavelets in the regularizing term, and, in particular, we consider a sparsity promoting $\ell^1$ type as well as an $\ell^0$ type regularizing term. We have shown the existence of minimizers for the proposed models. Further, we have provided algorithms for the proposed models. We have shown how to implement the concepts of a generalized forward backward-scheme with Gauss-Seidel type update and a trajectory method as well as the well-established concept of a cyclic proximal point algorithm for wavelet sparse regularization in the manifold setup. To this end, we have derived expressions for the (sub)gradients and proximal mappings of the atoms of the wavelet regularizing terms. This includes the manifold analogues of $\ell^1$ and $\ell^0$ sparse wavelet regularization. Finally, we have shown the potential of the proposed algorithms in the experimental section by applying them to data living in the unit circle, in the two-dimensional sphere as well as in the space of positive matrices.
